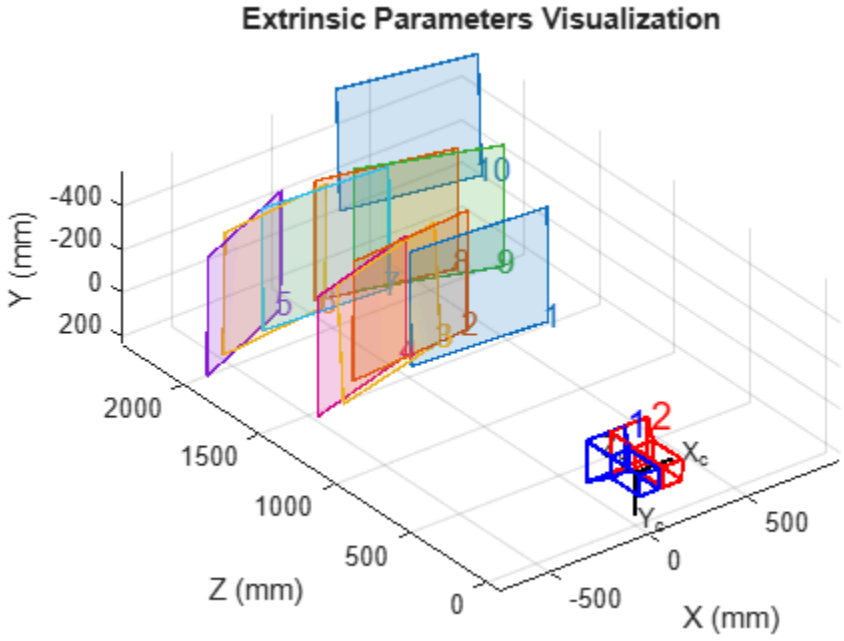
```
squareSize = 108; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Calibrate the stereo camera system. Both cameras have the same resolution.

```
I = readimage(leftImages,1);
imageSize = size(I,1:2);
params = estimateCameraParameters(imagePoints,worldPoints,ImageSize=imageSize);
```



Visualize the calibration accuracy.

```
showReprojectionErrors(params)
```

Visualize camera extrinsics.

```
figure
showExtrinsics(params)
```

Convert to structure.

```
paramsStruct = toStruct(params)
```

```
paramsStruct = struct with fields:
       CameraParameters1: [1×1 struct]
       CameraParameters2: [1×1 struct]
       RotationOfCamera2: [3×3 double]
    TranslationOfCamera2: [-119.8720 -0.4005 -0.0258]
                 Version: [1×1 struct]
     RectificationParams: [1×1 struct]
```

Estimate Camera Parameters Using Circle Grid

Create a set of calibration images.

```
imds = imageDatastore(fullfile(toolboxdir("vision"),"visiondata",...
                        "calibration","circleGrid","mono"));
calibrationImages = readall(imds);
calibrationImages = cat(4,calibrationImages{:});
```

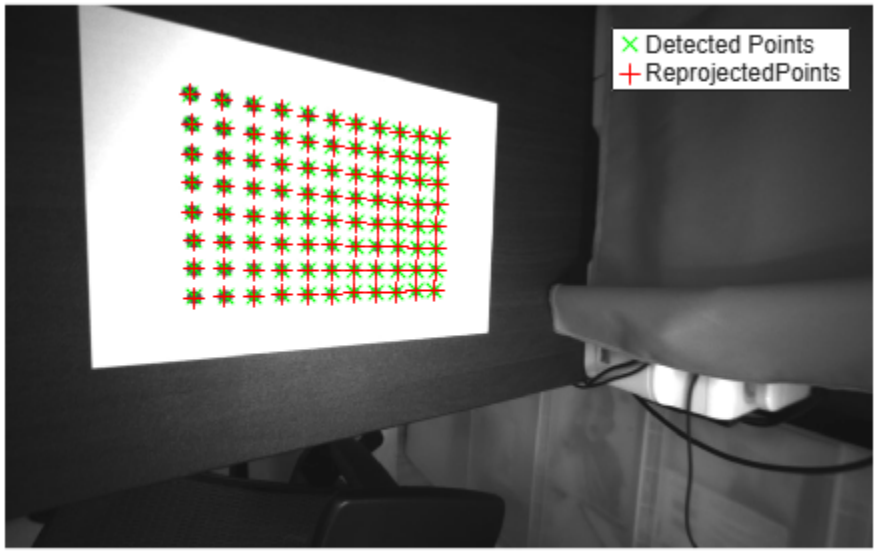
Define the circle grid pattern dimensions.

```
patternDims = [8 11];
```

Detect the pattern in the calibration images.

```
imagePoints = detectCircleGridPoints(calibrationImages, patternDims,...
                        PatternType="symmetric");
```

Specify the world coordinates for the circle grid keypoints. Center distance is in millimeters.



```
centerDistance = 18; % millimeters
worldPoints = patternWorldPoints("circle-grid-symmetric",patternDims,centerDistance);
```

Calibrate the camera using the calibration images.

```
imageSize = size(calibrationImages,1:2);
params = estimateCameraParameters(imagePoints,worldPoints,ImageSize=imageSize);
```

Plot the detected pattern grid and the reprojected points.

```
figure
imshow(calibrationImages(:,:,:,1))
hold on
plot(imagePoints(:,1,1), imagePoints(:,2,1),"gx",MarkerSize=8)
plot(params.ReprojectedPoints(:,1,1),params.ReprojectedPoints(:,2,1),"r+",MarkerSize=8)
legend("Detected Points","ReprojectedPoints")
hold off
```

Input Arguments

`imagePoints` — Key points of calibration pattern

M-by-2-by-*numImages* | *M*-by-2-by-*numPairs*-by-2 array

Key points of calibration pattern, specified as an array of [*x*,*y*] intrinsic image coordinates.

Calibration	Input Array of [*x*,*y*] Key Points
Single Camera	*M*-by-2-by-*numImages* array of [*x*,*y*] points. • The number of images, *numImages*, must be greater than or equal to 2. • The number of keypoint coordinates in each pattern, *M*, must be greater than 3. Partially detected patterns are only supported for single camera calibration. To include partially detected patterns in the estimate, use `[NaN,NaN]` as *x*-*y* coordinates for missing keypoints.
Stereo Camera	*M*-by-2-by-*numPairs*-by-2 array of [*x*,*y*] points. • *numPairs* is the number of stereo image pairs containing the calibration pattern. Must be greater than 2. • The number of keypoint coordinates in each pattern, *M*, must be greater than 3. • `imagePoints(:,:,:,1)` are the points from camera 1. • `imagePoints(:,:,:,2)` are the points from camera 2.

Data Types: `single` | `double`

`worldPoints` — Key points of calibration pattern in world coordinates
M-by-2 array

Key points of calibration pattern in world coordinates, specified as an *M*-by-2 array of *M* number of [*x*,*y*] world coordinates. The pattern must be planar; therefore, *z*-coordinates are zero. Calibration images must not be coplanar. Use only one calibration image per spatial plane.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

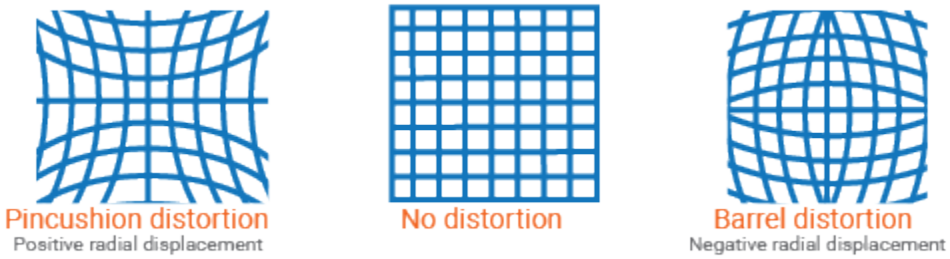
Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `"WorldUnits","mm"` sets the world point units to millimeters.

`WorldUnits` — World points units
`"mm"` (default) | character vector | string scalar

World points units, specified as a character vector or string scalar.

`EstimateSkew` — Estimate skew
`false` (default) | `true`



Estimate skew, specified as a logical scalar. When you set this property to `true`, the function estimates the image axes skew. When set to `false`, the image axes are exactly perpendicular and the function sets the skew to zero.

`NumRadialDistortionCoefficients` — Number of radial distortion coefficients
2 (default) | 3

Number of radial distortion coefficients to estimate, specified as the value 2 or 3.

Radial distortion is the displacement of image points along radial lines extending from the principal point.

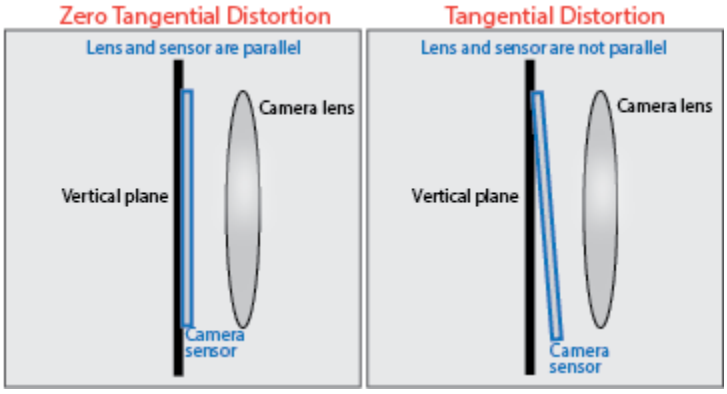
- As image points move away from the principal point (positive radial displacement), image magnification decreases and a pincushion-shaped distortion occurs on the image.
- As image points move toward the principal point (negative radial displacement), image magnification increases and a barrel-shaped distortion occurs on the image.

The radial distortion coefficients model this type of distortion. The distorted points are denoted as $(x_{\text{distorted}}, y_{\text{distorted}})$:

$x_{distorted} = x(1 + k_1*r^2 + k_2*r^4 + k_3*r^6)$

$y_{distorted} = y(1 + k_1*r^2 + k_2*r^4 + k_3*r^6)$

- x, y — Undistorted pixel locations. x and y are in normalized image coordinates. Normalized image coordinates are calculated from pixel coordinates by translating to the optical center and dividing by the focal length in pixels. Thus, x and y are dimensionless.
- k_1, k_2, and k_3 — Radial distortion coefficients of the lens.
- $r^2 = x^2 + y^2$



Typically, two coefficients are sufficient for calibration. For severe distortion, such as in wide-angle lenses, you can select three coefficients to include k_3.

`EstimateTangentialDistortion` — Tangential distortion flag

`false` (default) | `true`

Tangential distortion flag, specified as a logical scalar. When you set this property to `true`, the function estimates the tangential distortion. When you set it to `false`, the tangential distortion is negligible.

Tangential distortion occurs when the lens and the image plane are not parallel. The tangential distortion coefficients model this type of distortion.

The distorted points are denoted as $(x_{distorted}, y_{distorted})$:

$x_{distorted} = x + [2 * p_1 * x * y + p_2 * (r^2 + 2 * x^2)]$

$y_{distorted} = y + [p_1 * (r^2 + 2 * y^2) + 2 * p_2 * x * y]$

- x, y — Undistorted pixel locations. x and y are in normalized image coordinates. Normalized image coordinates are calculated from pixel coordinates by translating to the optical center and dividing by the focal length in pixels. Thus, x and y are dimensionless.
- p_1 and p_2 — Tangential distortion coefficients of the lens.
- $r^2 = x^2 + y^2$

`InitialK` — Initial guess for camera intrinsics

`[ ]` (default) | 3-by-3 matrix

Initial guess for camera intrinsics, specified as a 3-by-3 matrix. The matrix has this format:

$$\begin{bmatrix} f_x & s & c_x \\ 0 & f_y & c_y \\ 0 & 0 & 1 \end{bmatrix}$$

The coordinates $[c_x\ c_y]$ represent the optical center (the principal point), in pixels. When the *x*- and *y*-axes are exactly perpendicular, the skew parameter *s* equals `0`.

$f_x = F*s_x$
$f_y = F*s_y$

- *F* is the focal length in world units, typically expressed in millimeters.
- s_x and s_y are the number of pixels per world unit in the *x*- and *y*-direction respectively.
- f_x and f_y are expressed in pixels.

If you do not provide an initial value, the function computes the initial intrinsic matrix using linear least squares.

`InitialRadialDistortion` — Initial guess for radial distortion coefficients
`[ ]` (default) | 2-element vector | 3-element vector

Initial guess for radial distortion coefficients, specified as a 2- or 3-element vector. If you do not provide an initial value, the function uses `0` as the initial value for all the coefficients.

`ImageSize` — Image size produced by camera
1-by-2 [*mrows*, *ncols*] vector | []

Image size produced by camera, specified as a 1-by-2 [*mrows*, *ncols*] vector. To return the camera `Intrinsics` property values, you must specify the `ImageSize` name-value argument.

Output Arguments

`cameraParams` — Camera parameters
`cameraParameters` object

Camera parameters, returned as a `cameraParameters` object. If the `ImageSize` name-value argument was not specified with the input, the `cameraParams` object will not contain the `Intrinsics` property values.

`imagesUsed` — Images used to estimate camera parameters
numImages-by-1 logical array

Images you use to estimate camera parameters, returned as a *numImages*-by-1 logical array. *numImages* corresponds to the number of images. The array indicates which images you used to estimate the camera parameters. A logical `true` value in the array indicates which images you used to estimate the camera parameters.

The function computes a homography between the world points and the points detected in each image. If the homography computation fails for an image, the function issues a warning. The points for that image are not used for estimating the camera parameters. The function also sets the corresponding element of `imagesUsed` to `false`.

`estimationErrors` — Standard errors of estimated parameters
`cameraCalibrationErrors` object | `stereoCalibrationErrors` object

Standard errors of estimated parameters, returned as a `cameraCalibrationErrors` object or a `stereoCalibrationErrors` object.

`stereoParams` — Camera parameters for stereo system
`stereoParameters` object

Camera parameters for stereo system, returned as a `stereoParameters` object. The object contains the intrinsic, extrinsic, and lens distortion parameters of the stereo camera system.

`pairsUsed` — Image pairs used to estimate stereo camera parameters
numPairs-by-1 logical array

Image pairs used to estimate camera parameters, returned as a *numPairs*-by-1 logical array. *numPairs* corresponds to the number of image pairs. A logical `true` value in the array indicates which image pairs you used to estimate the camera parameters.

Algorithms

Calibration Algorithm

You can use the Camera Calibrator app with cameras up to a field of view (FOV) of 95 degrees. The calibration algorithm assumes a pinhole camera model.

This equation provides the transformation that relates a world coordinate $[X\ Y\ Z]$ and the corresponding image point $[x\ y]$:

$$w\begin{bmatrix} x \\ y \\ 1 \end{bmatrix} = K[R\ t]\begin{bmatrix} X \\ Y \\ Z \\ 1 \end{bmatrix}$$

- w: arbitrary scale factor
- K: camera intrinsic matrix
- R: matrix representing the 3-D rotation of the camera
- t: translation of the camera relative to the world coordinate system

Camera calibration estimates the values of the intrinsic parameters, the extrinsic parameters, and the distortion coefficients. There are two steps involved in camera calibration:

1. Solve for the intrinsics and extrinsics in closed form, assuming that lens distortion is zero. [1]
2. Estimate all parameters simultaneously including the distortion coefficients using nonlinear least-squares minimization (Levenberg–Marquardt algorithm). Use the closed form solution from the preceding step as the initial estimate of the intrinsics and extrinsics. Then set the initial estimate of the distortion coefficients to zero. [1][2]

Version History

Introduced in R2014b

R2025a: MATLAB Compiler support will be removed
Warns starting in R2025a

Support for using MATLAB Compiler™ will be removed in a future release.

R2022b: Supports premultiply geometric transformation convention

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, to specify an initial guess for camera intrinsics in the premultiply convention, use the new `InitialK` name-value argument.

Although you can still specify an initial guess for camera intrinsics using the `InitialIntrinsicMatrix` name-value argument, this argument is not recommended because it uses the postmultiply convention. You can streamline your geometric transformation workflows by switching to the premultiply geometric transformation convention. For more information, see "Migrate Geometric Transformations to Premultiply Convention".

estimateFundamentalMatrix

Estimate fundamental matrix from corresponding points in stereo images

Syntax

```
estimateFundamentalMatrix
F = estimateFundamentalMatrix(matchedPoints1,matchedPoints2)
[F,inliersIndex] = estimateFundamentalMatrix(matchedPoints1,matchedPoints2)
[F,inliersIndex,status] = estimateFundamentalMatrix(matchedPoints1,
matchedPoints2)
[F,inliersIndex,status] = estimateFundamentalMatrix(matchedPoints1,
matchedPoints2,Name=Value)
```

Description

`estimateFundamentalMatrix` estimates the fundamental matrix from corresponding points in stereo images. This function can be configured to use all corresponding points or to exclude outliers. You can exclude outliers by using a robust estimation technique such as random-sample consensus (RANSAC). When you use robust estimation, results may not be identical between runs because of the randomized nature of the algorithm.

`F = estimateFundamentalMatrix(matchedPoints1,matchedPoints2)` returns the 3-by-3 fundamental matrix, `F`, using the least median of squares (LMedS) method from matched feature points in stereo images.

`[F,inliersIndex] = estimateFundamentalMatrix(matchedPoints1,matchedPoints2)` additionally returns logical indices, `inliersIndex`, for the inliers used to compute the fundamental matrix. The `inliersIndex` output is an *M*-by-1 vector. The function sets the elements of the vector to `true` when the corresponding point was used to compute the fundamental matrix. The elements are set to `false` if they are not used.

`[F,inliersIndex,status] = estimateFundamentalMatrix(matchedPoints1, matchedPoints2)` additionally returns a status code.

`[F,inliersIndex,status] = estimateFundamentalMatrix(matchedPoints1, matchedPoints2,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `estimateFundamentalMatrix(matchedPoints1,matchedPoints2,Method="MSAC")` specifies MSAC as the method to compute the fundamental matrix.

Examples

Compute Fundamental Matrix

Use the random sample consensus (RANSAC) method to compute the fundamental matrix. The RANSAC method requires that the input points are putatively matched. You can use the matchFeatures function to return these matched points. Outlier points which may still be contained within putatively matched points are further eliminated by using the RANSAC algorithm.

Load stereo points into the workspace.

```
load stereoPointPairs
```

Estimate the fundamental matrix.

```
fRANSAC = estimateFundamentalMatrix(matchedPoints1, ...
    matchedPoints2,Method="RANSAC", ...
    NumTrials=2000,DistanceThreshold=1e-4)
```

```
fRANSAC = 3×3

    0.0000   -0.0004    0.0348
    0.0004    0.0000   -0.0937
   -0.0426    0.0993    0.9892
```

Use Least Median of Squares Method to Find Inliers

Load the putatively matched points into the workspace.

```
load stereoPointPairs
[fLMedS,inliers] = estimateFundamentalMatrix(matchedPoints1,matchedPoints2,NumTrials=2000)
```

```
fLMedS = 3×3

    0.0000   -0.0004    0.0349
    0.0004    0.0000   -0.0938
   -0.0426    0.0994    0.9892

inliers = 18×1 logical array

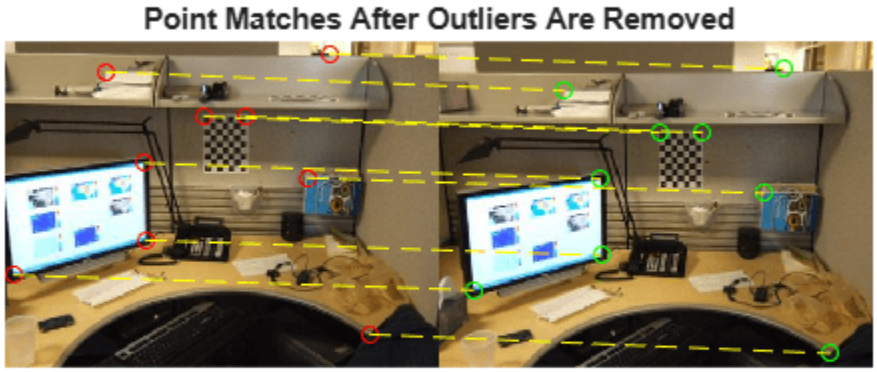
```

Load the stereo images.

```
I1 = imread("viprectification_deskLeft.png");
I2 = imread("viprectification_deskRight.png");
```



Show the putatively matched points.

```
figure;
showMatchedFeatures(I1,I2,matchedPoints1,matchedPoints2,"montage",PlotOptions=["ro","go","y--"]);
title("Putative Point Matches");
```

Show the inlier points.

```
figure;
showMatchedFeatures(I1,I2,matchedPoints1(inliers,:),matchedPoints2(inliers,:),"montage",PlotOptio
title("Point Matches After Outliers Are Removed");
```

Use Normalized Eight-Point Algorithm to Compute Fundamental Matrix

Load the stereo point pairs into the workspace.

```
load stereoPointPairs
```

Compute the fundamental matrix for input points which do not contain any outliers.

```
inlierPts1 = matchedPoints1(knownInliers,:);
inlierPts2 = matchedPoints2(knownInliers,:);
fNorm8Point = estimateFundamentalMatrix(inlierPts1,inlierPts2,Method="Norm8Point")
```

```
fNorm8Point = 3×3

    0.0000   -0.0004    0.0348
    0.0004    0.0000   -0.0937
   -0.0426    0.0993    0.9892
```

Input Arguments

`matchedPoints1` — Coordinates of corresponding points

M-by-2 matrix | point feature object

Coordinates of corresponding points in image one, specified as an *M*-by-2 matrix of *M* number of [*x* *y*] coordinates, or as one of the point feature objects described in “Point Feature Types”. The `matchedPoints1` input must contain points which do not lie on a single planar surface, (e.g., a wall, table, or book) and are putatively matched by using a function such as `matchFeatures`.

`matchedPoints2` — Coordinates of corresponding points

M-by-2 matrix | point feature object

Coordinates of corresponding points in image one, specified as an *M*-by-2 matrix of *M* number of [*x* *y*] coordinates, or as one of the point feature objects described in “Point Feature Types”. The `matchedPoints1` input must contain points which do not lie on a single planar surface, (e.g., a wall, table, or book) and are putatively matched by using a function such as `matchFeatures`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `estimateFundamentalMatrix(matchedPoints1,matchedPoints2,Method="MSAC")` specifies MSAC as the method to compute the fundamental matrix.

`Method` — Method used to compute the fundamental matrix

`LMedS` (default) | `MSAC` | `Norm8Point`

Method used to compute the fundamental matrix, specified as one of the following:

`"LMedS"`	Least Median of Squares. Use this method if at least 50% of the points in `matchedPoints1` and `matchedPoints2` are inliers. The function stops the search for inliers and the estimation of the fundamental matrix after 50% of the inliers are found.
`"MSAC"`	M-estimator SAmple Consensus. Select the M-estimator SAmple Consensus method if you would like to set the distance threshold for the inliers. Generally, the MSAC method converges more quickly than the RANSAC method.
`"Norm8Point"`	Normalized eight-point algorithm [1]. To produce reliable results, the inputs, `matchedPoints1` and `matchedPoints2` must match precisely.

To produce reliable results using the `Norm8Point` algorithm, the inputs, `matchedPoints1` and `matchedPoints2`, must match precisely. The other methods can tolerate outliers and therefore only require putatively matched input points. You can obtain putatively matched points by using the `matchFeatures` function.

`OutputClass` — Fundamental matrix class
`"double"` (default) | `"single"`

Fundamental matrix class, specified as `"double"` or `"single"`. Use this property to specify the class for the fundamental matrix and for the function's internal computations.

`NumTrials` — Number of random trials for finding outliers
`500` (default) | integer

Number of random trials for finding the outliers, specified as an integer. This argument applies when you set the `Method` to `LMedS` or `MSAC`.

- `LMedS` — The function uses the actual number of trials as the parameter value.
- `MSAC` — The function uses the maximum number of trials as the parameter value.

The actual number of trials depends on `matchedPoints1`, `matchedPoints2`, and the value of the `Confidence` parameter. Select the number of random trials to optimize speed and accuracy.

`DistanceThreshold` — Distance threshold for finding outliers
`0.01` (default)

Distance threshold for finding outliers, specified as a positive scalar. This parameter applies when you set the `Method` to `MSAC`.

`Confidence` — Desired confidence for finding maximum number of inliers
`99` (default) | scalar

Desired confidence for finding maximum number of inliers, specified as a percentage scalar in the range `(0 100)`. This argument applies when you set `Method` to `MSAC`.

`ReportRuntimeError` — Report runtime error
`true` (default) | `false`

Report runtime error, specified as a logical value. Set this parameter to `true` to report run-time errors when the function cannot compute the fundamental matrix from `matchedPoints1` and `matchedPoints2`. When you set this parameter to `false`, you can check the `status` output to verify validity of the fundamental matrix.

Output Arguments

F — Fundamental matrix

3-by-3 matrix

Fundamental matrix, returned as a 3-by-3 matrix that is computed from the points in the inputs `matchedPoints1` and `matchedPoints2`.

$$[P_2\ 1]*FundamentalMatrix*[P_1\ 1]' = 0$$

P_1, the point in `matchedPoints1` of image 1 in pixels, corresponds to the point, P_2, the point in `matchedPoints2` in image 2.

In computer vision, the fundamental matrix is a 3-by-3 matrix which relates corresponding points in stereo images. When two cameras view a 3-D scene from two distinct positions, there are a number of geometric relations between the 3-D points and their projections onto the 2-D images that lead to constraints between the image points. Two images of the same scene are related by epipolar geometry.

inliersIndex — Inliers index

M-by-1 logical vector

Inliers index, returned as an *M*-by-1 logical index vector. An element set to `true` means that the corresponding indexed matched points in `matchedPoints1` and `matchedPoints2` were used to compute the fundamental matrix. An element set to `false` means the indexed points were not used for the computation.

Data Types: `logical`

status — Status code

`0` | `1` | `2`

Status code, returned as one of the following possible values:

status	Value
0:	No error.
1:	`matchedPoints1` and `matchedPoints2` do not contain enough points. The `Norm8Point` and `MSAC` methods require at least 8 points, and the `LMedS` method requires 16 points.
2:	Not enough inliers found.

Data Types: `int32`

Tips

Use `estimateEssentialMatrix` when you know the camera intrinsics. You can obtain the intrinsics using the Camera Calibrator app. Otherwise, you can use the `estimateFundamentalMatrix` function that does not require camera intrinsics. Note that the fundamental matrix cannot be estimated from coplanar world points.

Algorithms

Computing the Fundamental Matrix

When you choose the `Norm8Point` method, the function uses all points in `matchedPoints1` and `matchedPoints2` to compute the fundamental matrix. When you choose any other method, the function uses the following algorithm to exclude outliers and compute the fundamental matrix from inliers:

1. Initialize the fundamental matrix, F, to a 3-by-3 matrix of zeros.
2. Set the loop counter n, to zero, and the number of loops N, to the number of random trials specified.
3. Loop through the following steps while $n < N$:
   a. Randomly select 8 pairs of points from `matchedPoints1` and `matchedPoints2`.
   b. Use the selected 8 points to compute a fundamental matrix, f, by using the normalized 8-point algorithm.
   c. Compute the fitness of f for all points in `matchedPoints1` and `matchedPoints2`.
   d. If the fitness of f is better than F, replace F with f.

      For the `MSAC` method, update N.
   e. $n = n + 1$

Number of Random Samplings for the MSAC Method

The MSAC method updates the number of random trials N for every iteration in the algorithm loop. The function resets N, according to the following:

$N = \min(N, \frac{\log(1-p)}{\log(1-r^8)})$.

Where, p represents the confidence parameter you specified, and r is calculated as follows:

$\sum_{i}^{N} \text{sgn}(d(u_i, v_i), t)/N$, where $\text{sgn}(a, b) = 1$ if $a \le b$ and 0 otherwise.

When you use the `MSAC` method, results may not be identical between runs because of the randomized nature of the algorithm.

Sampson Distance

The function uses the Sampson distance to measure the distance of a pair of points according to a fundamental matrix. The equation below can be used to calculate the Sampson distance. In the equation, u represents `matchedPoints1` and v represents `matchedPoints2`.

$$d(u_i, v_i) = (v_i F u_i^T)^2 \left[\frac{1}{(Fu_i^T)_1^2 + (Fu_i^T)_2^2} + \frac{1}{(v_i F)_1^2 + (v_i F)_2^2} \right]$$

where i represents the index of the corresponding points, and $\left(Fu_i^T\right)_j^2$, the square of the j-th entry of the vector Fu_i^T.

Fitness of Fundamental Matrix for Corresponding Points

The following table summarizes how each method determines the fitness of the computed fundamental matrix:

Method	Measure of Fitness
LMedS	$median(d(u_i, v_i); i = 1:N)$, the number of input points. The smaller the value, the better the fitness.
MSAC	$\sum_{i}^{N} \min(d(u_i, v_i), t)$. The smaller the value, the better the fitness.

estimateEssentialMatrix

Estimate essential matrix from corresponding points in a pair of images

Syntax

```
E = estimateEssentialMatrix(matchedPoints1,matchedPoints2,intrinsics)
E = estimateEssentialMatrix(matchedPoints1,matchedPoints2,intrinsics1,
intrinsics2)

[E,inliersIndex] = estimateEssentialMatrix( ___ )
[E,inliersIndex,status] = estimateEssentialMatrix( ___ )

[ ___ ] = estimateEssentialMatrix( ___ ,Name=Value)
```

Description

`E = estimateEssentialMatrix(matchedPoints1,matchedPoints2,intrinsics)` returns the 3-by-3 essential matrix, `E`, using the M-estimator sample consensus (MSAC) algorithm. The input points can be *M*-by-2 matrices of *M* number of [*x*,*y*] coordinates, or a `KAZEPoints` , `SIFTPoints`,`SURFPoints`, `MSERRegions`, `BRISKPoints`, or `cornerPoints` object. The `instinsics` object contains the intrinsic parameters of the camera used to take the images.

`E = estimateEssentialMatrix(matchedPoints1,matchedPoints2,intrinsics1, intrinsics2)` returns the essential matrix relating two images taken by different cameras. `intrinsics1` and `intrinsics2` are `cameraIntrinsics` objects containing the intrinsic parameters of camera 1 and camera 2 respectively.

`[E,inliersIndex] = estimateEssentialMatrix( ___ )` additionally returns an *M*-by-1 logical vector, `inliersIndex`, used to compute the essential matrix. The function sets the elements of the vector to `true` when the corresponding point was used to compute the fundamental matrix. The elements are set to `false` if they are not used.

`[E,inliersIndex,status] = estimateEssentialMatrix( ___ )` additionally returns a status code to indicate the validity of points.

`[ ___ ] = estimateEssentialMatrix( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `(MaxNumTrials=500)` sets the maximum number of random trials for finding outliers to `500`.

Examples

Estimate Essential Matrix from a Pair of Images

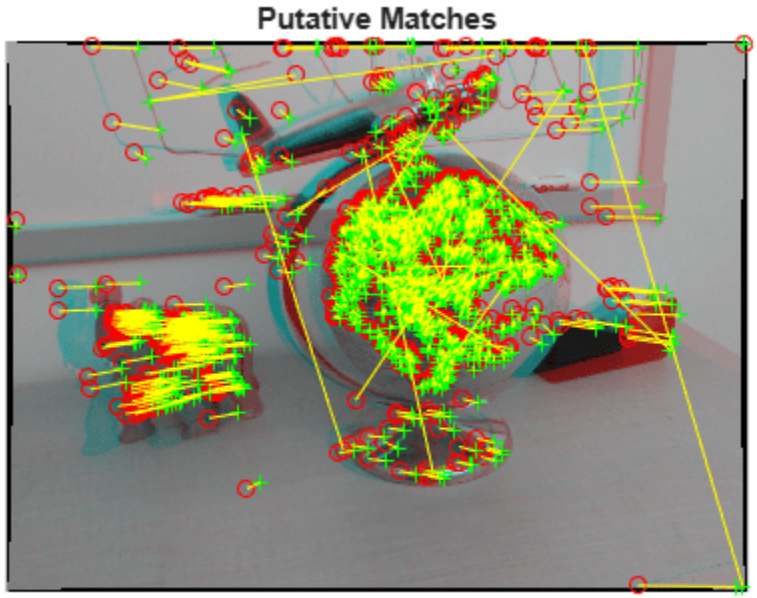
Load a MAT file containing precomputed camera parameters into the workspace.

```
load upToScaleReconstructionCameraParameters.mat
```

Read and undistort two images.

```
imageDir = fullfile(toolboxdir("vision"),"visiondata","upToScaleReconstructionImages");
images = imageDatastore(imageDir);
I1 = undistortImage(readimage(images,1),cameraParams);
I2 = undistortImage(readimage(images,2),cameraParams);
I1gray = im2gray(I1);
I2gray = im2gray(I2);
```

Detect feature points each image.



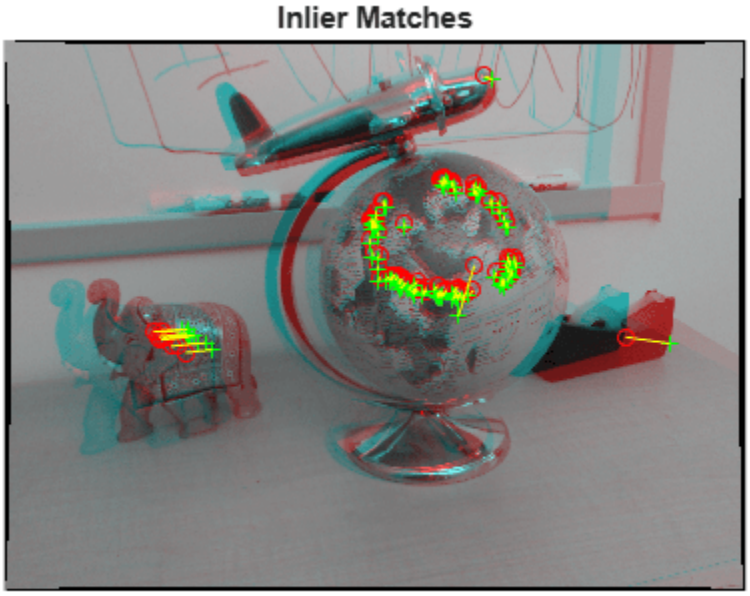
```
imagePoints1 = detectSIFTFeatures(I1gray);
imagePoints2 = detectSIFTFeatures(I2gray);
```

Extract feature descriptors from each image.

```
[features1, imagePoints1] = extractFeatures(I1gray,imagePoints1);
[features2, imagePoints2] = extractFeatures(I2gray,imagePoints2);
```

Match features across the images.

```
indexPairs = matchFeatures(features1,features2,MatchThreshold=10,Unique=true);
matchedPoints1 = imagePoints1(indexPairs(:,1));
matchedPoints2 = imagePoints2(indexPairs(:,2));
figure
showMatchedFeatures(I1,I2,matchedPoints1,matchedPoints2);
title("Putative Matches")
```



Estimate the essential matrix.

```
[E,inliers] = estimateEssentialMatrix(matchedPoints1,matchedPoints2,cameraParams);
```

Display the inlier matches.

```
inlierPoints1 = matchedPoints1(inliers);
inlierPoints2 = matchedPoints2(inliers);
```

```
figure
showMatchedFeatures(I1,I2,inlierPoints1,inlierPoints2);
title("Inlier Matches")
```

Input Arguments

`matchedPoints1` — Coordinates of corresponding points
M-by-2 matrix of [*x*,*y*] coordinates | `KAZEPoints` | `SIFTPoints` | `SURFPoints` | `BRISKPoints` | `MSERRegions` | `cornerPoints`

Coordinates of corresponding points in image 1, specified as an *M*-by-2 matrix of *M* of [*x*,*y*] coordinates, or as a `KAZEPoints`, `SIFTPoints`, `SURFPoints`, `BRISKPoints`, `MSERRegions`, or `cornerPoints` object. The `matchedPoints1` input must contain at least five points, which are putatively matched by using a function such as `matchFeatures`.

`matchedPoints2` — Coordinates of corresponding points
`SIFTPoints` | `SURFPoints` | `cornerPoints` | `MSERRegions` | `BRISKPoints` | *M*-by-2 matrix of [*x*,*y*] coordinates

Coordinates of corresponding points in image 1, specified as an *M*-by-2 matrix of *M* of [*x*,*y*] coordinates, or as a `KAZEPoints`, `SIFTPoints`, `SURFPoints`, `MSERRegions`, `BRISKPoints`,or `cornerPoints` object. The `matchedPoints2` input must contain at least five points, which are putatively matched by using a function such as `matchFeatures`.

`intrinsics` — Object for storing intrinsic parameters
`cameraIntrinsics` object

Camera intrinsic parameters, specified as a `cameraIntrinsics` object.

`intrinsics1` — Intrinsic parameters for camera 1
`cameraIntrinsics` object

Camera intrinsic parameters, specified as a `cameraIntrinsics` object.

`intrinsics2` — Intrinsic parameters for camera 2
`cameraIntrinsics` object

Camera intrinsic parameters, specified as a `cameraIntrinsics` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `estimateEssentialMatrix(matchedPoints1,matchedPoints2,intrinsics,MaxNumTrials=500)` sets the maximum number of random trials for finding outliers to `500`.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `estimateEssentialMatrix(matchedPoints1,matchedPoints2,intrinsics,"MaxNumTrials",500)` sets the maximum number of random trials for finding outliers to `500`.

`MaxNumTrials` — Maximum number of random trials for finding the outliers
`500` (default) | positive integer

Maximum number of random trials for finding outliers, specified as the comma-separated pair consisting of '`MaxNumTrials`' and a positive integer. The actual number of trials depends on `matchedPoints1`, `matchedPoints2`, and the value of the `Confidence` parameter. To optimize speed and accuracy, select the number of random trials.

`Confidence` — Desired confidence for finding maximum number of inliers
`99` (default) | scalar

Desired confidence for finding the maximum number of inliers, specified as the comma-separated pair consisting of '`Confidence`' and a percentage scalar value in the range (0,100). Increasing this value improves the robustness of the output but increases the amount of computations.

`MaxDistance` — Sampson distance threshold
`0.1` (default) | scalar

Sampson distance threshold, specified as the comma-separated pair consisting of '`MaxDistance`' and a scalar value. The function uses the threshold to find outliers returned in pixels squared. The Sampson distance is a first-order approximation of the squared geometric distance between a point and the epipolar line. Increase this value to make the algorithm converge faster, but this can also adversely affect the accuracy of the result.

Output Arguments

`E` — Essential matrix
3-by-3 matrix

Essential matrix, returned as a 3-by-3 matrix that is computed from the points in the `matchedPoints1` and `matchedPoints2` inputs with known camera intrinsics.

$$[P_2\ 1]*EssentialMatrix*[P_1\ 1]' = 0$$

The P_1 point in image 1, in normalized image coordinates, corresponds to the , P_2 point in image 2.

In computer vision, the essential matrix is a 3-by-3 matrix which relates corresponding points in stereo images which are in normalized image coordinates. When two cameras view a 3-D scene from two distinct positions, the geometric relations between the 3-D points and their projections onto the 2-D images lead to constraints between image points. The two images of the same scene are related by epipolar geometry.

Data Types: `double`

`inliersIndex` — Inliers index
M-by-1 logical vector

Inliers index, returned as an *M*-by-1 logical index vector. An element set to `true` indicates that the corresponding indexed matched points in `matchedPoints1` and `matchedPoints2` were used to compute the essential matrix. An element set to `false` means the indexed points were not used for the computation.

Data Types: `logical`

`status` — Status code
`0` | `1` | `2`

Status code, returned as one of the following possible values:

status	Value
0:	No error.
1:	`matchedPoints1` and `matchedPoints2` do not contain enough points. At least five points are required.
2:	Not enough inliers found. A least five inliers are required.

Data Types: `int32`

Tips

Use `estimateEssentialMatrix` when you know the camera intrinsics. You can obtain the intrinsics using the Camera Calibrator app. Otherwise, you can use the `estimateFundamentalMatrix` function that does not require camera intrinsics. The fundamental matrix cannot be estimated from coplanar world points.

Version History

Introduced in R2016b

R2019b: Intrinsic Parameters Object Replaces Camera Parameters Object
Behavior changed in R2019b

The intrinsic objects `intrinsics`, `intrinsics1`, and `intrinsics2`, which are specified as `cameraIntrinsics` objects that contain the intrinsic parameters of the camera used to take the images replaces the camera parameters objects `cameraParams`, `cameraParams1`, and `cameraParams2`.

estimateStereoBaseline

Estimate baseline of stereo camera

Syntax

```
[stereoParams,pairsUsed,estimationErrors] = estimateStereoBaseline(
imagePoints,worldPoints,intrinsics1,intrinsics2)
[stereoParams,pairsUsed,estimationErrors] = estimateStereoBaseline(
imagePoints,worldPoints,intrinsics1,intrinsics2,'WorldUnits',units)
```

Description

`[stereoParams,pairsUsed,estimationErrors] = estimateStereoBaseline( imagePoints,worldPoints,intrinsics1,intrinsics2)` estimates the translation and orientation between two cameras of the same resolution.

The `estimateStereoBaseline` function is best used for a stereo system with a wide baseline when the cameras are so far apart that you cannot capture the complete calibration pattern in the field-of-view of each camera. This function estimates extrinsic parameters using fixed camera intrinsics that have been estimated independently for each camera. Calibrating each camera independently results in more precise estimates of the intrinsics.

`[stereoParams,pairsUsed,estimationErrors] = estimateStereoBaseline( imagePoints,worldPoints,intrinsics1,intrinsics2,'WorldUnits',units)` specifies the units in which `worldPoints` are measured.

Examples

Estimate Baseline of a Stereo System

Load camera intrinsic parameters.

```
ld = load('wideBaselineStereo');
```

Specify stereo calibration images.

```
leftImages = imageDatastore(fullfile(toolboxdir('vision'),'visiondata', ...
    'calibration','wideBaseline','left'));
rightImages = imageDatastore(fullfile(toolboxdir('vision'),'visiondata', ...
    'calibration','wideBaseline','right'));
```

Detect the checkerboards.

```
[imagePoints,patternDims] = ...
    detectCheckerboardPoints(leftImages.Files,rightImages.Files);
```

Specify world coordinates of checkerboard keypoints.

```
squareSize = 29; % in millimeters
worldPoints = patternWorldPoints('checkerboard',patternDims,squareSize);
```

Estimate the baseline and extrinsic parameters.

```
params = estimateStereoBaseline(imagePoints,worldPoints, ...
    ld.intrinsics1,ld.intrinsics2)
```

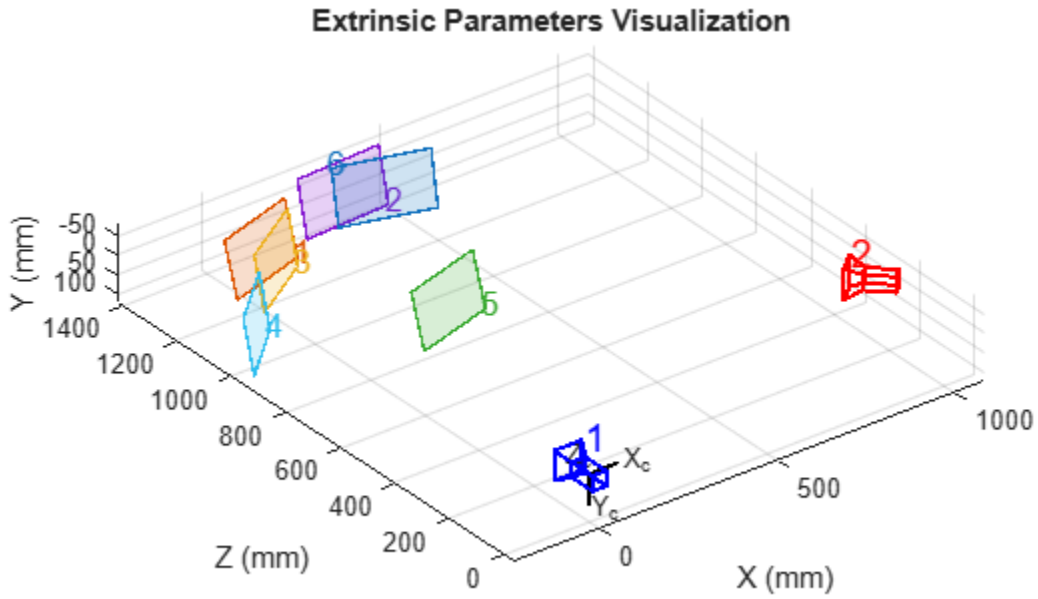
```
params =
  stereoParameters with properties:

   Parameters of Two Cameras
        CameraParameters1: [1×1 cameraParameters]
        CameraParameters2: [1×1 cameraParameters]

   Inter-camera Geometry
              PoseCamera2: [1×1 rigidtform3d]
        FundamentalMatrix: [3×3 double]
          EssentialMatrix: [3×3 double]

   Accuracy of Estimation
    MeanReprojectionError: 0.2586

   Calibration Settings
              NumPatterns: 6
              WorldPoints: [54×2 double]
               WorldUnits: 'mm'
```



Visualize calibration accuracy.

```
figure
showReprojectionErrors(params)
```

Visualize camera extrinsics.

```
figure
showExtrinsics(params)
```

Input Arguments

`imagePoints` — Key points of calibration pattern

M-by-2-by-*numPairs*-by-2 array

Key points of calibration pattern, specified as an *M*-by-2-by-*numPairs*-by-2 array. The array contains the [*x*,*y*] intrinsic image coordinates of key points in the calibration pattern.

- *numPairs* is the number of stereo image pairs containing the calibration pattern. Must be greater than 2.
- The number of keypoint coordinates in each pattern, *M*, must be greater than 3.
- `imagePoints(:,:,:,1)` are the points from camera 1.
- `imagePoints(:,:,:,2)` are the points from camera 2.

Data Types: `single` | `double`

`worldPoints` — Key points of calibration pattern in world coordinates

M-by-2 array

Key points of calibration pattern in world coordinates, specified as an *M*-by-2 array of *M* number of [*x*,*y*] world coordinates. The pattern must be planar; therefore, *z*-coordinates are zero. Calibration images must not be coplanar. Use only one calibration image per spatial plane.

Data Types: `single` | `double`

`intrinsics1` — Intrinsic parameters of camera 1

`cameraIntrinsics` object

Intrinsic parameters of camera 1, specified as a `cameraIntrinsics` object. The intrinsics object stores information about a camera's intrinsic calibration parameters, including lens distortion.

`intrinsics2` — Intrinsic parameters of camera 2
`cameraIntrinsics` object

Intrinsic parameters of camera 2, specified as a `cameraIntrinsics` object. The intrinsics object stores information about a camera's intrinsic calibration parameters, including lens distortion.

`units` — World points units
`'mm'` (default) | string

World points units, specified as a string representing units.

Output Arguments

`stereoParams` — Camera parameters for stereo system
`stereoParameters` object

Camera parameters for stereo system, returned as a `stereoParameters` object. The object contains the intrinsic, extrinsic, and lens distortion parameters of the stereo camera system.

`pairsUsed` — Image pairs used to estimate camera parameters
numPairs-by-1 logical vector

Image pairs used to estimate camera parameters, returned as a *numPairs*-by-1 logical array. A logical `true` value in the vector indicates which that the image pairs was used to estimate the camera parameters. An image pair will not be used for estimation if the algorithm fails to estimate a homography between the world points and the points detected in that pair of images.

`estimationErrors` — Standard errors of estimated parameters
`stereoCalibrationErrors` object

Standard errors of estimated parameters, returned as a `stereoCalibrationErrors` object.

Version History

Introduced in R2018a

estimateStereoRectification

Uncalibrated stereo rectification

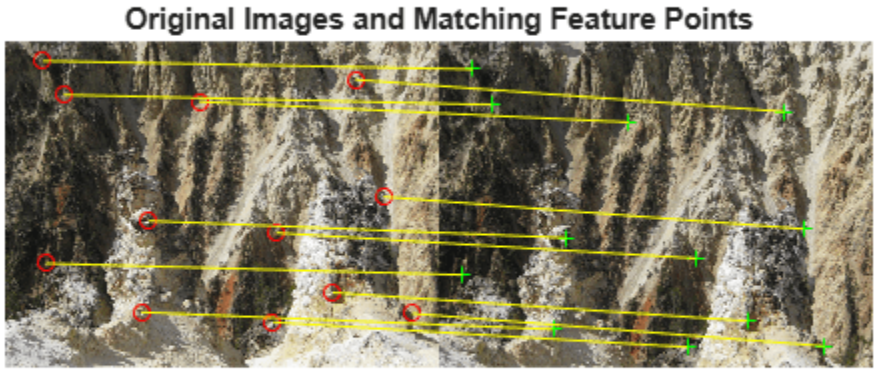
Syntax

```
[tform1,tform2] = estimateStereoRectification(F,inlierPoints1,inlierPoints2,
imageSize)
```

Description

`[tform1,tform2] = estimateStereoRectification(F,inlierPoints1,inlierPoints2, imageSize)` returns projective transformations for rectifying stereo images. This function does not require intrinsic or extrinsic camera parameters.

Examples



Estimate and Apply Stereo Rectification

Load the stereo images and feature points which are already matched.

```
I1 = imread("yellowstone_left.png");
I2 = imread("yellowstone_right.png");
load yellowstone_inlier_points;
```

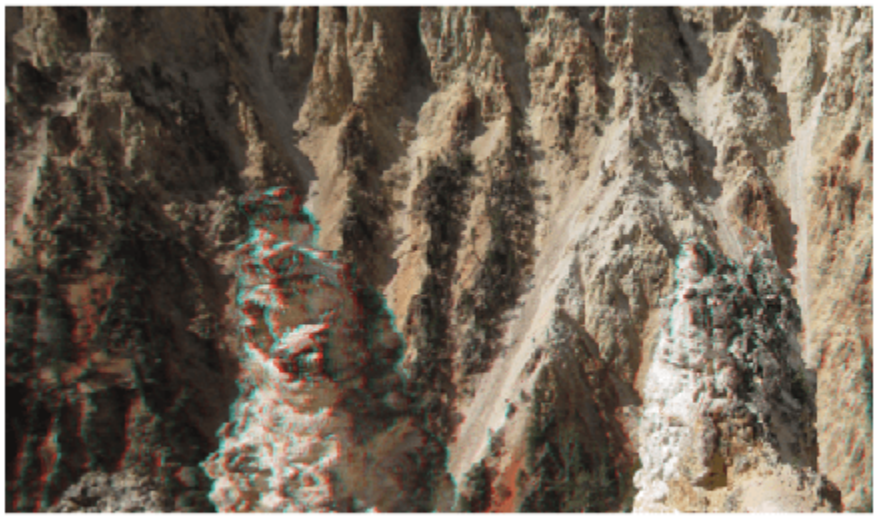
Display point correspondences. Notice that the matching points are in different rows, indicating that the stereo pair is not rectified.

```
showMatchedFeatures(I1,I2,inlier_points1,inlier_points2,"montage");
title("Original Images and Matching Feature Points");
```

Calculate the fundamental matrix from the corresponding points.

```
f = estimateFundamentalMatrix(inlier_points1,inlier_points2, ...
    "Method","Norm8Point");
```

Calculate the rectification transformations.



```
[tform1,tform2] = estimateStereoRectification(f,inlier_points1,...
    inlier_points2,size(I2));
```

Rectify the stereo images using projective transformations `tform1` and `tform2`.

```
[I1Rect,I2Rect] = rectifyStereoImages(I1,I2,tform1,tform2);
```

Display the stereo anaglyph, which can also be viewed with 3-D glasses.

```
figure
imshow(stereoAnaglyph(I1Rect,I2Rect))
```

Input Arguments

F — Fundamental matrix

3-by-3 matrix

Fundamental matrix for the stereo images, specified as a 3-by-3 matrix. The fundamental matrix satisfies this criteria for P_1, a point in image 1, and P_2, a corresponding point in image 2:

$[P_2,1] * F * [P_1,1]' = 0$

Data Types: `single` | `double`

`inlierPoints1` — Coordinates of points in image 1

M-by-2 matrix | point feature object

Coordinates of points in image 1, specified as an *M*-by-2 matrix of *M* number of [*x* *y*] coordinates, or as one of the point feature objects described in “Point Feature Types”.

`inlierPoints2` — Coordinates of corresponding points in image 2

M-by-2 matrix | point feature object

Coordinates of corresponding points in image 2, specified as an *M*-by-2 matrix of *M* number of [*x* *y*] coordinates, or as one of the point feature objects described in “Point Feature Types”.

`imageSize` — Size of image 2

numeric vector

Size of image 2, specified as a numeric vector in the format returned by the `size` function.

Output Arguments

`tform1` — Projective transformation 1

`projtform2d` object

Projective transformation 1 describing the projective transformations for input image 1, returned as a `projtform2d` object.

`tform2` — Projective transformation 2

`projtform2d` object

Projective transformation 2 describing the projective transformations for input image 2, returned as a `projtform2d` object.

Tips

- Applying the output uncalibrated rectification of `tform1` (or `tform2`) to image 1 (or image 2) can result in an undesired distortion if an epipole exists within the image. You can check for an epipole within an image by applying the `isEpipoleInImage` function.

Version History

Introduced in R2022b

R2022b: Recommended over `estimateUncalibratedRectification`

Starting in R2022b, many Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `estimateUncalibratedRectification` function uses the postmultiply convention. Although there are no plans to remove `estimateUncalibratedRectification` at this time, you can streamline your geometric transformation workflows by switching to the `estimateStereoRectification` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

estimateWorldCameraPose

(Not recommended) Estimate camera pose from 3-D to 2-D point correspondences

Note `estimateWorldCameraPose` is not recommended. Use the `estworldpose` function instead. For more information, see “Version History”.

Syntax

```
[worldOrientation,worldLocation] = estimateWorldCameraPose(imagePoints,
worldPoints,cameraParams)
[___,inlierIdx] = estimateWorldCameraPose(imagePoints,worldPoints,
cameraParams)
[___,status] = estimateWorldCameraPose(imagePoints,worldPoints,cameraParams)
[___] = estimateWorldCameraPose(___,Name,Value)
```

Description

`[worldOrientation,worldLocation] = estimateWorldCameraPose(imagePoints, worldPoints,cameraParams)` returns the orientation and location of a calibrated camera in a world coordinate system. The input `worldPoints` must be defined in the world coordinate system.

This function solves the perspective-*n*-point (PnP) problem using the perspective-three-point (P3P) algorithm [1]. The function eliminates spurious outlier correspondences using the M-estimator sample consensus (MSAC) algorithm. The inliers are the correspondences between image points and world points that are used to compute the camera pose.

`[___,inlierIdx] = estimateWorldCameraPose(imagePoints,worldPoints, cameraParams)` returns the indices of the inliers used to compute the camera pose, in addition to the arguments from the previous syntax.

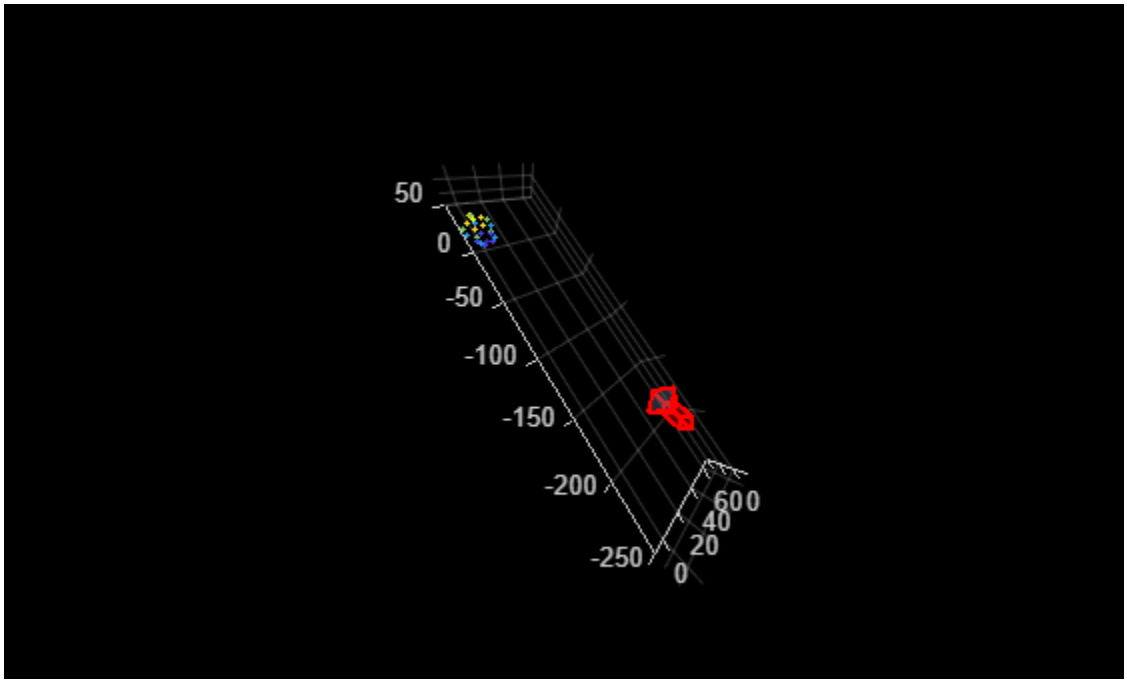
`[___,status] = estimateWorldCameraPose(imagePoints,worldPoints,cameraParams)` additionally returns a status code to indicate whether there were enough points.

`[___] = estimateWorldCameraPose(___,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments, using any of the preceding syntaxes.

Examples

Determine Camera Pose from World-to-Image Correspondences

Load previously calculated world-to-image correspondences.



```
data = load('worldToImageCorrespondences.mat');
```

Estimate the world camera pose.

```
[worldOrientation,worldLocation] = estimateWorldCameraPose(...
     data.imagePoints,data.worldPoints,data.cameraParams);
```

Plot the world points.

```
pcshow(data.worldPoints,'VerticalAxis','Y','VerticalAxisDir','down', ...
    'MarkerSize',30);
hold on
plotCamera('Size',10,'Orientation',worldOrientation,'Location',...
    worldLocation);
hold off
```

Input Arguments

`imagePoints` — Coordinates of undistorted image points

M-by-2 array

Coordinates of undistorted image points, specified as an *M*-by-2 array of [*x*,*y*] coordinates. The number of image points, *M*, must be at least four.

The function does not account for lens distortion. You can either undistort the images using the `undistortImage` function before detecting the image points, or you can undistort the image points themselves using the `undistortPoints` function.

Data Types: `single` | `double`

`worldPoints` — Coordinates of world points

M-by-3 array

Coordinates of world points, specified as an *M*-by-3 array of [*x*,*y*,*z*] coordinates.

Data Types: `single` | `double`

`cameraParams` — Object for storing camera parameters

`cameraParameters` object | `cameraIntrinsics` object

Camera parameters, specified as a `cameraParameters` or `cameraIntrinsics` object. You can return the `cameraParameters` object using the `estimateCameraParameters` function. The `cameraParameters` object contains the intrinsic, extrinsic, and lens distortion parameters of a camera.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'MaxNumTrials',1000`

`MaxNumTrials` — Maximum number of random trials
`1000` (default) | positive integer scalar

Maximum number of random trials, specified as a positive integer scalar. The actual number of trials depends on the number of image and world points, and the values for the `MaxReprojectionError` and `Confidence` properties. Increasing the number of trials improves the robustness of the output at the expense of additional computation.

`Confidence` — Confidence for finding maximum number of inliers
`99` (default) | scalar in the range (0,100)

Confidence for finding maximum number of inliers, specified as a scalar in the range (0,100). Increasing this value improves the robustness of the output at the expense of additional computation.

`MaxReprojectionError` — Reprojection error threshold
`1` (default) | positive numeric scalar

Reprojection error threshold for finding outliers, specified as a positive numeric scalar in pixels. Increasing this value makes the algorithm converge faster, but can reduce the accuracy of the result. Correspondences with a reprojection error larger than the `MaxReprojectionError` are considered outliers, and are not used to compute the camera pose.

Output Arguments

`worldOrientation` — Orientation of camera in world coordinates
3-by-3 matrix

Orientation of camera in world coordinates, returned as a 3-by-3 matrix.

Data Types: `double`

`worldLocation` — Location of camera
1-by-3 vector

Location of camera, returned as a 1-by-3 unit vector.

Data Types: `double`

`inlierIdx` — Indices of inlier points
M-by-1 logical vector

Indices of inlier points, returned as an *M*-by-1 logical vector. A logical true value in the vector corresponds to inliers represented in `imagePoints` and `worldPoints`.

`status` — Status code
integer value

Status code, returned as `0`, `1`, or `2`.

Status code	Status
`0`	No error
`1`	`imagePoints` and `worldPoints` do not contain enough points. A minimum of four points are required.
`2`	Not enough inliers found. A minimum of 4 inliers are required.

Version History

Introduced in R2016b

R2022b: Not recommended
Not recommended starting in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `estimateWorldCameraPose` function uses the postmultiply convention. Although there are no plans to remove `estimateWorldCameraPose` at this time, you can streamline your geometric transformation workflows by switching to the `estworldpose` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

To update your code:

- Change instances of the function name `estimateWorldCameraPose` to `estworldpose`.
- Specify the `cameraParams` argument as a `cameraIntrinsics` object. If you have a `cameraParameters` object, then you can get a `cameraIntrinsics` object by querying the `Intrinsics` property. If the `Intrinsics` property is empty according to the `isempty` function, then set the `ImageSize` property of the `cameraParameters` object to an arbitrary vector before querying the `Intrinsics` property. For example:

  ```
  load worldToImageCorrespondences.mat
  if(isempty(cameraParams.Intrinsics))
      cameraParams.ImageSize = [128 128];
  end
  intrinsics = cameraParams.Intrinsics;
  ```
- Replace the two output arguments `worldOrientation` and `worldLocation` with a single output argument, `worldPose`. If you need to obtain the orientation matrix and location vector, then you can query the `R` and the `Translation` properties of the `rigidtform3d` object returned by the `worldPose` argument. Note that the value of `R` is the transpose of `worldOrientation`.

The table shows examples of how to update your code.

Discouraged Usage	Recommended Replacement

This example estimates a camera pose using the `estimateWorldCameraPose` function with the `cameraParams` argument specified as a `cameraParameters` object.
 	
`[worldOrientation,worldLocation] = estimateWorldCameraPose( ...`
`  imagePoints,worldPoints,cameraParams);`
	This example gets the camera intrinsics using the `Intrinsics` property of the `cameraParameters` object, then estimates a camera pose using the `estworldpose` function.
	
	`intrinsics = cameraParams.Intrinsics;`
	`worldPose = estworldpose( ...`
	`  imagePoints,worldPoints,intrinsics);`
	
	If you need to obtain the camera orientation and location, then you can query properties of `worldPose`.
	
	`worldOrientation = worldPose.R;`
	`worldLocation = worldPose.Translation;`
	
	If you want the orientation in the postmultiply convention, take the transpose of `worldPose.R`.
	
	`worldOrientation = worldPose.R';`

estrelpose

Calculate relative rotation and translation between camera poses

Syntax

```
relativePose = estrelpose(M,intrinsics,inlierPoints1,inlierPoints2)
relativePose = estrelpose(M,intrinsics1,intrinsics2,inlierPoints1,
inlierPoints2)
[relativePose,validPointsFraction] = estrelpose( ___ )
```

Description

`relativePose = estrelpose(M,intrinsics,inlierPoints1,inlierPoints2)` returns the pose of a calibrated camera relative to its previous pose. The two poses are related by the fundamental, essential, or homography matrix `M`. The function calculates the camera location up to scale.

`relativePose = estrelpose(M,intrinsics1,intrinsics2,inlierPoints1, inlierPoints2)` returns the pose of the second camera relative to the first one.

`[relativePose,validPointsFraction] = estrelpose( ___ )` additionally returns the fraction of the inlier points that project in front of both cameras.

Examples

Estimate Camera Pose Relative to Prior Pose

Load a previously calculated fundamental matrix, camera parameters, and image points for a single camera.

```
load("relCameraPoseData.mat")
intrinsics = cameraParams.Intrinsics;
```

Calculate the camera pose relative to its previous pose.

```
relPose = estrelpose(M,intrinsics,inlierPoints1,inlierPoints2)
```

```
relPose =
  rigidtform3d with properties:

    Dimensionality: 3
       Translation: [0.9952 -0.0887 -0.0412]
                 R: [3×3 double]

                 A: [ 0.9911    0.0203   -0.1314    0.9952
                     -0.0196    0.9998    0.0065   -0.0887
                      0.1315   -0.0039    0.9913   -0.0412
                           0         0         0    1.0000]
```

Input Arguments

`M` — Fundamental, essential, or homography matrix

3-by-3 matrix | `affinetform2d` object | `projtform2d` object | `simtform2d` object

Fundamental, essential, or homography matrix, specified as a 3-by-3 matrix, an `affinetform2d` object, `projtform2d` object, or a `simtform2d` object containing a homography matrix. You can obtain the 3-by-3 matrix using one of these functions:

- `estimateFundamentalMatrix` for the fundamental matrix.
- `estimateEssentialMatrix` for the essential matrix
- `estgeotform2d` for the projective, affine, or similarity 2-D object.

Data Types: `single` | `double`

`intrinsics` — Camera intrinsics

`cameraIntrinsics` object

Camera intrinsics, specified as a `cameraIntrinsics` object.

`intrinsics1` — Camera intrinsics for camera 1

`cameraParameters` object | `cameraIntrinsics` object

Camera intrinsics for camera 1, specified as a `cameraIntrinsics` object.

`intrinsics2` — Camera parameters for camera 2

`cameraParameters` object | `cameraIntrinsics` object

Camera intrinsics for camera 2, specified as a `cameraIntrinsics` object.

`inlierPoints1` — Coordinates of corresponding points in view 1

M-by-2 matrix | point feature object

Coordinates of corresponding points in view 1, specified as an *M*-by-2 matrix of *M* number of [*x* *y*] coordinates, or as one of the point feature objects described in “Point Feature Types”. You can obtain these points using the `estimateFundamentalMatrix` function or the `estimateEssentialMatrix`.

`inlierPoints2` — Coordinates of corresponding points in view 2

M-by-2 matrix | point feature object

Coordinates of corresponding points in view 2, specified as an *M*-by-2 matrix of *M* number of [*x* *y*] coordinates, or as one of the point feature objects described in “Point Feature Types”. You can obtain these points using the `estimateFundamentalMatrix` function or the `estimateEssentialMatrix`.

Output Arguments

`relativePose` — Relative camera pose

`rigidtform3d` object

Relative camera pose in world coordinates, returned as a `rigidtform3d` object. The `"R"` and the `"Translation"` properties of the object represent the orientation and location of the camera. If you

use only one camera, the properties describe the orientation and location of the second camera pose relative to the first camera pose. If you use two cameras, the matrix describes the orientation and location of camera 2 relative to camera 1.

`validPointsFraction` — Fraction of valid inlier points
scalar

Fraction of valid inlier points that project in front of both cameras, returned as a scalar. If `validPointsFraction` is too small, typically less than 0.9, it can indicate that the fundamental matrix is incorrect.

Tips

- You can calculate the camera extrinsics according to:

```
relativeOrientation = relativePose.R;
relativeLocation = relativePose.Translation;
camPose = rigidtform3d(relativeOrientation,relativeLocation);
extrinsics = pose2extr(camPose)
```

- The `estrelpose` function uses the `inlierPoints1` and `inlierPoints2` arguments to determine which of the multiple possible solutions is physically realizable. If the input `M` is a `projtform2d` object, there could be up to two solutions that are equally realizable.

Version History

Introduced in R2022b

R2022b: Recommended over `relativeCameraPose`

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `relativeCameraPose` function uses the postmultiply convention. Although there are no plans to remove `relativeCameraPose` at this time, you can streamline your geometric transformation workflows by switching to the `estrelpose` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

estworldpose

Estimate camera pose from 3-D to 2-D point correspondences

Syntax

```
worldPose = estworldpose(imagePoints,worldPoints,intrinsics)
[worldPose,inlierIdx] = estworldpose(imagePoints,worldPoints,intrinsics)
[worldPose,inlierIdx,status] = estworldpose(imagePoints,worldPoints,
intrinsics)
[___] = estworldpose(___,Name=Value)
```

Description

`worldPose = estworldpose(imagePoints,worldPoints,intrinsics)` returns the pose of a calibrated camera in a world coordinate system. The input `worldPoints` must be defined in the world coordinate system.

This function solves the perspective-*n*-point (PnP) problem using the perspective-three-point (P3P) algorithm [1]. The function eliminates spurious outlier correspondences using the M-estimator sample consensus (MSAC) algorithm. The inliers are the correspondences between image points and world points that are used to compute the camera pose.

`[worldPose,inlierIdx] = estworldpose(imagePoints,worldPoints,intrinsics)` returns the indices of the inliers used to compute the camera pose, in addition to the arguments from the previous syntax.

`[worldPose,inlierIdx,status] = estworldpose(imagePoints,worldPoints, intrinsics)` additionally returns a status code to indicate whether there were enough points.

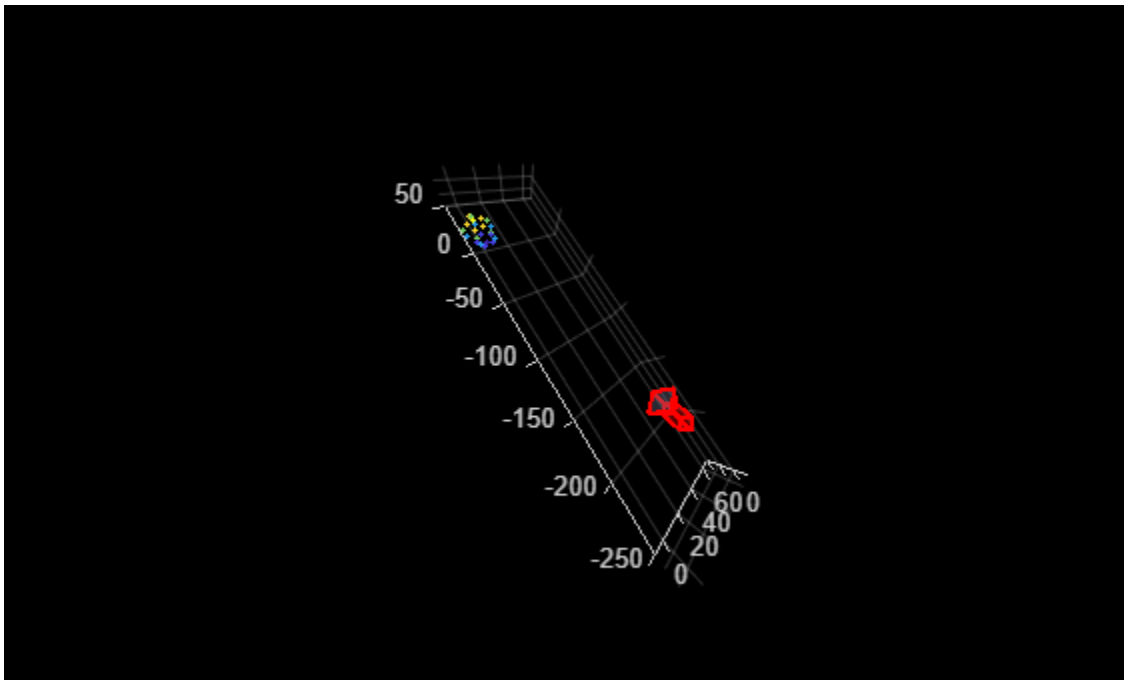
`[___] = estworldpose(___,Name=Value)` uses additional options specified by one or more name-value arguments, using any of the preceding syntaxes.

Examples

Determine Camera Pose from World-to-Image Correspondences

Load previously calculated world-to-image correspondences.

```
load("worldToImageCorrespondences.mat");
cameraParams.ImageSize = [128 128];
intrinsics = cameraParams.Intrinsics;
```



Estimate the world camera pose.

```
worldPose = estworldpose(imagePoints,worldPoints,intrinsics);
```

Plot the world points.

```
pcshow(worldPoints,VerticalAxis="Y",VerticalAxisDir="down", ...
    MarkerSize=30);
```

```
hold on
plotCamera(Size=10,Orientation=worldPose.R', ...
    Location=worldPose.Translation);
hold off
```

Input Arguments

`imagePoints` — Coordinates of undistorted image points

M-by-2 array

Coordinates of undistorted image points, specified as an *M*-by-2 array of [*x*, *y*] coordinates. The number of image points, *M*, must be at least four.

The function does not account for lens distortion. You can either undistort the images using the `undistortImage` function before detecting the image points, or you can undistort the image points themselves using the `undistortPoints` function.

Data Types: `single` | `double`

`worldPoints` — Coordinates of world points

M-by-3 array

Coordinates of world points, specified as an *M*-by-3 array of [*x*, *y*, *z*] coordinates.

Data Types: `single` | `double`

`intrinsics` — Camera intrinsics

`cameraIntrinsics` object

Camera intrinsics, specified as a `cameraIntrinsics` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `MaxNumTrials=1000`

`MaxNumTrials` — Maximum number of random trials
`1000` (default) | positive integer scalar

Maximum number of random trials, specified as a positive integer scalar. The actual number of trials depends on the number of image and world points, and the values for the `MaxReprojectionError` and `Confidence` properties. Increasing the number of trials improves the robustness of the output at the expense of additional computation.

`Confidence` — Confidence for finding maximum number of inliers
`99` (default) | scalar in the range (0, 100)

Confidence for finding maximum number of inliers, specified as a scalar in the range (0, 100). Increasing this value improves the robustness of the output at the expense of additional computation.

`MaxReprojectionError` — Reprojection error threshold
`1` (default) | positive numeric scalar

Reprojection error threshold for finding outliers, specified as a positive numeric scalar in pixels. Increasing this value makes the algorithm converge faster, but can reduce the accuracy of the result. Correspondences with a reprojection error larger than the `MaxReprojectionError` are considered outliers, and are not used to compute the camera pose.

Output Arguments

`worldPose` — Camera pose
`rigidtform3d` object

Camera pose in world coordinates, returned as a `rigidtform3d` object. The `R` and the `Translation` properties of the object represent the orientation and location of the camera.

`inlierIdx` — Indices of inlier points
M-by-1 logical vector

Indices of inlier points, returned as an *M*-by-1 logical vector. A logical true value in the vector corresponds to inliers represented in `imagePoints` and `worldPoints`.

`status` — Status code
integer value

Status code, returned as `0`, `1`, or `2`.

Status code	Status
`0`	No error
`1`	`imagePoints` and `worldPoints` do not contain enough points. A minimum of four points are required.

Status code	Status
2	Not enough inliers found. A minimum of 4 inliers are required.

Tips

- This function does not account for lens distortion. You can undistort the images using the `undistortImage` function before detecting the image points. You can undistort the image points themselves using the `undistortPoints` function.

Version History

Introduced in R2022b

R2024a: Support for MATLAB Function block

Support added to use this function in a MATLAB Function block

R2022b: Recommended over `estimateWorldCameraPose`

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `estimateWorldCameraPose` function uses the postmultiply convention. Although there are no plans to remove `estimateWorldCameraPose` at this time, you can streamline your geometric transformation workflows by switching to the `estworldpose` function, which supports the premultiply convention. cameraPoseToExtrinsics

(Not recommended) Convert camera pose to extrinsics

Note `cameraPoseToExtrinsics` is not recommended. Use the `pose2extr` function instead. For more information, see “Version History”.

Syntax

```
tform = cameraPoseToExtrinsics(cameraPose)
[rotationMatrix,translationVector] = cameraPoseToExtrinsics(orientation,
location)
```

Description

`tform = cameraPoseToExtrinsics(cameraPose)` returns a `rigid3d` object that contains the transformation from world coordinates to camera coordinates. `cameraPose` is the orientation and location of the camera in world coordinates, specified as a `rigid3d` object.

`[rotationMatrix,translationVector] = cameraPoseToExtrinsics(orientation, location)` returns the camera extrinsics, `rotationMatrix` and `translationVector`, which represent the coordinate system transformation from world coordinates to camera coordinates. The inputs, `orientation` and `location`, represent the 3-D camera pose in the world coordinates.

Examples

Convert World Coordinates to Camera Coordinates

Create the 3-D orientation matrix and the location vector.

```
orientation = eye(3);
location = [0 0 10];
```

Compute the rotation matrix and translation vector to transform points from world coordinates to camera coordinates.

```
[rotationMatrix,translationVector] = cameraPoseToExtrinsics(orientation,location)
```

```
rotationMatrix = 3×3

     1     0     0
     0     1     0
     0     0     1

translationVector = 1×3

     0     0   -10
```

Compute the transformation from world coordinates to camera coordinates as a rigid 3-D object.

```
cameraPose = rigid3d(orientation,location);
tform = cameraPoseToExtrinsics(cameraPose)
```

```
tform =
  rigid3d with properties:

       Rotation: [3×3 double]
    Translation: [0 0 -10]
```

Input Arguments

`cameraPose` — Orientation and location of the camera

`rigid3d` object

Orientation and location of the camera in world coordinates, specified as a `rigid3d` object.

`orientation` — 3-D orientation

3-by-3 matrix

3-D orientation of the camera in world coordinates, specified as a 3-by-3 matrix. The `orientation` and `location` inputs must be the same data type.

Data Types: `double` | `single`

`location` — 3-D location

three-element vector

3-D location of the camera in world coordinates, specified as a three-element vector. The `orientation` and `location` inputs must be the same data type.

Data Types: `double` | `single`

Output Arguments

`tform` — Transformation

`rigid3d`

Transformation from world coordinates to camera coordinates, returned as a `rigid3d` object. The transformation allows you to transform points from the world coordinate system to the camera coordinate system. `tform` is computed as:

```
tform.Rotation = cameraPose.Rotation'
tform.Translation = -cameraPose.Translation * cameraPose.Rotation'
```

`rotationMatrix` — 3-D rotation

3-by-3 matrix

3-D rotation, returned as a 3-by-3 matrix. The rotation matrix, together with the translation vector allows you to transform points from the world coordinate system to the camera coordinate system.

The relationship between the rotation matrix and the input orientation matrix is:
`rotationMatrix = orientation'`

`translationVector` — 3-D translation
1-by-3 vector

3-D translation, returned as a 1-by-3 vector. The translation vector together with the rotation matrix, enables you to transform points from the world coordinate system to the camera coordinate system.

The relationship between the translation vector and the input orientation matrix is :
`translationVector = -location*orientation'`

Version History

Introduced in R2016b

R2022b: Not recommended
Not recommended starting in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `cameraPoseToExtrinsics` function uses the postmultiply convention. Although there are no plans to remove `cameraPoseToExtrinsics` at this time, you can streamline your geometric transformation workflows by switching to the `pose2extr` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

To update your code:

- Change instances of the function name `cameraPoseToExtrinsics` to `pose2extr`.
- Specify the camera pose as a `rigidtform3d` object using the `cameraPose` argument. `pose2extr` does not support specifying the camera pose using the `orientation` and `translation` input arguments. Note that you create the `rigidtform3d` object using the transpose of `orientation` or the transpose of the transformation matrix in the `T` property of `tform`.

Discouraged Usage	Recommended Replacement

This example specifies the camera pose as a rotation matrix `orientation` in the premultiply convention and a translation vector `location`, then converts the camera pose to extrinsics using the `cameraPoseToExtrinsics` function, using the transpose of `orientation`.
 	
`orientation = eye(3);`
`location = [0 0 10];`
`[rotationMatrixOld,translationVector] = cameraPoseToExtrinsics( ...`
`    orientation',location)`
	This example specifies the camera pose as a `rigidtform3d` object, then converts the camera pose to extrinsics using the `pose2extr` function.
	
	`orientation = eye(3);`
	`location = [0 0 10];`
	`cameraPose = rigidtform3d(orientation,location);`
	`extrinsics = pose2extr(cameraPose);`
	
	If you need to obtain a rotation matrix and translation vector, then you can query properties of `extrinsics`.
	
	`rotationMatrix = extrinsics.R;`
	`translationVector = extrinsics.Translation;`
	
	If you want the rotation matrix in the postmultiply convention, take the transpose of `extrinsics.R`.
	
	`rotationMatrixOld = extrinsics.R';`

This example specifies a camera pose as a `rigid3d` object using the transpose of the geometric transformation matrix `A` in the premultiply convention, then converts the camera pose to extrinsics using the `cameraPoseToExtrinsics` function.
 	
`A = [1 0 0 0; 0 1 0 0; 0 0 1 10; 0 0 0 1];`
`cameraPoseOld = rigid3d(A');`
`extrinsicsOld = cameraPoseToExtrinsics(cameraPoseOld);`
	This example specifies the camera pose as a `rigidtform3d` object using the geometric transformation matrix `A`, then converts the camera pose to extrinsics using the `pose2extr` function.
	
	`A = [1 0 0 0; 0 1 0 0; 0 0 1 10; 0 0 0 1];`
	`cameraPose = rigidtform3d(A);`
	`extrinsics = pose2extr(cameraPose);`
	If instead you start with an existing `rigid3d` object `cameraPoseOld`, then you can get the geometric transformation matrix in the postmultiply convention by querying the property `T` of `cameraPoseOld`.
	
	`T = cameraPoseOld.T;`
	`cameraPose = rigidtform3d(T');`
	`extrinsics = pose2extr(cameraPose);`

Extended Capabilities

extr2pose

Convert extrinsics to camera pose

Syntax

```
cameraPose = extr2pose(camExtrinsics)
```

Description

`cameraPose = extr2pose(camExtrinsics)` returns the camera pose, `cameraPose`, in world coordinates, given the camera extrinsics.

Examples

Convert Camera Coordinates to World Coordinates

Create a 3-D rigid geometric transformation from a rotation matrix and a translation vector.

```
rotationMatrix = eye(3);
translationVector = [0 0 -10];
tform = rigidtform3d(rotationMatrix,translationVector);
```

Compute the camera pose in world coordinates.

```
cameraPose = extr2pose(tform)
```

```
cameraPose =
  rigidtform3d with properties:

    Dimensionality: 3
       Translation: [0 0 10]
                 R: [3×3 double]

                 A: [1     0     0     0
                     0     1     0     0
                     0     0     1    10
                     0     0     0     1]
```

Input Arguments

`camExtrinsics` — Camera extrinsics

`rigidtform3d` object | `se3` object

Camera extrinsics, specified as a `rigidtform3d` or `se3` object. The extrinsics are a transformation from world coordinates to camera coordinates that enables you to transform points from the world coordinate system to the camera coordinate system.

Output Arguments

cameraPose — Camera pose
`rigidtform3d` object | `se3` object

Camera pose in world coordinates, returned as a `rigidtform3d` or `se3` object. `cameraPose` is the inverse of `camExtrinsics` as calculated using the `invert` function.

Version History

Introduced in R2022b

R2022b: Recommended over `extrinsicsToCameraPose`

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `extrinsicsToCameraPose` function uses the postmultiply convention. Although there are no plans to remove `extrinsicsToCameraPose` at this time, you can streamline your geometric transformation workflows by switching to the `extr2pose` function, which supports the premultiply convention. extrinsicsToCameraPose

(Not recommended) Convert extrinsics to camera pose

Note `extrinsicsToCameraPose` is not recommended. Use the `extr2pose` function instead. For more information, see “Version History”.

Syntax

```
cameraPose = extrinsicsToCameraPose(tform)
[orientation,location] = extrinsicsToCameraPose(rotationMatrix,
translationVector)
```

Description

`cameraPose = extrinsicsToCameraPose(tform)` returns a `rigid3d` object that contains the camera pose, `cameraPose`, in world coordinates. `tform` is a transformation from world coordinates to camera coordinates, specified as a `rigid3d` object.

`[orientation,location] = extrinsicsToCameraPose(rotationMatrix, translationVector)` returns 3-D camera pose orientation and location in world coordinates. The inputs, `rotationMatrix` and `translationVector`, represent the transformation from world coordinates to camera coordinates.

Examples

Convert Camera Coordinates to World Coordinates

Create a rotation matrix and a translation vector.

```
rotationMatrix = eye(3);
translationVector = [0 0 -10];
```

Compute the camera orientation matrix and location vector in world coordinates.

```
[orientation,location] = extrinsicsToCameraPose(rotationMatrix,translationVector)
```

```
orientation = 3×3

     1     0     0
     0     1     0
     0     0     1

location = 1×3

     0     0    10
```

Compute the camera pose in world coordinates as a rigid 3-D object.

```
tform = rigid3d(rotationMatrix,translationVector);
cameraPose = extrinsicsToCameraPose(tform)
```

```
cameraPose =
  rigid3d with properties:

      Rotation: [3×3 double]
    Translation: [0 0 10]
```

Input Arguments

`tform` — Transformation

`rigid3d` object

Transformation from world coordinates to camera coordinates, specified as a `rigid3d` object. The transformation allows you to transform points from the world coordinate system to the camera coordinate system.

`rotationMatrix` — 3-D rotation

3-by-3 matrix

3-D rotation, specified as a 3-by-3 matrix. The rotation matrix, together with the translation vector allows you to transform points from the world coordinate system to the camera coordinate system.

Data Types: `double` | `single`

`translationVector` — 3-D translation

1-by-3 vector

3-D translation, specified as a 1-by-3 vector. The translation vector together with the rotation matrix, enables you to transform points from the world coordinate system to the camera coordinate system.

Data Types: `double` | `single`

Output Arguments

`cameraPose` — Camera pose

`rigid3d` object

Camera pose in world coordinates, returned as a `rigid3d` object. `cameraPose` is computed as:

```
cameraPose.Rotation = tform.Rotation'
cameraPose.Translation = -tform.Translation * tform.Rotation'
```

`orientation` — 3-D orientation

3-by-3 matrix

3-D orientation of the camera in world coordinates, returned as a 3-by-3 matrix.

The relationship between the rotation matrix and the output orientation matrix is:
`orientation = rotationMatrix'`

`location` — 3-D location
3-element vector

3-D location of the camera in world coordinates, specified as a three-element vector.

The relationship between the translation vector and the output orientation matrix is:

`location = -translationVector*rotationMatrix'`

Version History

Introduced in R2016b

R2022b: Not recommended
Not recommended starting in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `extrinsicsToCameraPose` function uses the postmultiply convention. Although there are no plans to remove `extrinsicsToCameraPose` at this time, you can streamline your geometric transformation workflows by switching to the `extr2pose` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

- Change instances of the function name `cameraPoseToExtrinsics` to `pose2extr`.
- Specify the extrinsics as a `rigidtform3d` object using the `extrinsics` argument. `extr2pose` does not support specifying extrinsics using the `rotationMatrix` and `translationVector` input arguments. Note that you create the `rigidtform3d` object using the transpose of `rotationMatrix` or the transpose of the transformation matrix in the `T` property of `tform`.

Discouraged Usage	Recommended Replacement

This example specifies the extrinsics as a rotation matrix `rotationMatrix` in the premultiply convention and a translation vector `translationVector`, then converts the extrinsics to a camera pose using the `extrinsicsToCameraPose` function, using the transpose of `rotationMatrix`.
 	
`rotationMatrix = eye(3);`
`translationVector = [0 0 -10];`
`[orientationOld,location] = ...`
`  extrinsicsToCameraPose(rotationMatrix',translationVector);`
	This example specifies extrinsics as a `rigidtform3d` object, then converts the extrinsics to a camera pose using the `extr2pose` function.
	
	`rotationMatrix = eye(3);`
	`translationVector = [0 0 -10];`
	`extrinsics = rigidtform3d(orientation,location);`
	`cameraPose = extr2pose(extrinsics);`
	
	If you need to obtain the camera orientation and location, then you can query properties of `cameraPose`.
	
	`orientation = cameraPose.R;`
	`location = cameraPose.Translation;`
	
	If you want the orientation in the postmultiply convention, take the transpose of `cameraPose.R`.
	
	`orientationOld = cameraPose.R;`

This example specifies extrinsics as a `rigid3d` object using the transpose of the geometric transformation matrix `T` in the premultiply convention, then converts the extrinsics to a camera pose using the `extrinsicsToCameraPose` function.
 	
`A = [1 0 0 0; 0 1 0 0; 0 0 1 -10; 0 0 0 1];`
`extrinsicsOld = rigid3d(A');`
`cameraPoseOld = extrinsicsToCameraPose(extrinsicsOld);`
	This example specifies extrinsics as a `rigidtform3d` object using the geometric transformation matrix `T`, then converts the extrinsics to a camera pose using the `extr2pose` function.
	
	`A = [1 0 0 0; 0 1 0 0; 0 0 1 -10; 0 0 0 1];`
	`extrinsics = rigidtform3d(A);`
	`cameraPose = extr2pose(extrinsics);`
	If instead you start with an existing `rigid3d` object `extrinsicsOld`, then you can get the geometric transformation matrix in the postmultiply convention by querying the property `T` of `extrinsicsOld`.
	
	`T = extrinsicsOld.T;`
	`extrinsics = rigidtform3d(T');`
	`cameraPose = extr2pose(extrinsics);`

Extended Capabilities

trainACFObjectDetector

Train ACF object detector

Syntax

```
detector = trainACFObjectDetector(trainingData)
detector = trainACFObjectDetector(trainingData,Name=Value)
```

Description

`detector = trainACFObjectDetector(trainingData)` returns a trained aggregate channel features (ACF) object detector. The function uses positive instances of objects in images stored in a table or a datastore, and specified by `trainingData`. The function automatically collects negative instances from the images during training. To create a ground truth table, use the Image Labeler or Video Labeler app.

`detector = trainACFObjectDetector(trainingData,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `ObjectTrainingSize=[100,100]` sets the height and width of objects during training.

Examples

Train Stop Sign Detector Using ACF Object Detector

Use the `trainACFObjectDetector` with training images to create an ACF object detector that can detect stop signs. Test the detector with a separate image.

Load the training data.

```
load('stopSignsAndCars.mat')
```

Prefix the full path to the stop sign images.

```
stopSigns = fullfile(toolboxdir('vision'),'visiondata',stopSignsAndCars{:,1});
```

Create datastores to load the ground truth data for stop signs.

```
imds = imageDatastore(stopSigns);
blds = boxLabelDatastore(stopSignsAndCars(:,2));
```

Combine the image and box label datastores.

```
ds = combine(imds,blds);
```

Train the ACF detector. Set the number of negative samples to use at each stage to 2. You can turn off the training progress output by specifying `Verbose=false`, as a `Name-Value` argument.

```
acfDetector = trainACFObjectDetector(ds,NegativeSamplesFactor=2);
```

```
ACF Object Detector Training
The training will take 4 stages. The model size is 34x31.
```

```
Sample positive examples(~100% Completed)

The trained classifier has 19 weak learners.
--------------------------------------------
Stage 2:
Sample negative examples(~100% Completed)
Found 84 new negative examples for training.
Compute aggregated channel features...Completed.
Train classifier with 42 positive examples and 84 negative examples...Completed.
The trained classifier has 20 weak learners.
--------------------------------------------
Stage 3:
Sample negative examples(~100% Completed)
Found 84 new negative examples for training.
Compute aggregated channel features...Completed.
Train classifier with 42 positive examples and 84 negative examples...Completed.
The trained classifier has 54 weak learners.
--------------------------------------------
Stage 4:
Sample negative examples(~100% Completed)
Found 84 new negative examples for training.
Compute aggregated channel features...Completed.
Train classifier with 42 positive examples and 84 negative examples...Completed.
The trained classifier has 61 weak learners.
--------------------------------------------
ACF object detector training is completed. Elapsed time is 17.9982 seconds.
```

Test the ACF detector on a test image.

```
img = imread('stopSignTest.jpg');
[bboxes,scores] = detect(acfDetector,img);
```

Display the detection results and insert the bounding boxes for objects into the image.

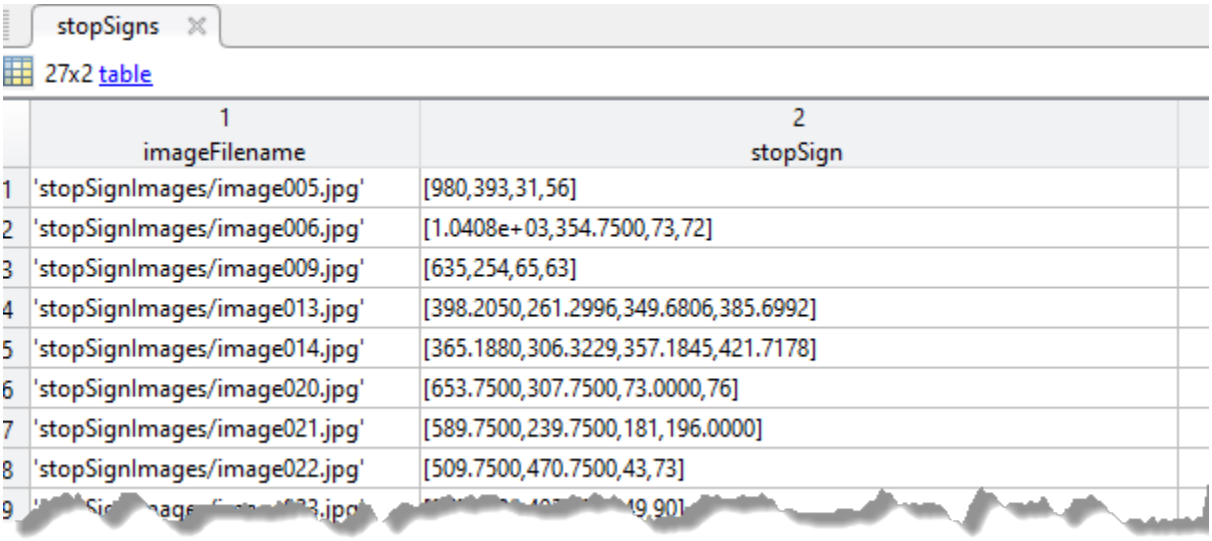
```
for i = 1:length(scores)
   annotation = sprintf('Confidence = %.1f',scores(i));
   img = insertObjectAnnotation(img,'rectangle',bboxes(i,:),annotation);
end

figure
imshow(img)
```

Input Arguments

`trainingData` — Labeled ground truth

datastore | table



Labeled ground truth, specified as a datastore or a table.

- If you use a datastore, your data must be set up so that calling the datastore with the `read` and `readall` functions returns a cell array or table with at least two columns. The table describes the data contained in the columns:

Images	***boxes***	***labels (optional)***
Cell vector of grayscale or RGB images.	*M*-by-4 matrices of bounding boxes of the form [*x*, *y*, *width*, *height*], where [x,y] represent the top-left coordinates of the bounding box.	Cell array that contains an *M*-element categorical vector containing object class names. All categorical data returned by the datastore must contain the same categories. When you provide this data, the function uses the class label to fill the `ModelName` property of the trained detector, specified as an `acfObjectDetector` object. Otherwise, the class labels are not required for training because the ACF object detector is a single class detector.

- If you use a table, the table must have two or more columns. The first column of the table must contain image file names with paths. The images must be grayscale or truecolor (RGB) and they

can be in any format supported by `imread`. Each of the remaining columns must be a cell vector that contains *M*-by-4 matrices that represent a single object class, such as *vehicle*, *flower*, or *stop sign*. The columns contain 4-element double arrays of *M* bounding boxes in the format [*x*,*y*,*width*,*height*]. The format specifies the upper-left corner location and size of the bounding box in the corresponding image. To create a ground truth table, you can use the Image Labeler app or Video Labeler app. To create a table of training data from the generated ground truth, use the `objectDetectorTrainingData` function.

9		

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `ObjectTrainingSize=[100,100]` sets the height and width of objects during training.

`ObjectTrainingSize` — Size of objects during training

`'Auto'` (default) | 2-element vector

Size of objects during training, specified as a 2-element vector of the form [*height width*] in pixels. The minimum training size is `[8 8]`. During the training process, objects are resized to the height and width specified by `'ObjectTrainingSize'`. Increasing the size can improve detection accuracy, but also increases training and detection times.

When you specify `'Auto'`, the size is set based on the median width-to-height ratio of the positive instances.

Example: `[100,100]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`NumStages` — Number of training stages

4 (default) | positive integer

Number of training stages for the iterative training process, specified as a positive integer. Increasing this number can improve the detector and reduce training errors, at the expense of longer training time.

Data Types: `double`

`NegativeSamplesFactor` — Negative sample factor
5 (default) | real-valued scalar

Negative sample factor, specified as a real-valued scalar. The number of negative samples to use at each stage is equal to

`NegativeSamplesFactor` × *number of positive samples used at each stage*

Data Types: `double`

`MaxWeakLearners` — Maximum number of weak learners
`2048` (default) | positive integer scalar | vector of positive integers

Maximum number of weak learners for the last stage, specified as a positive integer scalar or vector of positive integers. If the input is a scalar, `MaxWeakLearners` specifies the maximum number for the last stage. If the input is a vector, `MaxWeakLearners` specifies the maximum number for each of the stages and must have a length equal to '`NumStages`'. These values typically increase throughout the stages. The ACF object detector uses the boosting algorithm to create an ensemble of weaker learners. You can use higher values to improve the detection accuracy, at the expense of reduced detection performance speeds. Recommended values range from 300 to 5000.

Data Types: `double`

`Verbose` — Display progress information
`true` (default) | `false`

Option to display progress information for the training process, specified as `true` or `false`.

Data Types: `logical`

Output Arguments

`detector` — Trained ACF-based object detector
`acfObjectDetector` object

Trained ACF-based object detector, returned as an `acfObjectDetector` object.

Version History

Introduced in R2017a

R2025a: MATLAB Compiler support will be removed
Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

trainRCNNObjectDetector

(Not recommended) Train R-CNN deep learning object detector

Note `trainRCNNObjectDetector` is not recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` detector. For more information, see “Version History”.

Syntax

```
detector = trainRCNNObjectDetector(trainingData,network,options)
detector = trainRCNNObjectDetector( ___ ,Name,Value)
detector = trainRCNNObjectDetector( ___ ,'RegionProposalFcn',proposalFcn)
[detector,info] = trainRCNNObjectDetector( ___ )

detector = trainRCNNObjectDetector( ___ ,Name=Value)
```

Description

`detector = trainRCNNObjectDetector(trainingData,network,options)` trains an R-CNN (regions with convolutional neural networks) based object detector. The function uses deep learning to train the detector to detect multiple object classes.

This implementation of R-CNN does not train an SVM classifier for each object class.

This function requires that you have Deep Learning Toolbox and Statistics and Machine Learning Toolbox. It is recommended that you also have Parallel Computing Toolbox to use with a CUDA-enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

`detector = trainRCNNObjectDetector( ___ ,Name,Value)` returns a `detector` object with optional input properties specified by one or more `Name,Value` pair arguments.

`detector = trainRCNNObjectDetector( ___ ,'RegionProposalFcn',proposalFcn)` optionally trains an R-CNN detector using a custom region proposal function.

`[detector,info] = trainRCNNObjectDetector( ___ )` also returns information on the training progress, such as training loss and accuracy, for each iteration.

`detector = trainRCNNObjectDetector( ___ ,Name=Value)` uses additional options specified by one or more name-value pair arguments and any of the previous inputs.

Examples

Train R-CNN Stop Sign Detector

Load training data and network layers.

```
load('rcnnStopSigns.mat', 'stopSigns', 'layers')
```

Add the image directory to the MATLAB path.

```
imDir = fullfile(matlabroot, 'toolbox', 'vision', 'visiondata',...
  'stopSignImages');
addpath(imDir);
```

Set network training options to use mini-batch size of 32 to reduce GPU memory usage. Lower the InitialLearnRate to reduce the rate at which network parameters are changed. This is beneficial when fine-tuning a pre-trained network and prevents the network from changing too rapidly.

```
options = trainingOptions('sgdm', ...
  'MiniBatchSize', 32, ...
  'InitialLearnRate', 1e-6, ...
  'MaxEpochs', 10);
```

Train the R-CNN detector. Training can take a few minutes to complete.

```
rcnn = trainRCNNObjectDetector(stopSigns, layers, options, 'NegativeOverlapRange', [0 0.3]);
```

```

|========================================================================================|
Training finished: Max epochs completed.

Network training complete.

--> Training bounding box regression models for each object class...100.00%...done.

Detector training complete.
*********************************************************************
```

Test the R-CNN detector on a test image.

```
img = imread('stopSignTest.jpg');

[bbox, score, label] = detect(rcnn, img, MiniBatchSize=32);
```

Display strongest detection result.

```
[score, idx] = max(score);

bbox = bbox(idx, :);
annotation = sprintf('%s: (Confidence = %f)', label(idx), score);

detectedImg = insertObjectAnnotation(img, 'rectangle', bbox, annotation);

figure
imshow(detectedImg)
```

Remove the image directory from the path.

```
rmpath(imDir);
```

Resume Training an R-CNN Object Detector

Resume training an R-CNN object detector using additional data. To illustrate this procedure, half the ground truth data will be used to initially train the detector. Then, training is resumed using all the data.

Load training data and initialize training options.

```
load('rcnnStopSigns.mat', 'stopSigns', 'layers')

stopSigns.imageFilename = fullfile(toolboxdir('vision'),'visiondata', ...
    stopSigns.imageFilename);
```

```
options = trainingOptions('sgdm', ...
    'MiniBatchSize', 32, ...
    'InitialLearnRate', 1e-6, ...
    'MaxEpochs', 10, ...
    'Verbose', false);
```

Train the R-CNN detector with a portion of the ground truth.

```
rcnn = trainRCNNObjectDetector(stopSigns(1:10,:), layers, options, 'NegativeOverlapRange', [0 0.3
```

Get the trained network layers from the detector. When you pass in an array of network layers to `trainRCNNObjectDetector`, they are used as-is to continue training.

```
network = rcnn.Network;
layers = network.Layers;
```

Resume training using all the training data.

```
rcnnFinal = trainRCNNObjectDetector(stopSigns, layers, options);
```

Create a Network for Multiclass R-CNN Object Detection

Create an R-CNN object detector for two object classes: dogs and cats.

```
objectClasses = {'dogs','cats'};
```

The network must be able to classify both dogs, cats, and a "background" class in order to be trained using `trainRCNNObjectDetector`. In this example, a one is added to include the background.

```
numClassesPlusBackground = numel(objectClasses) + 1;
```

The final fully connected layer of a network defines the number of classes that the network can classify. Set the final fully connected layer to have an output size equal to the number of classes plus a background class.

```
layers = [ ...
    imageInputLayer([28 28 1])
    convolution2dLayer(5,20)
    fullyConnectedLayer(numClassesPlusBackground);
    softmaxLayer()
    classificationLayer()];
```

These network layers can now be used to train an R-CNN two-class object detector.

Use A Saved Network In R-CNN Object Detector

Create an R-CNN object detector and set it up to use a saved network checkpoint. A network checkpoint is saved every epoch during network training when the `trainingOptions` 'CheckpointPath' parameter is set. Network checkpoints are useful in case your training session terminates unexpectedly.

Load the stop sign training data.

```
load('rcnnStopSigns.mat','stopSigns','layers')
```

Add full path to image files.

```
stopSigns.imageFilename = fullfile(toolboxdir('vision'),'visiondata', ...
      stopSigns.imageFilename);
```

Set the 'CheckpointPath' using the `trainingOptions` function.

```
checkpointLocation = tempdir;
options = trainingOptions('sgdm','Verbose',false, ...
    'CheckpointPath',checkpointLocation);
```

Train the R-CNN object detector with a few images.

```
rcnn = trainRCNNObjectDetector(stopSigns(1:3,:),layers,options);
```

Load a saved network checkpoint.

```
wildcardFilePath = fullfile(checkpointLocation,'convnet_checkpoint__*.mat');
contents = dir(wildcardFilePath);
```

Load one of the checkpoint networks.

```
filepath = fullfile(contents(1).folder,contents(1).name);
checkpoint = load(filepath);

checkpoint.net
```

```
ans =

  SeriesNetwork with properties:

    Layers: [15×1 nnet.cnn.layer.Layer]
```

Create a new R-CNN object detector and set it up to use the saved network.

```
rcnnCheckPoint = rcnnObjectDetector();
rcnnCheckPoint.RegionProposalFcn = @rcnnObjectDetector.proposeRegions;
```

Set the Network to the saved network checkpoint.

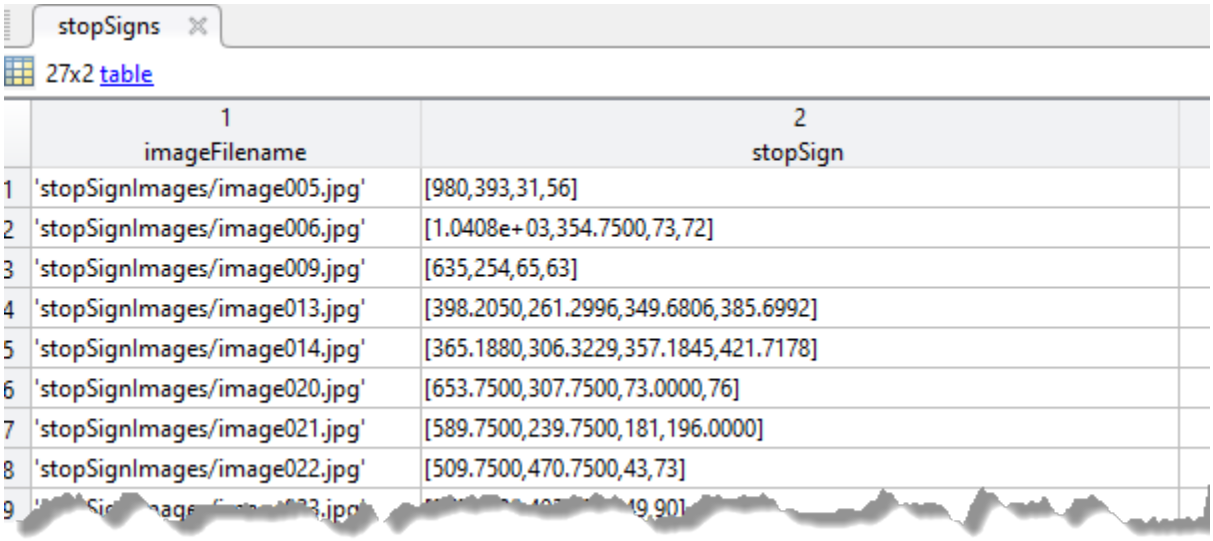
```
rcnnCheckPoint.Network = checkpoint.net
```

```
rcnnCheckPoint =

  rcnnObjectDetector with properties:

            Network: [1×1 SeriesNetwork]
         ClassNames: {'stopSign'  'Background'}
```

```
    RegionProposalFcn: @rcnnObjectDetector.proposeRegions
```



Input Arguments

`trainingData` — Labeled ground truth images

table

Labeled ground truth images, specified as a table with two or more columns.

If you use a table, the table must have two or more columns. The first column of the table must contain image file names with paths. The images must be grayscale or truecolor (RGB) and they can be in any format supported by `imread`. Each of the remaining columns must be a cell vector that contains *M*-by-4 matrices that represent a single object class, such as *vehicle*, *flower*, or *stop sign*. The columns contain 4-element double arrays of *M* bounding boxes in the format [*x*,*y*,*width*,*height*]. The format specifies the upper-left corner location and size of the bounding box in the corresponding image. To create a ground truth table, you can use the Image Labeler app or Video Labeler app. To create a table of training data from the generated ground truth, use the `objectDetectorTrainingData` function.

stopSigns

27x2 table

	1 imageFilename	2 stopSign
1	'stopSignImages/image005.jpg'	[980,393,31,56]
2	'stopSignImages/image006.jpg'	[1.0408e+03,354.7500,73,72]
3	'stopSignImages/image009.jpg'	[635,254,65,63]
4	'stopSignImages/image013.jpg'	[398.2050,261.2996,349.6806,385.6992]
5	'stopSignImages/image014.jpg'	[365.1880,306.3229,357.1845,421.7178]
6	'stopSignImages/image020.jpg'	[653.7500,307.7500,73.0000,76]
7	'stopSignImages/image021.jpg'	[589.7500,239.7500,181,196.0000]
8	'stopSignImages/image022.jpg'	[509.7500,470.7500,43,73]
9		

The table variable name defines the object class name. To create the ground truth table, use the Image Labeler app. Boxes smaller than 32-by-32 are not used for training.

`network` — Network

`SeriesNetwork` object | array of `Layer` objects | `LayerGraph` object | network name

Network, specified as a `SeriesNetwork`, an array of `Layer` objects, a `layerGraph` object, or by the network name. The network is trained to classify the object classes defined in the `trainingData` table. The `SeriesNetwork`, `Layer`, and `layerGraph` objects are available in the Deep Learning Toolbox.

- When you specify the network as a `SeriesNetwork`, an array of `Layer` objects, or by the network name, the network is automatically transformed into a R-CNN network by adding new classification and regression layers to support object detection.

- The array of `Layer` objects must contain a classification layer that supports the number of object classes, plus a background class. Use this input type to customize the learning rates of each layer. An example of an array of `Layer` objects:

  ```
  layers = [imageInputLayer([28 28 3])
          convolution2dLayer([5 5],10)
          reluLayer()
          fullyConnectedLayer(10)
          softmaxLayer()
          classificationLayer()];
  ```

- When you specify the network as `SeriesNetwork`, `Layer` array, or network by name, the weights for convolution and fully-connected layers are initialized to `'narrow-normal'`.
- The network name must be one of the following valid networks names. You must also install the corresponding Add-on.
  - `'alexnet'`
  - `'vgg16'`
  - `'vgg19'`
  - `'resnet18'`
  - `'resnet50'`
  - `'resnet101'`
  - `'inceptionv3'`
  - `'googlenet'`
  - `'inceptionresnetv2'`
  - `'squeezenet'`
  - `'mobilenetv2'`
- The `LayerGraph` object must be a valid R-CNN object detection network. You can also use a `LayerGraph` object to train a custom R-CNN network.

See “Getting Started with R-CNN, Fast R-CNN, and Faster R-CNN” to learn more about how to create a R-CNN network.

`options` — Training options
`trainingOptions` output

Training options, returned by the `trainingOptions` function from the Deep Learning Toolbox. To specify solver and other options for network training, use `trainingOptions`.

Note `trainRCNNObjectDetector` does not support these training options:

- The `ValidationData`, `ValidationFrequency`, or `ValidationPatience` options

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `PositiveOverlapRange=[0.5 1]`

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `"PositiveOverlapRange",[0.5 1]`

`PositiveOverlapRange` — Positive training sample ratios for range of bounding box overlap
`[0.5 1]` (default) | two-element vector

Positive training sample ratios for range of bounding box overlap, specified as a two-element vector. The vector contains values in the range [0,1]. Region proposals that overlap with ground truth bounding boxes within the specified range are used as positive training samples.

The overlap ratio used for both the `PositiveOverlapRange` and `NegativeOverlapRange` is defined as:

$$\frac{area(A \cap B)}{area(A \cup B)}$$

A and B are bounding boxes.

`NegativeOverlapRange` — Negative training sample ratios for range of bounding box overlap
`[0.1 0.5]` (default) | two-element vector

Negative training sample ratios for range of bounding box overlap, specified as a two-element vector. The vector contains values in the range [0,1]. Region proposals that overlap with the ground truth bounding boxes within the specified range are used as negative training samples.

`NumStrongestRegions` — Maximum number of strongest region proposals
`2000` (default) | integer

Maximum number of strongest region proposals to use for generating training samples, specified as an integer. Reduce this value to speed up processing time, although doing so decreases training accuracy. To use all region proposals, set this value to `inf`.

`RegionProposalFcn` — Custom region proposal
function handle

Custom region proposal function handle, specified as a function handle. If you do not specify a custom region proposal function, the default variant of the Edge Boxes algorithm [3], set in `rcnnObjectDetector`, is used. A custom `proposalFcn` must have the following functional form:

```
[bboxes,scores] = proposalFcn(I)
```

The input, `I`, is an image defined in the `groundTruth` table. The function must return rectangular bounding boxes in an *M*-by-4 array. Each row of `bboxes` contains a four-element vector, [*x*,*y*,*width*,*height*], that specifies the upper–left corner and size of a bounding box in pixels. The function must also return a score for each bounding box in an *M*-by-1 vector. Higher scores indicate that the bounding box is more likely to contain an object. The scores are used to select the strongest regions, which you can specify in `NumStrongestRegions`.

`BoxRegressionLayer` — Box regression layer name
`'auto'` (default) | character vector

Box regression layer name, specified as a character vector. Valid values are `'auto'` or the name of a layer in the input network. The output activations of this layer are used as features to train a regression model for refining the detected bounding boxes.

If the name is `'auto'`, then `trainRCNNObjectDetector` automatically selects a layer from the input network based on the type of input network:

- If the input `network` is a `SeriesNetwork` or an array of `Layer` objects, then the function selects the last convolution layer.
- If the input `network` is a `LayerGraph`, then the function selects the source of the last fully connected layer.

`ExperimentManager` — Detector training experiment monitoring
`'none'` (default) | `experiments.Monitor` object

Detector training experiment monitoring, specified as an `experiments.Monitor` object for use with the Experiment Manager app. You can use this object to track the progress of training, update information fields in the training results table, record values of the metrics used by the training, and to produce training plots.

Information monitored during training:

- Training loss at each iteration.
- Training accuracy at each iteration.
- Training root mean square error (RMSE) for the box regression layer.
- Learning rate at each iteration.

Output Arguments

`detector` — Trained R-CNN-based object detector
`rcnnObjectDetector` object

Trained R-CNN-based object detector, returned as an `rcnnObjectDetector` object. You can train an R-CNN detector to detect multiple object classes.

`info` — Training information
structure

Training information, returned as a structure with the following fields. Each field is a numeric vector with one element per training iteration. Values that have not been calculated at a specific iteration are represented by `NaN`.

- `TrainingLoss` — Training loss at each iteration. This is the combination of the classification and regression loss used to train the R-CNN network.
- `TrainingAccuracy` — Training set accuracy at each iteration
- `BaseLearnRate` — Learning rate at each iteration

Limitations

- This implementation of R-CNN does not train an SVM classifier for each object class.

Tips

- To accelerate data preprocessing for training, `trainRCNNObjectDetector` automatically creates and uses a parallel pool based on your parallel preference settings. This requires Parallel Computing Toolbox.
- VGG-16, VGG-19, ResNet-101, and Inception-ResNet-v2 are large models. Training with large images may produce "Out of Memory" errors. To mitigate these errors, manually resize the images along with the bounding box ground truth data before calling `trainRCNNObjectDetector`.
- This function supports transfer learning. When a network is input by name, such as `'resnet50'`, then the software automatically transforms the network into a valid R-CNN network model based on the pretrained `resnet50` model. Alternatively, manually specify a custom R-CNN network using the `LayerGraph` extracted from a pretrained DAG network. See “Create R-CNN Object Detection Network”.
- Use the `trainingOptions` function to enable or disable verbose printing.

Version History

Introduced in R2016b

R2025a: MATLAB Compiler support will be removed

Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

R2024b: Not Recommended

Not recommended starting in R2024b

Starting in R2024b, R-CNN object detectors are no longer recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` object. These object detectors are faster than R-CNN object detectors. For more information, see “Choose an Object Detector”.

estimateGeometricTransform2D

(Not recommended) Estimate 2-D geometric transformation from matching point pairs

Note `estimateGeometricTransform2D` is not recommended. Use the `estgeotform2d` function instead. For more information, see “Version History”.

Syntax

```
tform = estimateGeometricTransform2D(matchedPoints1,matchedPoints2,
transformType)
[tform,inlierIndex] = estimateGeometricTransform2D( ___ )
[tform,inlierIndex,status] = estimateGeometricTransform2D( ___ )
[ ___ ] = estimateGeometricTransform2D( ___ , Name,Value)
```

Description

`tform = estimateGeometricTransform2D(matchedPoints1,matchedPoints2, transformType)` estimates a 2-D geometric transformation between two images by mapping the inliers in the matched points from one image `matchedPoints1` to the inliers in the matched points from another image `matchedPoints2`.

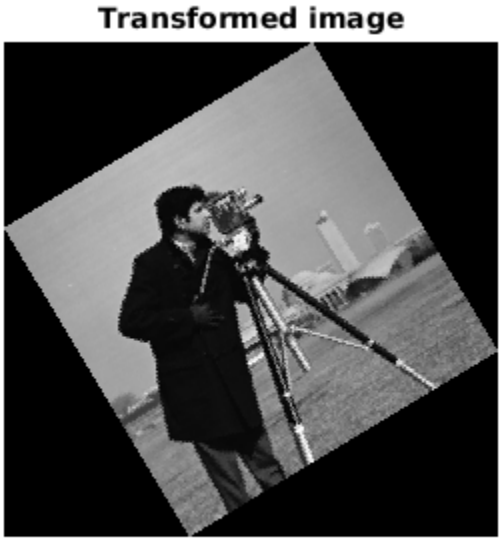
`[tform,inlierIndex] = estimateGeometricTransform2D( ___ )` additionally returns a vector specifying each matched point pair as either an inlier or an outlier using the input arguments from the previous syntax.

`[tform,inlierIndex,status] = estimateGeometricTransform2D( ___ )` additionally returns a status code indicating whether or not the function could estimate a transformation and, if not, why it failed. If you do not specify the `status` output, the function instead returns an error for conditions that cannot produce results.

`[ ___ ] = estimateGeometricTransform2D( ___ , Name,Value)` specifies additional options using one or more name-value pair arguments in addition to any combination of arguments from previous syntaxes. For example, `"Confidence",99` sets the confidence value for finding the maximum number of inliers to 99.

Examples

Recover Transformed Image Using SURF Feature Points

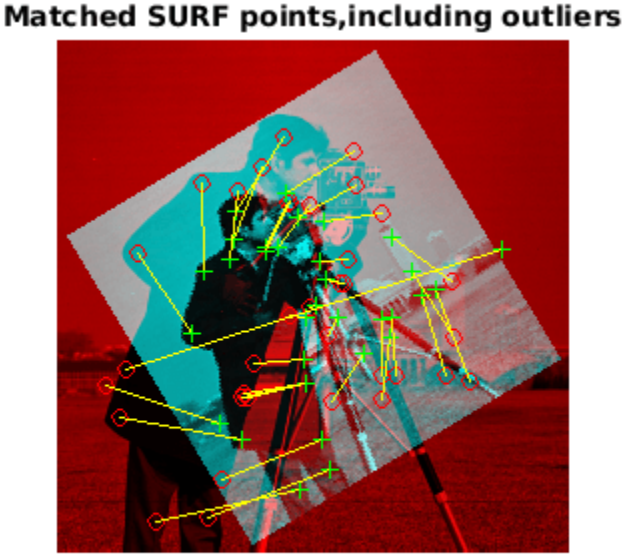


Read an image and display it.

```
original = imread('cameraman.tif');
imshow(original)
title('Base Image')
```

Distort and display the transformed image.

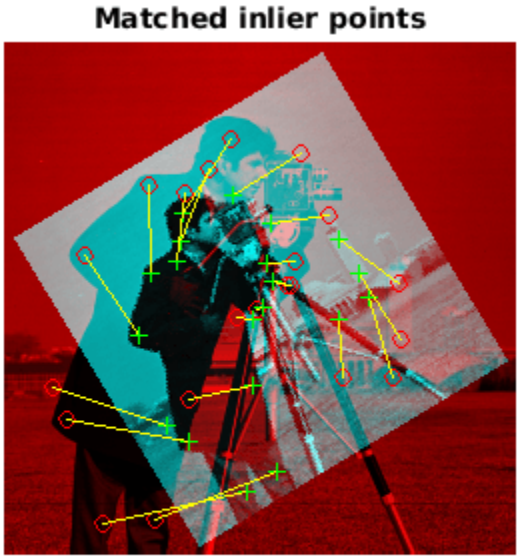
```
distorted = imresize(original,0.7);
distorted = imrotate(distorted,31);
figure
imshow(distorted)
title('Transformed Image')
```



Detect and extract features from the original and the transformed images.

```
ptsOriginal  = detectSURFFeatures(original);
ptsDistorted = detectSURFFeatures(distorted);
[featuresOriginal,validPtsOriginal] = extractFeatures(original,ptsOriginal);
[featuresDistorted,validPtsDistorted] = extractFeatures(distorted,ptsDistorted);
```

Match and display features between the images.



```
index_pairs = matchFeatures(featuresOriginal,featuresDistorted);
matchedPtsOriginal  = validPtsOriginal(index_pairs(:,1));
matchedPtsDistorted = validPtsDistorted(index_pairs(:,2));
figure
showMatchedFeatures(original,distorted,matchedPtsOriginal,matchedPtsDistorted)
title('Matched SURF Points With Outliers');
```

Exclude the outliers, estimate the transformation matrix, and display the results.

```
[tform,inlierIdx] = estimateGeometricTransform2D(matchedPtsDistorted,matchedPtsOriginal,'similar
inlierPtsDistorted = matchedPtsDistorted(inlierIdx,:);
inlierPtsOriginal  = matchedPtsOriginal(inlierIdx,:);

figure
showMatchedFeatures(original,distorted,inlierPtsOriginal,inlierPtsDistorted)
title('Matched Inlier Points')
```

Use the estimated transformation to recover and display the original image from the distorted image.

```
outputView = imref2d(size(original));
Ir = imwarp(distorted,tform,'OutputView',outputView);
figure
imshow(Ir);
title('Recovered Image');
```

Input Arguments

`matchedPoints1` — Matched points from first image

`cornerPoints` object | `SURFPoints` object | `MSERRegions` object | `ORBPoints` object | `BRISKPoints` object | `KAZEPoints` object | *M*-by-2 matrix of [*x*,*y*] coordinates

Matched points from the first image, specified as either a `KAZEPoints` object, `cornerPoints` object, `SURFPoints` object, `MSERRegions` object, `ORBPoints` object, `BRISKPoints` object, or an *M*-by-2 matrix in which each row is a pair of [*x*,*y*] coordinates and *M* is the number of matched points.

`matchedPoints2` — Matched points from second image

`cornerPoints` object | `SURFPoints` object | `MSERRegions` object | `ORBPoints` object | `BRISKPoints` object | `KAZEPoints` object | *M*-by-2 matrix of [*x*,*y*] coordinates

Matched points from the second image, specified as either a `KAZEPoints` object, `cornerPoints` object, `SURFPoints` object, `MSERRegions` object, `ORBPoints` object, `BRISKPoints` object, or an *M*-by-2 matrix in which each row is a pair of [*x*,*y*] coordinates and *M* is the number of matched points.

`transformType` — Transformation type

`"rigid"` | `"similarity"` | `"affine"` | `"projective"`

Transformation type, specified as a character string. You can set the transform type to `"rigid"`, `"similarity"`, `"affine"`, or `"projective"`. Each transform type requires a minimum number of matched pairs of points to estimate a transformation. You can generally improve the accuracy of a transformation by using a larger number of matched pairs of points. This table shows the type of object associated with each transformation type and the minimum number of matched pairs of points the transformation requires.

Transformation Type	`tform` Object	Minimum Number of Matched Pairs of Points
`"rigid"`	`rigid2d`	2
`"similarity"`	`affine2d`	2
`"affine"`	`affine2d`	3
`"projective"`	`projective2d`	4

Data Types: `string`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `"Confidence",99` sets the confidence value for finding the maximum number of inliers to `99`.

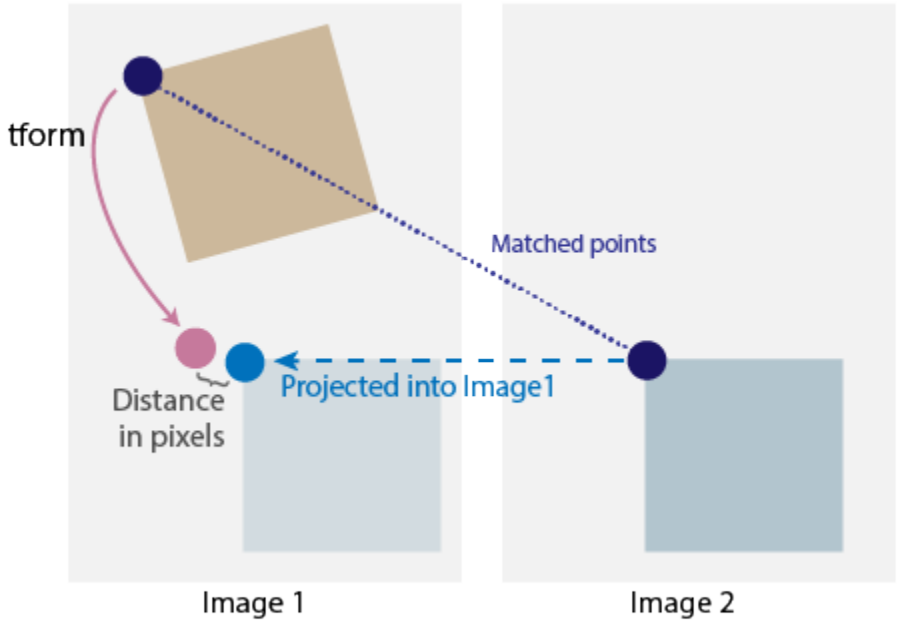
`MaxNumTrials` — Maximum random trials

`1000` (default) | positive integer

Maximum number of random trials, specified as the comma-separated pair consisting of `"MaxNumTrials"` and a positive integer. This value specifies the number of randomized attempts the function makes to find matching point pairs. Specifying a higher value causes the function to perform additional computations, which increases the likelihood of finding inliers.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Confidence` — Confidence of finding maximum number of inliers
99 (default) | positive numeric scalar



Confidence of finding the maximum number of inliers, specified as the comma-separated pair consisting of `"Confidence"` and a positive numeric scalar in the range (0, 100). Increasing this value causes the function to perform additional computations, which increases the likelihood of finding a greater number of inliers.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`MaxDistance` — Maximum distance from point to projection
`1.5` (default) | positive numeric scalar

Maximum distance from a point to the projection of the corresponding point, specified as the comma-separated pair consisting of `"MaxDistance"` and a positive numeric scalar. `"MaxDistance"` specifies the maximum distance, in pixels, that a point can differ from the projected location of its corresponding point to be considered an inlier. The corresponding projection is based on the estimated transform.

The function checks for a transformation from `matchedPoints1` to `matchedPoints2`, and then calculates the distance between the matched points in each pair after applying the transformation. If the distance between the matched points in a pair is greater than the `"MaxDistance"` value, then the pair is considered an outlier for that transformation. If the distance is less than `"MaxDistance"`, then the pair is considered an inlier.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`tform` — Geometric transformation

`rigid2d` object | `affine2d` object | `projective2d` object

Geometric transformation, returned as a `rigid2d`, `affine2d`, or `projective2d` object.

The returned geometric transformation matrix maps the inliers in `matchedPoints1` to the inliers in `matchedPoints2`. The function returns an object specific to the transformation type specified by the `transformType` input argument.

`transformType`	Geometric Transformation Object
`"rigid"`	`rigid2d`
`"similarity"`	`affine2d`
`"affine"`	`affine2d`
`"projective"`	`projective2d`

`inlierIndex` — Index of inliers

M-by-1 logical vector

Index of inliers, returned as an *M*-by-1 logical vector, where *M* is the number of point pairs. Each element contains either a logical `1` (`true`), indicating that the corresponding point pair is an inlier, or a logical `0` (`false`), indicating that the corresponding point pair is an outlier.

Data Types: `logical`

`status` — Status code

`0` | `1` | `2`

Status code, returned as `0`, `1`, or `2`. The status code indicates whether or not the function could estimate the transformation and, if not, why it failed.

Value	Description
`0`	No error
`1`	`matchedPoints1` and `matchedPoints2` inputs do not contain enough points
`2`	Not enough inliers found

If you do not specify the `status` code output, the function returns an error if it cannot produce results.

Data Types: `int32`

Algorithms

The function excludes outliers using the M-estimator sample consensus (MSAC) algorithm. The MSAC algorithm is a variant of the random sample consensus (RANSAC) algorithm. Results may not be identical between runs due to the randomized nature of the MSAC algorithm.

Version History

Introduced in R2020b

R2022b: Not recommended

Not recommended starting in R2022b

Starting in R2022b, many Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `estimateGeometricTransform2d` function estimates geometric transformations using the postmultiply convention. Although there are no plans to remove `estimateGeometricTransform2d` at this time, you can streamline your geometric transformation workflows by switching to the `estgeotform2d` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

To update your code, change instances of the function name `estimateGeometricTransform2d` to `estgeotform2d`. You do not need to change the other arguments.

estimateGeometricTransform3D

(Not recommended) Estimate 3-D geometric transformation from matching point pairs

Note `estimateGeometricTransform3D` is not recommended. Use the `estgeotform3d` function instead. For more information, see “Version History”.

Syntax

```
tform = estimateGeometricTransform3D(matchedPoints1,matchedPoints2,
transformType)
[tform,inlierIndex] = estimateGeometricTransform3D( ___ )
[tform,inlierIndex,status] = estimateGeometricTransform3D( ___ )
[ ___ ] = estimateGeometricTransform3D( ___ , Name,Value)
```

Description

`tform = estimateGeometricTransform3D(matchedPoints1,matchedPoints2, transformType)` estimates a 3-D geometric transformation between two sets of 3-D points by mapping the inliers in the matched points from one set of 3-D points `matchedPoints1` to the inliers in the matched points from the other set of 3-D points `matchedPoints2`.

`[tform,inlierIndex] = estimateGeometricTransform3D( ___ )` additionally returns a vector specifying each matched point pair as either an inlier or an outlier using the input arguments from the previous syntax.

`[tform,inlierIndex,status] = estimateGeometricTransform3D( ___ )` additionally returns a status code indicating whether or not the function could estimate a transformation and, if not, why it failed. If you do not specify the `status` output, the function instead returns an error for conditions that cannot produce results.

`[ ___ ] = estimateGeometricTransform3D( ___ , Name,Value)` specifies additional options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `"Confidence",99` sets the confidence value for finding the maximum number of inliers to `99`.

Examples

Estimate Transformation Between Two Point Clouds

Load a point cloud file into the workspace.

```
ptCloud1 = pcread('teapot.ply')
```

```
ptCloud1 =
  pointCloud with properties:

     Location: [41472×3 single]
        Count: 41472
```

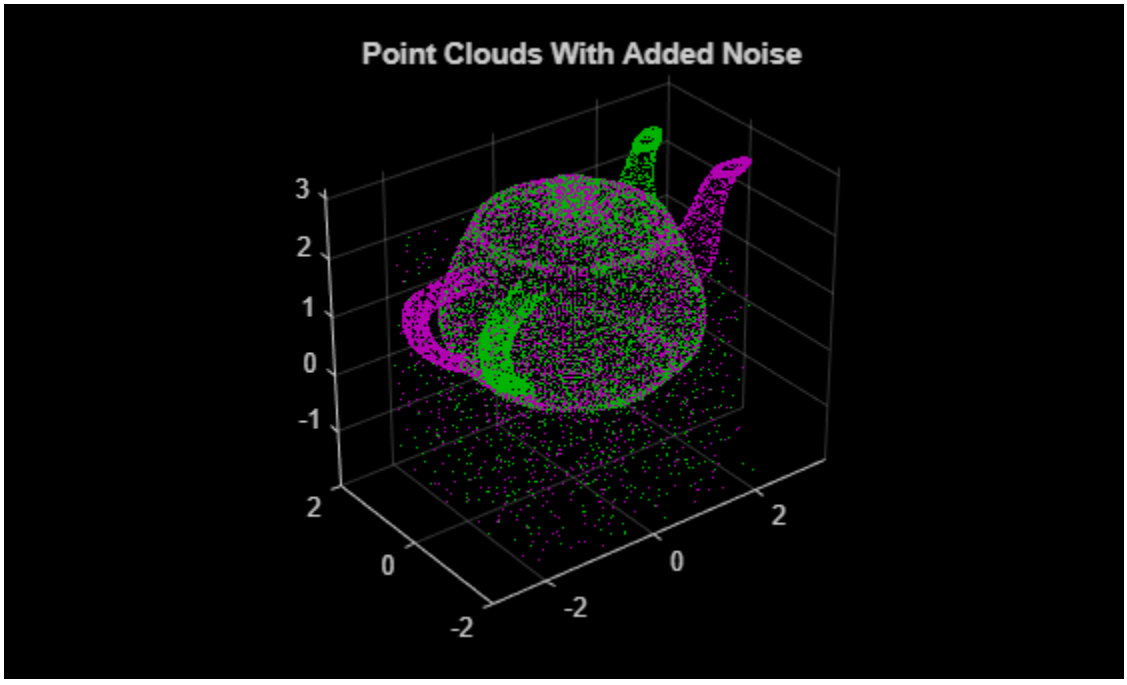
```
      XLimits: [-3 3.4340]
      YLimits: [-2 2]
      ZLimits: [0 3.1500]
        Color: []
       Normal: []
    Intensity: []
```

```
ptCloud1 = pcdownsample(ptCloud1,'random',0.25);
```

Create a rigid 3-D transformation object with a 30-degree rotation.

```
theta = 30; % degrees
rot = [cosd(theta)  sind(theta) 0; ...
      -sind(theta)  cosd(theta) 0; ...
            0           0       1];
trans = [0 0 0];
tform = rigid3d(rot,trans);
```

Transform the point cloud using the transformation object.



```
ptCloud2 = pctransform(ptCloud1,tform);
```

To introduce noise, add random points to both point clouds.

```
noise1 = rescale(rand(1000,3),-2,2);
ptCloud1 = pointCloud([ptCloud1.Location;noise1]);
noise2 = rescale(rand(1000,3),-2,2);
ptCloud2 = pointCloud([ptCloud2.Location;noise2]);
```

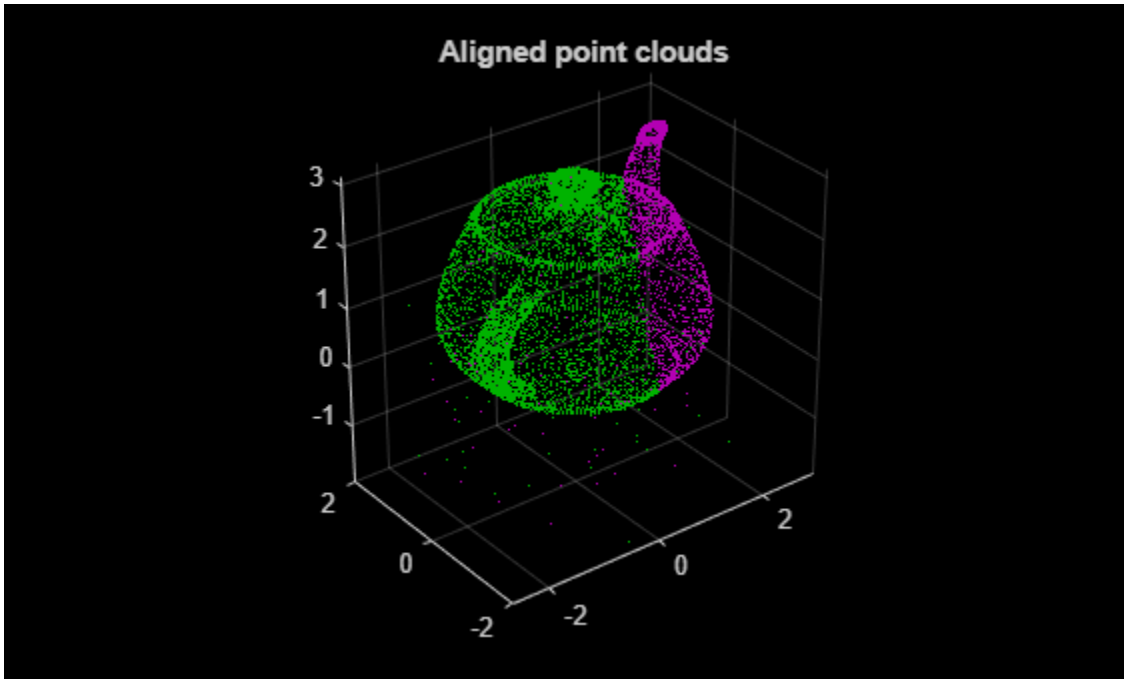
Visualize the noisy point clouds.

```
figure
pcshowpair(ptCloud1,ptCloud2)
title('Point Clouds With Added Noise')
```

Extract matched points from the point clouds.

```
matchedPoints1 = ptCloud1.Location;
matchedPoints2 = ptCloud2.Location;
```

Estimate the rigid transformation between the point clouds.



```
[tformEst,inlierIndex] = estimateGeometricTransform3D(matchedPoints1, ...
    matchedPoints2,'rigid');
```

Extract the inlier points.

```
inliersPtCloud1 = transformPointsForward(tformEst,matchedPoints1(inlierIndex,:));
inliersPtCloud2 = matchedPoints2(inlierIndex,:);
```

Visualize the inliers of the aligned point clouds.

```
figure
firstPtCloud = pointCloud(inliersPtCloud1);
secondPtCloud = pointCloud(inliersPtCloud2);
pcshowpair(firstPtCloud,secondPtCloud)
title('Aligned point clouds')
```

Input Arguments

`matchedPoints1` — First set of matched 3-D points

M-by-3 matrix of [*x*,*y*,*z*] coordinates

First set of matched 3-D points, specified as an *M*-by-3 matrix in which each row is a set of (*x*,*y*,*z*) coordinates and *M* is the number of matched points.

`matchedPoints2` — Second set of matched 3-D points
M-by-3 matrix of [*x*,*y*,*z*] coordinates

Second set of matched 3-D points, specified as an *M*-by-3 matrix in which each row is a set of (*x*,*y*,*z*) coordinates and *M* is the number of matched points.

`transformType` — Transformation type
`"rigid"` | `"similarity"`

Transformation type, specified as `"rigid"` or `"similarity"`. Each transform type requires a minimum number of matched pairs of points to estimate a transformation. You can generally improve the accuracy of a transformation by using a larger number of matched pairs of points. This table shows the type of object associated with each transformation type and the minimum number of matched pairs of points the transformation requires.

`transformType`	`tform` Object	Minimum Number of Matched Pairs of Points
`"rigid"`	`rigid3d`	3
`"similarity"`	`affine3d`	3

Data Types: `string`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

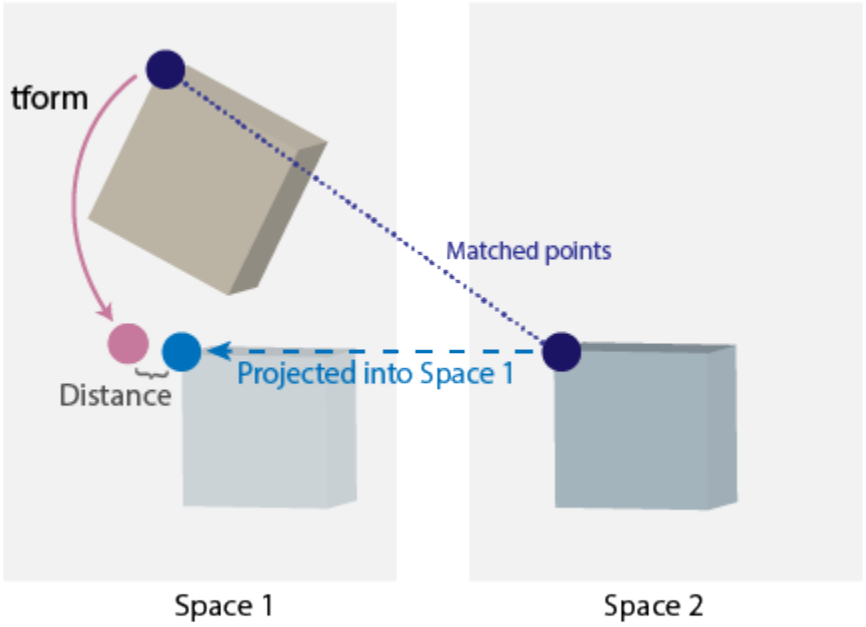
Example: `"Confidence",99` sets the confidence value for finding the maximum number of inliers to `99`.

`MaxNumTrials` — Maximum random trials
`1000` (default) | positive integer

Maximum number of random trials, specified as a positive integer. This value specifies the number of randomized attempts the function makes to find matching point pairs. Specifying a higher value causes the function to perform additional computations, which increases the likelihood of finding inliers.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Confidence` — Confidence of finding maximum number of inliers
`99` (default) | positive numeric scalar



Confidence of finding the maximum number of inliers, specified as a positive numeric scalar in the range (0, 100). Increasing this value causes the function to perform additional computations, which increases the likelihood of finding a greater number of inliers.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`MaxDistance` — Maximum distance from point to projection
`1.5` (default) | positive numeric scalar

Maximum distance from a point to the projection of the corresponding point, specified as a positive numeric scalar. `"MaxDistance"` specifies the maximum distance, in pixels, that a point can differ from the projected location of its corresponding point to be considered an inlier. The corresponding projection is based on the estimated transform.

The function checks for a transformation from `matchedPoints1` to `matchedPoints2`, and then calculates the distance between the matched points in each pair after applying the transformation. If the distance between the matched points in a pair is greater than the `"MaxDistance"` value, then the pair is considered an outlier for that transformation. If the distance is less than `"MaxDistance"`, then the pair is considered an inlier.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`tform` — Geometric transformation

`rigid3d` object | `affine3d` object

Geometric transformation, returned as an `affine3d` or a `rigid3d` object.

The returned geometric transformation matrix maps the inliers in `matchedPoints1` to the inliers in `matchedPoints2`. The function returns an object specific to the transformation type specified by the `transformType` input argument.

`transformType`	`tform`
`"rigid"`	`rigid3d`
`"similarity"`	`affine3d`

`inlierIndex` — Inliers

M-by-1 logical vector

Inliers, returned as an *M*-by-1 logical vector of *M* point pairs. Each element contains either a logical true, `1`, to indicate the point pair is an inlier, or a logical false, `0`, to indicate the point pair is an outlier.

`status` — Status code
`0` | `1` | `2`

Status code, returned as `0`, `1`, or `2`. The status code indicates whether or not the function could estimate the transformation and, if not, why it failed.

Value	Description
`0`	No error
`1`	`matchedPoints1` and `matchedPoints2` inputs do not contain enough points
`2`	Not enough inliers found

If you do not specify the `status` code output, the function returns an error if it cannot produce results.

Data Types: `int32`

Algorithms

The function excludes outliers using the M-estimator sample consensus (MSAC) algorithm. The MSAC algorithm is a variant of the random sample consensus (RANSAC) algorithm. Results may not be identical between runs due to the randomized nature of the MSAC algorithm.

estimateGeometricTransform

(Not recommended) Estimate geometric transform from matching point pairs

Note `estimateGeometricTransform` is not recommended. Use the `estgeotform2d` or `estgeotform3d` function instead. For more information, see “Version History”.

Syntax

```
tform = estimateGeometricTransform(matchedPoints1,matchedPoints2,
transformType)

[tform,inlierpoints1,inlierpoints2] = estimateGeometricTransform(
matchedPoints1,matchedPoints2,transformType)
[___,status] = estimateGeometricTransform(matchedPoints1,matchedPoints2,
transformType)

[___] = estimateGeometricTransform(matchedPoints1,matchedPoints2,
transformType, Name,Value)
```

Description

`tform = estimateGeometricTransform(matchedPoints1,matchedPoints2, transformType)` returns a 2-D geometric transform object, `tform`. The `tform` object maps the inliers in `matchedPoints1` to the inliers in `matchedPoints2`.

The function excludes outliers using the M-estimator SAmple Consensus (MSAC) algorithm. The MSAC algorithm is a variant of the Random Sample Consensus (RANSAC) algorithm. Results may not be identical between runs because of the randomized nature of the MSAC algorithm.

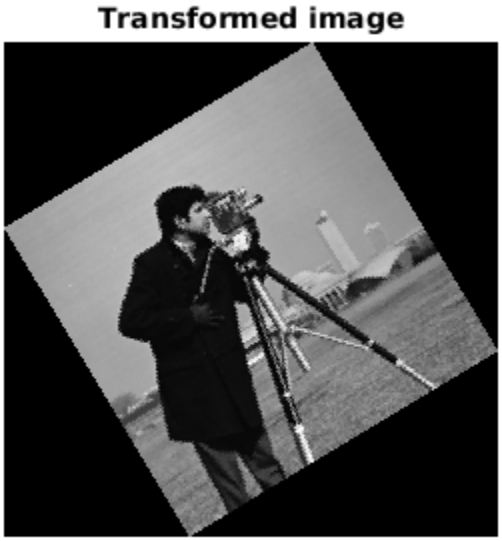
`[tform,inlierpoints1,inlierpoints2] = estimateGeometricTransform( matchedPoints1,matchedPoints2,transformType)` returns the corresponding inlier points in `inlierpoints1` and `inlierpoints2`.

`[___,status] = estimateGeometricTransform(matchedPoints1,matchedPoints2, transformType)` returns a status code of `0`, `1`, or `2`. If you do not request the `status` code output, the function returns an error for conditions that cannot produce results.

`[___] = estimateGeometricTransform(matchedPoints1,matchedPoints2, transformType, Name,Value)` uses additional options specified by one or more name-value arguments.

Examples

Recover Transformed Image Using SURF Feature Points

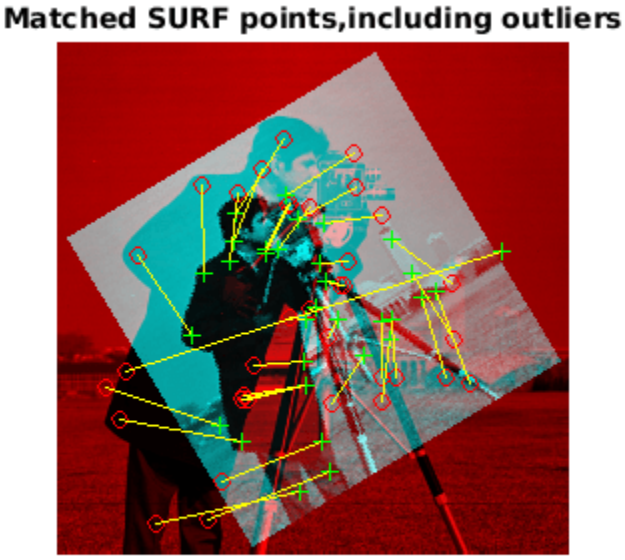


Read an image and display it.

```
original = imread('cameraman.tif');
imshow(original)
title('Base Image')
```

Distort and display the transformed image.

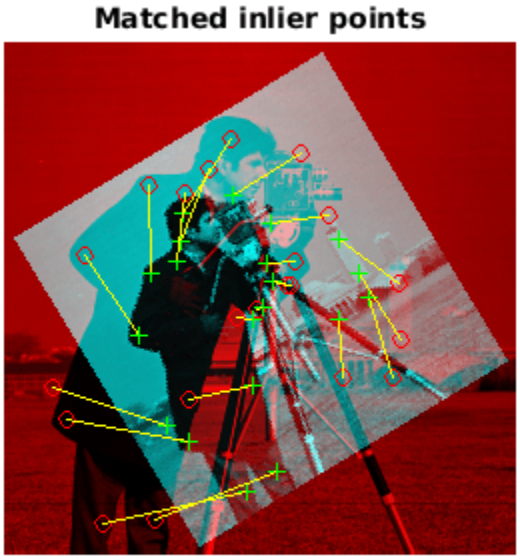
```
distorted = imresize(original,0.7);
distorted = imrotate(distorted,31);
figure
imshow(distorted)
title('Transformed Image')
```



Detect and extract features from the original and the transformed images.

```
ptsOriginal  = detectSURFFeatures(original);
ptsDistorted = detectSURFFeatures(distorted);
[featuresOriginal,validPtsOriginal] = extractFeatures(original,ptsOriginal);
[featuresDistorted,validPtsDistorted] = extractFeatures(distorted,ptsDistorted);
```

Match and display features between the images.



```
index_pairs = matchFeatures(featuresOriginal,featuresDistorted);
matchedPtsOriginal  = validPtsOriginal(index_pairs(:,1));
matchedPtsDistorted = validPtsDistorted(index_pairs(:,2));
figure
showMatchedFeatures(original,distorted,matchedPtsOriginal,matchedPtsDistorted)
title('Matched SURF Points With Outliers');
```

Exclude the outliers, estimate the transformation matrix, and display the results.

```
[tform,inlierIdx] = estimateGeometricTransform2D(matchedPtsDistorted,matchedPtsOriginal,'similar
inlierPtsDistorted = matchedPtsDistorted(inlierIdx,:);
inlierPtsOriginal  = matchedPtsOriginal(inlierIdx,:);

figure
showMatchedFeatures(original,distorted,inlierPtsOriginal,inlierPtsDistorted)
title('Matched Inlier Points')
```

Use the estimated transformation to recover and display the original image from the distorted image.

```
outputView = imref2d(size(original));
Ir = imwarp(distorted,tform,'OutputView',outputView);
figure
imshow(Ir);
title('Recovered Image');
```

Input Arguments

`matchedPoints1` — Matched points from image 1

`cornerPoints` object | `SIFTPoints` | `SURFPoints` object | `MSERRegions` object | `ORBPoints` object | `BRISKpoints` | `KAZEPoints` | *M*-by-2 matrix of [*x*,*y*] coordinates

Matched points from image 1, specified as either a `KAZEPoints`, `cornerPoints` object, `SIFTPoints`, `SURFPoints` object, `MSERRegions` object, `ORBPoints` object, `BRISKPoints` or an *M*-by-2 matrix of [x,y] coordinates. The function excludes outliers using the M-estimator SAmple Consensus (MSAC) algorithm. The MSAC algorithm is a variant of the Random Sample Consensus (RANSAC) algorithm.

`matchedPoints2` — Matched points from image 2

`cornerPoints` object | `SIFTPoints` | `SURFPoints` object | `MSERRegions` object | `ORBPoints` object | `BRISKpoints` | `KAZEPoints` | *M*-by-2 matrix of [*x*,*y*] coordinates

Matched points from image 2, specified as either a `KAZEPoints`, `cornerPoints` object, `SIFTPoints`, `SURFPoints` object, `MSERRegions` object, `ORBPoints` object, `BRISKPoints` or an *M*-by-2 matrix of [x,y] coordinates. The function excludes outliers using the M-estimator SAmple Consensus (MSAC) algorithm. The MSAC algorithm is a variant of the Random Sample Consensus (RANSAC) algorithm.

`transformType` — Transform type

`"similarity"` | `"affine"` | `"projective"`

Transform type, specified as `"similarity"`, `"affine"`, or `"projective"`. The greater the number of matched pairs of points, the greater the accuracy of the estimated transformation. The minimum number of matched pairs of points for each transform type:

Transform Type	Minimum Number of Matched Pairs of Points
`"similarity"`	2
`"affine"`	3
`"projective"`	4

Data Types: `string` | `char`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

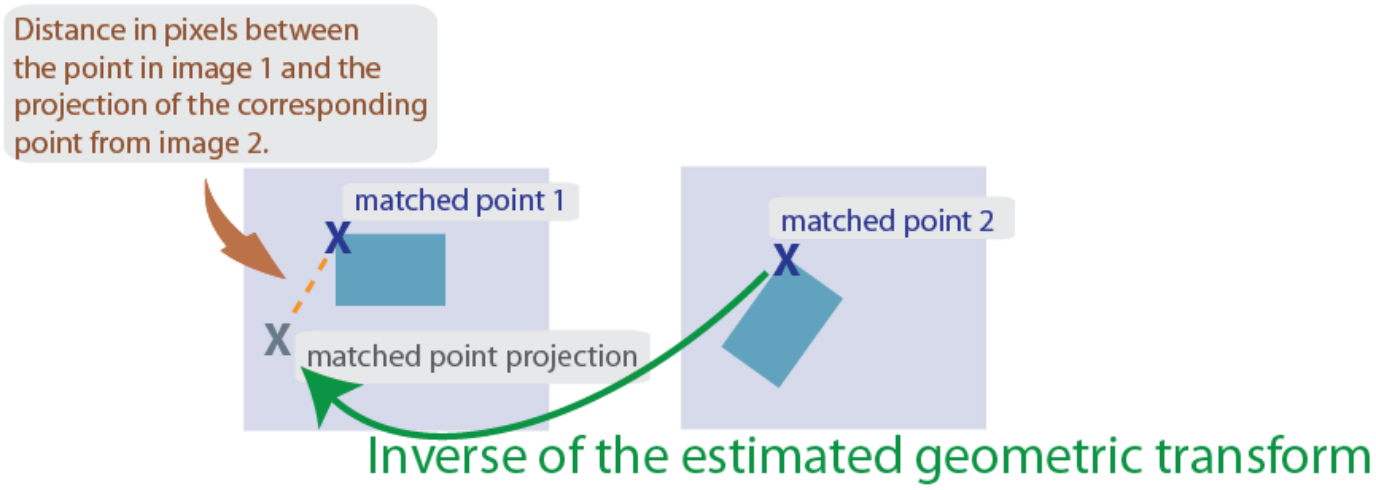
Example: `"Confidence",99` sets the confidence value to 99.

`MaxNumTrials` — Maximum random trials

`1000` (default) | positive integer

Maximum number of random trials for finding the inliers, specified as a positive integer scalar. Increasing this value improves the robustness of the results at the expense of additional computations.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`



`Confidence` — Confidence of finding maximum number of inliers
99 (default) | positive numeric scalar

Confidence of finding the maximum number of inliers, specified as a percentage numeric scalar in the range (0 100). Increasing this value improves the robustness of the results at the expense of additional computations.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`MaxDistance` — Maximum distance from point to projection
`1.5` (default) | positive numeric scalar

Maximum distance in pixels, from a point to the projection of its corresponding point, specified as a positive numeric scalar. The corresponding projection is based on the estimated transform.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`tform` — Geometric transformation
`affine2d` object | `projective2d` object

Geometric transformation, returned as either an `affine2d` object or a `projective2d` object.

The returned geometric transformation matrix maps the inliers in `matchedPoints1` to the inliers in `matchedPoints2`. When you set the `transformType` input to either `"similarity"` or `"affine"`, the function returns an `affine2d` object. Otherwise, it returns a `projective2d` object.

`inlierpoints1` — Inlier points in image 1
inlier points

Inlier points in image 1, returned as the same type as the input matching points.

`inlierpoints2` — Inlier points in image 2
inlier points

Inlier points in image 2, returned as the same type as the input matching points.

`status` — Status code
`0` | `1` | `2`

Status code, returned as the value `0`, `1`, or `2`.

`status`	Description
`0`	No error.
`1`	`matchedPoints1` and `matchedPoints2` inputs do not contain enough points.
`2`	Not enough inliers found.

If you do not request the `status` code output, the function will throw an error for the two conditions that cannot produce results.

Data Types: `double`

Version History

Introduced in R2013a

R2022b: Not recommended
Not recommended starting in R2022b

Starting in R2022b, many Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `estimateGeometricTransform` function estimates geometric transformations using the postmultiply convention. Although there are no plans to remove `estimateGeometricTransform` at this time, you can streamline your geometric transformation workflows by switching to the `estgeotform2d` and `estgeotform3d` functions, which support the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

estimateUncalibratedRectification

(Not recommended) Uncalibrated stereo rectification

Note `estimateUncalibratedRectification` is not recommended. Use the `estimateStereoRectification` function instead. For more information, see “Version History”.

Syntax

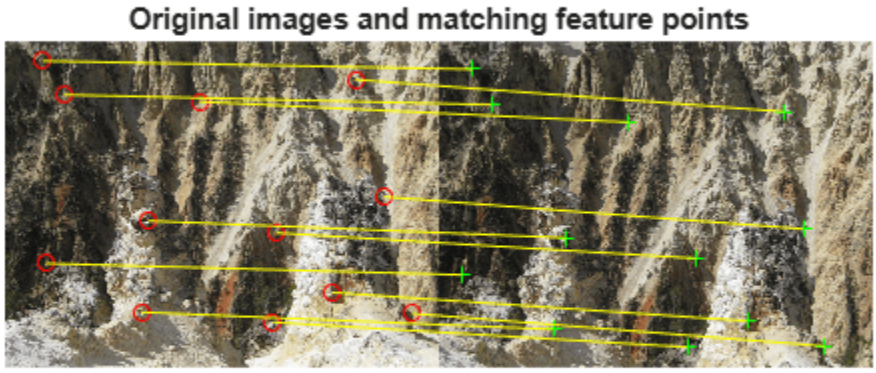
```
[T1,T2] = estimateUncalibratedRectification(F,inlierPoints1,inlierPoints2,
imagesize)
```

Description

`[T1,T2] = estimateUncalibratedRectification(F,inlierPoints1,inlierPoints2, imagesize)` returns projective transformations for rectifying stereo images. This function does not require either intrinsic or extrinsic camera parameters.

Examples

Find Fundamental Matrix Describing Epipolar Geometry



This example shows how to compute the fundamental matrix from corresponding points in a pair of stereo images.

Load the stereo images and feature points which are already matched.

```
I1 = imread('yellowstone_left.png');
I2 = imread('yellowstone_right.png');
load yellowstone_inlier_points;
```

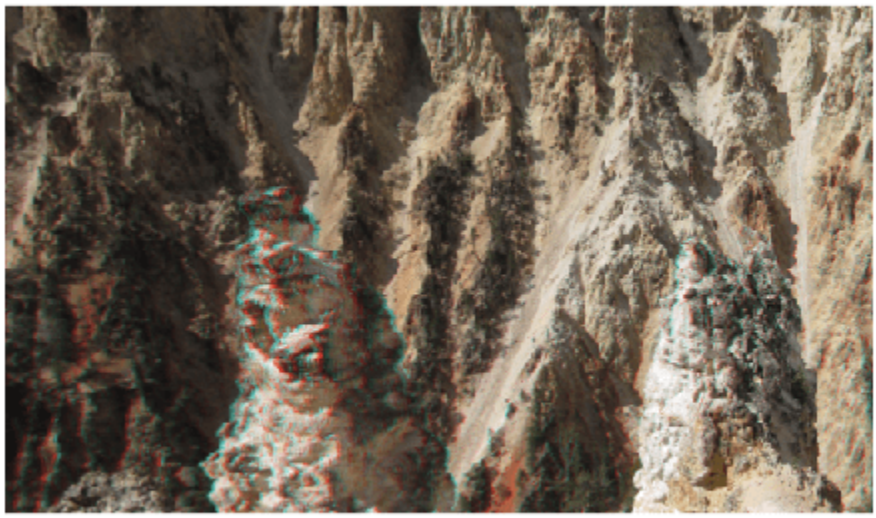
Display point correspondences. Notice that the matching points are in different rows, indicating that the stereo pair is not rectified.

```
showMatchedFeatures(I1, I2,inlier_points1,inlier_points2,'montage');
title('Original images and matching feature points');
```

Compute the fundamental matrix from the corresponding points.

```
f = estimateFundamentalMatrix(inlier_points1,inlier_points2,...
    'Method','Norm8Point');
```

Compute the rectification transformations.



```
[t1, t2] = estimateUncalibratedRectification(f,inlier_points1,...
    inlier_points2,size(I2));
```

Rectify the stereo images using projective transformations t1 and t2.

```
[I1Rect,I2Rect] = rectifyStereoImages(I1,I2,t1,t2);
```

Display the stereo anaglyph, which can also be viewed with 3-D glasses.

```
figure;
imshow(stereoAnaglyph(I1Rect,I2Rect));
```

Input Arguments

F — Fundamental matrix for stereo images

3-by-3 matrix

Fundamental matrix for the stereo images, specified as a 3-by-3 fundamental matrix. The fundamental matrix satisfies the following criteria:
If P_1, a point in image 1, corresponds to P_2, a point in image 2, then:
$[P_2,1] * F * [P_1,1]' = 0$

Data Types: `single` | `double`

inlierPoints1 — Coordinates of corresponding points

`ORBPoints` | `BRISKPoints` | `SIFTPoints` | `SURFPoints` | `cornerPoints` | `MSERRegions` | *M*-by-2 matrix of [*x*,*y*] coordinates

Coordinates of corresponding points in image one, specified as an *M*-by-2 matrix of *M* number of [x y] coordinates, or as a `ORBPoints`, `BRISKPoints`, `SIFTPoints`, `SURFPoints`, `MSERRegions`, or `cornerPoints` object.

inlierPoints2 — Coordinates of corresponding points

`ORBPoints` | `BRISKPoints` | `SIFTPoints` | `SURFPoints` | `cornerPoints` | `MSERRegions` | *M*-by-2 matrix of [*x*,*y*] coordinates

Coordinates of corresponding points in image two, specified as an *M*-by-2 matrix of *M* number of [x y] coordinates, or as a `ORBPoints`, `BRISKPoints`, `SIFTPoints`, `SURFPoints`, `MSERRegions` , or `cornerPoints` object.

imagesize — Input image size

single | double | integer

Second input image size, specified as a double, single, or integer value and in the format returned by the `size` function. The size of input image 2 corresponds to `inlierPoints2`.

Output Arguments

T1 — Projective transformation one

3-by-3 matrix

Projective transformation, returned as a 3-by-3 matrix describing the projective transformations for input image `T1`.

T2 — Projective transformation two

3-by-3 matrix

Projective transformation, returned as a 3-by-3 matrix describing the projective transformations for input image `T2`.

Tips

- An epipole may be located in the first image or the second image. Applying the output uncalibrated rectification of `T1` (or `T2`) to image `1` (or image `2`) may result in an undesired distortion. You can check for an epipole within an image by applying the `isEpipoleInImage` function.

Version History

Introduced in R2012b

R2022b: Not recommended

Not recommended starting in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `estimateUncalibratedRectification` function uses the postmultiply convention. Although there are no plans to remove `estimateUncalibratedRectification` at this time, you can streamline your geometric transformation workflows by switching to the `estimateStereoRectification` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

To update your code:

- Change instances of the function name `estimateUncalibratedRectification` to `estimateStereoRectification`.
- The `estimateStereoRectification` function returns the projective transformations as `projtform2d` objects, which use the premultiply convention. If you need to obtain the projective transformation matrices, then you can query the `A` property of the `projtform2d` objects. Note that the values of `A` are the transpose of `T1` and `T2`.

eul

Convert transformation or rotation into Euler angles

Syntax

```
angles = eul(transformation)
angles = eul(rotation)
angles = eul( ___ ,sequence)
```

Description

`angles = eul(transformation)` converts the rotation of the transformation `transformation` to the Euler angles `angles`.

`angles = eul(rotation)` converts the rotation `rotation` to the Euler angles `angles`.

`angles = eul( ___ ,sequence)` specifies the sequence of the Euler-angle rotations `sequence` using any of the input arguments in previous syntaxes. For example, a sequence of `"ZYX"` first rotates the *z*-axis, followed by the *y*-axis and *x*-axis.

Examples

Convert SE(3) Transformation to Euler Angles

Create SE(3) transformation with no translation but with a rotation defined by a Euler angles.

```
eul1 = [pi/4 pi/3 pi/8]
```

```
eul1 = 1×3

    0.7854    1.0472    0.3927
```

```
T = se3(eul1,"eul")
```

```
T = se3
    0.3536   -0.4189    0.8364         0
    0.3536    0.8876    0.2952         0
   -0.8660    0.1913    0.4619         0
         0         0         0    1.0000
```

Get the Euler angles from the transformation.

```
eul2 = eul(T)
```

```
eul2 = 1×3

    0.7854    1.0472    0.3927
```

Convert SO(3) Rotation to Euler Angles

Create SO(3) rotation defined by a Euler angles.

```
eul1 = [pi/4 pi/3 pi/8]
```

```
eul1 = 1×3

    0.7854    1.0472    0.3927
```

```
R = so3(eul1,"eul")
```

```
R = so3
    0.3536   -0.4189    0.8364
    0.3536    0.8876    0.2952
   -0.8660    0.1913    0.4619
```

Get the Euler angles from the transformation.

```
eul2 = eul(R)
```

```
eul2 = 1×3

    0.7854    1.0472    0.3927
```

Input Arguments

`transformation` — Transformation

`se3` object | *N*-element array of `se3` objects

Transformation, specified as an `se3` object or as an *N*-element array of `se3` objects. *N* is the total number of transformations.

`rotation` — Rotation

`so3` object | *N*-element array of `so3` objects

Rotation, specified as an `so3` object or as an *N*-element array of `so3` objects. *N* is the total number of rotations.

`sequence` — Axis-rotation sequence

`"ZYX"` (default) | `"ZYZ"` | `"ZXY"` | `"ZXZ"` | `"YXY"` | `"YZX"` | `"YXZ"` | `"YZY"` | `"XYX"` | `"XYZ"` | `"XZX"` | `"XZY"`

Axis-rotation sequence for the Euler angles, specified as one of these string scalars:

- `"ZYX"` (default)
- `"ZYZ"`
- `"ZXY"`
- `"ZXZ"`

- `"YXY"`
- `"YZX"`
- `"YXZ"`
- `"YZY"`
- `"XYX"`
- `"XYZ"`
- `"XZX"`
- `"XZY"`

Each character indicates the corresponding axis. For example, if the sequence is `"ZYX"`, then the three specified Euler angles are interpreted in order as a rotation around the *z*-axis, a rotation around the *y*-axis, and a rotation around the *x*-axis. When applying this rotation to a point, it will apply the axis rotations in the order *x*, then *y*, then *z*.

Data Types: `string` | `char`

Output Arguments

`angles` — Euler angles

M-by-3 matrix

Euler angles, returned as an *M*-by-3 matrix of Euler rotation angles. Each row represents one Euler angle set.

See Also

`se3` | `so3`

evaluateDetectionMissRate

(To be removed) Evaluate miss rate metric for object detection

Note `evaluateDetectionMissRate` will be removed in a future release. Use `evaluateObjectDetection` instead.

Syntax

```
logAverageMissRate = evaluateDetectionMissRate(detectionResults,
groundTruthData)
[logAverageMissRate,fppi,missRate] = evaluateDetectionMissRate( ___ )
[ ___ ] = evaluateDetectionMissRate( ___ ,threshold)
```

Description

`logAverageMissRate = evaluateDetectionMissRate(detectionResults, groundTruthData)` returns the log-average miss rate of the `detectionResults` compared to `groundTruthData`, which is used to measure the performance of the object detector. For a multiclass detector, the log-average miss rate is a vector of scores for each object class in the order specified by `groundTruthData`.

`[logAverageMissRate,fppi,missRate] = evaluateDetectionMissRate( ___ )` returns data points for plotting the log miss rate–false positives per image (FPPI) curve, using input arguments from the previous syntax.

`[ ___ ] = evaluateDetectionMissRate( ___ ,threshold)` specifies the overlap threshold for assigning a detection to a ground truth box.

Input Arguments

`detectionResults` — Object locations and scores

table

Object locations and scores, specified as a two-column table containing the bounding boxes and scores for each detected object. For multiclass detection, a third column contains the predicted label for each detection. The bounding boxes must be stored in an *M*-by-4 cell array. The scores must be stored in an *M*-by-1 cell array, and the labels must be stored as a categorical vector.

When detecting objects, you can create the detection results table by using `imageDatastore`.

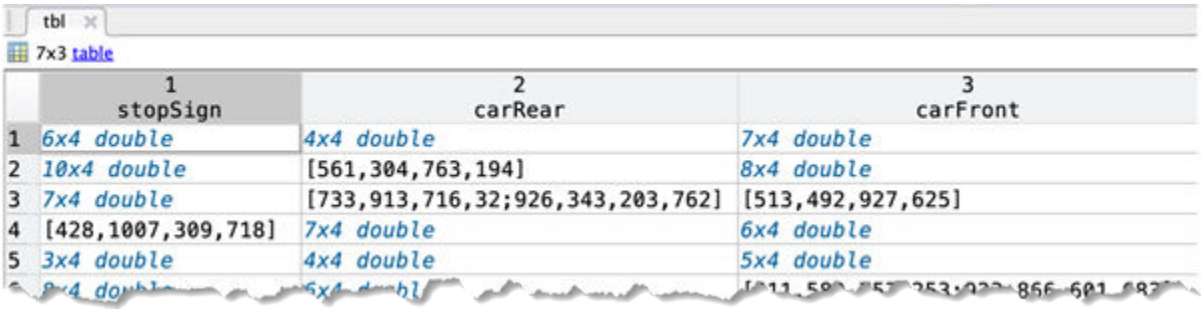
```
ds = imageDatastore(stopSigns.imageFilename);
detectionResults = detect(detector,ds);
```

Data Types: `table`

`groundTruthData` — Labeled ground truth

datastore | table

Labeled ground truth, specified as a datastore or a table.



Each bounding box must be in the format [*x y width height*].

- Datastore — A datastore whose `read` and `readall` functions return a cell array or a table with at least two columns of bounding box and labels cell vectors. The bounding boxes must be in a cell array of *M*-by-4 matrices in the format [*x*,*y*,*width*,*height*]. The datastore's `read` and `readall` functions must return one of the formats:

  - {*boxes*,*labels*} — The `boxLabelDatastore` creates this type of datastore.
  - {*images*,*boxes*,*labels*} — A combined datastore. For example, using `combine(imds,blds)`.

  See `boxLabelDatastore`.

- Table — One or more columns. All columns contain bounding boxes. Each column must be a cell vector that contains *M*-by-4 matrices that represent a single object class, such as *stopSign*, *carRear*, or *carFront*. The columns contain 4-element double arrays of *M* bounding boxes in the format [*x*,*y*,*width*,*height*]. The format specifies the upper-left corner location and size of the bounding box in the corresponding image.

tbl

7x3 table

	1 stopSign	2 carRear	3 carFront
1	6x4 double	4x4 double	7x4 double
2	10x4 double	[561,304,763,194]	8x4 double
3	7x4 double	[733,913,716,32;926,343,203,762]	[513,492,927,625]
4	[428,1007,309,718]	7x4 double	6x4 double
5	3x4 double	4x4 double	5x4 double

`threshold` — Overlap threshold
0.5 | numeric scalar

Overlap threshold for a detection assigned to a ground truth box, specified as a numeric scalar. The overlap ratio is computed as the intersection over union.

Output Arguments

`logAverageMissRate` — Log-average miss rate metric
numeric scalar | vector

Log-average miss rate metric, returned as either a numeric scalar or vector. For a multiclass detector, the log-average miss rate is returned as a vector of values that correspond to the data points for each class.

`fppi` — False positives per image
vector of numeric scalars | cell array

False positives per image, returned as either a vector of numeric scalars or as a cell array. For a multiclass detector, the FPPI and log miss rate are cell arrays, where each cell contains the data points for each object class.

`missRate` — Log miss rate
vector of numeric scalars | cell array

Log miss rate, returned as either a vector of numeric scalars or as a cell array. For a multiclass detector, the FPPI and log miss rate are cell arrays, where each cell contains the data points for each object class.

Version History

Introduced in R2017a

R2023b: `evaluateDetectionMissRate` will be removed in a future release
Not recommended starting in R2023b

The `evaluateDetectionMissRate` function will be removed in a future release. Use the `evaluateObjectDetection` function to evaluate object detection results with metrics such as the log-average miss rate, instead.

evaluateDetectionPrecision

(To be removed) Evaluate precision metric for object detection

Note Use `evaluateObjectDetection` instead of `evaluateDetectionPrecision`, which will be removed in a future release. The more recent `evaluateObjectDetection` can be used to perform a comprehensive analysis of object detector performance.

Syntax

```
averagePrecision = evaluateDetectionPrecision(detectionResults,
groundTruthData)
[averagePrecision,recall,precision] = evaluateDetectionPrecision( ___ )
[ ___ ] = evaluateDetectionPrecision( ___ ,threshold)
```

Description

`averagePrecision = evaluateDetectionPrecision(detectionResults, groundTruthData)` returns the average precision, of the `detectionResults` compared to the `groundTruthData`. You can use the average precision to measure the performance of an object detector. For a multiclass detector, the function returns `averagePrecision` as a vector of scores for each object class in the order specified by `groundTruthData`.

`[averagePrecision,recall,precision] = evaluateDetectionPrecision( ___ )` returns data points for plotting the precision–recall curve, using input arguments from the previous syntax.

`[ ___ ] = evaluateDetectionPrecision( ___ ,threshold)` specifies the overlap threshold for assigning a detection to a ground truth box.

Input Arguments

`detectionResults` — Object locations and scores

table

Object locations and scores, specified as a two-column table containing the bounding boxes and scores for each detected object. For multiclass detection, a third column contains the predicted label for each detection. The bounding boxes must be stored in an *M*-by-4 cell array. The scores must be stored in an *M*-by-1 cell array, and the labels must be stored as a categorical vector.

When detecting objects, you can create the detection results table by using `imageDatastore`.

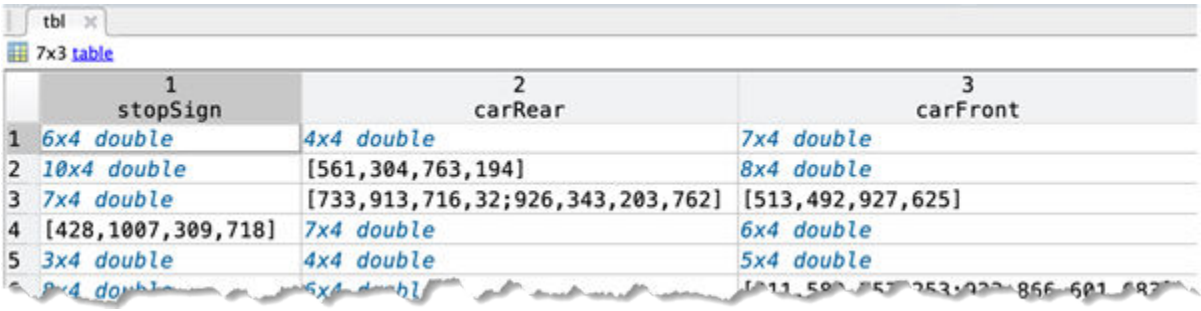
```
ds = imageDatastore(stopSigns.imageFilename);
detectionResults = detect(detector,ds);
```

Data Types: `table`

`groundTruthData` — Labeled ground truth

datastore | table

Labeled ground truth, specified as a datastore or a table.



Each bounding box must be in the format [*x y width height*].

- Datastore — A datastore whose `read` and `readall` functions return a cell array or a table with at least two columns of bounding box and labels cell vectors. The bounding boxes must be in a cell array of *M*-by-4 matrices in the format [*x*,*y*,*width*,*height*]. The datastore's `read` and `readall` functions must return one of the formats:

  - {*boxes*,*labels*} — The `boxLabelDatastore` creates this type of datastore.
  - {*images*,*boxes*,*labels*} — A combined datastore. For example, using `combine(imds,blds)`.

  See `boxLabelDatastore`.

- Table — One or more columns. All columns contain bounding boxes. Each column must be a cell vector that contains *M*-by-4 matrices that represent a single object class, such as *stopSign*, *carRear*, or *carFront*. The columns contain 4-element double arrays of *M* bounding boxes in the format [*x*,*y*,*width*,*height*]. The format specifies the upper-left corner location and size of the bounding box in the corresponding image.

tbl

7x3 table

	1 stopSign	2 carRear	3 carFront
1	6x4 double	4x4 double	7x4 double
2	10x4 double	[561,304,763,194]	8x4 double
3	7x4 double	[733,913,716,32;926,343,203,762]	[513,492,927,625]
4	[428,1007,309,718]	7x4 double	6x4 double
5	3x4 double	4x4 double	5x4 double

`threshold` — Overlap threshold
`0.5` (default) | numeric scalar

Overlap threshold for assigned a detection to a ground truth box, specified as a numeric scalar. The overlap ratio is computed as the intersection over union.

Output Arguments

`averagePrecision` — Average precision
numeric scalar | vector

Average precision over all the detection results, returned as a numeric scalar or vector. Precision is a ratio of true positive instances to all positive instances of objects in the detector, based on the ground truth. For a multiclass detector, the average precision is a vector of average precision scores for each object class.

`recall` — Recall values from each detection
vector of numeric scalars | cell array

Recall values from each detection, returned as an *M*-by-1 vector of numeric scalars or as a cell array. The length of *M* equals 1 + the number of detections assigned to a class. For example, if your detection results contain 4 detections with class label `'car'`, then `recall` contains 5 elements. The first value of recall is always `0`.

Recall is a ratio of true positive instances to the sum of true positives and false negatives in the detector, based on the ground truth. For a multiclass detector, `recall` and `precision` are cell arrays, where each cell contains the data points for each object class.

`precision` — Precision values from each detection
vector of numeric scalars | cell array

Precision values from each detection, returned as an *M*-by-1 vector of numeric scalars or as a cell array. The length of *M* equals 1 + the number of detections assigned to a class. For example, if your detection results contain 4 detections with class label `'car'`, then `precision` contains 5 elements. The first value of `precision` is always `1`.

Precision is a ratio of true positive instances to all positive instances of objects in the detector, based on the ground truth. For a multi-class detector, `recall` and `precision` are cell arrays, where each cell contains the data points for each object class.

Version History

Introduced in R2017a

R2023b: `evaluateDetectionPrecision` will be removed in a future release
Not recommended starting in R2023b

Use `evaluateObjectDetection` instead of `evaluateDetectionPrecision`, which will be removed in a future release. The more recent `evaluateObjectDetection` can be used to perform a comprehensive analysis of object detector performance.

evaluateImageRetrieval

Evaluate image search results

Syntax

```
averagePrecision = evaluateImageRetrieval(queryImage,imageIndex,expectedIDs)
[averagePrecision,imageIDs,scores] = evaluateImageRetrieval(queryImage,
imageIndex,expectedIDs)
[averagePrecision,imageIDs,scores] = evaluateImageRetrieval( ___ ,Name,Value)
```

Description

`averagePrecision = evaluateImageRetrieval(queryImage,imageIndex,expectedIDs)` returns the average precision metric for measuring the accuracy of image search results for the `queryImage`. The `expectedIDs` input contains the indices of images within `imageIndex` that are known to be similar to the query image.

`[averagePrecision,imageIDs,scores] = evaluateImageRetrieval(queryImage, imageIndex,expectedIDs)` optionally returns the indices corresponding to images within `imageIndex` that are visually similar to the query image. It also returns the corresponding similarity scores.

`[averagePrecision,imageIDs,scores] = evaluateImageRetrieval( ___ ,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments, using any of the preceding syntaxes.

Examples

Evaluate Image Retrieval Results

Define a set of images.

```
dataDir = fullfile(toolboxdir('vision'),'visiondata','bookCovers');
bookCovers = imageDatastore(dataDir);
```

Display the set of images.

```
thumbnailGallery = [];
for i = 1:length(bookCovers.Files)
    img = readimage(bookCovers,i);
    thumbnail = imresize(img,[300 300]);
    thumbnailGallery = cat(4,thumbnailGallery,thumbnail);
end
figure
montage(thumbnailGallery);
```

Index the images. This will take a few minutes.

```
imageIndex = indexImages(bookCovers);
```

```
Creating an inverted image index using Bag-Of-Features.
-------------------------------------------------------

Creating Bag-Of-Features.
-------------------------

* Selecting feature point locations using the Detector method.
* Extracting SURF features from the selected feature point locations.
** detectSURFFeatures is used to detect key points for feature extraction.

* Extracting features from 58 images...done. Extracted 29216 features.

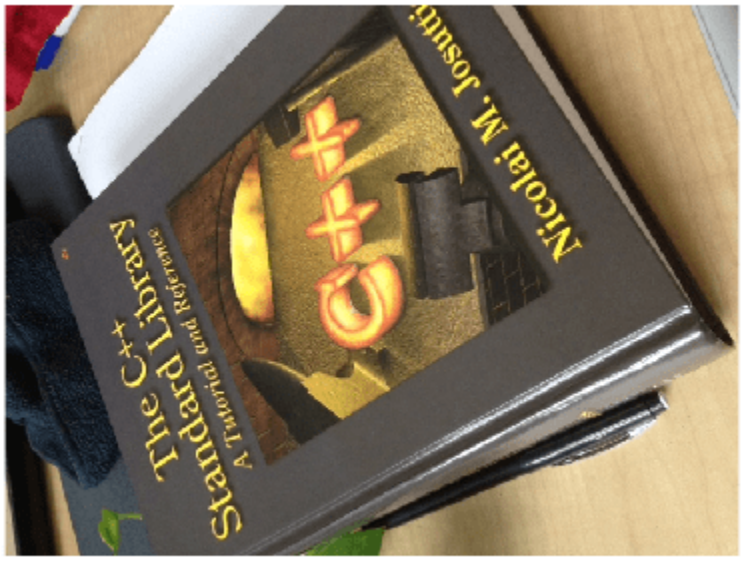
* Keeping 80 percent of the strongest features from each category.

* Balancing the number of features across all image categories to improve clustering.
** Image category 1 has the least number of strongest features: 23373.
** Using the strongest 23373 features from each of the other image categories.

* Creating a 20000 word visual vocabulary.
* Number of levels: 1
* Branching factor: 20000
* Number of clustering steps: 1

* [Step 1/1] Clustering vocabulary level 1.
* Number of features          : 23373
* Number of clusters          : 20000
* Initializing cluster centers...100.00%.
* Clustering...completed 5/100 iterations (~1.23 seconds/iteration)...converged in 5 iterations.
```

```
* Finished creating Bag-Of-Features



Encoding images using Bag-Of-Features.
--------------------------------------

* Encoding 58 images...done.
Finished creating the image index.
```

Select and display the query image.

```
queryDir = fullfile(dataDir,'queries',filesep);
query = imread([queryDir 'query2.jpg']);

figure
imshow(query)
```

Evaluation requires knowing the expected results. Here, the query image is known to be the 3rd book in the imageIndex.

```
expectedID = 3;
```

Find and report the average precision score.

```
[averagePrecision,actualIDs] = evaluateImageRetrieval(query,...
    imageIndex,expectedID);

fprintf('Average Precision: %f\n\n',averagePrecision)
```

```
Average Precision: 0.125000
```

Show the query and best match side-by-side.

```
bestMatch = actualIDs(1);
bestImage = imread(imageIndex.ImageLocation{bestMatch});
```

```
figure
imshowpair(query,bestImage,'montage')
```

Compute Mean Average Precision (MAP) for Image Retrieval

Create an image set of book covers.

```
dataDir = fullfile(toolboxdir('vision'),'visiondata','bookCovers');
bookCovers = imageDatastore(dataDir);
```

Index the image set. The indexing may take a few minutes.

```
imageIndex = indexImages(bookCovers,'Verbose',false);
```

Create a set of query images.

```
queryDir = fullfile(dataDir,'queries',filesep);
querySet = imageDatastore(queryDir);
```

Specify the expected search results for each query image.

```
expectedIDs = [1 2 3];
```

Evaluate each query image and collect average precision scores.

```
for i = 1:numel(querySet.Files)
    query = readimage(querySet,i);
    averagePrecision(i) = evaluateImageRetrieval(query, imageIndex, expectedIDs(i));
end
```

Compute mean average precision (MAP).

```
  map = mean(averagePrecision)

map =
0.8333
```

Input Arguments

queryImage — Input query image

M-by-*N*-by-3 truecolor image | *M*-by-*N* 2-D grayscale image

Input query image, specified as either an *M*-by-*N*-by-3 truecolor image or an *M*-by-*N* 2-D grayscale image.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

imageIndex — Image search index

`invertedImageIndex` object

Image search index, specified as an `invertedImageIndex` object. The `indexImages` function creates the `invertedImageIndex` object, which stores the data used for the image search.

expectedIDs — Image indices

row or column vector

Image indices, specified as a row or column vector. The indices correspond to the images within `imageIndex` that are known to be similar to the query image.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'NumResults',25`

NumResults — Maximum number of search results to evaluate

`Inf` (default) | positive integer value

Maximum number of search results to evaluate, specified as the comma-separated pair consisting of '`NumResults`' and a positive integer value. The function evaluates the top `NumResults` and returns the average-precision-at-`NumResults` metric.

ROI — Rectangular search region

`[1 1 size(queryImage,2) size(queryImage,1)]` (default) | [*x y width height*] vector

Rectangular search region within the query image, specified as the comma-separated pair consisting of 'ROI' and a [*x y width height*] formatted vector.

Output Arguments

averagePrecision — Average precision metric

scalar value in the range [0 1]

Average precision metric, returned as a scalar value in the range [0 1]. The average precision metric represents the accuracy of image search results for the query image.

`imageIDs` — Ranked index of retrieved images
M-by-1 vector

Ranked index of retrieved images, returned as an *M*-by-1 vector. The image IDs are returned in ranked order, from the most to least similar matched image.

`scores` — Similarity metric
N-by-1 vector

Similarity metric, returned as an *N*-by-1 vector. This output contains the scores that correspond to the retrieved images in the `imageIDs` output. The scores are computed using the cosine similarity and range from 0 to 1.

Version History

Introduced in R2015a

Extended Capabilities

C/C++ Code Generation

evaluateInstanceSegmentation

Evaluate instance segmentation data set against ground truth

Syntax

```
metrics = evaluateInstanceSegmentation(dsResults,dsTruth)
metrics = evaluateInstanceSegmentation(dsResults,dsTruth,threshold)
metrics = evaluateInstanceSegmentation( ___ ,Verbose=verbose)
```

Description

`metrics = evaluateInstanceSegmentation(dsResults,dsTruth)` calculates various metrics to evaluate the quality of the instance segmentation results, `dsResults`, against the ground truth segmentation, `dsTruth`.

`metrics = evaluateInstanceSegmentation(dsResults,dsTruth,threshold)` also specifies an overlap threshold for the intersection over union (IoU) metric, or Jaccard Index. When the IoU of the predicted object mask in `dsResults` and the ground truth object mask in `dsTruth` is equal to or greater than the overlap threshold, the prediction is considered a true positive.

`metrics = evaluateInstanceSegmentation( ___ ,Verbose=verbose)` also specifies whether to display evaluation progress information in the command window.

Input Arguments

`dsResults` — Predicted instance segmentation

datastore

Predicted instance segmentation, specified as a datastore. The data must be set up so that calling the datastore with the `read` function returns a cell array with at least three elements. The table describes the format of the three required elements.

masks	*labels*	*scores*
Predicted binary masks, specified as a logical array of size *H*-by-*W*-by-*M*. Each mask is the segmentation of one instance in the image.	Predicted object labels, specified as an *M*-by-1 categorical vector.	Predicted scores, specified as an *M*-by-1 numeric vector.

The order of the elements does not matter. When the datastore returns a cell array with more than three elements, the `evaluateInstanceSegmentation` function assumes that the first element with logical data contains the instance masks, the first element with categorical data contains the label data, and the first element with numeric data contains the scores.

You can get predicted instance segmentations by using the `segmentObjects` function.

`dsTruth` — Ground truth instance segmentation

datastore

Ground truth instance segmentation, specified as a datastore. The data must be set up so that calling the datastore with the `read` function returns a cell array with at least two elements. The table describes the format of the two required elements.

masks	***labels***
Ground truth binary masks, specified as a logical array of size *H*-by-*W*-by-*M*. Each mask is the segmentation of one instance in the image.	Ground truth object labels, specified as an *M*-by-1 categorical vector.

The order of the elements does not matter. When the datastore returns a cell array with more than two elements, the `evaluateInstanceSegmentation` function assumes that the first element with logical data contains the instance masks, and the first element with categorical data contains the label data.

`threshold` — Overlap threshold
`0.5` (default) | numeric scalar | numeric vector

Overlap threshold for a predicted object mask to be considered a true positive, specified as a numeric scalar or numeric vector. When you specify a numeric vector, the `evaluateInstanceSegmentation` function calculates metrics for each threshold.

`verbose` — Display evaluation progress
`1` (default) | `0`

Display evaluation progress information in the command window, specified as a numeric or logical `1` (`true`) or `0` (`false`). The displayed information includes a progress bar, elapsed time, estimated time remaining, and data set metrics.

Data Types: `logical`

Output Arguments

`metrics` — Instance segmentation metrics
`instanceSegmentationMetrics` object

Instance segmentation metrics, returned as an `instanceSegmentationMetrics` object. The `OverlapThreshold` property of the object is set as the value of the `threshold` argument.

Version History

Introduced in R2022b

evaluateSemanticSegmentation

Evaluate semantic segmentation data set against ground truth

Syntax

```
ssm = evaluateSemanticSegmentation(dsResults,dsTruth)
ssm = evaluateSemanticSegmentation(imageSetConfusion,classNames)
[ssm,blockMetrics] = evaluateSemanticSegmentation(blockSetConfusion,
classNames)
[___] = evaluateSemanticSegmentation(___,Name,Value)
```

Description

`ssm = evaluateSemanticSegmentation(dsResults,dsTruth)` computes various metrics to evaluate the quality of the semantic segmentation results, `dsResults`, against the ground truth segmentation, `dsTruth`.

`ssm = evaluateSemanticSegmentation(imageSetConfusion,classNames)` computes various metrics to evaluate the quality of the semantic segmentation results from confusion matrices, `imageSetConfusion`, with segmentation classes `classNames`.

`[ssm,blockMetrics] = evaluateSemanticSegmentation(blockSetConfusion, classNames)` computes various metrics to evaluate the quality of the block-based semantic segmentation results from confusion matrices, `blockSetConfusion` with classes `classNames`.

`[___] = evaluateSemanticSegmentation(___,Name,Value)` computes semantic segmentation metrics using one or more name-value arguments to control the evaluation, in addition to output arguments from the previous syntaxes.

Examples

Evaluate Semantic Segmentation Results

The `triangleImages` data set has 100 test images with ground truth labels. Define the location of the data set.

```
dataSetDir = fullfile(toolboxdir("vision"),"visiondata","triangleImages");
```

Define the location of the test images and ground truth labels.

```
testImagesDir = fullfile(dataSetDir,"testImages");
testLabelsDir = fullfile(dataSetDir,"testLabels");
```

Create an `imageDatastore` holding the test images.

```
imds = imageDatastore(testImagesDir);
```

Define the class names and their associated label IDs.

```
classNames = ["triangle" "background"];
labelIDs   = [255 0];
```

Create a `pixelLabelDatastore` holding the ground truth pixel labels for the test images.

```
pxdsTruth = pixelLabelDatastore(testLabelsDir,classNames,labelIDs);
```

Load a semantic segmentation network that has been trained on the training images of `triangleImages`.

```
net = load("triangleSegmentationNetwork");
net = net.net;
```

Run the network on the test images. Predicted labels are written to disk in a temporary directory and returned as a `pixelLabelDatastore`.

```
pxdsResults = semanticseg(imds,net,Classes=classNames,WriteLocation=tempdir);
```

```
Running semantic segmentation network
-------------------------------------
* Processed 100 images.
```

Evaluate the prediction results against the ground truth.

```
metrics = evaluateSemanticSegmentation(pxdsResults,pxdsTruth);
```

```
Evaluating semantic segmentation results
----------------------------------------
* Selected metrics: global accuracy, class accuracy, IoU, weighted IoU, BF score.
* Processed 100 images.
* Finalizing... Done.
* Data set metrics:

    GlobalAccuracy    MeanAccuracy    MeanIoU    WeightedIoU    MeanBFScore
    ______________    ____________    _______    ___________    ___________

    background    0.99063      0.9903      0.93918
```

Display the normalized confusion matrix that is stored in the `NormalizedConfusionMatrix` property.

```
metrics.ConfusionMatrix
```

```
ans=2×2 table
                  triangle    background
                  ________    __________

    triangle         4697           33
    background        915         96755
```

Input Arguments

`dsResults` — Predicted pixel labels

datastore | cell array of datastore objects

Predicted pixel labels resulting from semantic segmentation, specified as a datastore or a cell array of datastore objects. `dsResults` can be any datastore that returns categorical images, such as `PixelLabelDatastore`. The `read(dsResults)` must return a categorical array, a cell array, or a table. If the `read` function returns a multicolumn cell array or table, the second column must contain categorical arrays.

`dsTruth` — Ground truth pixel labels

datastore | cell array of datastore objects

Ground truth pixel labels, specified as a datastore or a cell array of datastore objects. `dsTruth` can be any datastore that returns categorical images, such as `PixelLabelDatastore`. Using `read(dsTruth)` must return a categorical array, a cell array, or a table. If the `read` function returns a multicolumn cell array or table, the second column must contain categorical arrays.

`imageSetConfusion` — Confusion matrices for segmented images

table | cell array

Confusion matrix for the classes in the segmented images, specified as one of the following, where *F* is the number of images in the data set.

- Table with *F* rows and one variable with the name `ConfusionMatrix`. Each row in the table contains a cell array with the confusion matrix for the corresponding image.
- *F*-by-one cell array. Each element of the cell array contains the confusion matrix for the corresponding image.

`blockSetConfusion` — Confusion matrices for segmented blocks

table

Confusion matrices for segmented blocks, specified as a table with *B* rows and three columns, where *B* is the total number of blocks in all images in the data set. The three columns are the variables

`ImageNumber`, `ConfusionMatrix`, and `BlockInfo`. You can obtain a table of the correct format by using the `segmentationConfusionMatrix` function within a call to the block-based `apply` function. For an example, see “Calculate Segmentation Metrics in Block-Based Workflow”.

`classNames` — Class names
array of strings | cell array of character vectors

Class names, specified as an array of strings or a cell array of character vectors.

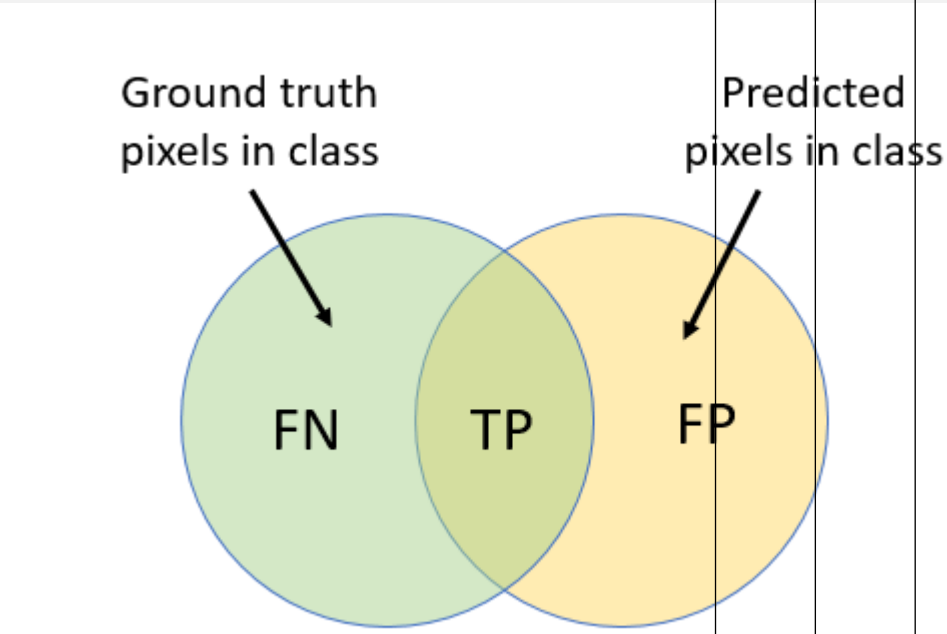
Example: `["sky" "grass" "building" "sidewalk"]`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `metrics = evaluateSemanticSegmentation(pxdsResults,pxdsTruth,Metrics="bfscore")` computes only the mean BF score of each class, each image, and the entire data set.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*



Example: `metrics = evaluateSemanticSegmentation(pxdsResults,pxdsTruth,"Metrics","bfscore")` computes only the mean BF score of each class, each image, and the entire data set.

`Metrics` — Segmentation metrics
`"all"` (default) | vector of strings

Segmentation metrics in `semanticSegmentationMetrics` to compute, specified as a vector of strings. This argument specifies which variables in the `DataSetMetrics`, `ClassMetrics`, and `ImageMetrics` tables to compute. `ConfusionMatrix` and `NormalizedConfusionMatrix` are computed regardless of the value of `Metrics`.

Value	Description	Aggregate Data Set Metric	Image Metric	Class Metric
`"all"`	Evaluate all semantic segmentation metrics. The function excludes `MeanBFScore` from the semantic segmentation metrics when you specify a confusion matrix (`imageSetConfusion` or `blockSetConfusion`) as input to the function.	All aggregate data set metrics	All image metrics	All class metrics

Value	Description	Aggregate Data Set Metric	Image Metric	Class Metric
`"accuracy"`	Accuracy indicates the percentage of correctly identified pixels for each class. Use the accuracy metric if you want to know how well each class correctly identifies pixels. • For each class, `Accuracy` is the ratio of correctly classified pixels to the total number of pixels in that class, according to the ground truth. In other words, Accuracy score = TP / (TP + FN) TP is the number of true positives and FN is the number of false negatives. • For the aggregate data set, `MeanAccuracy` is the average `Accuracy` of all classes in all images. • For each image, `MeanAccuracy` is the average `Accuracy` of all classes in that particular image. The class accuracy is a simple metric analogous to global accuracy, but it can be misleading. For example, labeling all pixels "car" gives a perfect score for the "car" class (although not for the other classes). Use class accuracy in conjunction with IoU for a more complete evaluation of segmentation results.	`MeanAccuracy`	`MeanAccuracy`	`Accuracy`
`"bfscore"`	The boundary F1 (BF) contour matching score indicates how well the predicted boundary of each class aligns with the true boundary. Use the BF score if you want a metric that tends to correlate better with human qualitative assessment than the IoU metric. • For each class, `MeanBFScore` is the average BF score of that class over all images. • For each image, `MeanBFScore` is the average BF score of all classes in that particular image. • For the aggregate data set, `MeanBFScore` is the average BF score of all classes in all images. For more information, see `bfscore`. This metric is not available when you specify a confusion matrix (`imageSetConfusion` or `blockSetConfusion`) as input to the function.	`MeanBFScore`	`MeanBFScore`	`MeanBFScore`
`"global-accuracy"`	`GlobalAccuracy` is the ratio of correctly classified pixels, regardless of class, to the total number of pixels. Use the global accuracy metric if you want a quick and computationally inexpensive estimate of the percentage of correctly classified pixels.	`GlobalAccuracy`	`GlobalAccuracy`	none

Value	Description	Aggregate Data Set Metric	Image Metric	Class Metric
`"iou"`	Intersection over union (IoU), also known as the Jaccard similarity coefficient, is the most commonly used metric. Use the IoU metric if you want a statistical accuracy measurement that penalizes false positives. • For each class, `IoU` is the ratio of correctly classified pixels to the total number of ground truth and predicted pixels in that class. In other words, IoU score = TP / (TP + FP + FN) The image describes the true positives (TP), false positives (FP), and false negatives (FN).  • For each image, `MeanIoU` is the average IoU score of all classes in that particular image. • For the aggregate data set, `MeanIoU` is the average IoU score of all classes in all images. For more information, see `jaccard`.	`MeanIoU`	`MeanIoU`	`IoU`
`"weighted-iou"`	Average IoU of each class, weighted by the number of pixels in that class. Use this metric if images have disproportionally sized classes, to reduce the impact of errors in the small classes on the aggregate quality score.	`WeightedIoU`	`WeightedIoU`	none

Example: `["global-accuracy","iou"]` calculates the global accuracy and IoU metrics across the data set, images, and classes.

Data Types: `string`

`Verbose` — Flag to display evaluation progress
`1` (default) | `0`

Flag to display evaluation progress information in the command window, specified as `1` (`true`) or `0` (`false`).

The displayed information includes a progress bar, elapsed time, estimated time remaining, and data set metrics. When `Verbose` is `0` (`false`), the `evaluateSemanticSegmentation` function calculates segmentation metrics without displaying progress information.

Data Types: `logical`

Output Arguments

`ssm` — Semantic segmentation metrics
`semanticSegmentationMetrics` object

Semantic segmentation metrics, returned as a `semanticSegmentationMetrics` object.

`blockMetrics` — Block-based semantic segmentation metrics
F-by-1 cell array

Block-based semantic segmentation metrics, returned as an *F*-by-1 cell array, where *F* is the number of images in the data set. Each element in the cell array contains information about all of the metrics calculated for all blocks in the corresponding image, formatted as a table.

Each table has *K*(*f*) rows, where *K*(*f*) is the number of blocks in the *f*th image in the data set. The table has up to five variables:

- The table always includes the `BlockInfo` variable, which corresponds to the `BlockInfo` column specified in the `blockSetConfusion` input argument. The table data in this variable are structs that provide spatial information about the block. The four fields of the struct are `BlockStartWorld`, `BlockEndWorld`, `DataStartWorld`, and `DataEndWorld`. For more information about these fields, see the `IncludeBlockInfo` name-value pair argument of the `apply` function.
- The table includes the metrics in the `DataSetMetrics` property of the `ssm` output argument. By default, the metrics are `GlobalAccuracy`, `MeanAccuracy`, `MeanIoU`, and `WeightedIoU`. However, if you create the `ssm` and specify a subset of the metrics to calculate by using the `Metrics` name-value argument, then the table includes only the specified metrics.

To return block-based semantic segmentation metrics, you must specify the `blockSetConfusion` and `classNames` input arguments.

Tips

- A value of `NaN` in the dataset, class, or image metrics, indicates that one or more classes were missing during the computation of the metrics when using the `evaluateSemanticSegmentation` function. In this case, the software was unable to accurately compute the metrics.

The missing classes can be found by looking at the `ClassMetrics` property, which provides the metrics for each class. To more accurately evaluate your network, augment your ground truth with more data that includes the missing classes.

Version History

Introduced in R2017b

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

- To run in parallel, set `'UseParallel'` to `true` or enable this by default using the Computer Vision Toolbox preferences.

  For more information, see “Parallel Computing Toolbox Support”.
- Parallel processing is only supported when the input datastores are `pixelLabelDatastore` objects.

extractFeatures

Extract interest point descriptors

Syntax

```
[features,validPoints] = extractFeatures(I,points)
[features,validPoints] = extractFeatures(I,points,Name=Value)
```

Description

`[features,validPoints] = extractFeatures(I,points)` returns extracted feature vectors, also known as descriptors, and their corresponding locations, from a binary or intensity image.

The function derives the descriptors from pixels surrounding an interest point. The pixels represent and match features specified by a single-point location. Each single-point specifies the center location of a neighborhood. The method you use for descriptor extraction depends on the class of the input `points`.

`[features,validPoints] = extractFeatures(I,points,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `extractFeatures(I,points,Method="Block")` sets the method to extract descriptors to `Block`.

Examples

Extract Corner Features from an Image

Read the image.

```
I = imread("cameraman.tif");
```

Find and extract corner features from the image.

```
corners = detectHarrisFeatures(I);
[features,valid_corners] = extractFeatures(I,corners);
```

Display image.

```
figure;
imshow(I);
hold on
```

Plot valid corner points.

```
plot(valid_corners);
```

Extract SURF Features from an Image

Read image.

```
I = imread("cameraman.tif");
```

Find and extract features from the input image.

```
points = detectSURFFeatures(I);
[features,valid_points] = extractFeatures(I,points);
```

Display and plot ten strongest SURF features.

```
figure;
imshow(I);
hold on;
plot(valid_points.selectStrongest(10),showOrientation=true);
```

Extract MSER Features from an Image

Read image.

```
I = imread("cameraman.tif");
```

Find features in the image using MSER feature detection.

```
regions = detectMSERFeatures(I);
[features,valid_points] = extractFeatures(I,regions,Upright=true);
```

Display features corresponding to the MSER ellipse centers.

```
figure;
imshow(I);
hold on;
plot(valid_points,showOrientation=true);
```

Input Arguments

`I` — Input image

binary image | *M*-by-*N* 2-D grayscale image

Input image, specified as either a binary or 2-D grayscale image.

Data Types: `logical` | `single` | `double` | `int16` | `uint8` | `uint16`

`points` — Center location point

M-by-2 matrix | point feature object

Center location point of a square neighborhood,specified as an *M*-by-2 matrix of *M* number of [*x y*] coordinates, or as one of the point feature objects described in “Point Feature Types”. The table lists the possible input classes of points that can be used for extraction.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `extractFeatures(I,points,Method="Block")` sets the method to extract descriptors to `Block`.

`Method` — Descriptor extraction method

`"Auto"` | point feature object | *M*-by-2 matrix

Descriptor extraction method, specified as one of the point feature objects described in “Point Feature Types” or `"Auto"`.

The table describes how the function implements the descriptor extraction methods:

Method	Feature Vector (Descriptor)
`SIFT`	Scale-Invariant Feature Transform (SIFT). The function sets the `Orientation` property of the `validPoints` output object to the orientation of the extracted features, in radians.
`BRISK`	Binary Robust Invariant Scalable Keypoints (BRISK). The function sets the `Orientation` property of the `validPoints` output object to the orientation of the extracted features, in radians.
`FREAK`	Fast Retina Keypoint (FREAK). The function sets the `Orientation` property of the `validPoints` output object to the orientation of the extracted features, in radians.
`SURF`	Speeded-Up Robust Features (SURF). The function sets the `Orientation` property of the `validPoints` output object to the orientation of the extracted features, in radians. When you use an `MSERRegions` object with the `SURF` method, the `Centroid` property of the object extracts SURF descriptors. The `Axes` property of the object selects the scale of the SURF descriptors such that the circle representing the feature has an area proportional to the MSER ellipse area. The scale is calculated as `1/4*sqrt((majorAxes/2).*(minorAxes/2))` and saturated to `1.6`, as required by the `SURFPoints` object.
`ORB`	Oriented FAST and rotated BRIEF (ORB) features. The `Orientation` property of the `validPoints` output object is automatically set to the `Orientation` property of the input `ORBPoints` object `points`.
`KAZE`	Non-linear pyramid-based features. The function sets the `Orientation` property of the `validPoints` output object to the orientation of the extracted features, in radians. When you use an `MSERRegions` object with the `KAZE` method, the `Location` property of the object is used to extract KAZE descriptors. The `Axes` property of the object selects the scale of the KAZE descriptors such that the circle representing the feature has an area proportional to the MSER ellipse area.

Method	Feature Vector (Descriptor)
`Block`	Simple square neighborhood. The `Block` method extracts only the neighborhoods fully contained within the image boundary. Therefore, the output, `validPoints`, can contain fewer points than the input `POINTS`.
`Auto`	The function selects the `Method`, based on the class of the input points and implements: The `FREAK` method for a `cornerPoints` input object. The `SURF` method for a `SURFPoints` or `MSERRegions` input object. The `BRISK` method for a `BRISKPoints` input object. The `ORB` method for a `ORBPoints` input object. For an *M*-by-2 input matrix of [*x y*] coordinates, the function implements the `Block` method.

Note The descriptor extraction method must be `ORB`, if the input `points` is an `ORBPoints` object. Also, `ORB` descriptor extraction method is not supported for any other class of points, except `ORBPoints`.

`BlockSize` — Block size

`11` (default) | odd integer scalar

Block size, specified as an odd integer scalar. This value defines the local square neighborhood `BlockSize`-by-`BlockSize`, centered at each interest point. This option applies only when the function implements the `Block` method.

`Upright` — Rotation invariance flag

`false` | logical scalar

Rotation invariance flag, specified a logical scalar. When you set this property to `true`, the orientation of the feature vectors are not estimated and the feature orientation is set to pi/2. Set this to `true` when you do not need the image descriptors to capture rotation information. When you set this property to `false`, the orientation of the features is estimated and the features are then invariant to rotation.

Note The rotation invariance flag `"Upright"` is not supported if the input `points` is an `ORBPoints` object.

`FeatureSize` — Length of feature vector

`64` (default) | `128`

Length of the feature vector (descriptor), specified as `64` or `128`. This option applies only when the function implements the `SURF` or `KAZE` method. The larger feature size of `128` provides greater accuracy, but decreases the feature matching speed.

Output Arguments

`features` — Feature vectors

M-by-*N* matrix | `binaryFeatures` object

Feature vectors, returned as a `binaryFeatures` object or an *M*-by-*N* matrix of *M* feature vectors, also known as descriptors. Each descriptor is of length *N*.

`validPoints` — Valid points

M-by-2 matrix of [*x*,*y*] coordinates | point feature object

Valid points associated with each output feature vector (descriptor) in `features`, returned in the same format as the input. Valid points can be an *M*-by-2 matrix of [*x*,*y*] coordinates or as one of the point feature objects described in “Point Feature Types”.

The function extracts descriptors from a region around each interest point. If the region lies outside of the image, or if interest point lies too close to the edge of the image, the function cannot compute the feature descriptor. In this case, the function ignores the point. The point is not included in the valid points output.

For `SIFT` features, more than one descriptor can be extracted at a single location, but at different orientations. Therefore, the number of points returned in `validPoints` can be greater than or equal to the number of input points to `extractFeatures`. For input point features other than `SIFT` features, `validPoints` can be less than or equal to the number of input points.

Version History

Introduced in R2011a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- `'Method'` must be a compile-time constant.
- Supports MATLAB Function block for `BRISK`, `FREAK`, and `SURF` methods only.
- Generates portable C code using a C++ compiler that links to OpenCV libraries for `SIFT`, `BRISK`, `ORB`, `FREAK`, and `SURF` Methods. See “Portable C Code Generation for Functions That Use OpenCV Library”.
- The `KAZE` method and the `detectKAZEFeatures` function do not support code generation.
- Code generation does not support arrays of point feature objects returned by this function. Instead, use the `Location` property to obtain an *M*-by-2 matrix of coordinates:

  ```
  locations = valid_points.Location;
  ```

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

extractHOGFeatures

Extract histogram of oriented gradients (HOG) features

Syntax

```
features = extractHOGFeatures(I)
[features,validPoints] = extractHOGFeatures(I,points)
[___, visualization] = extractHOGFeatures(I,points)
[___] = extractHOGFeatures(___,Name,Value)
```

Description

`features = extractHOGFeatures(I)` returns extracted HOG features from a truecolor or grayscale input image, `I`. The features are returned in a 1-by-*N* vector, where *N* is the HOG feature length. The returned features encode local shape information from regions within an image. You can use this information for many tasks including classification, detection, and tracking.

`[features,validPoints] = extractHOGFeatures(I,points)` returns HOG features extracted around specified point locations. The function also returns `validPoints`, which contains the input point locations whose surrounding region is fully contained within `I`. Scale information associated with the points is ignored.

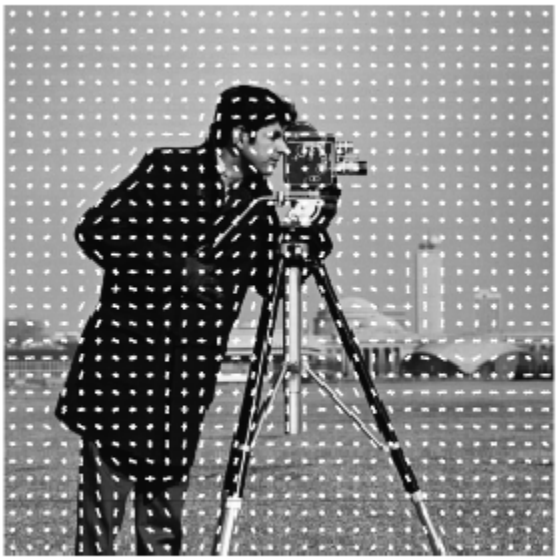
`[___, visualization] = extractHOGFeatures(I,points)` optionally returns a HOG feature visualization. You can display this visualization using `plot(visualization)`.

`[___] = extractHOGFeatures(___,Name,Value)` uses additional options specified by one or more Name,Value pair arguments, using any of the preceding syntaxes.

Examples

Extract and Plot HOG Features

Read the image of interest.



```
img = imread('cameraman.tif');
```

Extract HOG features.

```
[featureVector,hogVisualization] = extractHOGFeatures(img);
```

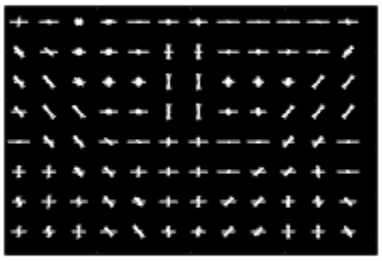
Plot HOG features over the original image.

```
figure;
imshow(img);
hold on;
plot(hogVisualization);
```

Extract HOG Features Using CellSize

Read the image of interest.

```
I1 = imread('gantrycrane.png');
```



Extract HOG features.

```
[hog1,visualization] = extractHOGFeatures(I1,'CellSize',[32 32]);
```

Display the original image and the HOG features.

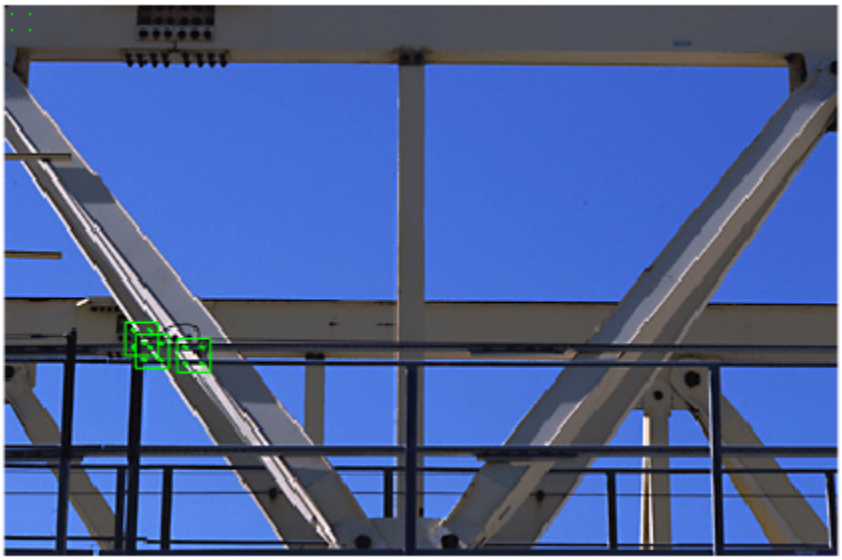
```
subplot(1,2,1);
imshow(I1);
subplot(1,2,2);
plot(visualization);
```

Extract HOG Features Around Corner Points

Read in the image of interest.

```
I2 = imread('gantrycrane.png');
```

Detect and select the strongest corners in the image.



```
corners   = detectFASTFeatures(im2gray(I2));
strongest = selectStrongest(corners,3);
```

Extract HOG features.

```
[hog2,validPoints,ptVis] = extractHOGFeatures(I2,strongest);
```

Display the original image with an overlay of HOG features around the strongest corners.

```
figure;
imshow(I2);
hold on;
plot(ptVis,'Color','green');
```

Input Arguments

`I` — Input image

M-by-*N*-by-3 truecolor image | *M*-by-*N* 2-D grayscale image

Input image, specified in either *M*-by-*N*-by-3 truecolor or *M*-by-*N* 2-D grayscale. The input image must be a real, nonsparse value. If you have tightly cropped images, you may lose shape information that the HOG function can encode. You can avoid losing this information by including an extra margin of pixels around the patch that contains background pixels.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

`points` — Center location point

`BRISKPoints` object | `cornerPoints` object | `SURFPoints` object | `MSERRegions` object | *M*-by-2 matrix of [*x*, *y*] coordinates

Center location point of a square neighborhood, specified as either a `BRISKPoints`, `SURFPoints`, `MSERRegions`, `ORBPoints` or `cornerPoints` object, or an *M*-by-2 matrix of *M* number of [*x*, *y*] coordinates. The function extracts descriptors from the neighborhoods that are fully contained within the image boundary. You can set the size of the neighborhood with the `BlockSize` parameter. Only neighborhoods fully contained within the image are used to determine the valid output points. The function ignores scale information associated with these points.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'BlockSize',[2 2]` sets the `BlockSize` to be a 2-by-2 square block.

`CellSize` — Size of HOG cell
`[8 8]` (default) | 2-element vector

Size of HOG cell, specified in pixels as a 2-element vector. To capture large-scale spatial information, increase the cell size. When you increase the cell size, you may lose small-scale detail.

`BlockSize` — Number of cells in block
`[2 2]` (default) | 2-element vector

Number of cells in a block, specified as a 2-element vector. A large block size value reduces the ability to suppress local illumination changes. Because of the number of pixels in a large block, these changes may get lost with averaging. Reducing the block size helps to capture the significance of local pixels. Smaller block size can help suppress illumination changes of HOG features.

`BlockOverlap` — Number of overlapping cells between adjacent blocks
`ceil(BlockSize/2)` (default)

Number of overlapping cells between adjacent blocks, specified as a 2-element vector. To ensure adequate contrast normalization, select an overlap of at least half the block size. Large overlap values can capture more information, but they produce larger feature vector size. This property applies only when you are extracting HOG features from regions and not from point locations. When you are extracting HOG features around a point location, only one block is used, and thus, no overlap occurs.

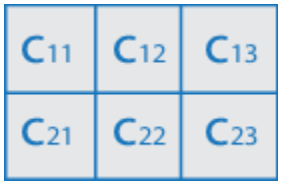
`NumBins` — Number of orientation histogram bins
9 (default) | positive scalar

Number of orientation histogram bins, specified as positive scalar. To encode finer orientation details, increase the number of bins. Increasing this value increases the size of the feature vector, which requires more time to process.

`UseSignedOrientation` — Selection of orientation values
`false` (default) | logical scalar

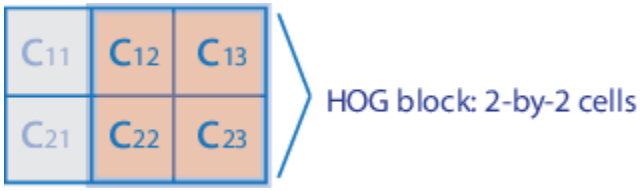
Selection of orientation values, specified as a logical scalar. When you set this property to `true`, orientation values are evenly spaced in bins between -180 and 180 degrees. When you set this property to `false`, they are evenly spaced from 0 through 180. In this case, values of theta that are less than 0 are placed into a theta + 180 value bin. Using signed orientation can help differentiate light-to-dark versus dark-to-light transitions within an image region.

Output Arguments



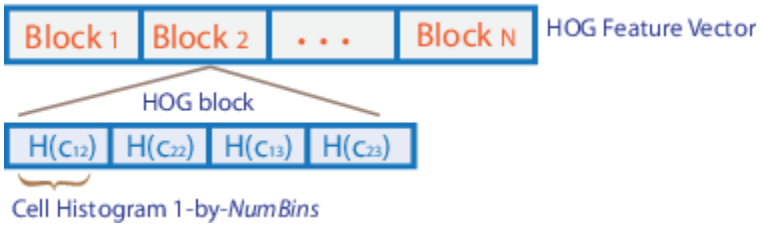
`features` — Extracted HOG features
1-by-*N* vector | *P*-by-*Q* matrix

Extracted HOG features, returned as either a 1-by-*N* vector or a *P*-by-*Q* matrix. The features encode local shape information from regions or from point locations within an image. You can use this information for many tasks including classification, detection, and tracking.

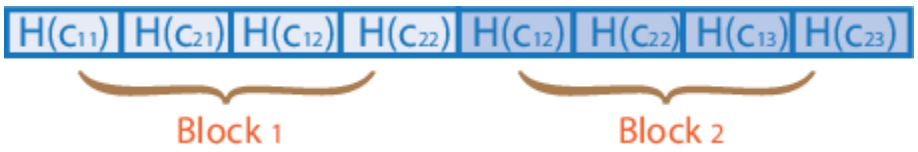


features output	Description
1-by-*N* vector	HOG feature length, *N*, is based on the image size and the function parameter values. *N* = `prod`([*BlocksPerImage*, `BlockSize`, `NumBins`]) *BlocksPerImage* = `floor`((`size`(`I`)./`CellSize` – `BlockSize`)./(`BlockSize` – `BlockOverlap`) + 1)
P-by-*Q* matrix	*P* is the number of valid points whose surrounding region is fully contained within the input image. You provide the `points` input value for extracting point locations. The surrounding region is calculated as: `CellSize`.*`BlockSize`. The feature vector length, *Q*, is calculated as: `prod`([`NumBins`,`BlockSize`]).

Example 3.1. Arrangement of Histograms in HOG Feature Vectors



The figure below shows an image with six cells.



If you set the `BlockSize` to `[2 2]`, it would make the size of each HOG block, 2-by-2 cells. The size of the cells are in pixels. You can set it with the `CellSize` property.

The HOG feature vector is arranged by HOG blocks. The cell histogram, $H(C_{yx})$, is 1-by-`NumBins`.

The figure below shows the HOG feature vector with a 1-by-1 cell overlap between blocks.

`validPoints` — Valid points
`cornerPoints` object | `BRISKPoints` object | `SURFPoints` object | `MSERRegions` object | `ORBPoints` object | *M*-by-2 matrix of [*x*,*y*] coordinates

Valid points associated with each `features` descriptor vector output. This output can be returned as either a `cornerPoints` object, `BRISKPoints`, `SURFPoints` object, `MSERRegions` object, `ORBPoints` object or an *M*-by-2 matrix of [*x*,*y*] coordinates. The function extracts *M* number of descriptors from valid interest points in a region of size equal to [`CellSize`.*`BlockSize`]. The extracted descriptors are returned as the same type of object or matrix as the input. The region must be fully contained within the image.

`visualization` — HOG feature visualization
object

HOG feature visualization, returned as an object. The function outputs this optional argument to visualize the extracted HOG features. You can use the `plot` method with the `visualization` output. See the “Extract and Plot HOG Features” on page 3-817 example.

HOG features are visualized using a grid of uniformly spaced `rose` plots. The cell size and the size of the image determines the grid dimensions. Each rose plot shows the distribution of gradient orientations within a HOG cell. The length of each petal of the rose plot is scaled to indicate the contribution each orientation makes within the cell histogram. The plot displays the edge directions, which are normal to the gradient directions. Viewing the plot with the edge directions allows you to better understand the shape and contours encoded by HOG. Each rose plot displays two times `NumBins` petals.

You can use the following syntax to plot the HOG features:
`plot(visualization)` plots the HOG features as an array of rose plots.
`plot(visualization,AX)` plots HOG features into the axes AX.
`plot(___,'Color',colorValue)` Specifies the color used to plot HOG features, where `colorValue` represents the color as a 1-by-3 RGB vector, a short, or a long color name, described in the Color Value on page 3-823 table.

More About

Color Value

Color Name	Short Name	RGB Triplet	Appearance
`"red"`	`"r"`	`[1 0 0]`	
`"green"`	`"g"`	`[0 1 0]`	
`"blue"`	`"b"`	`[0 0 1]`	
`"cyan"`	`"c"`	`[0 1 1]`	
`"magenta"`	`"m"`	`[1 0 1]`	
`"yellow"`	`"y"`	`[1 1 0]`	

Color Name	Short Name	RGB Triplet	Appearance
"black"	"k"	[0 0 0]	
"white"	"w"	[1 1 1]

fitPolynomialRANSAC

Fit polynomial to points using RANSAC

Syntax

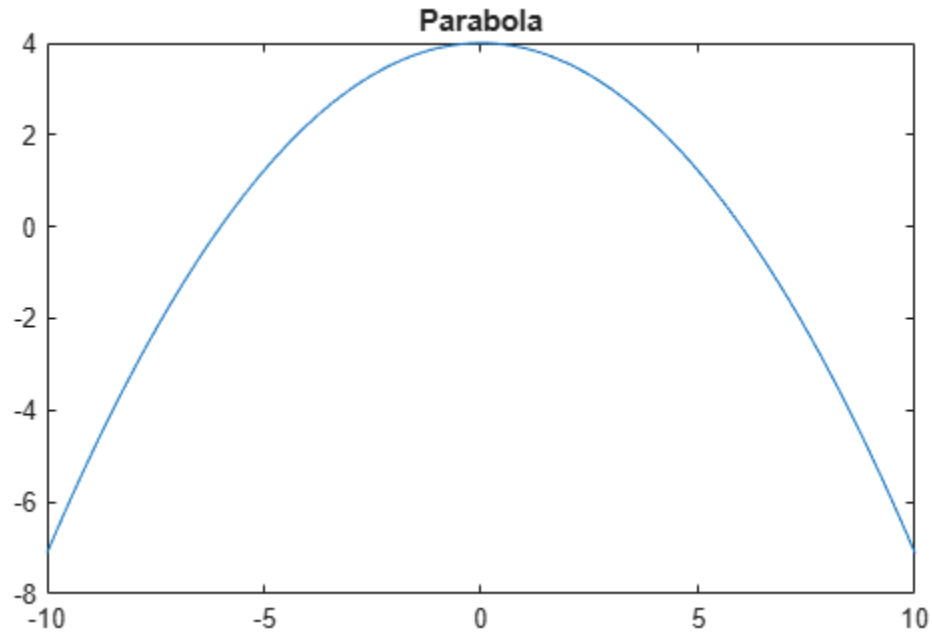
```
P = fitPolynomialRANSAC(xyPoints,N,maxDistance)
[P,inlierIdx] = fitPolynomialRANSAC( ___ )
[ ___ ] = fitPolynomialRANSAC( ___ ,Name=Value)
```

Description

`P = fitPolynomialRANSAC(xyPoints,N,maxDistance)` finds the *N*th-degree polynomial coefficients, `P`, by sampling a small set of points given in `xyPoints` and generating the *N*th polynomial fits. The fit that has the most inliers within `maxDistance` is returned. If a fit cannot be found, then `P` is returned empty. The function uses the M-estimator sample consensus (MSAC) algorithm, a variation of the random sample consensus (RANSAC) algorithm to fit the data.

`[P,inlierIdx] = fitPolynomialRANSAC( ___ )` returns a logical array, `inlierIdx`, that specifies the indices for data points that are inliers to the fit polynomial based on `maxDistance`. Use the input arguments from the previous syntax.

`[ ___ ] = fitPolynomialRANSAC( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `(MaxNumTrials=2000)` sets the maximum number of random trials to `2000`.

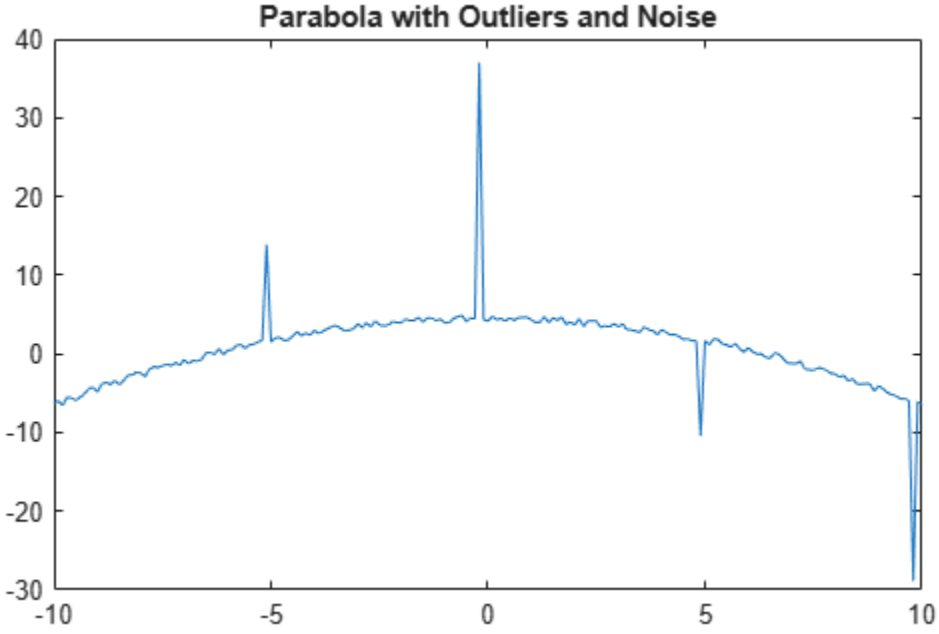


Examples

Fit Parabola to Noisy Data Using RANSAC

Use the RANSAC algorithm to generate a polynomial that fits a set of noisy data. The `fitPolynomialRANSAC` function generates a polynomial by sampling a small set of points from `[x y]` point data and generating polynomial fits. The fit with the most inliers within `maxDistance` is returned.

Construct and plot a parabola with `[x y]` points.

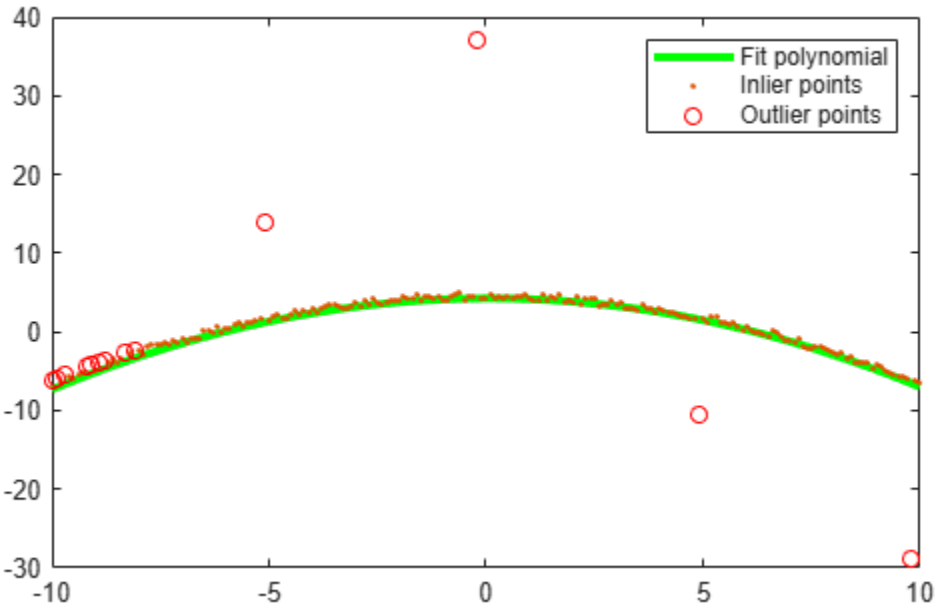


```
x = (-10:0.1:10)';
y = (36-x.^2)/9;
figure
plot(x,y)
title('Parabola')
```

Add noise and outlier points to the points on the parabola.

```
y = y+rand(length(y),1);
y([50,150,99,199]) = [y(50)+12,y(150)-12,y(99)+33,y(199)-23];

plot(x,y)
title('Parabola with Outliers and Noise')
```



Use `fitPolynomialRANSAC` to generate coefficients for a second-degree polynomial. Also get the inliers identified by the specified `maxDistance` from the polynomial fit.

```
N = 2;           % second-degree polynomial
maxDistance = 1; % maximum allowed distance for a point to be inlier

[P, inlierIdx] = fitPolynomialRANSAC([x,y],N,maxDistance);
```

Evaluate the polynomial using `polyval`. Plot the curve and overlay the `[x y]` points. Mark outliers with a red circle.

```
yRecoveredCurve = polyval(P,x);
figure
plot(x,yRecoveredCurve,'-g','LineWidth',3)
hold on
plot(x(inlierIdx),y(inlierIdx),'.',x(~inlierIdx),y(~inlierIdx),'ro')
legend('Fit polynomial','Inlier points','Outlier points')
hold off
```

Input Arguments

`xyPoints` — `[x y]` coordinate points

m-by-2 matrix

`[x y]` coordinate points, specified as an *m*-by-2 matrix. The polynomial is fit to these points.

Data Types: `double` | `single` | `uint32` | `int32` | `uint16` | `int16`

`N` — Degree of polynomial fit

integer

Degree of polynomial fit, `P`, specified as an integer. The degree of a polynomial is the highest degree of the terms in the equation. For example, a polynomial of degree 2 is:

Ax^2+Bx+C

A, B, and C are constants. In general, higher degree polynomials allow for a better fit, but the fit depends on your data.

`maxDistance` — Maximum distance for inlier points
positive scalar

Maximum distance from the polynomial fit curve to an inlier point, specified as a positive scalar. Any points further away are considered outliers. The RANSAC algorithm creates a fit from a small sample of points but tries to maximize the number of inlier points. Lowering the maximum distance helps to improve the polynomial fit by putting a tighter tolerance on inlier points. For an M-by-2 matrix of points in the form [x y], the distance is defined as `abs`(y - `polyval`(`model`,x)).

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `(MaxNumTrials=2000)` sets the maximum number of random trials to `2000`.

`MaxNumTrials` — Maximum number of random trials
`1000` (default) | integer

Maximum number of random trials, specified as an integer. A single trial uses a minimum number of random points from `xyPoints` to fit a parabolic model. Then, the trial checks the number of inliers within the `maxDistance` from the model. After all trials, the model with the highest number of inliers is selected. Increasing the number of trials improves the robustness of the output at the expense of additional computation.

`Confidence` — Confidence of final solution
`99` (default) | scalar from 0 to 100

Confidence that the final solution finds the maximum number of inliers for the polynomial fit, specified as a scalar from 0 to 100. Increasing this value improves the robustness of the output at the expense of additional computation.

`ValidatePolynomialFcn` — Function to validate polynomial
function handle

Function to validate polynomial, specified as a function handle. The function returns `true` if the polynomial is accepted based on criteria defined in the function. Use this function to reject specific polynomial fits. The function must be of the form:

```
isValid = validatePolynomialFcn(P,varargin)
```

If no function is specified, all polynomials are assumed to be valid.

`MaxSamplingAttempts` — Maximum number of sample attempts
`100` (default) | integer

Maximum number of attempts to find a sample that yields a valid polynomial, specified as an integer.

Output Arguments

`P` — Polynomial coefficients
vector of numeric scalars

Polynomial coefficients, returned as a vector of numeric scalars. Each element corresponds to a constant in the polynomial equation with degree `N`. For example, for a second-degree polynomial, Ax^2+Bx+C:

```
P = [A B C];
```

Data Types: `single` | `double`

`inlierIdx` — Inlier points
logical vector

Inlier points, returned as a logical vector. The vector is the same length as `xyPoints`, and each element indicates if that point is an inlier for the polynomial fit based on `maxDistance`.

extrinsics

(Not recommended) Compute location of calibrated camera

Note `extrinsics` is not recommended. Use the `estimateExtrinsics` function instead. For more information, see "Version History".

Syntax

```
[rotationMatrix,translationVector] = extrinsics(imagePoints,worldPoints,
cameraParams)
```

Description

`[rotationMatrix,translationVector] = extrinsics(imagePoints,worldPoints, cameraParams)` returns the 3-D rotation matrix and the 3-D translation vector to allow you to transform points from the world coordinate to the camera coordinate system.

Examples

Compute Camera Extrinsics

Create a set of calibration images.

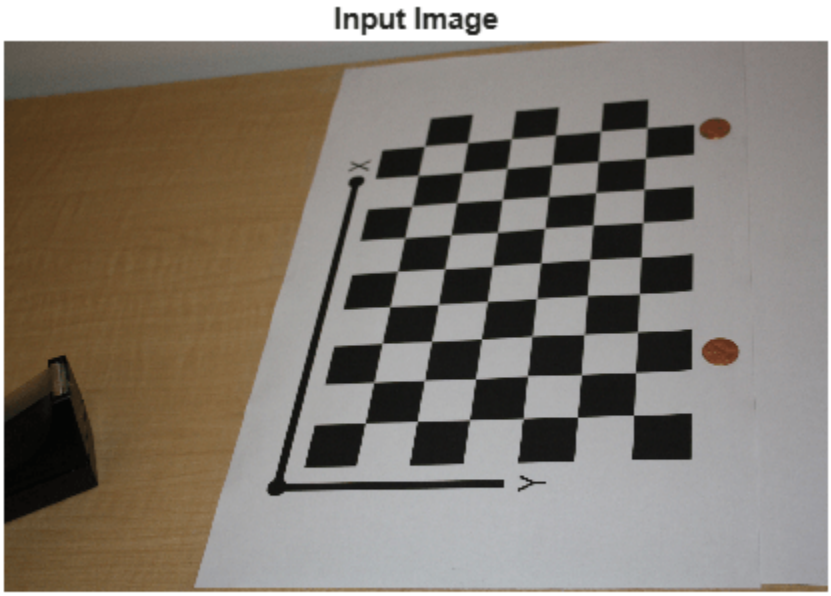
```
  images = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
      "calibration", "slr"));
```

Detect the checkerboard corners in the images.

```
[imagePoints,patternDims] = detectCheckerboardPoints(images.Files);
```

Generate the world coordinates of the checkerboard corners in the pattern-centric coordinate system, with the upper-left corner at (0,0). The square size is in millimeters.

```
squareSize = 29;
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```



Calibrate the camera.

```
I = readimage(images,1);
imageSize = [size(I,1), size(I,2)];
cameraParams = estimateCameraParameters(imagePoints,worldPoints, ...
                                        ImageSize=imageSize);
intrinsics = cameraParams.Intrinsics;
```

Load image at new location.

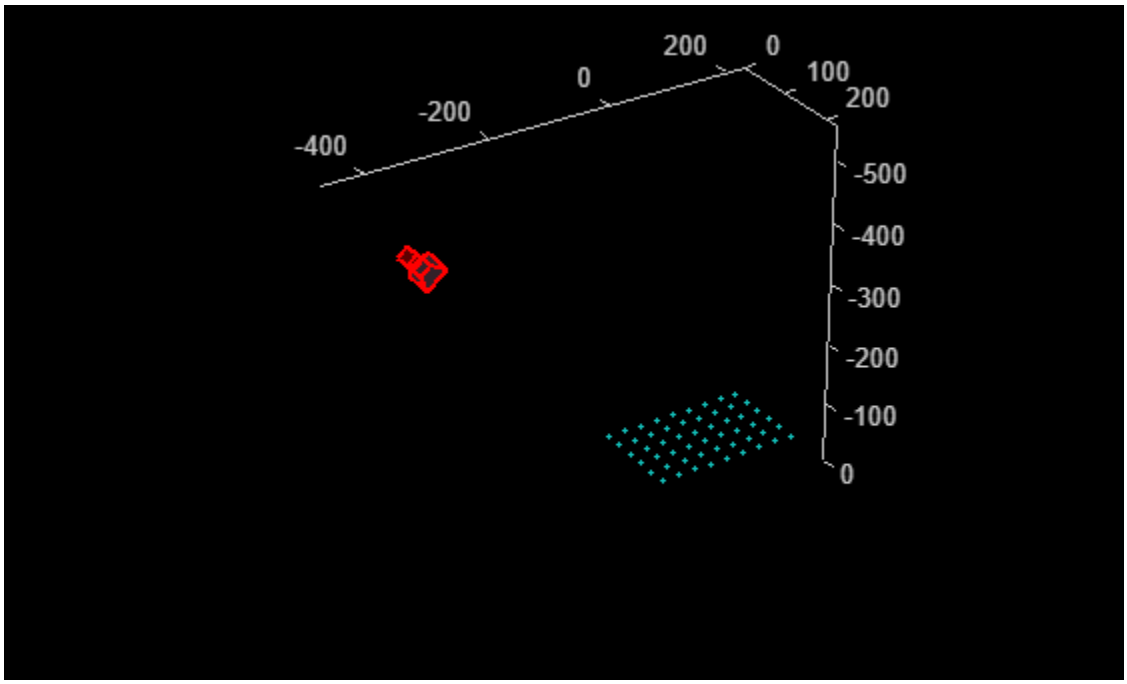
```
imOrig = imread(fullfile(matlabroot,"toolbox","vision","visiondata", ...
    "calibration","slr","image9.jpg"));
figure
```

```
imshow(imOrig);
title("Input Image");
```

Undistort image.

```
[im,newIntrinsics] = undistortImage(imOrig,intrinsics,OutputView="full");
```

Find reference object in new image.



```
[imagePoints,patternDims] = detectCheckerboardPoints(im);
```

Compute new extrinsics.

```
[rotationMatrix, translationVector] = ...
    extrinsics(imagePoints,worldPoints,newIntrinsics);
```

Compute camera pose.

```
[orientation, location] = extrinsicsToCameraPose(rotationMatrix,translationVector);
figure
plotCamera(Location=location,Orientation=orientation,Size=20);
hold on
pcshow([worldPoints,zeros(size(worldPoints,1),1)], ...
  VerticalAxisDir="down",MarkerSize=40);
```

Input Arguments

`imagePoints` — Image coordinates of points

M-by-2 array

Image coordinates of points, specified as an *M*-by-2 array. The array contains *M* number of [*x*, *y*] coordinates. The `imagePoints` and `worldPoints` inputs must both be `double` or both be `single`.

Data Types: `single` | `double`

`worldPoints` — World coordinates corresponding to image coordinates

M-by-2 matrix

World coordinates corresponding to image coordinates, specified as an *M*-by-2 matrix. The `imagePoints` and `worldPoints` inputs must both be `double` or both be `single`. The function assumes that the points are coplanar with $z = 0$ and the number of points, *M*, must be at least 4.

Data Types: `single` | `double`

`cameraParams` — Camera parameters

`cameraParameters` object | `cameraIntrinsics` object | `fisheyeIntrinsics` object

Object for storing camera parameters, specified as a `cameraParameters`, `cameraIntrinsics`, or `fisheyeIntrinsics` object. These objects are returned by the `estimateCameraParameters` function, the `estimateFisheyeParameters` function, or the Camera Calibrator app. The object contains the intrinsic, extrinsic, and lens distortion parameters of a camera.

Output Arguments

`rotationMatrix` — 3-D rotation

3-by-3 matrix

3-D rotation, returned as a 3-by-3 matrix. The rotation matrix together with the translation vector allows you to transform points from the world coordinate to the camera coordinate system.

If you set the `imagePoints` and `worldPoints` inputs to class `double`, then the function returns the `rotationMatrix` and `translationVector` as `double`. Otherwise, they are `single`.

`translationVector` — 3-D translation

1-by-3 vector

3-D translation, returned as a 1-by-3 vector. The rotation matrix together with the translation vector allows you to transform points from the world coordinate to the camera coordinate system.

If you set the `imagePoints` and `worldPoints` inputs to class `double`, then the function returns the `rotationMatrix` and `translationVector` as `double`. Otherwise, they are `single`.

Algorithms

The `extrinsics` function uses two different algorithms to compute the extrinsics depending on whether `worldPoints` are specified as an *M*-by-2 matrix. Use an *M*-by-2 matrix for coplanar points where $z = 0$.

The `extrinsics` function computes the rotation matrix and translation vector for a single image in closed form. During calibration, the extrinsics are estimated numerically to minimize the reprojection errors for all calibration images. Therefore, using the `extrinsics` function on one of the calibration images returns rotation matrix and translation vector slightly different from the ones obtained during calibration.

Version History

Introduced in R2014a

R2022b: Not recommended

Not recommended starting in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `extrinsics` function uses the postmultiply convention. Although there are no plans to remove `extrinsics` at this time, you can streamline your geometric transformation workflows by switching to the `estimateExtrinsics`

function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

To update your code:

- Change instances of the function name `extrinsics` to `estimateExtrinsics`.
- Specify the `cameraParams` argument as a `cameraIntrinsics` or `fisheyeIntrinsics` object. If you have a `cameraParameters` object, then you can get a `cameraIntrinsics` object by querying the `Intrinsics` property. If the `Intrinsics` property is empty according to the `isempty` function, then set the `ImageSize` property of the `cameraParameters` object to an arbitrary vector before querying the `Intrinsics` property. For example:

  ```
  load worldToImageCorrespondences.mat
  if(isempty(cameraParams.Intrinsics))
      cameraParams.ImageSize = [128 128];
  end
  intrinsics = cameraParams.Intrinsics;
  ```
- Replace the two output arguments `rotationMatrix` and `translationVector` with a single output argument, `camExtrinsics`. The `camExtrinsics` argument returns a `rigidtform3d` object. If you need to obtain the orientation matrix and location vector, then you can query the `R` and `Translation` properties of the object. Note that the value of `R` is the transpose of `rotationMatrix`.

The table shows examples of how to update your code.

Discouraged Usage	Recommended Replacement

This example calculates the location of a calibrated camera using the `exrinsics` function with the `cameraParams` argument specified as a `cameraParameters` object.
 	
`[rotMatrix,transVector] = extrinsics( ...`
`  imagePoints,worldPoints,cameraParams);`
	This example gets the camera intrinsics using the `Intrinsics` property of a `cameraParameters` object, then calculates the location of the calibrated camera using the `estimateExtrinsics` function.
	
	`intrinsics = cameraParams.Intrinsics;`
	`camExtrinsics = estimateExtrinsics( ...`
	`  imagePoints,worldPoints,intrinsics);`
	
	If you need to obtain the camera orientation and location, then you can query properties of `camExtrinsics`.
	
	`rotMatrix = camExtrinsics.R;`
	`transVector = camExtrinsics.Translation;`
	
	If you want the orientation in the postmultiply convention, take the transpose of `camExtrinsics.R`.
	
	`rotMatrix = camExtrinsics.R';`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use in a MATLAB Function block is not supported.
- Use of a `fisheyeIntrinsics` object as the `cameraParams` input is not supported.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

generalizedDice

Generalized Sørensen-Dice similarity coefficient for image segmentation

Syntax

```
similarity = generalizedDice(X,target)
similarity = generalizedDice(X,target,'DataFormat',dataFormat)
```

Description

The generalized Dice similarity coefficient measures the overlap between two segmented images. Generalized Dice similarity is based on Sørensen-Dice similarity and controls the contribution that each class makes to the similarity by weighting classes by the inverse size of the expected region. When working with imbalanced data sets, class weighting helps to prevent the more prevalent classes from dominating the similarity score.

`similarity = generalizedDice(X,target)` calculates the generalized Sørensen-Dice similarity coefficient between test image `X` and target image `target`.

`similarity = generalizedDice(X,target,'DataFormat',dataFormat)` also specifies the dimension labels, `dataFormat`, of unformatted image data. You must use this syntax when the input are unformatted `dlarray` objects.

Examples

Calculate Generalized Dice Similarity

Load a pretrained network.

```
data = load("triangleSegmentationNetwork");
net = data.net;
```

Load the triangle image data set using `imageDatastore`.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata","triangleImages");
testImageDir = fullfile(dataDir,"testImages");
imds = imageDatastore(testImageDir);
```

Load ground truth labels for the triangle data set using `pixelLabelDatastore`.

```
labelDir = fullfile(dataDir,"testLabels");
classNames = ["triangle" "background"];
pixelLabelID = [255 0];
pxdsTruth = pixelLabelDatastore(labelDir,classNames,pixelLabelID);
```

Read a sample image and the corresponding ground truth labels.

```
I = readimage(imds,1);
gTruthLabels = readimage(pxdsTruth,1);
```

Run semantic segmentation on the image.

```
[predictions,scores] = semanticseg(I,net,Classes=classNames);
```

Encode the categorical predictions and targets using the `onehotencode` function.

```
featureDim = ndims(predictions) + 1;
encodedPredictions = onehotencode(predictions,featureDim);
encodedGroundTruthLabels = onehotencode(gTruthLabels,featureDim);
```

Ignore any undefined classes in the encoded data.

```
encodedPredictions(isnan(encodedPredictions)) = 0;
encodedGroundTruthLabels(isnan(encodedGroundTruthLabels)) = 0;
```

Compute generalized Dice similarity coefficient between the segmented image and the ground truth.

```
gDice = generalizedDice(encodedPredictions,encodedGroundTruthLabels)
```

```
gDice =
0.9346
```

Calculate Generalized Dice Loss of `dlarray` Input

Create input data as a formatted `dlarray` object containing 32 observations with unnormalized scores for ten output categories.

```
spatial = 10;
numCategories = 10;
batchSize = 32;
X = dlarray(rand(spatial,numCategories,batchSize),'SCB');
```

Convert unnormalized scores to probabilities of membership of each of the ten categories.

```
X = sigmoid(X);
```

Create target values for membership in the second and sixth category.

```
targets = zeros(spatial,numCategories,batchSize);
targets(:,2,:) = 1;
targets(:,6,:) = 1;
targets = dlarray(targets,'SCB');
```

Compute the generalized Dice similarity coefficient between probability vectors X and targets for multi-label classification.

```
Z = generalizedDice(X,targets);
whos Z
```

```
  Name      Size              Bytes  Class      Attributes

  Z         1x1x32              262  dlarray
```

Calculate the generalized Dice loss.

```
loss = 1 - mean(Z,'all')
```

```
loss =
  1(S) × 1(C) × 1(B) dlarray
```

```
1
```

Input Arguments

X — Test image

numeric array | `dlarray` object

Test image to be analyzed, specified as one of these values.

- A numeric array of any dimension. The last dimension must correspond to classes.
- An unformatted `dlarray` object. You must specify the data format using the `dataFormat` argument.
- A formatted `dlarray` object. The `dlarray` input must contain a channel dimension, `'C'` and can contain a batch dimension, `'B'`.

`dlarray` input requires Deep Learning Toolbox.

target — Target image

numeric array | `dlarray` object

Target image, specified as a numeric array or a `dlarray` object. The size and format of `target` must match the size and format of the test image, `X`. `dlarray` input requires Deep Learning Toolbox.

dataFormat — Dimension labels

string scalar | character vector

Dimension labels for unformatted `dlarray` image input, specified as a string scalar or character vector. Each character in `dataFormat` must be one of these labels:

- `S` — Spatial
- `C` — Channel
- `B` — Batch observations

The format must include one channel label. The format cannot include more than one channel label or batch label. Do not specify the '`dataFormat`' argument when the input images are formatted `dlarray` objects.

Example: `'SSC'` indicates that the array has two spatial dimensions and one channel dimension

Example: `'SSCB'` indicates that the array has two spatial dimensions, one channel dimension, and one batch dimension

Output Arguments

similarity — Generalized Dice similarity coefficient

numeric scalar | `dlarray` object

Generalized Dice similarity coefficient, returned as a numeric scalar or a `dlarray` object with values in the range [0, 1]. A `similarity` of 1 means that the segmentations in the two images are a perfect match.

- If the input arrays are numeric images, then `similarity` is a numeric scalar.
- If the input arrays are `dlarray` objects, then `similarity` is a `dlarray` object of the same dimensionality as the input images. The spatial and channel dimensions of `similarity` are singleton dimensions. There is one generalized Dice measurement for each element along the batch dimension.

More About

Generalized Dice Similarity

Generalized Dice similarity is based on Sørensen-Dice similarity for measuring overlap between two segmented images.

The generalized Dice similarity function S used by `generalizedDice` for the similarity between one image Y and the corresponding ground truth T is given by:

$$S = \frac{2\sum_{k=1}^{K} w_k \sum_{m=1}^{M} Y_{km} T_{km}}{\sum_{k=1}^{K} w_k \sum_{m=1}^{M} Y_{km}^2 + T_{km}^2}$$

K is the number of classes, M is the number of elements along the first two dimensions of Y, and w_k is a class specific weighting factor that controls the contribution each class makes to the score. This weighting helps counter the influence of larger regions on the generalized Dice score. w_k is typically the inverse area of the expected region:

$$w_k = \frac{1}{\left(\sum_{m=1}^{M} T_{km}\right)^2}$$

There are several variations of generalized Dice scores [1], [2]. The `generalizedDice` function uses squared terms to ensure that the derivative is 0 when the two images match [3].

generateCheckerboardPoints

Generate checkerboard corner locations

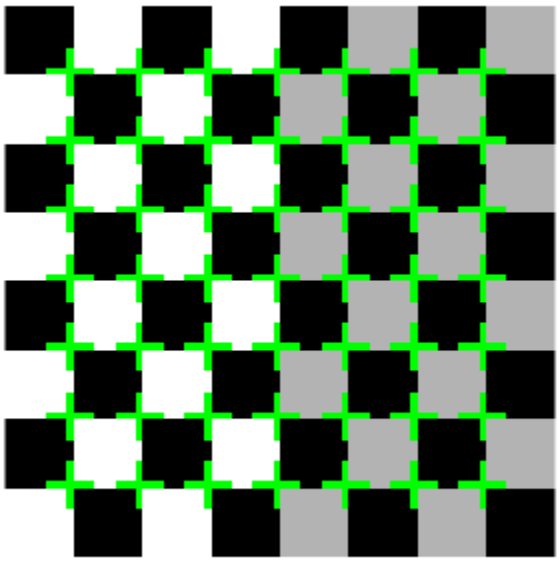
Syntax

```
worldPoints = generateCheckerboardPoints(boardSize,squareSize)
```

Description

`worldPoints = generateCheckerboardPoints(boardSize,squareSize)` returns an *M*-by-2 matrix containing *M* [*x*, *y*] corner coordinates for the squares on a checkerboard. The point [0,0] corresponds to the lower-right corner of the top-left square of the board.

Examples



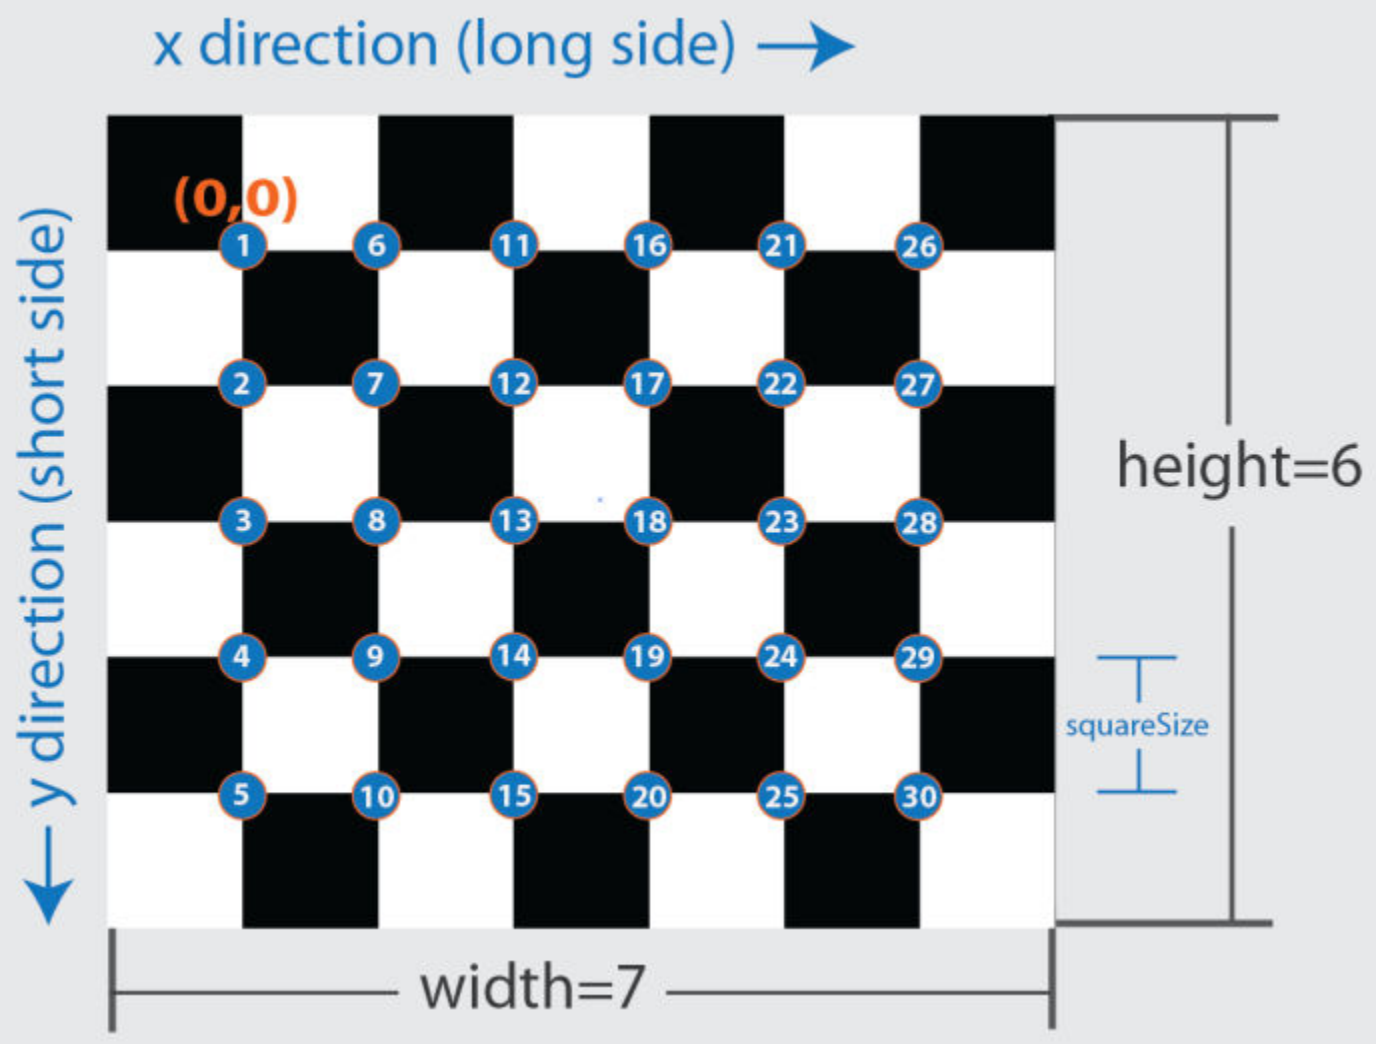
Generate and Plot Corners of an 8-by-8 Checkerboard

Generate the checkerboard, and obtain world coordinates.

```
I = checkerboard;
squareSize = 10;
worldPoints = generateCheckerboardPoints([8 8], squareSize);
```

Offset the points, placing the first point at the lower-right corner of the first square.

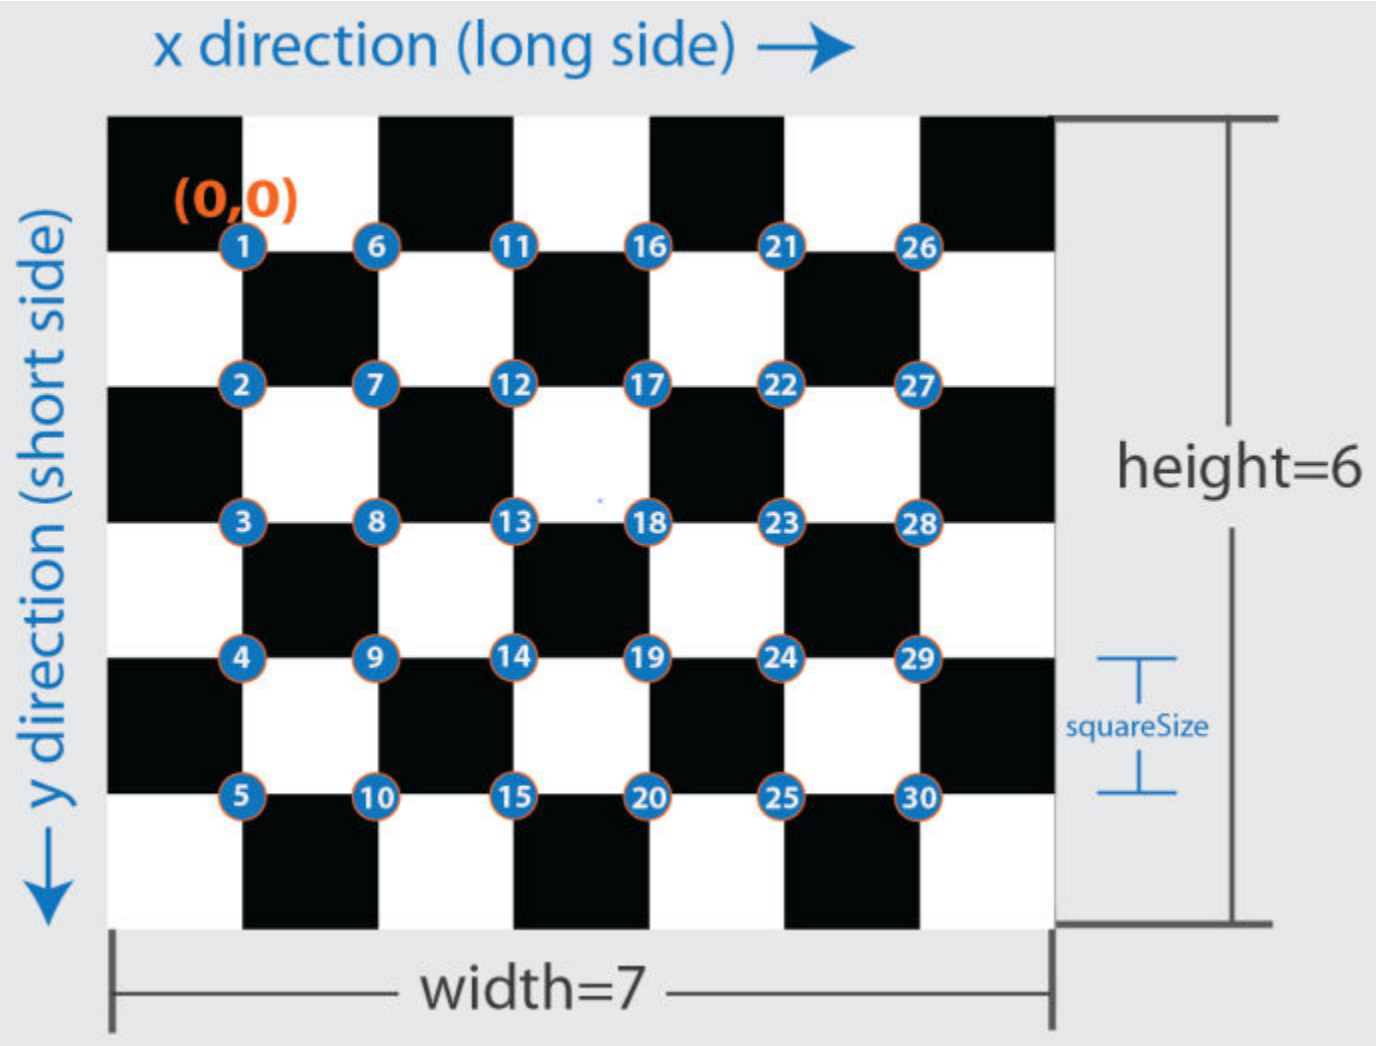
```
imshow(insertMarker(I, worldPoints + squareSize));
```



Input Arguments

`boardSize` — Generated checkerboard dimensions

2-element [*height*, *width*] vector



Generated checkerboard dimensions, specified as a 2-element [*height*, *width*] vector. You express the dimensions of the checkerboard in number of squares.

`squareSize` — Generated checkerboard square side length

scalar

Checkerboard square side length, specified as a scalar in world units. You express world units as a measurement, such as millimeters or inches.

Output Arguments

`worldPoints` — Generated checkerboard corner coordinates
M-by-2 matrix

Generated checkerboard corner coordinates, returned as an *M*-by-2 matrix of *M* number of [*x* *y*] coordinates. The coordinates represent the corners of the squares on the checkerboard. The point [0,0] corresponds to the lower-right corner of the top-left square of the board. The number of points, *M*, that the function returns are based on the number of squares on the checkerboard. This value is set with the `boardSize` parameter.
M = (`boardSize`(1)-1) * (`boardSize`(2)-1)

imageMetrics

Evaluate per-image object detection performance metrics

Syntax

```
imageSummary = imageMetrics(metrics)
[imageSummary,imagePredictions,imageGroundTruth] = imageMetrics(metrics)
[___] = imageMetrics(metrics,imageIndices)
[___] = imageMetrics(___,Name=Value)
```

Description

`imageSummary = imageMetrics(metrics)` evaluates the object detection metrics, `metrics`, for each image in the data set.

`[imageSummary,imagePredictions,imageGroundTruth] = imageMetrics(metrics)` evaluates the object detection metrics, `metrics`, for each image in the data set, and returns the performance summary, predictions, and ground truth information for each image.

`[___] = imageMetrics(metrics,imageIndices)` evaluates the object detection metrics, `metrics`, for images in the data set specified using the image indices, `imageIndices`.

`[___] = imageMetrics(___,Name=Value)` specifies options that configure per-image metrics using name-value arguments, in addition to the input arguments from the previous syntaxes. For example, `ClassNames=["person" "car"]` specifies to evaluate per-image metrics for the person and car classes.

Examples

Compute Per-Image Metrics for Multiclass Object Detection

Load Detection Results and Ground Truth Annotations

Load precomputed detection results and ground truth labels. The ground truth data is a subset of the Indoor Object Detection Dataset created by Bishwo Adhikari, and is in the form of a `boxLabelDatastore` that returns the object bounding boxes and their corresponding class labels for every image [1]. The MAT files containing the precomputed results and annotations are attached to this example as supporting files. To train an object detector on a custom dataset and generate the detection results, see Multiclass Object Detection Using YOLO v2 Deep Learning.

```
load("yolov2IndoorObjectDetectorAnnotation100.mat");
load("yolov2IndoorObjectDetectorResults100.mat");
```

Evaluate and Summarize Object Detection Metrics

Evaluate the object detection results against the ground truth using the `evaluateObjectDetection` function. Compute the metrics summary across the dataset and classes using the `summarize` function.

```
evalMetrics = evaluateObjectDetection(results,blds,[0.5,0.75,0.9]);
[summaryDataset,summaryClass] = summarize(evalMetrics);
disp(summaryDataset)
```

NumObjects	mAPOverlapAvg	mAP0.5	mAP0.75	mAP0.9
171	0.40012	0.74165	0.44671	0.012002

```
disp(summaryClass)
```

	NumObjects	APOverlapAvg	AP0.5	AP0.75	AP0.9
exit	53	0.60733	0.9619	0.82106	0.039027
fireextinguisher	49	0.54426	0.93878	0.68903	0.0049712
chair	55	0.35992	0.88449	0.19463	0.00062696
clock	13	0.4891	0.92308	0.52885	0.015385
trashbin	1	0	0	0	0
screen	0	NaN	NaN	NaN	NaN
printer	0	NaN	NaN	NaN	NaN

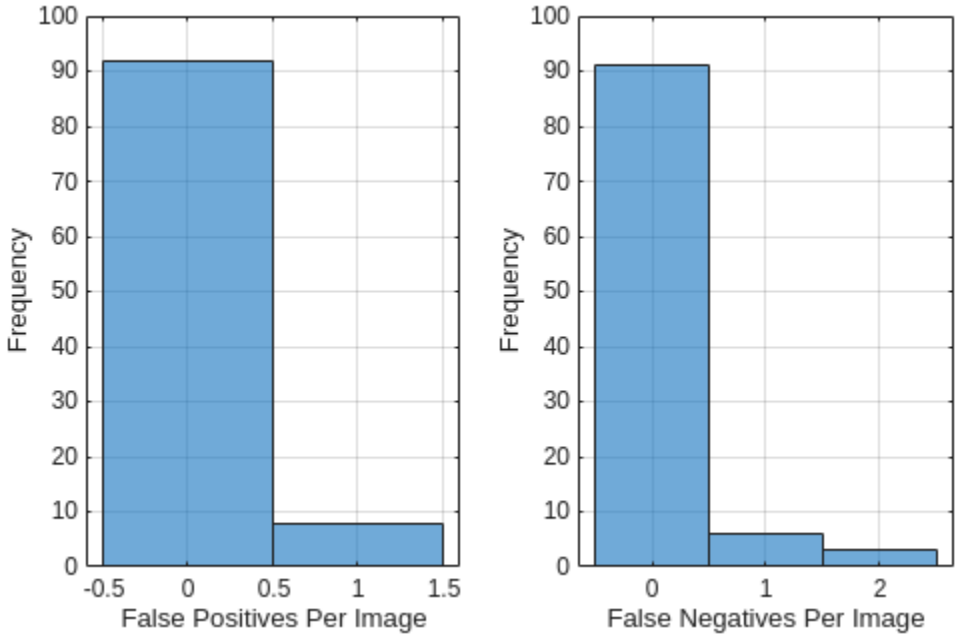
The summary across classes shows that the "trashbin" class has only one ground truth object in this evaluation dataset, while the "screen" and "printer" classes do not have any ground truth objects present.

Evaluate Per-Image Metrics

Compute per-image metrics for the data set.

```
imageSummary = imageMetrics(evalMetrics);
```

Display the first ten images and their summarized per-image metrics.



```
disp(imageSummary(1:10,:) )
```

ImageIndex	NumPredictedObjects	NumGroundTruthObjects	TP	FP	FN	Precision
1	2	2	2	0	0	1
2	2	2	2	0	0	1
3	1	1	1	0	0	1
4	0	2	0	0	2	NaN
5	3	2	2	1	0	0.66667
6	2	3	2	0	1	1
7	2	2	2	0	0	1
8	2	2	2	0	0	1
9	2	2	2	0	0	1
10	3	2	2	1	0	0.66667

Plot the histogram of false positive (FP) and false negative (FN) counts for each image.

```
figure;
subplot(1,2,1)
histogram(imageSummary.FP)
xlabel("False Positives Per Image")
ylabel("Frequency")
grid on
subplot(1,2,2)
```

```
histogram(imageSummary.FN)
xlabel("False Negatives Per Image")
ylabel("Frequency")
grid on
```

Most images have very few mistakes. The FP histogram shows that 8 images have one false positive detection. The FN histogram shows that 6 images have one false negative, and only 3 images have two false negatives.

[1] Adhikari, Bishwo; Peltomaki, Jukka; Huttunen, Heikki. (2019). Indoor Object Detection Dataset [Data set]. 7th European Workshop on Visual Information Processing 2018 (EUVIP), Tampere, Finland.

Analyze Object Detector Performance Across Size and Class

Load precomputed detection results and ground truth labels. The ground truth data is a subset of the Indoor Object Detection Dataset created by Bishwo Adhikari [1]. The MAT files containing the precomputed results and annotations are attached to this example as supporting files.

```
load("yolov2IndoorObjectDetectorAnnotation100.mat");
load("yolov2IndoorObjectDetectorResults100.mat");
```

Evaluate Object Detection Results

Evaluate the object detection results against the ground truth using the `evaluateObjectDetection` function. Specify three overlap thresholds for the evaluation: 0.5, 0.75, and 0.9.

```
evalMetrics = evaluateObjectDetection(results,blds,[0.5 0.75 0.9]);
```

Analyze Detector Performance Across Object Size and Class

Compute per-image metrics for the data set.

```
[imageSummary,imagePredictions,imageGroundTruths] = imageMetrics(evalMetrics);
```

To analyze object size- and class-based detector performance, create a visual representation of the number of true positives, false positives, false negatives for the entire data set. First, concatenate all prediction tables from all images into a single table `tblPreds`.

```
tblPreds = vertcat(imagePredictions{:});
```

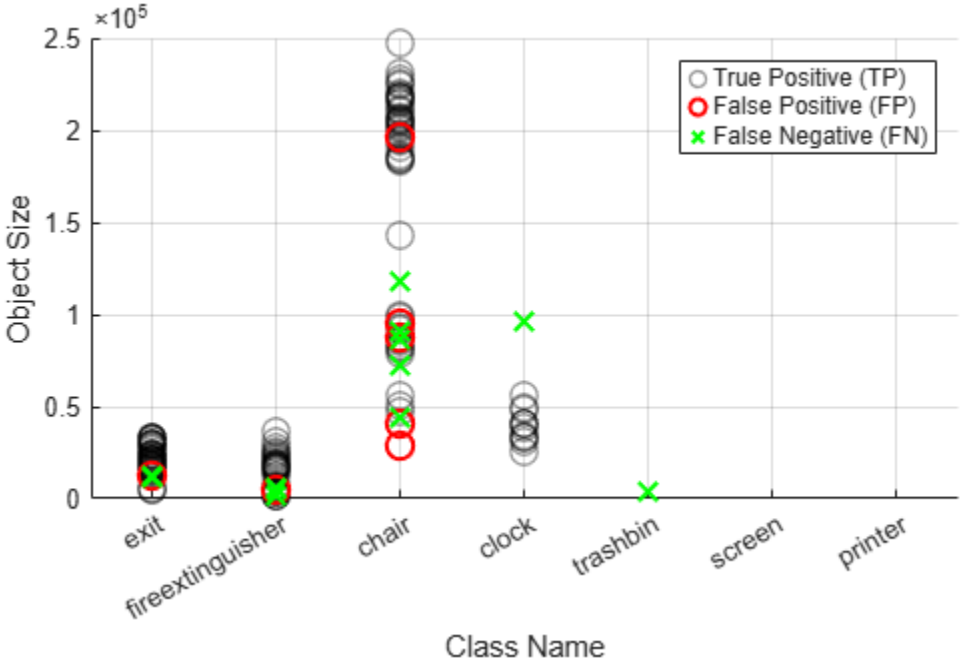
Create a logical array indicating which predictions are matched to ground truth objects, or are true positives (TPs).

```
isMatchedPred = logical(tblPreds.IsMatched);
```

Extract true positives (TPs) by keeping only the `Label` (class name) and `Area` (object size) columns for rows where predictions are matched to ground truth.

```
tp = tblPreds(isMatchedPred,["Label" "Area"]);
```

Extract false positives (FPs) by keeping only the `Label` (class name) and `Area` (object size) columns for rows where predictions are not matched to ground truth.



```
fp = tblPreds(~isMatchedPred,["Label" "Area"]);
```

Concatenate all ground truth tables into `tblTruths`, and create a logical array indicating which ground truths were matched by predictions. Extract false negatives (FNs) by keeping only `Label` and `Area` for ground truths not matched to any prediction.

```
tblTruths = vertcat(imageGroundTruths{:});
isMatchedGT = logical(tblTruths.IsMatched);
fn = tblTruths(~isMatchedGT,["Label" "Area"]);
```

Plot TPs as black circles using a swarm chart, with class name on the x-axis and object size on the y-axis. Plot false positives as red circles. Plot false negatives as green 'x' markers.

```
figure;
swarmchart(tp.Label,tp.Area,[],"k",XJitter="none",...
    LineWidth=1,SizeData=100,MarkerEdgeAlpha=0.4,DisplayName="True Positive (TP)")
hold on
swarmchart(fp.Label,fp.Area,[],"r",XJitter="none",...
    LineWidth=1.5,SizeData=100,DisplayName="False Positive (FP)")
swarmchart(fn.Label,fn.Area,[],"gx",XJitter="none",...
    LineWidth=1.5,SizeData=100,DisplayName="False Negative (FN)")
hold off
ylabel("Object Size")
xlabel("Class Name")
grid on
legend()
```

[1] Adhikari, Bishwo; Peltomaki, Jukka; Huttunen, Heikki. (2019). Indoor Object Detection Dataset [Data set]. 7th European Workshop on Visual Information Processing 2018 (EUVIP), Tampere, Finland.

Analyze Threshold-Based Object Detector Performance Metrics

Load precomputed detection results and ground truth labels. The ground truth data is a subset of the Indoor Object Detection Dataset created by Bishwo Adhikari [1]. The MAT files containing the precomputed results and annotations are attached to this example as supporting files.

```
load("yolov2IndoorObjectDetectorAnnotation100.mat");
load("yolov2IndoorObjectDetectorResults100.mat");
```

Evaluate Object Detection Results

Evaluate the object detection results against the ground truth using the `evaluateObjectDetection` function. Specify three overlap thresholds for the evaluation: 0.5, 0.75, and 0.9.

```
evalMetrics = evaluateObjectDetection(results,blds,[0.5 0.75 0.9]);
```

Compute Per-Image Metrics for Subset of Images

Compute the per-image metrics for a subset of images, and display the results.

```
imageResultsSubset = imageMetrics(evalMetrics,1:2:10);
disp(imageResultsSubset)
```

ImageIndex	NumPredictedObjects	NumGroundTruthObjects	TP	FP	FN	Precision

```
     1                2                2                2     0     0           1
     3                1                1                1     0     0           1
     5                3                2                2     1     0     0.66667
     7                2                2                2     0     0           1
     9                2                2                2     0     0           1
```

Compute Image Metrics at Specific Score Threshold

Specify a higher score threshold using the `ScoreThreshold` name-value argument, and compute the per-image metrics. At a higher score threshold, low confidence score predictions are dropped, leading to which will lead to fewer detected objects and more misses, or false negatives (FNs):

```
imageResultsThresh = imageMetrics(evalMetrics,1:2:10,ScoreThreshold=0.7);
disp(imageResultsThresh)
```

```
    ImageIndex    NumPredictedObjects    NumGroundTruthObjects    TP    FP    FN    Precision
    __________    ___________________    _____________________    __    __    __    _________

        1                 2                      2               2     0     0          1
        3                 1                      1               1     0     0          1
        5                 1                      2               1     0     1          1
        7                 1                      2               1     0     1          1
        9                 1                      2               1     0     1          1
```

Compute Image Metrics at Specific Overlap Threshold

Specify a higher overlap threshold using the `OverlapThreshold` name-value argument, and compute the per-image metrics. The `OverlapThreshold` value must be one of the overlap thresholds at which the detection results were evaluated using the `evaluateObjectDetection` function.

```
imageResultsThresh = imageMetrics(evalMetrics,1:2:10,ScoreThreshold=0.7,OverlapThreshold=0.75);
disp(imageResultsThresh)
```

```
    ImageIndex    NumPredictedObjects    NumGroundTruthObjects    TP    FP    FN    Precision
    __________    ___________________    _____________________    __    __    __    _________

        1                 2                      2               2     0     0          1
        3                 1                      1               1     0     0          1
        5                 1                      2               0     1     2          0
        7                 1                      2               1     0     1          1
        9                 1                      2               1     0     1          1
```

When you specify a higher overlap threshold, the detector misses more detections (more FNs).

[1] Adhikari, Bishwo; Peltomaki, Jukka; Huttunen, Heikki. (2019). Indoor Object Detection Dataset [Data set]. 7th European Workshop on Visual Information Processing 2018 (EUVIP), Tampere, Finland.

Analyze Object Detector Error Using Per-Image Metrics

Load precomputed detection results and ground truth labels. The ground truth data is a subset of the Indoor Object Detection Dataset created by Bishwo Adhikari [1]. The MAT files containing the precomputed results and annotations are attached to this example as supporting files.

```
load("yolov2IndoorObjectDetectorAnnotation100.mat");
load("yolov2IndoorObjectDetectorResults100.mat");
```

Evaluate Object Detection Results

Evaluate the object detection results against the ground truth using the `evaluateObjectDetection` function. Specify three overlap thresholds for the evaluation: 0.5, 0.75, and 0.9.

```
evalMetrics = evaluateObjectDetection(results,blds,[0.5 0.75 0.9]);
```

Identify Challenging Images Across All Classes

To identify images where the object detector performs poorly across all classes, analyze per-image detector performance using the false positive (FP) and false negative (FN) counts. First, compute the per-image metrics.

```
[summaryError,predsError,truthsError] = imageMetrics(evalMetrics,SortMetric="FP+FN",SortOrder="de
```

Select the 20 images with the highest number of incorrect detections, or the total number of FNs and FPs.

```
summaryError = summaryError(1:20,:);
predsError = predsError(1:20);
truthsError = truthsError(1:20);
```

Display the computed per-image metrics for the five images with the most incorrect detections.

```
disp(summaryError(1:5,:))
```

ImageIndex	NumPredictedObjects	NumGroundTruthObjects	TP	FP	FN	Precision
4	0	2	0	0	2	NaN
39	4	4	3	1	1	0.75
66	0	2	0	0	2	NaN
82	1	3	1	0	2	1
5	3	2	2	1	0	0.66667

Display the object predictions for the image with the index 39. The third "chair" class detection for this image is a FP, with its `IsMatched` column field set to `false`.

```
disp(predsError{2})
```

ImageIndex	Label	Score	OverlapScore	IsMatched	MatchedTruthLabel	MatchedTr
39	chair	0.87222	0.74144	true	chair	2
39	chair	0.86277	0.70789	true	chair	1
39	chair	0.66098	0	false	<undefined>	0
39	chair	0.62006	0.67055	true	chair	4

Identify Challenging Images for Specific Class

To identify images which are challenging for the object detector in detecting a specified class, analyze per-image detector performance using the FP and FN counts. To identify images where the detector struggled to identify objects of the "exit" class, specify the `ClassNames` name-value argument as `"exit"`.

```
[summaryErrorClass,predsErrorClass,truthsErrorClass] = imageMetrics(evalMetrics,ClassNames="exit"
    SortMetric="FP+FN",SortOrder="descend");
```

Select the 20 images with the highest number of incorrect detections, or the total number of FNs and FPs.

```
summaryErrorClass = summaryErrorClass(1:20,:);
predsErrorClass = predsErrorClass(1:20);
truthsErrorClass = truthsErrorClass(1:20,:);
```

Display the computed per-image metrics for the five images with the most incorrect detections.

```
disp(summaryErrorClass(1:5,:))
```

ImageIndex	NumPredictedObjects	NumGroundTruthObjects	TP	FP	FN	Precision
20	1	1	0	1	1	0
26	1	1	0	1	1	0
47	2	2	1	1	1	0.5
55	2	2	1	1	1	0.5
100	1	1	0	1	1	0

Display the object predictions for the image with the image index 47, which has one FP and one FN. The second "exit" class detection for this image is a FP, with its `IsMatched` column field set to `false`.

```
disp(predsErrorClass{3})
```

ImageIndex	Label	Score	OverlapScore	IsMatched	MatchedTruthLabel	MatchedTr
47	exit	0.90114	0.91124	true	exit	1
47	exit	0.68702	0.67807	false	<undefined>	0

Display the ground truth information for the image. The second ground truth row for this image indicates a FN, with its `IsMatched` column field set to `false`.

```
disp(truthsErrorClass{3})
```

ImageIndex	Label	IsMatched	Area	BoundingBox			
47	exit	true	19890	463	221	195	102
47	exit	false	27032	746	305	248	109

[1] Adhikari, Bishwo; Peltomaki, Jukka; Huttunen, Heikki. (2019). Indoor Object Detection Dataset [Data set]. 7th European Workshop on Visual Information Processing 2018 (EUVIP), Tampere, Finland.

Evaluate Per-Image Object Detection Using F-1 Metric

Load precomputed detection results and ground truth labels. The ground truth data is a subset of the Indoor Object Detection Dataset created by Bishwo Adhikari [1]. The MAT files containing the precomputed results and annotations are attached to this example as supporting files.

```
load("yolov2IndoorObjectDetectorAnnotation100.mat");
load("yolov2IndoorObjectDetectorResults100.mat");
```

Evaluate Object Detection Results

Evaluate the object detection results against the ground truth using the `evaluateObjectDetection` function. Specify three overlap thresholds for the evaluation: 0.5, 0.75, and 0.9.

```
evalMetrics = evaluateObjectDetection(results,blds,[0.5 0.75 0.9]);
```

Compute F1 Score Per Image

The F1 score is the harmonic mean of precision and recall, providing a balanced measure of classification performance. An F1 score of 1 indicates perfect precision and recall, while 0 indicates the worst performance.

Compute the image metrics over the data set.

```
[summaryError,predsError,truthsError] = imageMetrics(evalMetrics);
```

Display the first five rows of the per-image summary.

```
disp(summaryError(1:5,:))
```

ImageIndex	NumPredictedObjects	NumGroundTruthObjects	TP	FP	FN	Precision
1	2	2	2	0	0	1
2	2	2	2	0	0	1
3	1	1	1	0	0	1
4	0	2	0	0	2	NaN
5	3	2	2	1	0	0.66667

Note that precision is the ratio of the number of true positives and the total number of predicted positives. The value of precision on the 4th row is `NaN`, since there are no predictions on this particular image, leading to a division by zero in the ratio calculation. Recall is the ratio of the number of true positives and the number of ground truth objects in that image. The value of recall for this image is zero, since no objects are detected, while there are two ground truth objects actually present in the image.

Compute the F1 score over the data set using the precision and recall values from the `summaryError` table.

```
precision = summaryError.Precision;
recall = summaryError.Recall;
f1Score = 2 * (precision .* recall) ./ (precision + recall);
```

Organize the precision, recall and F1 score values into a table.

```
prfTable = table(precision, recall, f1Score, VariableNames={'Precision', 'Recall', 'F1 Score'});
```

Display the precision, recall, and F1 score values for the first five images.

```
disp(prfTable(1:5,:))
```

Precision	Recall	F1 Score

```
          1       1           1
          1       1           1
          1       1           1
        NaN       0         NaN
    0.66667       1         0.8
```

[1] Adhikari, Bishwo; Peltomaki, Jukka; Huttunen, Heikki. (2019). Indoor Object Detection Dataset [Data set]. 7th European Workshop on Visual Information Processing 2018 (EUVIP), Tampere, Finland.

Input Arguments

`metrics` — Object detection metrics

`objectDetectionMetrics` object

Object detection metrics, specified as an `objectDetectionMetrics` object.

`imageIndices` — Indices of images

N-element numeric vector

Indices of images for which to compute per-image object detection metrics, specified as a *N*-element numeric vector. Each element of the vector is a positive integer that represents an image index, and *N* is the number of images for which to compute metrics. By default, per-image metrics are returned for all images.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `imageMetrics(metrics,ClassNames=["person" "car"])` specifies to evaluate per-image metrics for the person and car classes.

`ClassNames` — Names of classes

`metrics.ClassNames` (default) | string scalar | character vector

Names of the classes for which to evaluate per-image metrics, specified as a string scalar or character vector. If multiple classes are specified, the function computes averaged metrics across the classes. By default, metrics will be computed for all classes stored in the ClassNames property of the `objectDetectionMetrics` object `metrics`.

`ScoreThreshold` — Confidence score threshold

`0.5` (default) | non-negative scalar

Confidence score threshold, specified as a non-negative scalar. The `imageMetrics` function returns per-image metrics for detections with a confidence score below this threshold. The value of `ScoreThreshold` must be in the predicted confidence score range specified by the `detectionResults` argument of the `evaluateObjectDetection` function. Set the score threshold above the confidence threshold at which the detector was run.

`OverlapThreshold` — Bounding box overlap threshold

`metrics.OverlapThreshold(1)` (default) | numeric scalar | numeric vector

Bounding box overlap threshold, specified as a numeric scalar or numeric vector. Each element of the numeric vector represents a box overlap threshold value over which the mean average precision is computed. By default, the overlap threshold is the first element of the OverlapThreshold property of the `objectDetectionMetrics` object `metrics`.

When the intersection over union (IoU) of the pixels in the ground truth bounding box and the predicted bounding box is equal to or greater than the overlap threshold, the detection is a match to the ground truth. The IoU is the number of pixels in the intersection of the bounding boxes divided by the number of pixels in the union of the bounding boxes.

`SortMetric` — Sorting metric
`"none"` (default) | `"FP"` | `"FN"` | `"FP+FN"` | `"Precision"` | `"Recall"`

Sorting metric that sorts the rows of the `imageMetrics` function output, specified as one of these options:

- `"none"` — Do not sort.
- `"FP"` — Sort by the number of false positive detections.
- `"FN"` — Sort by the number of false negative detections.
- `"FP+FN"` — Sort by the total number of false positive and false negative detections.
- `"Precision"` — Sort by the precision value.
- `"Recall"` — Sort by the recall value.

Tip Use the `SortMetric` argument to identify images with the most False Positives or False Negatives. This can help determine the types of images for which the detector exhibits the lowest performance.

`SortOrder` — Sorting order
`"descend"` (default) | `"ascend"`

Sorting order for the rows of the `imageMetrics` function output, specified as one of these options:

- `"descend"` — Sort in the descending order of the metric specified by the `SortMetric` name-value argument.
- `"ascend"` — Sort in the descending order of the metric specified by the `SortMetric` name-value argument.

Output Arguments

`imageSummary` — Per-image metrics summary
table

Metrics by area, returned as a table with *N* rows. *N* is the number of evaluated images. The columns are specified by these table variables.

- `ImageIndex` — Index of the image, based on image order in the `detectionResults` argument of the `evaluateObjectDetection` function, returned as a non-negative integer.
- `NumPredictedObjects` — The number of predicted objects in each image, returned as a positive integer.

- `NumGroundTruthObjects` — Number of ground truth objects in each image, returned as a positive integer.
- `TP` — Number of true positive detections, returned as a positive integer.
- `FP` — Number of false positives detections, returned as a positive integer.
- `FN` — Number of false negatives, returned as a positive integer.
- `Precision` — Precision, returned as a positive numeric scalar. Precision is the ratio of the number of true positives (*TP*) and the total number of predicted positives.
  Precision = *TP* / (*TP* + *FP*)

  FP is the number of false positives. Larger precision scores indicate that most detected objects match ground truth objects.
- `Recall` — Recall, returned as a positive numeric scalar. Recall is the ratio of the number of true positives (*TP*) and the number of ground truth objects – the sum of true positives (*TP*) and false negatives (*FN*).
  Recall = *TP* / (*TP* + *FN*)

  FN is the number of false negatives. Larger recall scores indicate that more of ground truth objects are detected.

`imagePredictions` — Per-image object predictions
N-by-1 cell array

Per-image object predictions, returned as an *N*-by-1 cell array. *N* is the number of evaluated images.

Each element of the cell array is a table with *P* rows, where *P* is the number of predictions each image, and these columns.

- `ImageIndex` — Index of the image, based on the image order in the `detectionResults` argument of the `evaluateObjectDetection` function, returned as a non-negative integer.
- `Label` — Predicted class label, returned as a string scalar or character vector.
- `Score` — Confidence score of the detector prediction, returned as a positive numeric scalar.
- `OverlapScore` — Bounding box overlap score between the ground truth and detected bounding boxes, returned as a positive numeric scalar.
- `IsMatched` — Logical that specifies if a predicted bounding box is a true positive or a false positive, returned as a numeric or logical `1` (`true`) or `0` (`false`), respectively.
- `MatchedTruthLabel` — If the predicted bounding box is a true positive (matched to a ground truth), then `MatchedTruthLabel` specifies the class of the ground truth box, returned as a categorical array. Otherwise, it is undefined.
- `MatchedTruthIndex` — If the predicted bounding box is a true positive (matched to a ground truth), then `MatchedTruthIndex` specifies the row index of the matched ground truth in the `imageGroundTruth` table, returned as a positive integer. Otherwise, it is *0*.
- `Area` — Area of the predicted bounding box, in pixels, returned as a positive integer.
- `BoundingBox` — Bounding box, returned as a 4-element or 5-element numeric vector. For an axis-aligned bounding box, the vector is of the form [*x y width height*]. For a rotated bounding box, the vector is of the form [x_{center} y_{center} *width height yaw*]. *x* and `y` specify the upper-left corner of the rectangle. *width* and *height* specify the width and height of the rectangle, which are its lengths along the *x*- and *y*-axes, respectively.

If you specify `"AOS"` as an additional metric to compute using the `AdditionalMetrics` name-value argument of the `evaluateObjectDetection` function, each table contains these additional columns.

- `Orientation` — The orientation angle of the predicted bounding box, returned as a non-negative numeric scalar. The angle specifies the clockwise rotation around the center of the bounding box. Units are in degrees.
- `OrientationDifference` — The difference between the ground truth and predicted bounding box orientations, returned as a non-negative numeric scalar. Units are in degrees.

`imageGroundTruth` — Per-image ground truth
table

Per-image ground truth, returned as an *N*-by-1 cell array. *N* is the number of evaluated images.

Each element of the cell array is a table with *M* rows and these columns. *M* is the number of ground truth objects for a given image.

- `ImageIndex` — Index of the image, based on the image order in the `detectionResults` argument of the `evaluateObjectDetection` function, returned as a non-negative integer.
- `Label` — Predicted class labels of the ground truth, returned as a string scalar or character vector.
- `IsMatched` — Logical that specifies if a prediction is matched to the ground truth or is a false negative, returned as a numeric or logical `1` (`true`) or `0` (`false`), respectively.
- `Area` — Area of the ground truth bounding box, in pixels, returned as a positive integer.
- `BoundingBox` — Bounding box, returned as a 4-element or 5-element numeric vector. For an axis-aligned bounding box, the vector is of the form [*x y width height*]. For a rotated bounding box, the vector is of the form [x_{center} y_{center} *width height yaw*]. *x* and `y` specify the upper-left corner of the rectangle. *width* and *height* specify the width and height of the rectangle, which are its lengths along the *x*- and *y*-axes, respectively.

If you specify `"AOS"` as an additional metric to compute using the `AdditionalMetrics` name-value argument of the `evaluateObjectDetection` function, each table contains this additional column.

- `Orientation` — The orientation angle of the ground truth bounding box, returned as a non-negative numeric scalar. The angle specifies the clockwise rotation around the center of the bounding box. Units are in degrees.

indexImages

Create image search index

Syntax

```
imageIndex = indexImages(imds)

imageIndex = indexImages(imds,bag)
imageIndex = indexImages( ___ ,Name,Value)
```

Description

`imageIndex = indexImages(imds)` creates an `invertedImageIndex` object, `imageIndex`, that contains a search index for `imds`. Use `imageIndex` with the `retrieveImages` function to search for images.

`imageIndex = indexImages(imds,bag)` returns a search index that uses a custom `bagOfFeatures` object, `bag`. Use this syntax with the `bag` you created when you want to modify the number of visual words or the feature type used to create the image search index for `imds`.

`imageIndex = indexImages( ___ ,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments, using any of the preceding syntaxes.

This object supports parallel computing using multiple MATLAB workers. Enable parallel computing from the “Computer Vision Toolbox Preferences” dialog box. To open Computer Vision Toolbox preferences, on the **Home** tab, in the **Environment** section, click **Preferences**. Then select **Computer Vision Toolbox** .

Examples

Search Image Set Using a Query Image

Create an image set.

```
setDir  = fullfile(toolboxdir('vision'),'visiondata','imageSets','cups');
imds = imageDatastore(setDir);
```

Index the image set.

```
imageIndex = indexImages(imds)
```

```
Creating an inverted image index using Bag-Of-Features.
-------------------------------------------------------

Creating Bag-Of-Features.
-------------------------

* Selecting feature point locations using the Detector method.
* Extracting SURF features from the selected feature point locations.
** detectSURFFeatures is used to detect key points for feature extraction.
```

```
* Extracting features from 6 images...done. Extracted 1708 features.

* Keeping 80 percent of the strongest features from each category.

* Balancing the number of features across all image categories to improve clustering.
** Image category 1 has the least number of strongest features: 1366.
** Using the strongest 1366 features from each of the other image categories.

* Creating a 1366 word visual vocabulary.
* Number of levels: 1
* Branching factor: 1366

               ImageID: [1 2 3 4 5 6]
        MatchThreshold: 0.0100
    WordFrequencyRange: [0.0100 0.9000]
```

```
queryImage = readimage(imds,4);

figure
imshow(queryImage)
```

Search for the image from image index using query image.

```
indices = retrieveImages(queryImage,imageIndex);
bestMatch = imageIndex.ImageLocation{indices(1)};
figure
imshow(bestMatch)
```

Input Arguments

`imds` — Images

`imageDatastore` object

Images, specified as an `imageDatastore` object. The object stores a collection of images.

`bag` — Bag of visual words

`bagOfFeatures` object

Bag of visual words, specified as a `bagOfFeatures` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'Verbose',true` sets the `'Verbose'` property to `true`

`SaveFeatureLocations` — Save feature locations

`true` (default) | `false`

Save feature locations, specified as the comma-separated pair consisting of '`SaveFeatureLocations`' and a logical scalar. When set to `true`, the image feature locations are saved in the `imageIndex` output object. Use location data to verify spatial or geometric image search results. If you do not require feature locations, set this property to false to reduce memory consumption.

`Verbose` — Display progress information
`true` (default) | `false`

Display progress information, specified as the comma-separated pair consisting of '`Verbose`' and a logical scalar.

Output Arguments

`imageIndex` — Image search index
`invertedImageIndex` object

Image search index, returned as an `invertedImageIndex` object.

Algorithms

`imageIndex` uses the bag-of-features framework with the speeded-up robust features (SURF) detector and extractor to learn a vocabulary of 20,000 visual words. The visual words are then used to create an index that maps visual words to the images in `imds`. You can use the index to search for images within `imds` that are similar to a given query image.

Version History

Introduced in R2015a

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

For code generation, the `indexImages` function does not support the `ImageDatastore` object as input. Instead, specify the input as a structure with fields `Images`, `Locations`, and `Labels`. The `Images` field must contain a cell array of grayscale or RGB color images. The `Locations` field must contain a cell array of the file paths to the locations of input images. The `Labels` field when non-empty, must contain image labels stored as categorical arrays.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

integralFilter

Filter using integral image

Syntax

```
J = integralFilter(intI,H)
```

Description

`J = integralFilter(intI,H)` filters an image given its integral image, `intI`, and a box filter, `H`.

Examples

Blur an Image Using an Average Filter

Read and display the input image.

```
I = imread('pout.tif');
imshow(I);
```

Compute the integral image.

```
intImage = integralImage(I);
```

Apply a 7-by-7 average filter.

```
avgH = integralKernel([1 1 7 7], 1/49);
J = integralFilter(intImage, avgH);
```

Cast the result back to the same class as the input image.

```
J = uint8(J);
figure
imshow(J);
```

Find Vertical and Horizontal Edges in Image

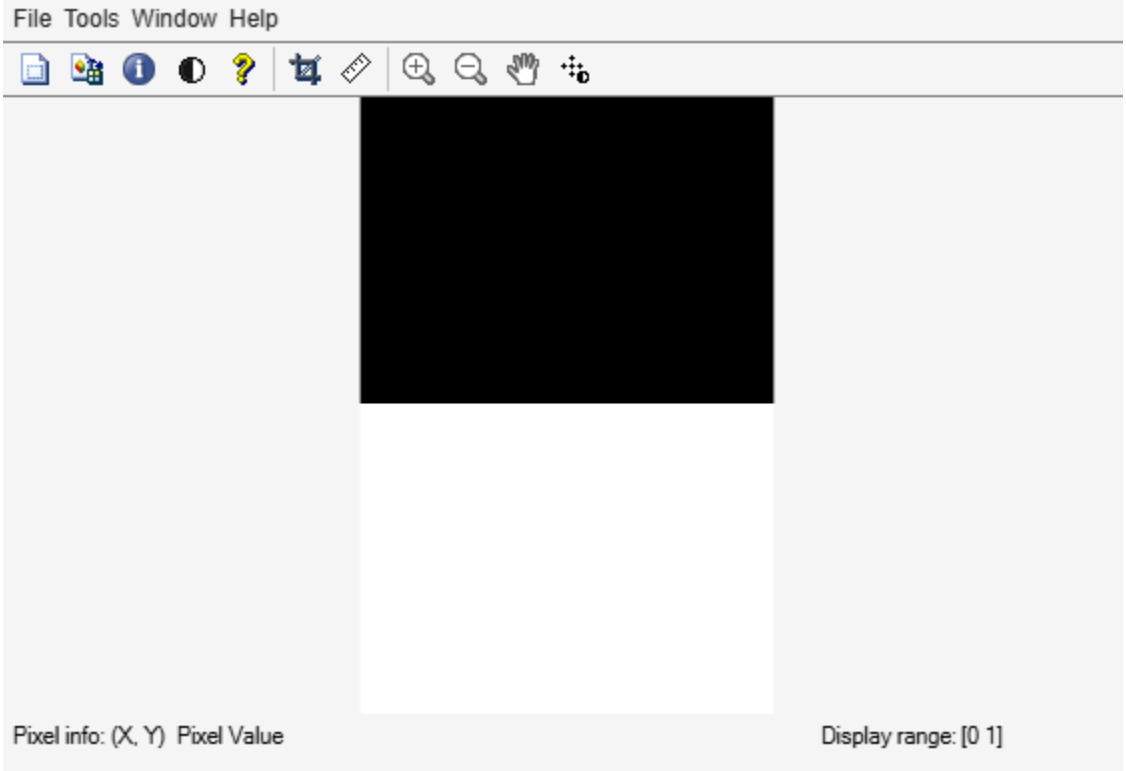
Construct Haar-like wavelet filters to find vertical and horizontal edges in an image.

Read the input image and compute the integral image.

```
I = imread('pout.tif');
intImage = integralImage(I);
```

Construct Haar-like wavelet filters. Use the dot notation to find the vertical filter from the horizontal filter.

```
horiH = integralKernel([1 1 4 3; 1 4 4 3],[-1, 1]);
vertH = horiH.'
```



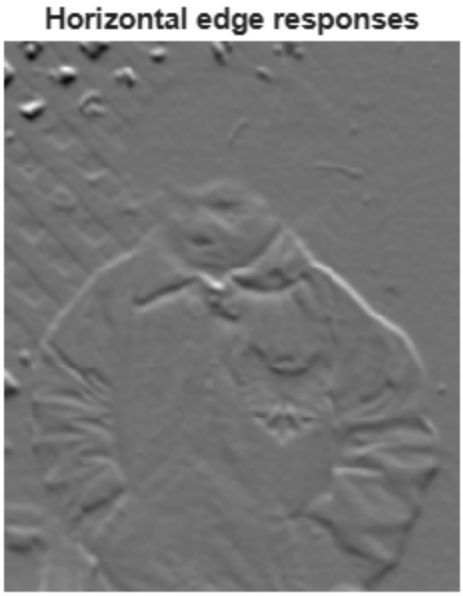
```
vertH =
  integralKernel with properties:

    BoundingBoxes: [2×4 double]
          Weights: [-1 1]
     Coefficients: [4×6 double]
           Center: [2 3]
```

```
            Size: [4 6]
     Orientation: 'upright'
```

Display the horizontal filter.

```
imtool(horiH.Coefficients, 'InitialMagnification','fit');
```



Compute the filter responses.

```
horiResponse = integralFilter(intImage,horiH);
vertResponse = integralFilter(intImage,vertH);
```

Display the results.

```
figure;
imshow(horiResponse,[]);
title('Horizontal edge responses');
```

```
figure;
imshow(vertResponse,[]);
title('Vertical edge responses');
```

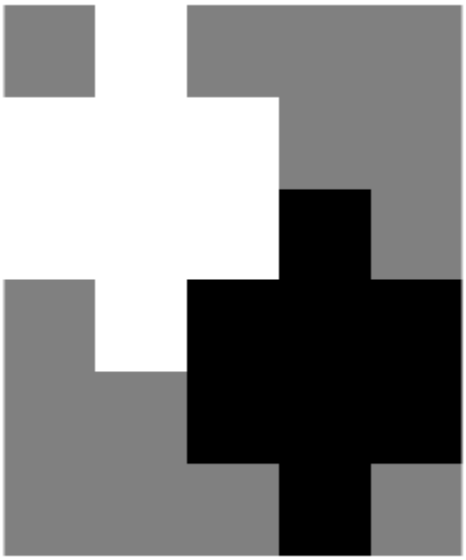
Compute a Rotated Edge Response Using Integral Filter

Read the input image.

```
I = imread("pout.tif");
```

Compute 45 degree edge responses of the image.

```
intImage = integralImage(I,"rotated");
figure;
imshow(I);
title("Original Image");
```

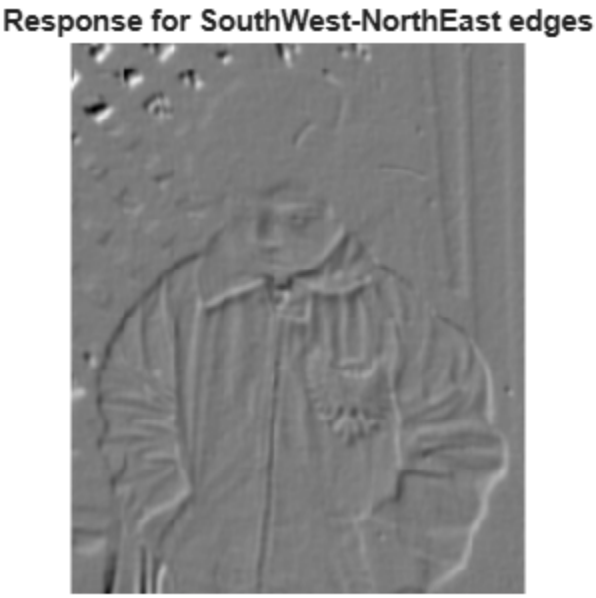


Construct 45 degree rotated Haar-like wavelet filters.

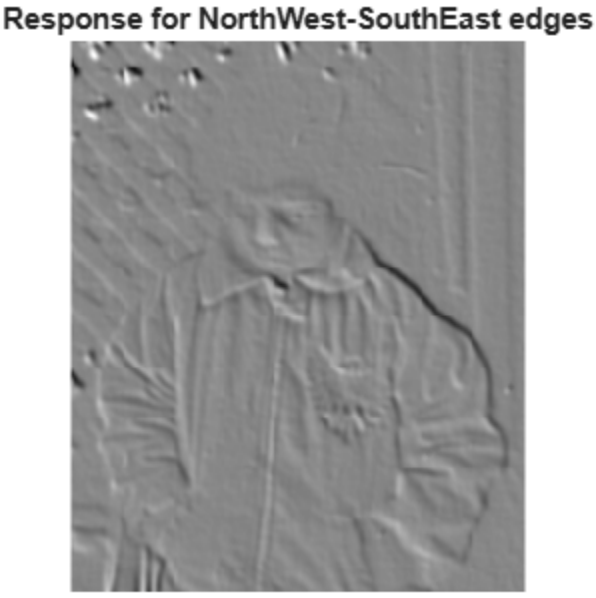
```
rotH = integralKernel([2 1 2 2;4 3 2 2],[1 -1],"rotated");
rotHTrans = rotH.';
```

Visualize the filter rotH.

```
figure;
imshow(rotH.Coefficients, []);
```



Compute filter responses.



```
rotHResponse = integralFilter(intImage,rotH);
rotHTransResponse = integralFilter(intImage,rotHTrans);
```

Display results.

```
figure;
imshow(rotHResponse, []);
title("Response for SouthWest-NorthEast edges");
```

```
figure;
imshow(rotHTransResponse, []);
title("Response for NorthWest-SouthEast edges");
```

Input Arguments

`intI` — Integral image

numeric array

Integral image, specified as a numeric array. You can obtain the integral image, `intI`, using the `integralImage` function.

Data Types: `single` | `double`

`H` — Box filter

`integralKernel` object

Box filter, specified as an `integralKernel` object.

Output Arguments

`J` — Filtered image

numeric array

Filtered image, returned as a numeric array. The filtered image, `J`, returns only the parts of correlation that are computed without padding. This results in `size(J) = size(intI) – H.Size` for an upright filter, and `size(J) = size(intI) – H.Size – [0 1]` for a rotated filter.

Tips

- The filter size does not affect the speed of the filtering operation. Thus, the `integralFilter` function is ideally suited to use for fast analysis of images at different scales, as demonstrated by the Viola-Jones algorithm [1].
- The `integralFilter` function uses correlation for filtering. Therefore, the filter is not rotated before calculating the result.

Version History

Introduced in R2012a

insertMarker

Insert markers in image or video

Syntax

```
RGB = insertMarker(I,position)
RGB = insertMarker(I,position,marker)
RGB = insertMarker(___,Name=Value)
```

Description

`RGB = insertMarker(I,position)` insert plus (+) markers into the truecolor or grayscale image `I`. The function draws markers by overwriting pixel values at the specified positions. The output image `RGB` is always a truecolor image.

`RGB = insertMarker(I,position,marker)` inserts markers of the specified marker type `marker`.

`RGB = insertMarker(___,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of input arguments from previous syntaxes. For example, `MarkerColor="red"` specifies to render the inserted position markers in red.

Examples

Draw Markers on an Image

Read an image into the workspace.

```
I = imread("peppers.png");
```

Insert a plus (+) marker onto the image at specified position.

```
RGB = insertMarker(I,[147 279]);
```

Specify the positions, colors, and sizes of four cross (x) markers and insert onto the image.

```
pos = [120 248; 195 246; 195 312; 120 312];
color = {"red","white","green","magenta"};
RGB = insertMarker(RGB,pos,"x",MarkerColor=color,Size=10);
```

Display the image.

```
imshow(RGB)
```

Input Arguments

`I` — Input image

M-by-*N*-by-3 truecolor image | *M*-by-*N* grayscale image

Input image, specified as an *M*-by-*N*-by-3 truecolor or an *M*-by-*N* grayscale image.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16`

`position` — Position of markers

M-by-2 matrix | *M*-element vector of points objects

Position of markers, specified as an *M*-by-2 matrix, where each row is an image coordinate pair of the form [*x* *y*], or an *M*-element vector of one of the points objects listed on the “Point Feature Types” page. *M* is the number of markers to insert into the image. The function defines the position of each marker as the [*x* *y*] pair of coordinates in the matrix, as the value of the `Location` property of the corresponding point feature object.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`marker` — Type of marker

`"plus"` (default) | character vector | string scalar

Type of marker, specified as a character vector or string scalar. You can specify the marker type using either the full text name or the corresponding symbol.

Full Text Name	Symbol
`"circle"`	`"o"`
`"x-mark"`	`"x"`

Full Text Name	Symbol
"plus"	"+"
"star"	"*"
"square"	"s"

Data Types: char | string

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: insertMarker(I,position,Color="yellow") sets the marker color to yellow.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: insertMarker(I,position,"Color","yellow") sets the marker color to yellow.

Size — Size of marker

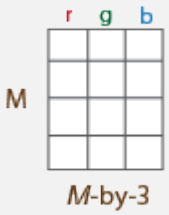
3 (default) | scalar

Size of the marker in pixels, specified as a scalar in the range [1,Inf).

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

MarkerColor — Marker color

"green" (default) | short color name | color name | vector of color names | three-column matrix of RGB triplets



Marker color, specified as a short color name, color name, vector of color names, three-column matrix of RGB triplets.

The supported colors table lists RGB intensities in the range [0, 1], but you must specify RGB triplets in the range of your selected data type. For example, if specifying this argument as a matrix of uint8 values, you must convert each intensity value to the range [0, 255]. To convert the listed intensity values to a uint8 data type, use the code uint8(255*intensity), where intensity is an RGB triplet value listed in the table.

You can specify a different color for each marker or one color for all markers. To specify one color for all markers, specify MarkerColor as a color name or an [*R G B*] vector.

Specification	Format	Example
Specify one color for all shapes (or markers)	Short color name or color name	"r" "red"
	RGB triplet	 [1 0 0]
Specify a color for each shape (or marker)	Vector of color names	["red","yellow","blue"]

Specification	Format	Example

	Three-column matrix of RGB triplets	`[1 0 0`
		` 0 1 1`
		` 1 0 1`
		` 1 1 1]`
		

This table lists the supported marker colors.

Color Name	Short Name	RGB Triplet	Appearance
`"red"`	`"r"`	`[1 0 0]`	
`"green"`	`"g"`	`[0 1 0]`	
`"blue"`	`"b"`	`[0 0 1]`	
`"cyan"`	`"c"`	`[0 1 1]`	
`"magenta"`	`"m"`	`[1 0 1]`	
`"yellow"`	`"y"`	`[1 1 0]`	
`"black"`	`"k"`	`[0 0 0]`	
`"white"`	`"w"`	`[1 1 1]`	

Data Types: `logical` | `uint8` | `uint16` | `int16` | `double` | `single` | `cell`

Output Arguments

RGB — Output image

M-by-*N*-by-3 truecolor image

Output image, returned as an *M*-by-*N*-by-3 truecolor image.

Version History

Introduced in R2013a

R2023b: Specify RGB color in the range [0,1]

Behavior changed in R2023b

Starting in R2023b, you can specify marker color with RGB values in the range [0,1].

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

- The input argument `marker` and the name-value argument `"MarkerColor"` must be compile-time constants.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

insertObjectAnnotation

Annotate truecolor or grayscale image or video

Syntax

```
RGB = insertObjectAnnotation(I,shape,position,label)
___ = insertObjectAnnotation( ___ ,Name=Value)
```

Description

`RGB = insertObjectAnnotation(I,shape,position,label)` annotates a grayscale or truecolor image with the specified `shape` and `label` at the specified `position`. The function returns a truecolor image.

`___ = insertObjectAnnotation( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to the previous syntax. For example, `FontSize=18` sets the annotation font size to `18`.

Examples

Annotate Image with Numbers and Strings

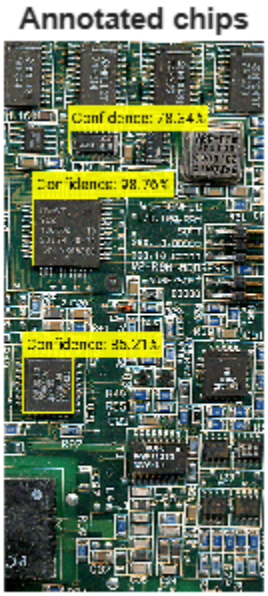
Read an image into the workspace.

```
I = imread("board.tif");
```

Create confidence value labels using floating point numbers.

```
label_str = cell(3,1);
conf_val = [85.212 98.76 78.342];
for ii = 1:3
    label_str{ii} = ['Confidence: ' num2str(conf_val(ii), '%0.2f') '%'];
end
```

Set the positions for the rectangular bounding boxes associated with the labels using the form [*x y width height*].



```
position = [23 373 60 66; 35 185 77 81; 77 107 59 26];
```

Insert the labels into the image.

```
RGB = insertObjectAnnotation(I,"rectangle",position,label_str,TextBoxOpacity=0.9,FontSize=18);
```

Display the annotated image.

```
figure
imshow(RGB)
title("Annotated chips")
```

Annotate Image with Integers

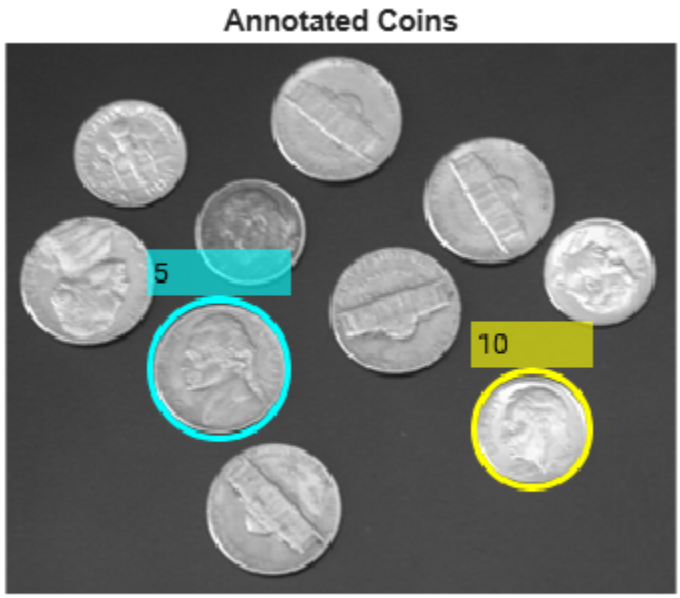
Read an image into the workspace.

```
I = imread("coins.png");
```

Set the positions on the image for the circular bounding boxes associated with the labels. The first two values of each row specify the center coordinates of a circle, (*x*,*y*) and the third value is the radius.

```
position = [96 146 31; 236 173 26];
```

Set the values for the labels to display as 5 and 10, in integers. These values represent US currency in the form of a nickle and dime, respectively.



```
label = [5 10];
```

Insert the annotations into the image.

```
RGB = insertObjectAnnotation(I,"circle",position,label,LineWidth=3,AnnotationColor=["cyan","yello
```

Display the annotated image.

```
figure
imshow(RGB)
title("Annotated Coins")
```

Input Arguments

`I` — Input image

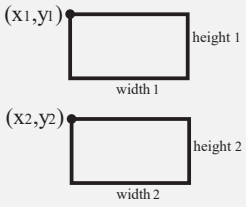
M-by-*N*-by-3 truecolor image | *M*-by-*N* grayscale image

Input image, specified as an *M*-by-*N*-by-3 truecolor or an *M*-by-*N* grayscale image.

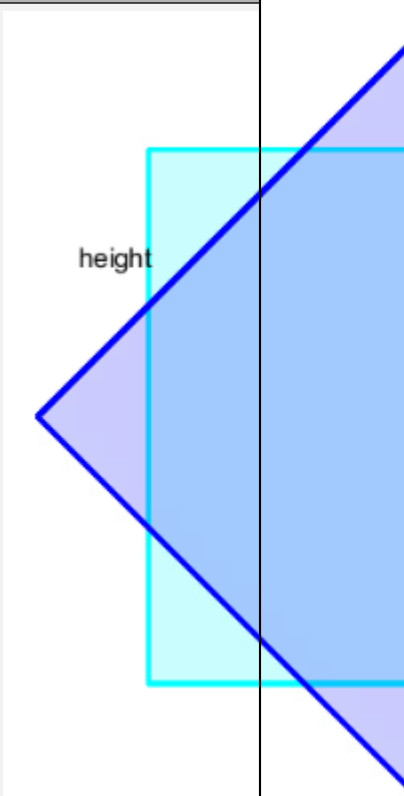
Data Types: `single` | `double` | `int16` | `uint8` | `uint16`

`shape` — Shape of annotation

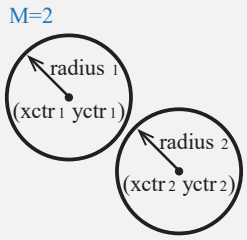
`"rectangle"` | `"circle"` | `"projected-cuboid"` | `"ellipse"`



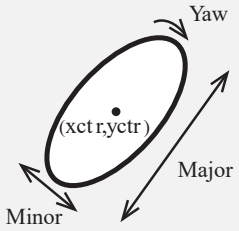
Shape of the annotation, specified as `"rectangle"`, `"circle"`, `"projected-cuboid"`, or `"ellipse"`. If you specify a `"rectangle"` annotation be specify the position of either an axis-aligned or rotated rectangle.



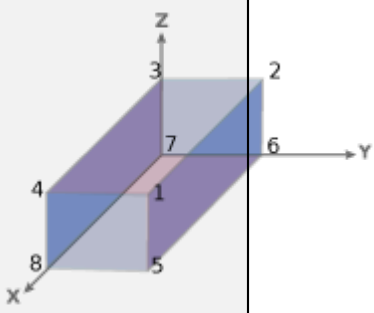
Data Types: `char` | `string`



`position` — Position of shape



matrix | vector | cell array



Position of the shape, specified according to the type of shape, as described in the table.

Shape	Position	Definition
`rectangle`	For one or more axis-aligned rectangles or filled rectangles, specify as an M-by-4 numeric matrix, where each row specifies a rectangle of the form $[x\ y\ width\ height]$. • M is the number of axis-aligned rectangles. • x and y specify the upper-left corner of the rectangle. • w specifies the width of the rectangle, which is its length along the x-axis. • h specifies the height of the rectangle, which is its length along the y-axis. $\begin{bmatrix} x_1 & y_1 & width_1 & height_1 \\ x_2 & y_2 & width_2 & height_2 \\ \vdots & \vdots & \vdots & \vdots \\ x_M & y_M & width_M & height_M \end{bmatrix}$	M=2 

Shape	Position	Definition
	For one or more rotated rectangles, specify in spatial coordinates as an *M*-by-5 numeric matrix, where each row specifies a rotated rectangle of the form [*xctr yctr w h yaw*]. • *M* is the number of rotated rectangles. • *xctr* and *yctr* specify the center of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis before rotation. • *h* specifies the height of the rectangle, which is its length along the *y*-axis before rotation. • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the rectangle.	

Shape	Position	Definition
`circle`	For one or more circles, specify spatial coordinates as an *M*-by-3 numeric matrix, where each row specifies a circle of the form [*xctr yctr radius*]. • *M* is the number of circles. • *xctr* and *yctr* specify the center of the circle. • *radius* specifies the radius of the circle. $\begin{bmatrix} xctr_1 & yctr_1 & radius_1 \\ xctr_2 & yctr_2 & radius_2 \\ \vdots & \vdots & \vdots \\ xctr_M & yctr_M & radius_M \end{bmatrix}$	

Shape	Position	Definition
`ellipse`	For one or more ellipses, specify in spatial coordinates as an *M*-by-5 matrix, where each row specifies an ellipse of the form [*xctr yctr major minor yaw*] • *M* is the number of ellipses. • *xctr* and *yctr* specify the center of the ellipse. • *major* and *minor* are the lengths of the major and minor ellipse axes, respectively. • *yaw* is the angle of rotation in degrees. The angle of rotation is clockwise positive around the center of the ellipse.	

Shape	Position	Definition
`projected-cuboid`	For one or more projected cuboids, specify in spatial coordinates as an 8-by-2-by-*M* array or an *M*-by-8 matrix, where *M* is the number of projected cuboids. When specified as an 8-by-2-by-*M* array, each row must contain the [*x y*] location of a projected cuboid vertex. The vertices connect to form a cuboid with six faces. The order of the input vertices must match the order shown in the diagram. When specified as an *M*-by-8 matrix, each row specifies the dimensions of the front-facing and rear-facing sides of a projected cuboid in the form, [*x1 y1 w1 h1 x2 y2 w2 h2*], where [*x1 y1*] and [*x2 y2*] specify the upper-left coordinates of the front-facing and rear-facing sides, respectively, and [*w1 h1*] and [*w2 h2*] specify the corresponding widths and heights.	

Data Types: `single` | `double` | `cell` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`label` — Label to associate with shape

M-element numeric vector | string array | vector of categorical labels | cell array of ASCII character vectors

Label to associate with a shape, specified as an *M*-element numeric vector, string array, vector of categorical labels, or a cell array of ASCII character vectors. If you use character vectors, string scalars, or categorical labels, you must encode them as ASCII characters. If you specify a cell array, it must be equal in length to the number of specified shape positions. You can specify a single label for all shapes using a numeric scalar, string scalar, or scalar categorical label.

Example: `[5 10]` marks the first shape with the label `5`, and the second shape with the label `10`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `insertObjectAnnotation(I,"rectangle",position,label,FontSize=18);` sets the font size to use for inserting annotations to `18`.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `insertObjectAnnotation(I,"rectangle",position,label,"FontSize","18");` sets the font size to use for inserting annotations to `18`.

`Font` — Font face of label text

`"Roboto-Regular"` (default) | character vector | string scalar

Font face of the label text, specified as a character vector or string scalar. The font face must be one of the available truetype fonts installed on your system. To get a list of available fonts on your system, use the `listTrueTypeFonts` function from the MATLAB command prompt.

Data Types: `char` | `string`

`FontSize` — Label text font size
`12` (default) | integer in range `[8 200]`

Label text font size, specified as an integer that corresponds to points in the range of `[8 200]`.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`FontColor` — Font color
`"black"` (default) | short color name | color name | vector of color names | three-column matrix of RGB triplets

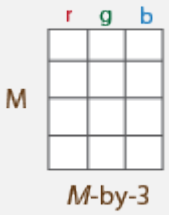
Font color, specified as a short color name, color name, vector of color names, three-column matrix of RGB triplets.

The supported colors table lists RGB intensities in the range [0, 1], but you must specify RGB triplets in the range of your selected data type. For example, if specifying this argument as a matrix of `uint8` values, you must convert each intensity value to the range [0, 255]. To convert the listed intensity values to a `uint8` data type, use the code `uint8(255*intensity)`, where intensity is an RGB triplet value listed in the table.

You can specify a different color for each font string or one color for all strings. To specify one color for all strings, specify `FontColor` as a color name or an [*R G B*] vector.

Data Types: `logical` | `uint8` | `uint16` | `int16` | `double` | `single`

`AnnotationColor` — Annotation color
`"yellow"` (default) | short color name | color name | vector of color names | three-column matrix of RGB triplets



Annotation color, specified as a short color name, color name, vector of color names, three-column matrix of RGB triplets.

The supported colors table lists RGB intensities in the range [0, 1], but you must specify RGB triplets in the range of your selected data type. For example, if specifying this argument as a matrix of `uint8` values, you must convert each intensity value to the range [0, 255]. To convert the listed intensity values to a `uint8` data type, use the code `uint8(255*intensity)`, where intensity is an RGB triplet value listed in the table.

You can specify a different color for each marker or one color for all markers. To specify one color for all markers, specify `AnnotationColor` as a color name or an [*R G B*] vector.

Specification	Format	Example
Specify one color for all shapes (or markers)	Short color name or color name	`"r"` `"red"`
	RGB triplet	 `[1 0 0]`
Specify a color for each shape (or marker)	Vector of color names	`["red","yellow","blue"]`

Specification	Format	Example

	Three-column matrix of RGB triplets	`[1 0 0`
		` 0 1 1`
		` 1 0 1`
		` 1 1 1]`
		

Supported colors are listed in the table.

Color Name	Short Name	RGB Triplet	Appearance
`"red"`	`"r"`	`[1 0 0]`	
`"green"`	`"g"`	`[0 1 0]`	
`"blue"`	`"b"`	`[0 0 1]`	
`"cyan"`	`"c"`	`[0 1 1]`	
`"magenta"`	`"m"`	`[1 0 1]`	
`"yellow"`	`"y"`	`[1 1 0]`	
`"black"`	`"k"`	`[0 0 0]`	
`"white"`	`"w"`	`[1 1 1]`	

Data Types: `cell` | `char` | `uint8` | `uint16` | `int16` | `double` | `single`

`TextBoxOpacity` — Opacity of text label box background
`0.6` (default) | scalar in the range of `[0 1]`

Opacity of the text label box background, specified as a scalar in the range of `[0, 1]`. A value of `0` renders the background of the label text box as fully transparent, while a value of `1` renders it as fully opaque.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`LineWidth` — Shape border line width
`1` (default) | positive integer

Shape border line width, specified as a positive integer, in pixels.

`ShowOrientation` — Original orientation indicator
`0` (`false`) (default) | `1` (`true`)

Original orientation indicator, specified as a numeric or logical `1` (`true`) or `0` (`false`). A value of `1` (`true`) displays the original orientation of the rotated rectangle by using an arrow annotation on the

bounding box. The original orientation is defined as a zero rotation angle. A value of `0` (`false`) does not show the arrow annotation.

This argument applies only when `Shape` describes a rotated rectangle or an ellipse.

Data Types: `logical` | `integer`

Output Arguments

`RGB` — Output image
M-by-*N*-by-3 truecolor image

Output image, returned as an *M*-by-*N*-by-3 truecolor image.

Version History

Introduced in R2012b

R2026a: Default value of `Font` changed to `Roboto-Regular`
Behavior changed in R2026a

Starting in R2026a, the default value of the `Font` name-value argument is `Roboto-Regular`. In previous releases, the default value was `LucidaSansRegular`.

R2024b: Support for ellipse shape

Added support for `"ellipse"` to visualize one or more ellipses on top of an image or on video data.

R2024b: Default value for orientation indicator changed from `true` to `false`
Behavior changed in R2024b

Starting in R2024b, the default value for the `ShowOrientation` name-value argument will be `false`.

R2023b: Specify RGB color in the range [0,1]
Behavior changed in R2023b

Starting in R2023b, you can specify marker color with RGB values in the range [0,1].

R2022b: Visualize projected cuboids

Added support to visualize projected cuboids.

R2023b: Rotated rectangle support for bounding box

You can specify a rotated rectangle bounding box using the form [*xctr yctr width height yaw*].

R2023b: Show orientation of rectangle of bounding box

You can now specify the `ShowOrientation` name-value argument to display the orientation and angle of a rotated rectangle bounding box.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Input image must be bounded. See “Specify Upper Bounds for Variable-Size Arrays in Generated Code” (MATLAB Coder).
- Code generation requires a C++ compiler. For a list of supported compilers, see Supported and Compatible Compilers

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

Functions

`insertMarker` | `insertText` | `insertShape` | `insertObjectMask` | `cuboid2img`

Topics

“Choose Function to Visualize Detected Objects”

insertObjectMask

Insert masks in image or video stream

Syntax

```
RGB = insertObjectMask(I,BW)
RGB = insertObjectMask(I,maskstack)
RGB = insertObjectMask( ___ ,Name=Value)
```

Description

`RGB = insertObjectMask(I,BW)` inserts a mask `BW` into the specified image `I` and returns the result as a truecolor image `RGB`.

`RGB = insertObjectMask(I,maskstack)` inserts a set of masks `maskstack` into the specified image `I` and returns the result as a truecolor image `RGB`.

`RGB = insertObjectMask( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `(MaskColor="red")` sets the color of the mask to red.

Examples

Insert Masks with White Borders

Read an image into the workspace.

```
I = imread("visionteam1.jpg");
```

Load a stack of binary masks into the workspace.

```
load("visionteam1Maskstack.mat")
```

Insert the masks with white outlines into the image.

```
RGB = insertObjectMask(I,maskstack,LineColor="white",LineWidth=2);
```

Display the image with the masks inserted.

```
figure
imshow(RGB)
```

Insert Masks and Assign Unique Color to Each

Read an image into the workspace.

```
I = imread("visionteam1.jpg");
```

Load a stack of binary mask images.

```
load("visionteam1Maskstack.mat");
```

Insert the masks into the image and specify a unique color for each mask.

```
numMasks = size(maskstack,3);
RGB = insertObjectMask(I,maskstack,MaskColor=lines(numMasks));
```

Display the image with the inserted masks.

```
figure
imshow(RGB)
```

Input Arguments

`I` — Input image

truecolor image | grayscale image

Input image, specified as a truecolor (RGB) image, *m*-by-*n*-by-3 array, or a grayscale image, *m*-by-*n* array.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16`

`BW` — Input mask image

m-by-*n* logical matrix

Input mask image, specified as an *m*-by-*n* logical matrix.

Data Types: `logical`

`maskstack` — Stack of mask images

m-by-*n*-by-*P* logical array

Stack of mask images, specified as an *m*-by-*n*-by-*P* logical array, where *P* is the total number of masks in the stack.

`maskstack` has the same width and height as `I`.

Data Types: `logical`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `LineColor="white"` set the inserted line color to white.

`MaskColor` — Mask color

`"green"` (default) | character vector | cell array of character vectors | string scalar | string array | *M*-by-3 matrix

Mask color, specified as a character vector, cell array of character vectors, vector, or *M*-by-3 matrix of RGB values.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. When using a data type of `uint8`, which is defined within the range of `[0,255]`, conversions are necessary to ensure that the expected range is met. For example, to specify the previous vector, you must convert it by using `uint8(255*[0.4 0.6 0.7])`.

You can specify a different color for each mask or one color for all masks. To specify one color for all masks, set `MaskColor` to a color string or an [*R G B*] vector.

Specification	Format	Example

Specify one color for all shapes (or markers)	Short color name or color name	`"r"`
		
		`"red"`

	RGB triplet	 `[1 0 0]`
Specify a color for each shape (or marker)	Vector of color names	`["red","yellow","blue"]`

	Three-column matrix of RGB triplets	`[1 0 0`
		` 0 1 1`
		` 1 0 1`
		` 1 1 1]`
		

Supported colors are listed in the table.

Color Name	Short Name	RGB Triplet	Appearance
"red"	"r"	[1 0 0]	
"green"	"g"	[0 1 0]	
"blue"	"b"	[0 0 1]	
"cyan"	"c"	[0 1 1]	
"magenta"	"m"	[1 0 1]	
"yellow"	"y"	[1 1 0]	
"black"	"k"	[0 0 0]	
"white"	"w"	[1 1 1]	

Color values must be specified in the range of the data type support that you use to specify them. For example, if you specify an input of `double` datatype, then values must be in the range `[0,1]`. If you specify an input of `uint8` datatype, then values must be in the range `[0 255]`. For example, `[0,0,1]` and `uint8([0,0,255])` are two formats for the same color blue.

Data Types: `logical` | `uint8` | `uint16` | `int16` | `double` | `single`

`Opacity` — Opacity of mask
`0.6` (default) | scalar in the range [0 1]

Opacity of mask, specified as a scalar value in the range [0 1]. The value `1` makes the mask completely opaque and the value `0` makes the mask completely transparent.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`LineColor` — Color of mask borders
`"auto"` (default) | RGB triplet | ColorSpec

Color of mask borders, specified as one of these values:

- `"auto"` — `LineColor` uses the same value or values as `MaskColor`.
- *P*-by-3 matrix of RGB triplets, where *P* is the total number of masks
- *P*-element vector of MATLAB ColorSpec names
- 1-by-3 RGB triplet or scalar MATLAB ColorSpec name, specifying the color to use for all masks.

  For a description of RGB color and how to specify it, see `MaskColor`.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical` | `char` | `string`

`LineOpacity` — Opacity of mask borders
1 (default) | 0

Opacity of the mask borders, specified as a scalar value in the range of [0 1].

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`LineWidth` — Width of mask borders
1 (default) | positive scalar

Width of mask borders, specified as a positive scalar in pixels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`RGB` — Output image
truecolor image

Output image, returned as a truecolor image of same datatype as the input image, with the same *m*-by-*n* dimensions as `I`.

Tips

- When masks overlap and the same pixel is in more than one mask, `maskstack(:,:,i)` takes precedence over `maskstack(:,:,j)`, where `i < j`.
- For better performance, set `LineOpacity` to `0` to disable drawing of the edges.

Version History

Introduced in R2020b

R2023b: Specify RGB color in the range [0,1]
Behavior changed in R2023b

Starting in R2023b, you can specify color with RGB values in the range [0,1].

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The value of the `LineWidth` parameter must be a compile-time constant.
- The values of the `MaskColor` and `LineColor` name-value arguments must be numeric. The MATLAB ColorSpec is not supported with code generation.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

insertObjectInImage

Insert object from source image into image

Syntax

```
[newImage,boundingBox,newMask] = insertObjectInImage(destinationImage,
sourceImage,mask)
[newImage,boundingBox,newMask] = insertObjectInImage( ___ ,Name=Value)
```

Description

`[newImage,boundingBox,newMask] = insertObjectInImage(destinationImage, sourceImage,mask)` inserts an object from a source image, `sourceImage`, into a destination image, `destinationImage`. By default, the `insertObjectInImage` function inserts an object from the source image into a randomized location on the destination image. The function returns the result as an augmented image, `newImage`, a bounding box, `boundingBox`, and a corresponding object mask, `newMask`.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

`[newImage,boundingBox,newMask] = insertObjectInImage( ___ ,Name=Value)` specifies options using one or more name-value arguments, in addition to the input arguments from the previous syntax. For example, `BoundaryConstraintMode="inbounds-exact"` specifies to insert objects only when they are completely within the destination image.

Examples

Create Annotated Synthetic Image

Read the destination image into the workspace and display the image.

```
destImage = imread("parkroad.jpg");
imshow(destImage)
```

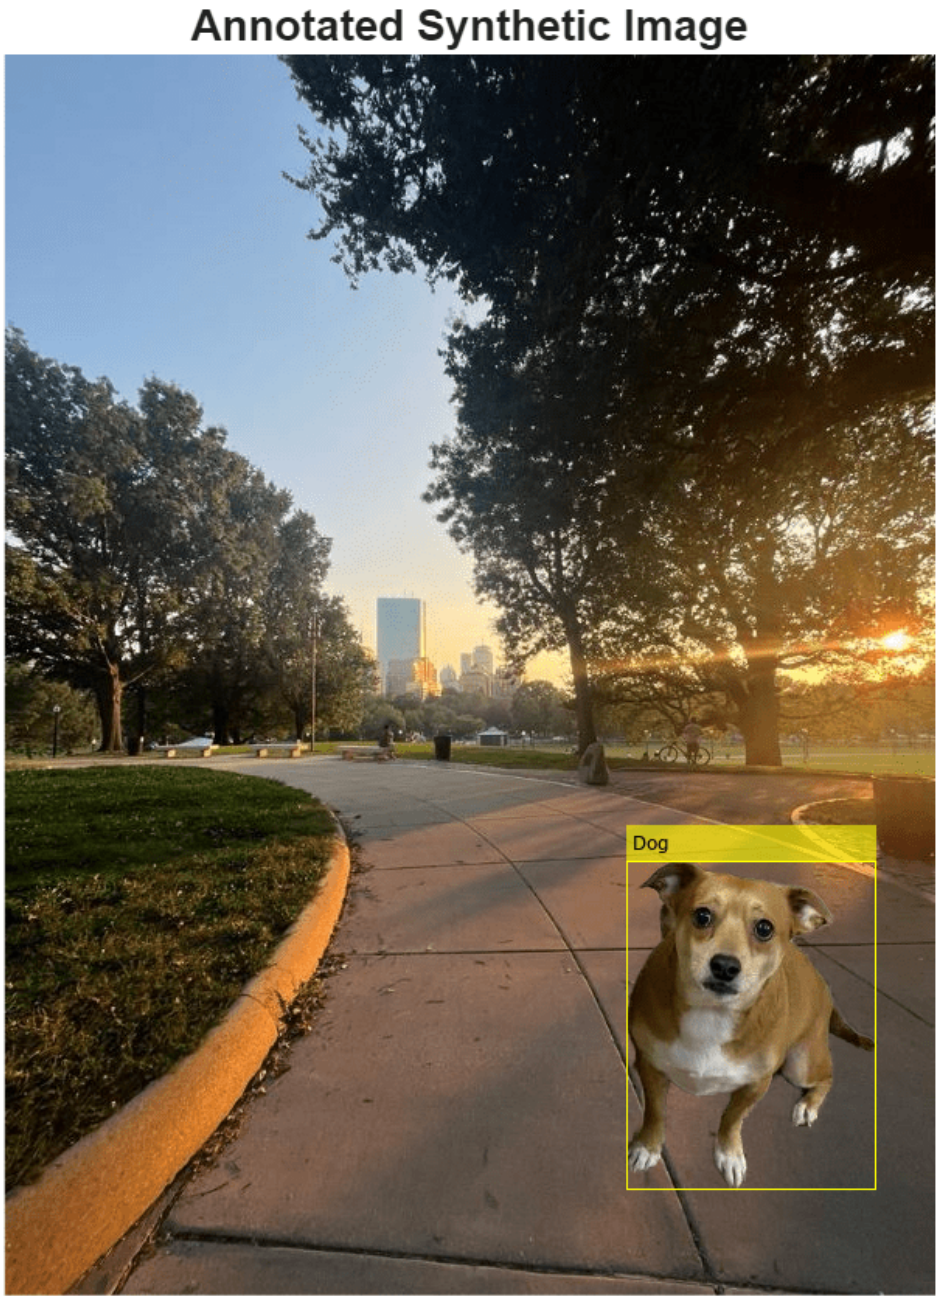
Read the source image containing the object, the small dog, into the workspace and display the image.

```
sourceImage = imread("DogTrio.jpg");
imshow(sourceImage)
```

Load the binary object mask into the workspace.

```
load("dogMask.mat");
```

Insert the object from the source image into a randomized location on the destination image. Generate the augmented synthetic image, the object mask, and the corresponding bounding box.



```
[newImage,boundingBox,newMask] = insertObjectInImage(destImage,sourceImage,dogMask);
```

Annotate the image at the position specified by the generated bounding boxes using the `insertObjectAnnotation` function.

```
annotedNewImage = insertObjectAnnotation(newImage,"rectangle",boundingBox,"Dog");
```

Display the annotated synthetic image.

```
figure
imshow(annotedNewImage)
title("Annotated Synthetic Image")
```

Annotated Synthetic Image
Dog

Input Arguments

`destinationImage` — Destination image

H-by-*W* matrix | *H*-by-*W*-by-3 numeric array

Destination image into which to insert an object, specified as one of these options:

Image Type	Data Format
Grayscale	*H*-by-*W* numeric matrix
Binary	*H*-by-*W* logical matrix
RGB	*H*-by-*W*-by-3 numeric array

`sourceImage` — Source image

H-by-*W* matrix | *H*-by-*W*-by-3 numeric array

Source image containing an object to insert into the destination image, specified as one of these options:

Image Type	Data Format
Grayscale	*H*-by-*W* numeric matrix
Binary	*H*-by-*W* logical matrix
RGB	*H*-by-*W*-by-3 numeric array

`mask` — Object mask

H-by-*W* logical matrix

Object mask of the source image, specified as an *H*-by-*W* logical matrix. *H* and *W* are the height and width of the source image, `sourceImage`, respectively.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `insertObjectInImage(destinationImage,sourceImage,mask,BoundaryConstraintMode="inbounds-exact")` specifies to insert objects only when they are completely within the destination image.

`RegionConstraintMask` — Region constraint mask

`true(size(destinationImage,[1 2]))` (default) | *M*-by-*N* logical array

Region constraint mask, specified as an *M*-by-*N* logical array. *M* and *N* are the height and width of the destination image `destinationImage`, respectively.

Specify the `RegionConstraintMask` value as `true` (or `1`) for only select pixel locations to insert the object from the source image into a specific location on the destination image. By default, the `insertObjectInImage` function inserts the object at a randomized location anywhere in the destination image.

`BoundaryConstraintMode` — Boundary constraint mode
`"inbounds-bbox"` (default) | `"inbounds-exact"` | `"center"`

Boundary constraint mode, specified as `"inbounds-bbox"`, `"inbounds-exact"`, or `"center"`. This name-value argument specifies the method used to constrain objects at the boundaries of images in the destination image `destinationImage`.

Value	Boundary Constraint Mode
`"inbounds-bbox"`	To insert an object, the entire bounding box containing the object must be completely within the destination image.
`"inbounds-exact"`	To insert an object, the object mask must be completely within the destination image.
`"center"`	To insert an object, only the object centroid must be inside the destination image, so objects can be partially visible and clipped at the image boundary.

`ObjectsInSceneMasks` — Stack of mask images containing inserted objects
`false(size(destinationImage,[1 2]))` (default) | *M*-by-*N*-by-*P* logical matrix

Stack of mask images containing inserted objects, specified as an *M*-by-*N*-by-*P* logical array. *P* is the total number of masks in the stack, and *M* and *N* are the height and width of the destination image `destinationImage`, respectively. The value of `ObjectsInSceneMasks` is `true` (or `1`) at the pixel locations which already contain an inserted object. By default, there are no existing inserted objects in the image.

`ObjectsInSceneMaxOverlap` — Maximum object overlap
`1` (default) | positive scalar in range [0, 1]

Maximum object overlap between an object in a source image `sourceImage` and a previously inserted object, specified as a positive scalar in range [0, 1]. Specify the `ObjectsInSceneMaxOverlap` value as `1` to insert new objects on top of existing objects. Decrease this value to decrease the overlap between the newly inserted objects and existing objects.

`MaxInsertionAttempts` — Maximum insertion attempts
`10` (default) | positive scalar

Maximum insertion attempts to satisfy the overlap value, specified as a positive scalar. The overlap value is specified by the `ObjectsInSceneMaxOverlap` name-value argument. If no insertion location can be found on the destination image after `MaxInsertionAttempts` iterations, the `insertObjectInImage` function will not insert the object from the source image into the destination image.

`BlendMethod` — Blend method
`"guidedfilter"` (default) | `"poisson"` | `"none"`

Blend method to use for inserting objects from the source image into the destination image, specified as one of these options:

BlendMethod Value	Blend Method
"guidedfilter"	Guided filter blending [1] – Blur the object mask of the source image at the mask-object boundary. Guided image filtering uses edge context from the source image to filter the mask prior to blending the object image with the destination image.
"poisson"	Poisson blending [2] – Blend the source object into the destination image by matching the color distribution of the source object to that of the boundary between the destination image and source object mask.
"none"	No blending – At insertion locations of the destination image, replace pixels of the destination image by the source image pixel values.

`GeometricAugmentation` — Geometric augmentation
`[ ]` (default) | function handle

Geometric augmentation, specified as a function handle that returns an `affinetform2d` object. The geometric augmentation warps a source image and the mask associated with the object in the image before it is inserted into the destination image. For example, specify the `GeometricAugmentation` value as `@() randomAffine2d("Scale",[0.9,1.1])` to apply a randomized scale transformation to an inserted object.

Output Arguments

`newImage` — Augmented image containing an inserted object
M-by-*N* matrix | *M*-by-*N*-by-*3* numeric array

Augmented image containing an inserted object, returned as one of these options:

Image Type	Data Format
Grayscale	*M*-by-*N* numeric matrix
Binary	*M*-by-*N* logical matrix
RGB	*M*-by-*N*-by-*3* numeric array

Tip Specify the `RegionConstraintMask` name-value argument to specify the region in the destination image in which to insert the object. Otherwise, the `insertObjectInImage` function inserts the object in the destination image at a randomized location.

`boundingBox` — Axis-aligned bounding box enclosing mask of inserted object region
4-element row vector

Axis-aligned bounding box enclosing mask of inserted object region, returned as a 4-element row vector. The row vector is of the form [*x y w h*], where:

- *x* and `y` specify the upper-left corner of the rectangle.
- *w* specifies the width of the rectangle, which is its length along the *x*-axis.
- *h* specifies the height of the rectangle, which is its length along the *y*-axis.

`newMask` — Mask containing inserted object region
M-by-*N* logical array

Mask containing inserted object region, returned as an *M*-by-*N* logical array. *M* and *N* are the height and width of the destination image, `destinationImage`, respectively. The value of the logical array returned by `newMask` is `true` (or `1`) at the pixel locations where object content is inserted into the destination image from the source image.

Tip Specify the `RegionConstraintMask` name-value argument to specify the region in the destination image in which to insert the object and the object mask. Otherwise, the `insertObjectInImage` function inserts the object and its corresponding mask in the destination image at a randomized location.

Version History

Introduced in R2025a

R2026a: Option to specify exact object mask for boundary constraint mode

Specify to insert an object only when the object mask is completely within the destination image by using the `BoundaryConstraintMode` name-value argument. By default, the `insertObjectInImage` function inserts an object when the bounding box containing the object is entirely within the destination image.

insertShape

Insert shapes in image or video

Syntax

```
RGB = insertShape(I,shape,position)
RGB = insertShape( ___ ,Name=Value)
```

Description

`RGB = insertShape(I,shape,position)` insert the specified `shape` into the truecolor or grayscale image `I`. The function draws the shapes by overwriting pixel values, and returns a truecolor image.

`RGB = insertShape( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to the input arguments from the input arguments from the previous syntax. For example, `LineWidth=5` sets the line width value to `5` of the inserted shapes.

Examples

Insert Circle and Filled Shapes onto Image

Read an image into the workspace.

```
I = imread("peppers.png");
```

Place a circle on the image with a border line width of 5 pixels.

```
RGB = insertShape(I,"circle",[150 280 35],LineWidth=5);
```

Place a filled triangle and a filled hexagon on the image.

```
pos_triangle = [183 297 302 250 316 297];
pos_hexagon = [340 163 305 186 303 257 334 294 362 255 361 191];
RGB = insertShape(RGB,"filled-polygon",{pos_triangle pos_hexagon}, ...
    ShapeColor=["white","green"],Opacity=0.7);
```

Display the resulting image.

```
imshow(RGB)
```

Input Arguments

`I` — Input image

M-by-*N*-by-3 truecolor image | *M*-by-*N* grayscale image

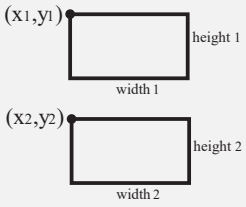
Input image, specified as an *M*-by-*N*-by-3 truecolor or an *M*-by-*N* grayscale image.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16`

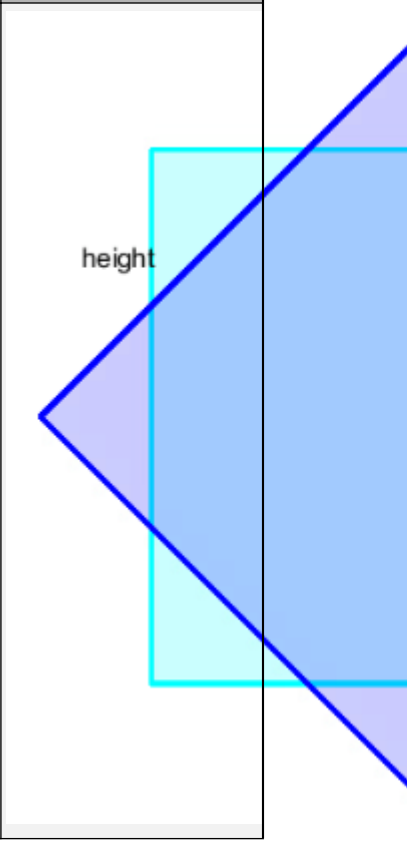
`shape` — Type of shape

`"rectangle"` | `"filled-rectangle"` | `"line"` | `"polygon"` | `"filled-polygon"` | `"circle"` | `"filled-circle"` | `"projected-cuboid"` | `"ellipse"` | `"filled-ellipse"`

Type of shape, specified as `"rectangle"`, `"filled-rectangle"`, `"line"`, `"polygon"`, `"filled-polygon"`, `"circle"`, `"filled-circle"`, `"projected-cuboid"`, `"ellipse"`, or `"filled-ellipse"`.

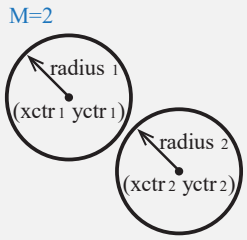


Data Types: `char` | `string`



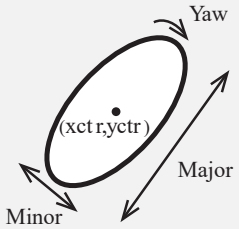
`position` — Position of shape

matrix | vector | cell array

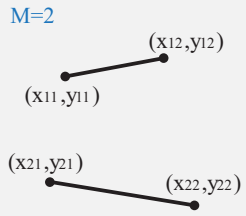


Position of shape, specified according to the type of shape, as described in the table.

Shape	Position	Definition

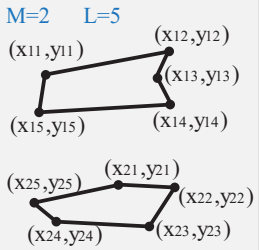


`rectangle`
 	
`filled-rectangle`
	For one or more axis-aligned rectangles or filled rectangles, specify as an M-by-4 numeric matrix, where each row specifies a rectangle of the form $[x\ y\ width\ height]$.
	
	• M is the number of axis-aligned rectangles.
	• x and y specify the upper-left corner of the rectangle.
	• w specifies the width of the rectangle, which is its length along the x-axis.
	• h specifies the height of the rectangle, which is its length along the y-axis.
	
	$\begin{bmatrix} x_1 & y_1 & width_1 & height_1 \\ x_2 & y_2 & width_2 & height_2 \\ \vdots & \vdots & \vdots & \vdots \\ x_M & y_M & width_M & height_M \end{bmatrix}$
		M=2
		

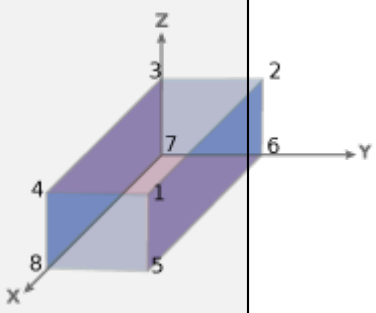


Shape	Position	Definition
	For one or more rotated rectangles, specify in spatial coordinates as an *M*-by-5 numeric matrix, where each row specifies a rotated rectangle of the form [*xctr yctr w h yaw*]. • *M* is the number of rotated rectangles. • *xctr* and *yctr* specify the center of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis before rotation. • *h* specifies the height of the rectangle, which is its length along the *y*-axis before rotation. • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the rectangle.	

Shape	Position	Definition



`circle`
 	
`filled-circle`
	For one or more circles, specify spatial coordinates as an *M*-by-3 numeric matrix, where each row specifies a circle of the form [*xctr yctr radius*].
	• *M* is the number of circles.
	• *xctr* and *yctr* specify the center of the circle.
	• *radius* specifies the radius of the circle.
	$\begin{bmatrix} xctr_1 & yctr_1 & radius_1 \\ xctr_2 & yctr_2 & radius_2 \\ \vdots & \vdots & \vdots \\ xctr_M & yctr_M & radius_M \end{bmatrix}$
		



Shape	Position	Definition

`ellipse`
 	
`filled-ellipse`
	For one or more ellipses, specify in spatial coordinates as an *M*-by-5 matrix, where each row specifies an ellipse of the form [*xctr yctr major minor yaw*]
	• *M* is the number of ellipses.
	• *xctr* and *yctr* specify the center of the ellipse.
	• *major* and *minor* are the lengths of the major and minor ellipse axes, respectively.
	• *yaw* is the angle of rotation in degrees. The angle of rotation is clockwise positive around the center of the ellipse.
		

Shape	Position	Definition
`line`	For one or more lines, specify spatial coordinates using one of these formats to specify a single line with connected endpoints, multiple lines with the same number of endpoints, or multiple lines with different numbers of endpoints. • Single lines with connected endpoints — Specify as a *P*-by-2 matrix, where each row specifies an endpoint in the form [*x y*], and the endpoint in one row connects directly to the endpoint in the next. *P* is the number of endpoints in the line. • Multiple lines with the same number of endpoints — Specify as an *M*-by-2*P* matrix, where each row specifies the consecutive endpoints of a single line in the form [*x1 y1 x2 y2 ... xp yp*]. Each [*x y*] pair is the coordinates of a single endpoint. *M* is the number of specified lines, and *P* is the number of endpoints per line. • Multiple lines with different numbers of endpoints — Specify as an *M*-by-1 cell array, where each cell contains the endpoints for a single line as a *P*-by-2 matrix or a 1-by-2*P* vector]. *M* is the number of specified lines, and *P* is the number of endpoints for each line	

Shape	Position	Definition

`polygon`
 	
`filled-polygon`
	For one or more polygons, specify in spatial coordinates as an M-by-1 cell array, where each cell contains an L-by-2 matrix of [x y] vertex locations or a 1-by-2L vector of consecutive vertex locations of the form [x_1, y_1, x_2,y_2, … x_L,y_L].
	• M is the number of polygons.
	• Each [x y] pair describes a vertex location or endpoint.
	• L is the number of vertices in a polygon or endpoints in a line. Each polygon or line can have a different number of vertices or endpoints.
		

Shape	Position	Definition
`projected-cuboid`	For one or more projected cuboids, specify in spatial coordinates as an 8-by-2-by-*M* array or an *M*-by-8 matrix, where *M* is the number of projected cuboids. When specified as an 8-by-2-by-*M* array, each row must contain the [*x y*] location of a projected cuboid vertex. The vertices connect to form a cuboid with six faces. The order of the input vertices must match the order shown in the diagram. When specified as an *M*-by-8 matrix, each row specifies the dimensions of the front-facing and rear-facing sides of a projected cuboid in the form, [*x1 y1 w1 h1 x2 y2 w2 h2*], where [*x1 y1*] and [*x2 y2*] specify the upper-left coordinates of the front-facing and rear-facing sides, respectively, and [*w1 h1*] and [*w2 h2*] specify the corresponding widths and heights.	

Data Types: `single` | `double` | `cell` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `insertShape(I,"circle",position,Color="yellow")` sets the shape color to yellow.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `insertShape(I,"circle",position,"Color","yellow")` sets the shape color to yellow.

`LineWidth` — Shape border line width
`1` (default) | positive integer

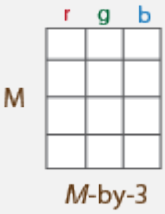
Shape border line width, specified as a positive integer, in pixels. This argument applies to only the `"Rectangle"`, `"Line"`, `"Polygon"`, and `"Circle"` shapes.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single`

`ShapeColor` — Shape color
`"green"` (default) | short color name | color name | vector of color names | three-column matrix of RGB triplets

Shape color, specified as a short color name, color name, vector of color names, three-column matrix of RGB triplets.

The supported colors table lists RGB intensities in the range [0, 1], but you must specify RGB triplets in the range of your selected data type. For example, if specifying this argument as a matrix of `uint8` values, you must convert each intensity value to the range [0, 255]. To convert the listed intensity



values to a `uint8` data type, use the code `uint8(255*intensity)`, where intensity is an RGB triplet value listed in the table.

You can specify a different color for each shape or one color for all shapes. To specify one color for all markers, specify `ShapeColor` as a color name or an [*R G B*] vector.

Specification	Format	Example

Specify one color for all shapes (or markers)	Short color name or color name	`"r"`
		
		`"red"`

	RGB triplet	 `[1 0 0]`
Specify a color for each shape (or marker)	Vector of color names	`["red","yellow","blue"]`

	Three-column matrix of RGB triplets	`[1 0 0`
		` 0 1 1`
		` 1 0 1`
		` 1 1 1]`
		

This table lists the supported shape colors.

Color Name	Short Name	RGB Triplet	Appearance
`"red"`	`"r"`	`[1 0 0]`	
`"green"`	`"g"`	`[0 1 0]`	
`"blue"`	`"b"`	`[0 0 1]`	
`"cyan"`	`"c"`	`[0 1 1]`	
`"magenta"`	`"m"`	`[1 0 1]`	
`"yellow"`	`"y"`	`[1 1 0]`	
`"black"`	`"k"`	`[0 0 0]`	
`"white"`	`"w"`	`[1 1 1]`	

Data Types: `logical` | `uint8` | `uint16` | `int16` | `double` | `single` | `cell`

`Opacity` — Opacity of filled shape
`0.6` (default) | scalar in range [0,1]

Opacity of a filled shape, specified as a scalar in the range [0 1]. The `Opacity` argument applies to only the `"filled-rectangle"`, `"filled-polygon"`, and `"filled-circle"` shapes.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`SmoothEdges` — Smooth shape edges
`true` or `1` (default) | `false` or `0`

Smooth shape edges, specified as a logical `1` (`true`) or `0` (`false`). A `true` value enables an antialiasing filter to smooth shape edges. This value applies to only nonrectangular shapes. When you enable antialiasing requires additional time to draw the shapes.

Data Types: `logical`

Output Arguments

`RGB` — Output image
M-by-*N*-by-3 truecolor image

Output image, returned as an *M*-by-*N*-by-3 truecolor image.

Version History

Introduced in R2014a

R2024b: Support for ellipse shape

Added support for `"ellipse"` and `"filled-ellipse"` to visualize one or more ellipses on top of an image or on video data.

R2023b: Specify RGB color in the range [0,1]
Behavior changed in R2023b

Starting in R2023b, you can specify marker color with RGB values in the range [0,1].

R2022b: Visualize projected cuboids

Added support to visualize projected cuboids.

R2023b: Rotated rectangle support for bounding box

You can specify a rotated rectangle bounding box using the form [*xctr yctr width height yaw*].

R2023b: Show orientation of rectangle of bounding box

You can now specify the `ShowOrientation` name-value argument to display the orientation and angle of a rotated rectangle bounding box.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument `shape` must be a compile-time constant.
- The `ShapeColor` and `SmoothEdges` name-value arguments must be compile-time constants.
- Code generation requires a C++ compiler. For a list of supported compilers, see Supported and Compatible Compilers

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

Topics

“Draw Markers on an Image” on page 3-874
“Insert Text into Image” on page 3-919
“Choose Function to Visualize Detected Objects”

insertText

Insert text in image or video

Syntax

```
RGB = insertText(I,position,text)
RGB = insertText(I,position,numericValue)
RGB = insertText(___,Name=Value)
```

Description

`RGB = insertText(I,position,text)` insert text into the truecolor or grayscale image `I`. The function returns a truecolor image.

`RGB = insertText(I,position,numericValue)` inserts numeric values into the input image.

`RGB = insertText(___,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of input arguments from previous syntaxes. For example, `FontColor="red"` renders the inserted text or numeric values in red.

Examples

Insert Text into Image

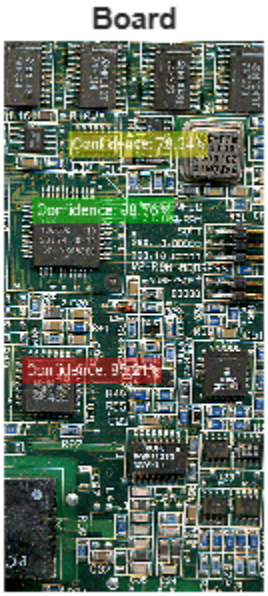
Read the image into the workspace.

```
I = imread("board.tif");
```

Create text string that contain fractions.

```
text_str = cell(3,1);
conf_val = [85.212 98.76 78.342];
for ii = 1:3
   text_str{ii} = ['Confidence: ' num2str(conf_val(ii), '%0.2f') '%'];
end
```

Define the positions and colors of the text boxes.



```
position = [23 373; 35 185; 77 107];
box_color = {"red","green","yellow"};
```

Insert the text strings with their respective box colors, and specify the font size, opacity, and text color of all strings.

```
RGB = insertText(I,position,text_str,FontSize=18,TextBoxColor=box_color, ...
    BoxOpacity=0.4,TextColor="white");
```

Display the image with annotations.

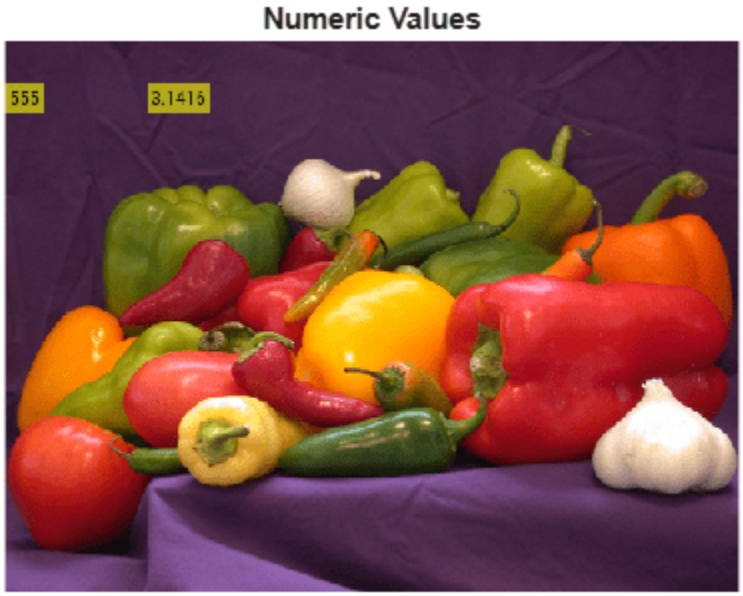
```
figure
imshow(RGB)
title("Board")
```

Insert Numeric Values into Image

Read the image into the workspace.

```
I = imread("peppers.png");
```

Define the numeric values and their *xy*-positions.



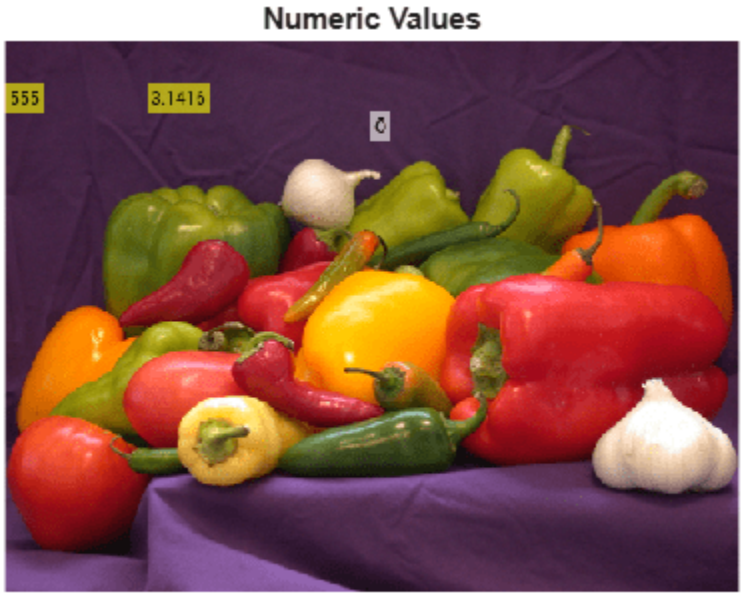
```
position =  [1 50; 100 50];
value = [555 pi];
```

Insert the numeric values using the bottom-left corner of each text box as its anchor point.

```
RGB = insertText(I,position,value,AnchorPoint="LeftBottom");
```

Display the image with the numeric values inserted.

```
figure
imshow(RGB)
title("Numeric Values")
```



Insert the Unicode U+014C into the image.

```
OWithMacron = native2unicode([hex2dec("C5") hex2dec("8C")],"UTF-8");
RGB = insertText(RGB,[256 50],OWithMacron,font="Roboto-Regular",TextBoxColor="white");
```

Display the image with the Unicode character inserted.

```
figure
imshow(RGB)
title("Numeric Values");
```

Input Arguments

`I` — Input image

M-by-*N*-by-3 truecolor image | *M*-by-*N* grayscale image

Input image, specified as an *M*-by-*N*-by-3 truecolor or an *M*-by-*N* grayscale image.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16`

`text` — Unicode text character vector

character vector | string scalar | *M*-element cell array of character vectors | *M*-element string array

Unicode text, specified as a character vector, string scalar, *M*-element cell array of character vectors, or *M*-element string array. *M* is the number of specified text positions in `position`. The function overwrites pixels with the value of `text`. If you specify a single string or character vector, the function uses it for all positions in the `position` matrix. Most unicode fonts contain ASCII characters. You can display non-English and English characters, including English numeric values, with a single font.

Data Types: `char` | `string` | `cell`

`numericValue` — Numeric value text

numeric scalar | *M*-element numeric vector

Numeric value text, specified as a numeric scalar or an *M*-element numeric vector. *M* is the number of specified positions in `position`. If you specify a scalar value, the function uses that value for all specified positions. The function converts each numeric value to a character vector using the `sprintf` format '`%0.5g`'.

Data Types: `numeric`

`position` — Position of inserted text
M-by-2 matrix

Position of the inserted text, specified as *M*-by-2 matrix. *M* is the number of specified text positions, and each row specifies the *xy*-coordinates of the `AnchorPoint` of a text box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `insertText(I,position,text,Font="Calibri")` sets the font face to `Calibri`.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `insertText(I,position,text,"Font","Calibri")` sets the font face to `Calibri`.

`Font` — Font face of text
`"Roboto-Regular"` (default) | character vector | string scalar

Font face of the text, specified as a character vector or a string scalar. The font face must be one of the available truetype fonts installed on your system. To get a list of available fonts on your system, use the `listTrueTypeFonts` function from the MATLAB command prompt.

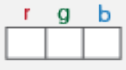
Data Types: `char` | `string`

`FontSize` — Font size
`12` (default) | positive integer in range [1, 200]

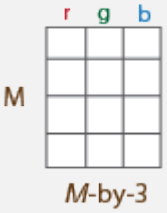
Font size, specified as a positive integer in the range [1, 200] in pixels.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`FontColor` — Font color
`"green"` (default) | short color name | color name | vector of color names | three-column matrix of RGB triplets



Font color, specified as a short color name, color name, vector of color names, three-column matrix of RGB triplets.



The supported colors table lists RGB intensities in the range [0, 1], but you must specify RGB triplets in the range of your selected data type. For example, if specifying this argument as a matrix of `uint8` values, you must convert each intensity value to the range [0, 255]. To convert the listed intensity values to a `uint8` data type, use the code `uint8(255*intensity)`, where intensity is an RGB triplet value listed in the table.

You can specify a different color for each font string or one color for all strings. To specify one color for all markers, specify `FontColor` as a color name or an [*R G B*] vector.

Specification	Format	Example

Specify one color for all shapes (or markers)	Short color name or color name	`"r"`
		
		`"red"`

	RGB triplet	 `[1 0 0]`
Specify a color for each shape (or marker)	Vector of color names	`["red","yellow","blue"]`

	Three-column matrix of RGB triplets	`[1 0 0`
		` 0 1 1`
		` 1 0 1`
		` 1 1 1]`
		

This table lists the supported marker colors.

Color Name	Short Name	RGB Triplet	Appearance
`"red"`	`"r"`	`[1 0 0]`	
`"green"`	`"g"`	`[0 1 0]`	
`"blue"`	`"b"`	`[0 0 1]`	
`"cyan"`	`"c"`	`[0 1 1]`	
`"magenta"`	`"m"`	`[1 0 1]`	
`"yellow"`	`"y"`	`[1 1 0]`	
`"black"`	`"k"`	`[0 0 0]`	
`"white"`	`"w"`	`[1 1 1]`	

Data Types: `logical` | `uint8` | `uint16` | `int16` | `double` | `single`

`TextBoxColor` — Text box color

`"green"` (default) | short color name | color name | vector of color names | three-column matrix of RGB triplets

Text box color, specified as a short color name, color name, vector of color names, three-column matrix of RGB triplets.

The supported colors table lists RGB intensities in the range [0, 1], but you must specify RGB triplets in the range of your selected data type. For example, if specifying this argument as a matrix of `uint8` values, you must convert each intensity value to the range [0, 255]. To convert the listed intensity values to a `uint8` data type, use the code `uint8(255*intensity)`, where intensity is an RGB triplet value listed in the table.

You can specify a different color for each font string or one color for all strings. To specify one color for all strings, specify `FontColor` as a color name or an [*R G B*] vector.

Data Types: `logical` | `uint8` | `uint16` | `int16` | `double` | `single`

`BoxOpacity` — Text box opacity
`0.6` (default) | scalar in the range of [`0` `1`]

Text box opacity of the text label box background, specified as a scalar in the range of `[0, 1]`. A value of `0` renders the background of the label text box as fully transparent, while a value of `1` renders it as fully opaque.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`AnchorPoint` — Text box reference point
`"LeftTop"` (default) | `"LeftCenter"` | `"LeftBottom"` | `"CenterTop"` | `"Center"` | `"CenterBottom"` | `"RightTop"` | `"RightCenter"` | `"RightBottom"`

Text box reference point, specified as one of these values:

- `"LeftTop"`
- `"LeftCenter"`
- `"LeftBottom"`
- `"CenterTop"`
- `"Center"`
- `"CenterBottom"`
- `"RightTop"`
- `"RightCenter"`
- `"RightBottom"`

The anchor point defines the relative location on each text box. You can position the text box specified by the corresponding row of `position`. For example, to place the center of the text box at the *xy*-coordinate specified by `position`, set `AnchorPoint` to `Center`.

Data Types: `char` | `string`

Output Arguments

`RGB` — Output image
M-by-*N*-by-3 truecolor image

Output image, returned as an *M*-by-*N*-by-3 truecolor image with the specified text inserted.

Limitations

- If you do not see a character in the output image, then the specified font does not contain the character. Select a different font. To get a list of available fonts on your system, at the MATLAB command prompt, enter `listTrueTypeFonts`.
- Increasing the font size also increases the preprocessing time and memory usage.
- The `insertText` function does not work for certain composite characters. For example, you cannot insert text when the rendering of one glyph corresponding to a character code influences the position, shape, or size of the adjacent glyph.

Version History

Introduced in R2013a

R2026a: Default value of `Font` changed to `Roboto-Regular`

Behavior changed in R2026a

Starting in R2026a, the default value of the `Font` name-value argument is `Roboto-Regular`. In previous releases, the default value was `LucidaSansRegular`.

R2023b: Specify RGB color in the range [0,1]

Behavior changed in R2023b

Starting in R2023b, you can specify marker color with RGB values in the range [0,1].

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- `Font` and `FontSize` must be compile-time constants.
- Non-ASCII characters are not supported.
- Code generation requires a C++ compiler. For a list of supported compilers, see Supported and Compatible Compilers

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

interp

Interpolate between transformations

Syntax

```
transformation0 = interp(transformation1,transformation2,points)
rotation0 = interp(rotation1,rotation2,points)
___  = interp( ___ ,transformation2,N)
```

Description

`transformation0 = interp(transformation1,transformation2,points)` interpolates at normalized positions `points` between transformations `transformation1` and `transformation2`.

The function interpolates rotations using a quaternion spherical linear interpolation, and linearly interpolates translations.

`rotation0 = interp(rotation1,rotation2,points)` interpolates at normalized rotations `points` between rotations `rotation1` and `rotation2`.

The function interpolates rotations using a quaternion spherical linear interpolation

`___  = interp( ___ ,transformation2,N)` interpolates `N` steps between the specified transformations or rotations.

Input Arguments

`transformation1` — First transformation

`se3` object | *N*-element array of transformation objects

First transformation, specified as a scalar `se3` object or as an *N*-element array of transformation objects, where *N* is the total number of transformations. If you specify `transformation1` as an array, each element must be of the same type.

Either `transformation1` or `transformation2` must be a scalar transformation object of the same type. For example, if `transformation1` is an array of `se3` objects, `transformation2` must be a scalar `se3` object.

`transformation2` — Last transformation

`se3` object | *N*-element array of transformation objects

Last transformation, specified as a scalar `se3` object or as an *N*-element array of transformation objects, where *N* is the total number of transformations. If you specify `transformation2` as an array, each element must be of the same type.

Either `transformation1` or `transformation2` must be a scalar transformation object of the same type. For example, if `transformation1` is an array of `se3` objects, `transformation2` must be a scalar `se3` object.

`rotation1` — First rotation
`so3` object | *N*-element array of rotation objects

First rotation, specified as a scalar `so3` object or as an *N*-element array of rotation objects, where *N* is the total number of rotations. If you specify `rotation1` as an array, each element must be of the same type.

Either `rotation1` or `rotation2` must be a scalar rotation object of the same type. For example, if `rotation1` is an array of `so3` objects, `rotation2` must be a scalar `so3` object.

`rotation2` — Last rotation
`so3` object | *N*-element array of rotation objects

Last rotation, specified as a scalar `so3` object or as an *N*-element array of rotation objects, where *N* is the total number of rotations. If you specify `rotation2` as an array, each element must be of the same type.

Either `rotation1` or `rotation2` must be a scalar rotation object of the same type. For example, if `rotation1` is an array of `se3` objects, `rotation2` must be a scalar `se3` object.

`points` — Normalized positions
N-element row vector of values in range `[0, 1]`

Normalized positions, specified as an *N*-element row vector of values in the range `[0, 1]`, where *N* is the total number of interpolated positions. Normalized positions `0` and `1` correspond to the first and last transformations or rotations, respectively.

Example: `interp(tf1,tf2,0.5)` interpolates a transformation halfway between `tf1` and `tf2`.

Example: `interp(r1,r2,0.5)` interpolates a rotation halfway between `r1` and `r2`.

`N` — Number of interpolated positions
positive integer

Number of interpolated positions, specified as a positive integer.

Example: `interp(tf1,tf2,5)` interpolates five transformations between transformations `tf1` and `tf2`.

Example: `interp(r1,r2,7)` interpolates seven rotations between rotations `r1` and `r2`.

Output Arguments

`transformation0` — Interpolated transformations
N-by-*M* matrix

Interpolated transformations, returned as an *N*-by-*M* matrix of the same transformation type as `transformation1` and `transformation2`, where *N* is the length of the longer argument between `transformation1` and `transformation2`, and *M* is the number of interpolated positions. Each row represents an interpolated transformation between `transformation1` and `transformation2`.

`rotation0` — Interpolated rotations
N-by-*M* matrix

Interpolated rotations, returned as an *N*-by-*M* matrix of the same rotation type as `rotation1` and `rotation2`, where *N* is the length of the longer argument between `rotation1` and `rotation2`, and

M is the number of interpolated positions. Each row represents an interpolated transformation between `rotation1` and `rotation2`.

isEpipoleInImage

Determine whether image contains epipole

Syntax

```
isIn = isEpipoleInImage(F,imageSize)
isIn = isEpipoleInImage(F',imageSize)
[isIn,epipole] = isEpipoleInImage( ___ )
```

Description

`isIn = isEpipoleInImage(F,imageSize)` determines whether the first stereo image associated with the fundamental matrix `F` contains an epipole. `imageSize` is the size of the first image, and is in the format returned by the function `size`.

`isIn = isEpipoleInImage(F',imageSize)` determines whether the second stereo image associated with the fundamental matrix `F'` contains an epipole.

`[isIn,epipole] = isEpipoleInImage( ___ )` also returns the epipole.

Examples

Determine Epipole Location in an Image

```
% Load stereo point pairs.
    load stereoPointPairs
    f = estimateFundamentalMatrix(matchedPoints1, matchedPoints2, 'NumTrials', 2000);
    imageSize = [200 300];

% Determine whether the image contains epipole and epipole location.
    [isIn,epipole] = isEpipoleInImage(f,imageSize)
```

```
isIn = logical
   1

epipole = 1×2

  256.5465  100.0140
```

Input Arguments

F — Fundamental matrix

3-by-3 matrix (default)

Fundamental matrix, specified as a 3-by-3 matrix computed from stereo images. `F` must be double or single. If P_1 represents a point in the first image I_1 that corresponds to P_2, a point in the second image I_2, then:

$[P_2,1] * F * [P_1,1]' = 0$

In computer vision, the fundamental matrix is a 3-by-3 matrix which relates corresponding points in stereo images. When two cameras view a 3-D scene from two distinct positions, there are a number of geometric relations between the 3-D points and their projections onto the 2-D images that lead to constraints between the image points. Two images of the same scene are related by epipolar geometry.

`imageSize` — Image size
row vector

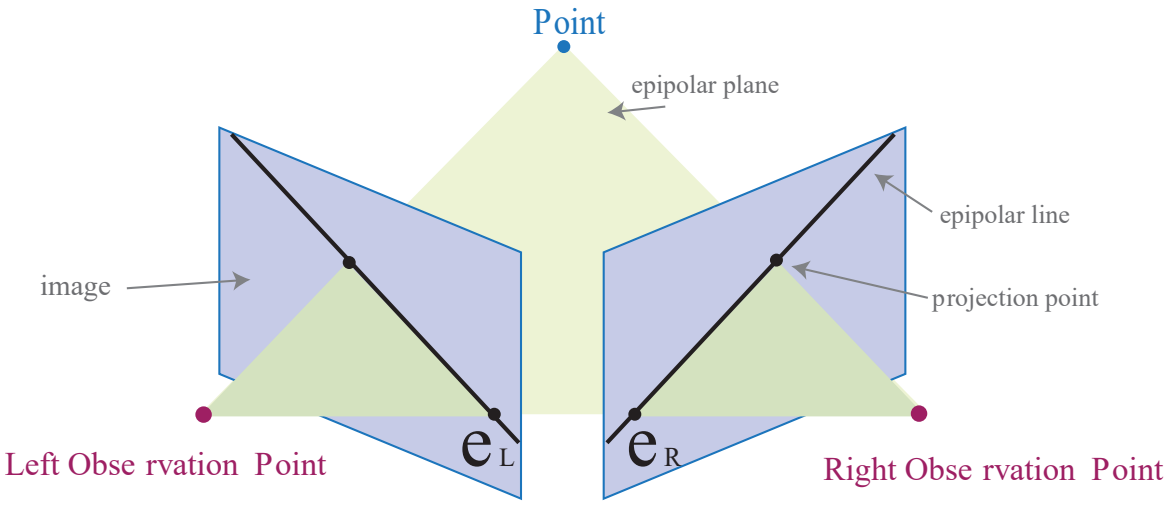

Image size, specified in the format returned by the `size` function.

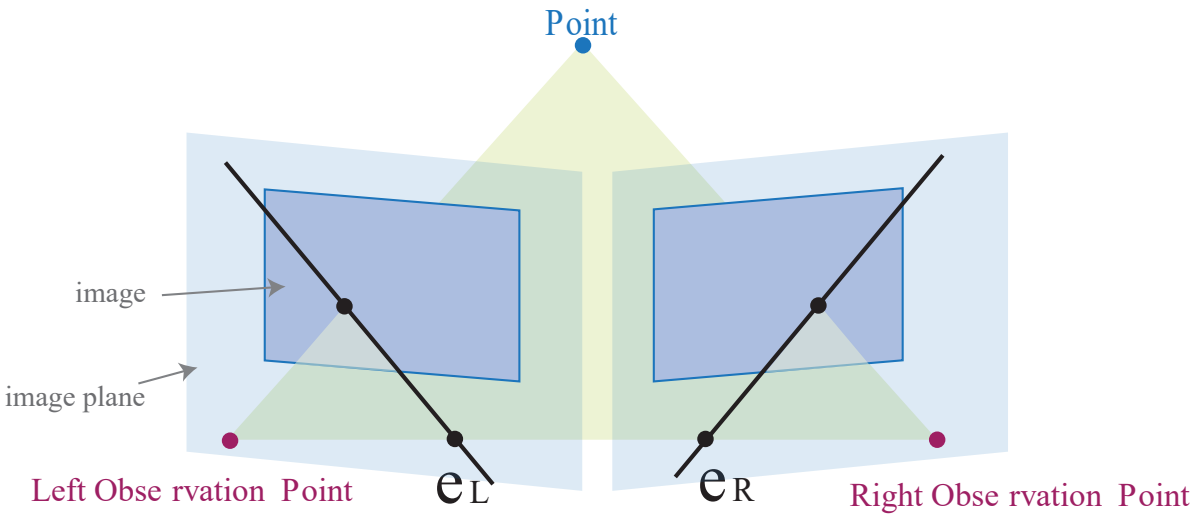
Output Arguments



`isIn` — Valid epipole
logical

Valid epipole logical, specified as `true` when the image contains an epipole, and `false` when the image does not contain an epipole. When the image planes are at a great enough angle to each other, you can expect the epipole to be located in the image. When the image planes are at a more subtle angle to each other, you can expect the epipole to be located outside of the image, (but still in the image plane).

Epipole located in image.

Point
epipolar plane
epipolar line
image
projection point
e L
e R
Left Obse rvation Point
Right Obse rvation Point

Epipole located outside of image.

Point
image
image plane
Left Obse rvation Point
e L
e R
Right Obse rvation Point

`epipole` — Location of epipole
1-by-2 vector

Location of epipole, returned as a 1-by-2 vector.

Version History

Introduced in R2011a

isfilterseparable

Determine whether filter coefficients are separable

Syntax

```
isSeparable = isfilterseparable(H)
[isSeparable,hcol,hrow] = isfilterseparable(H)
```

Description

`isSeparable = isfilterseparable(H)` returns logical `1` (true) when the filter kernel `H` is separable, and `0` (false) otherwise.

`[isSeparable,hcol,hrow] = isfilterseparable(H)` also returns the vertical coefficients `hcol` and horizontal coefficients `hrow` when the filter kernel, `H`, is separable. Otherwise, `hcol` and `hrow` are empty.

Examples

Determine If Gaussian Filter Is Separable

Determine if the Gaussian filter created using the `fspecial` function is separable.

Create a Gaussian filter.

```
twoDimensionalFilter = fspecial('gauss');
```

Test the filter.

```
[isseparable,hcol,hrow] = isfilterseparable(twoDimensionalFilter)
```

```
isseparable = logical
   1

hcol = 3×1

   -0.1065
   -0.7870
   -0.1065

hrow = 1×3

   -0.1065   -0.7870   -0.1065
```

Input Arguments

`H` — Filter kernel

2-D numeric matrix | 2-D logical matrix

Filter kernel, specified as a non-sparse 2-D numeric or logical matrix.

Output Arguments

`isSeparable` — Filter is separable

`1` (true) | `0` (false)

Filter is separable, returned as logical `1` (true) when the filter is separable and `0` (false) when the filter is not separable.

Data Types: `logical`

`hcol` — Vertical coefficients

numeric vector | `[]`

Vertical coefficients when the filter kernel `H` is separable, returned as a numeric vector. When `H` is not separable, `hcol` is empty. If `H` is of data type `single`, then `hcol` is also of data type `single`. Otherwise, `hcol` is of data type `double`.

`hrow` — Horizontal coefficients

numeric vector | `[]`

Horizontal coefficients when the filter kernel `H` is separable, returned as a numeric vector. When `H` is not separable, `hrow` is empty. If `H` is of data type `single`, then `hrow` is also of data type `single`. Otherwise, `hrow` is of data type `double`.

More About

Separable two dimensional filters

Separable two-dimensional filters reflect the outer product of two vectors. Separable filters help reduce the number of calculations required.

A two-dimensional convolution calculation requires a number of multiplications equal to the *width* × *height* for each output pixel. The general case equation for a two-dimensional convolution is:

$$Y(m,n) = \sum_k \sum_l H(k,l)U(m-k,n-l)$$

If the filter H is separable then,

$$H(k,l) = H_{row}(k)H_{col}(l)$$

Shifting the filter instead of the image, the two-dimensional equation becomes:

$$Y(m,n) = \sum_k H_{row}(k) \sum_l H_{col}(l)\, U(m-k,n-l)$$

This calculation requires only (width + height) number of multiplications for each pixel.

Algorithms

The `isfilterseparable` function uses the singular value decomposition `svd` function to determine the rank of the matrix.

Version History

Introduced in R2006a

MATLAB Central — Separable Convolution

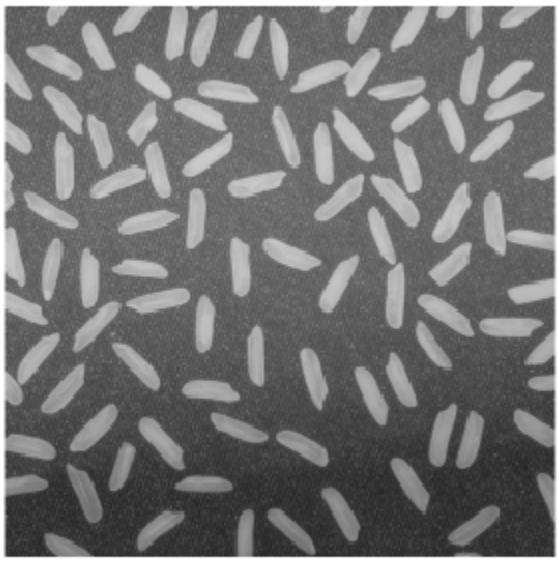
lineToBorderPoints

Intersection points of lines in image and image border

Syntax

```
points = lineToBorderPoints(lines,imageSize)
```

Description



`points = lineToBorderPoints(lines,imageSize)` computes the intersection points between one or more lines in an image with the image border.

Examples

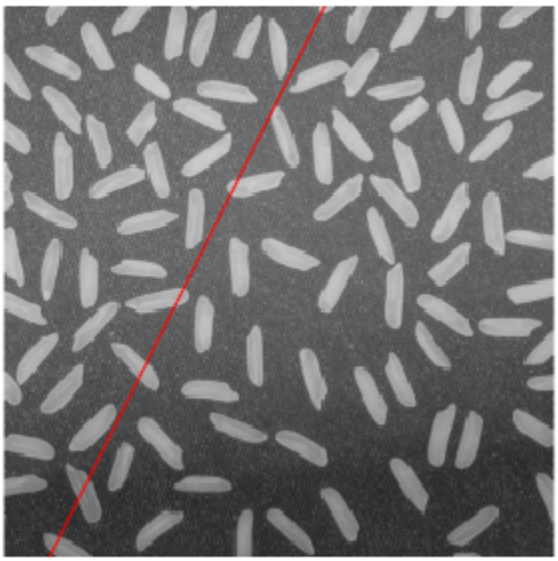
Find Intersection Points Between a Line and Image Border

Load and display an image.

```
I = imread('rice.png');
figure;
imshow(I);
hold on;
```

Define a line with the equation, 2 * x + y - 300 = 0.

```
aLine = [2,1,-300];
```



Compute the intersection points of the line and the image border.

```
points = lineToBorderPoints(aLine,size(I))
```

```
points = 1×4

  149.7500    0.5000   21.7500  256.5000
```

```
line(points([1,3]),points([2,4]),Color="r");
```

Input Arguments

`lines` — Line matrix

M-by-3 matrix (default)

Line matrix, specified as an *M*-by-3 matrix, where each row must be in the format, [*A*,*B*,*C*]. This matrix corresponds to the definition of the line:
$A * x + B * y + C = 0$.
M represents the number of lines.

`lines` must be `double` or `single`.

`imageSize` — Image size

integer (default) | row vector

Image size, specified as a row vector in the format returned by the `size` function.

Output Arguments

`points` — Intersection points

M-by-4 matrix

Intersection points, returned as an *M*-by-4 matrix. The function returns the matrix in the format of $[x_1, y_1, x_2, y_2]$. In this matrix, $[x_1\ y_1]$ and $[x_2\ y_2]$ are the two intersection points. When a line in the image and the image border do not intersect, the function returns `[-1,-1,-1,-1]`.

Version History

matchFeatures

Find matching features

Syntax

```
indexPairs = matchFeatures(features1,features2)
[indexPairs,matchmetric] = matchFeatures(features1,features2)
[indexPairs,matchmetric] = matchFeatures(features1,features2,Name=Value)
```

Description

`indexPairs = matchFeatures(features1,features2)` returns indices of the matching features in the two input feature sets. The input feature must be either `binaryFeatures` objects or matrices.

`[indexPairs,matchmetric] = matchFeatures(features1,features2)` also returns the distance between the matching features, indexed by `indexPairs`.

`[indexPairs,matchmetric] = matchFeatures(features1,features2,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `matchFeatures(__,Method="Exhaustive")` sets the matching method to `Exhaustive`.

Examples

Find Corresponding Interest Points Between Pair of Images

Find corresponding interest points between a pair of images using local neighborhoods and the Harris algorithm.

Read the stereo images.

```
I1 = im2gray(imread("viprectification_deskLeft.png"));
I2 = im2gray(imread("viprectification_deskRight.png"));
```

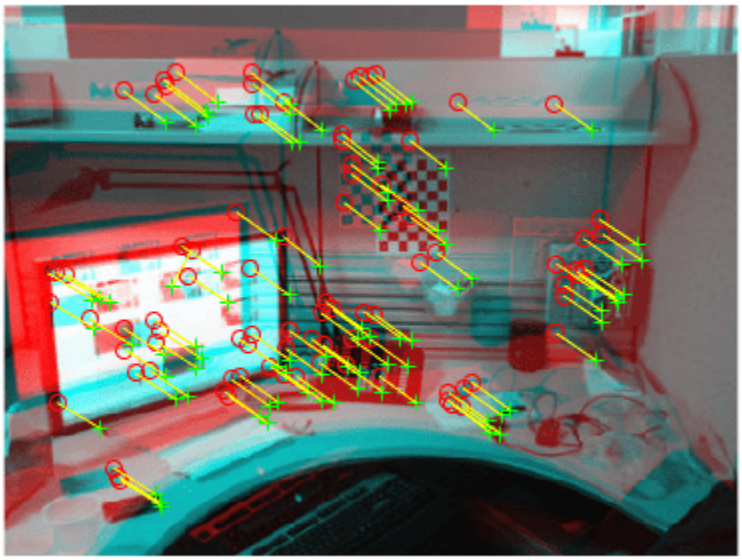
Find the corners.

```
points1 = detectHarrisFeatures(I1);
points2 = detectHarrisFeatures(I2);
```

Extract the neighborhood features.

```
[features1,valid_points1] = extractFeatures(I1,points1);
[features2,valid_points2] = extractFeatures(I2,points2);
```

Match the features.



```
indexPairs = matchFeatures(features1,features2);
```

Retrieve the locations of the corresponding points for each image.

```
matchedPoints1 = valid_points1(indexPairs(:,1),:);
matchedPoints2 = valid_points2(indexPairs(:,2),:);
```

Visualize the corresponding points. You can see the effect of translation between the two images despite several erroneous matches.

```
figure;
showMatchedFeatures(I1,I2,matchedPoints1,matchedPoints2);
```

Find Corresponding Points Using SURF Features

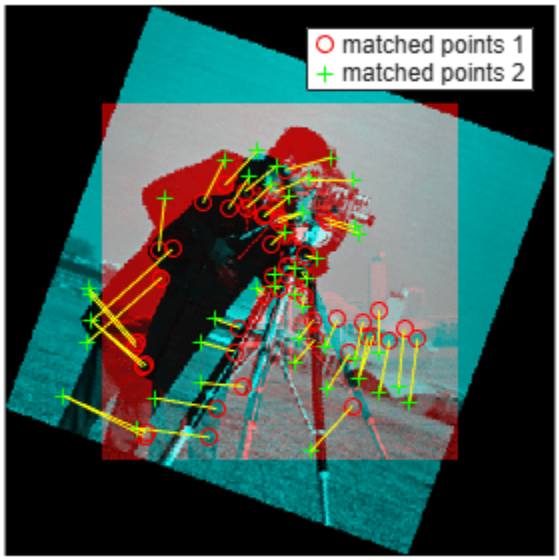
Read the two images.

```
I1 = imread("cameraman.tif");
I2 = imresize(imrotate(I1,-20),1.2);
```

Find the SURF features.

```
points1 = detectSURFFeatures(I1);
points2 = detectSURFFeatures(I2);
```

Extract the features.



```
[f1,vpts1] = extractFeatures(I1,points1);
[f2,vpts2] = extractFeatures(I2,points2);
```

Retrieve the locations of matched points.

```
indexPairs = matchFeatures(f1,f2) ;
matchedPoints1 = vpts1(indexPairs(:,1));
matchedPoints2 = vpts2(indexPairs(:,2));
```

Display the matching points. The data still includes several outliers, but you can see the effects of rotation and scaling on the display of matched features.

```
figure; showMatchedFeatures(I1,I2,matchedPoints1,matchedPoints2);
legend("matched points 1","matched points 2");
```

Input Arguments

`features1` — Feature set 1

`binaryFeatures` object | *M1*-by-*N* matrix | point feature object

Features set 1, specified as a `binaryFeatures` object, an *M1*-by-*N* matrix, or as one of the point feature objects described in “Point Feature Types”. The matrix contains *M1* features, and *N* corresponds to the length of each feature vector. You can obtain the `binaryFeatures` object using the `extractFeatures` function with the fast retina keypoint (FREAK), Oriented FAST and Rotated BRIEF (ORB), or binary robust invariant scalable keypoints (BRISK) descriptor method.

`features2` — Feature set 2

M2-by-*N* matrix | `binaryFeatures` object | point feature object

Features set 2, specified as a `binaryFeatures` object, an *M2*-by-*N* matrix, or as one of the point feature objects described in “Point Feature Types”. The matrix contains *M2* features, and *N* corresponds to the length of each feature vector. You can obtain the `binaryFeatures` object using the `extractFeatures` function with the fast retina keypoint (FREAK), Oriented FAST and Rotated BRIEF (ORB), or binary robust invariant scalable keypoints (BRISK) descriptor method.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Method="Exhaustive"` sets the matching method to `Exhaustive`

`Method` — Matching method
`"Exhaustive"` (default) | `"Approximate"`

Matching method, specified as `"Exhaustive"` or `"Approximate"`. The method specifies how nearest neighbors between `features1` and `features2` are found. Two feature vectors match when the distance between them is less than the threshold set by the `MatchThreshold` parameter.

`"Exhaustive"`	Compute the pairwise distance between feature vectors in `features1` and `features2`.
`"Approximate"`	Use an efficient approximate nearest neighbor search. Use this method for large feature sets. [3]

`MatchThreshold` — Matching threshold
`10.0` or `1.0` (default) | percent value in the range (0, 100]

Matching threshold, specified as a scalar percent value in the range (0,100]. The default values are set to either `10.0` for binary feature vectors or to `1.0` for nonbinary feature vectors. You can use the match threshold for selecting the strongest matches. The threshold represents a percent of the distance from a perfect match.

Two feature vectors match when the distance between them is less than the threshold set by `MatchThreshold`. The function rejects a match when the distance between the features is greater than the value of `MatchThreshold`. Increase the value to return more matches.

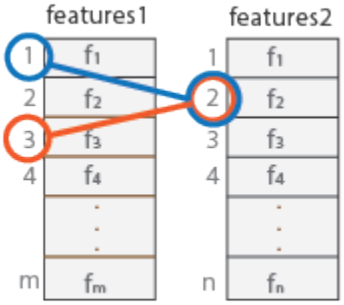
Inputs that are `binaryFeatures` objects typically require a larger value for the match threshold. The `extractFeatures` function returns the `binaryFeatures` objects when extracting FREAK, ORB, or BRISK descriptors.

`MaxRatio` — Ratio threshold
`0.6` (default) | ratio in the range (0,1]

Ratio threshold, specified as a scalar ratio value in the range (0,1]. Use the max ratio for rejecting ambiguous matches. Increase this value to return more matches.

`Metric` — Feature matching metric
`"SSD"` (default) | `"SAD"`

Feature matching metric, specified as `"SAD"` or `"SSD"`.



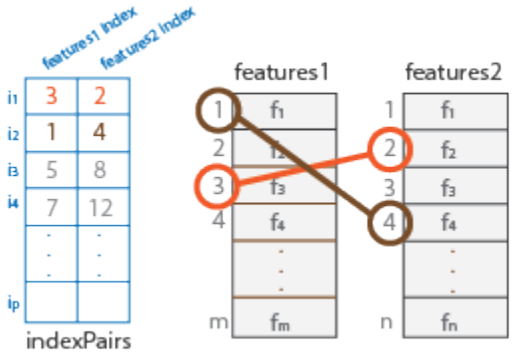
`"SAD"`	Sum of absolute differences
`"SSD"`	Sum of squared differences

This property applies when the input feature sets, `features1` and `features2`, are not `binaryFeatures` objects. When you specify the features as `binaryFeatures` objects, the function uses the Hamming distance to compute the similarity metric.

`Unique` — Unique matches
`false` (default) | `true`

Unique matches, specified as `false` or `true`. Set this value to `true` to return only unique matches between `features1` and `features2`.

When you set `Unique` to `false`, the function returns all matches between `features1` and `features2`. Multiple features in `features1` can match to one feature in `features2`.



When you set `Unique` to `true`, the function performs a forward-backward match to select a unique match. After matching `features1` to `features2`, it matches `features2` to `features1` and keeps the best match.

Output Arguments

`indexPairs` — Indices to corresponding features
P-by-2 matrix

Indices of corresponding features between the two input feature sets, returned as a *P*-by-2 matrix of *P* number of indices. Each index pair corresponds to a matched feature between the `features1` and `features2` inputs. The first element indexes the feature in `features1`. The second element indexes the matching feature in `features2`.

`matchmetric` — Distance between matching features
p-by-1 vector

Distance between matching features, returned as a *p*-by-1 vector. The value of the distances are based on the metric selected. Each *i*th element in `matchmetric` corresponds to the *i*th row in the `indexPairs` output matrix. When `Metric` is set to either `SAD` or `SSD`, the feature vectors are normalized to unit vectors before computation.

Metric	Range	Perfect Match Value
`SAD`	`[0, 2*sqrt(size(features1, 2))]`.	`0`
`SSD`	`[0,4]`	`0`
`Hamming`	`[0, features1.NumBits]`	`0`

Version History

Introduced in R2011a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Generates platform-dependent library for MATLAB host when using the `Approximate` method.
- Generates portable C code for non-host target only when using the `Exhaustive` method.
- Generates portable C code using a C++ compiler that links to OpenCV libraries when not using the `Exhaustive` method. See “Portable C Code Generation for Functions That Use OpenCV Library”.
- `'Method'` and `'Metric'` must be compile-time constants.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- CUDA code is generated only for the `exhaustive` matching method. If the `Approximate` method is selected, GPU Coder issues a warning and generates C/C++ code for this function.

matchFeaturesInRadius

Find matching features within specified radius

Syntax

```
indexPairs = matchFeaturesInRadius(features1,features2,points2,centerPoints,
radius)
[indexPairs,matchMetric] = matchFeaturesInRadius( ___ )
[indexPairs,matchMetric] = matchFeaturesInRadius( ___ ,Name,Value)
```

Description

`indexPairs = matchFeaturesInRadius(features1,features2,points2,centerPoints, radius)` returns the indices of the features most likely to correspond between the input feature sets within the specified radius or radii around each expected match location.

`[indexPairs,matchMetric] = matchFeaturesInRadius( ___ )` also returns the distance between the features in a matched pair in `indexPairs`.

`[indexPairs,matchMetric] = matchFeaturesInRadius( ___ ,Name,Value)` specifies options using one or more name-value arguments in addition of the input arguments in previous syntaxes.

Examples

Match Features Between Two Images

Load a MAT file containing an image and camera data into the workspace.

```
data = load('matchInRadiusData.mat');
```

Convert the camera pose to extrinsics.

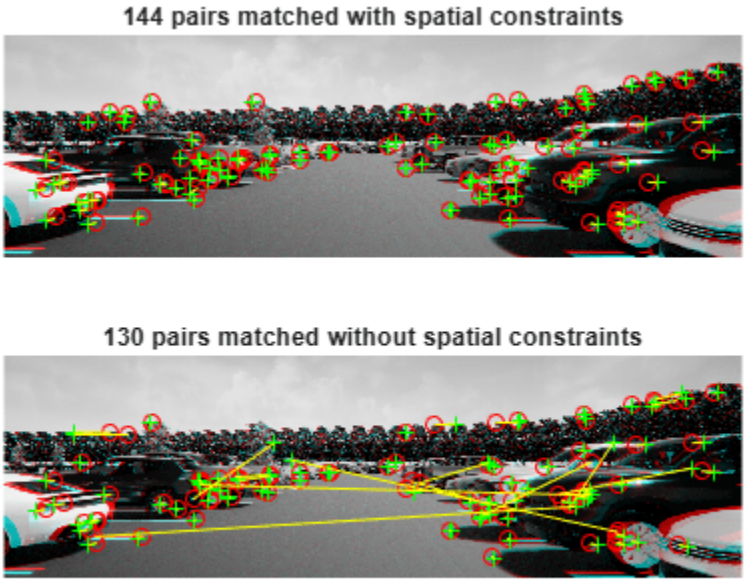
```
orientation = data.cameraPose2.Rotation;
location = data.cameraPose2.Translation;
[rotationMatrix,translationVector] = cameraPoseToExtrinsics(orientation,location);
```

Project the 3-D world points associated with feature set one onto the second image.

```
centerPoints = worldToImage(data.intrinsics,rotationMatrix,translationVector,data.worldPoints);
```

Match features between the two feature sets within spatial constraints.

```
indexPairs1 = matchFeaturesInRadius(data.features1,data.features2, ...
        data.points2,centerPoints,data.radius,'MatchThreshold',40, ...
        'MaxRatio',0.9);
```



Match features between the two feature sets without using spatial constraints.

```
indexPairs2 = matchFeatures(data.features1,data.features2, ...
        'MatchThreshold',40,'MaxRatio',0.9);
```

Visualize and compare the results between the two ways of matching features.

```
figure
subplot(2,1,1)
showMatchedFeatures(data.I1,data.I2,data.points1( ...
    indexPairs1(:,1)),data.points2(indexPairs1(:,2)));
title(sprintf('%d pairs matched with spatial constraints',size(indexPairs1,1)));

subplot(2,1,2)
showMatchedFeatures(data.I1,data.I2,data.points1( ...
    indexPairs2(:,1)),data.points2(indexPairs2(:,2)));
title(sprintf('%d pairs matched without spatial constraints',size(indexPairs2,1)));
```

Input Arguments

`features1` — Feature set one

`binaryFeatures` object | *M*1-by-*N* matrix

Feature set one, specified as a `binaryFeatures` object or an *M*1-by-*N* matrix. The matrix contains *M*1 features, and *N* corresponds to the length of each feature vector.

You can obtain the `binaryFeatures` object using the `extractFeatures` function with the fast retina keypoint (FREAK), oriented fast and rotated brief (ORB), or binary robust invariant scalable keypoints (BRISK) descriptor method.

Data Types: `logical` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `single` | `double` | `binaryFeature object`

`features2` — Feature set two

*M*2-by-*N* matrix | `binaryFeatures` object

Feature set two, specified as a `binaryFeatures` object or an *M*2-by-*N* matrix. The matrix contains *M*2 features, and *N* corresponds to the length of each feature vector.

You can obtain the `binaryFeatures` object using the `extractFeatures` function with the fast retina keypoint (FREAK), oriented fast and rotated brief (ORB), or binary robust invariant scalable keypoints (BRISK) descriptor method.

Data Types: `logical` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `single` | `double` | `binaryFeature object`

`points2` — Feature points of feature set two
*M*2-by-2 matrix | *M*2-element feature point array

Feature points of feature set two, specified as either an *M*2-by-2 matrix in the format [*x y*] or an *M*2-element feature point array. For a list of point feature types, see “Point Feature Types”.

Data Types: `single` | `double` | `point feature type`

`centerPoints` — Expected matched locations
*M*1-by-2 matrix

Expected matched locations in the second image that correspond to the feature points from `features1`, specified as an *M*1-by-2 matrix of coordinates in the format [*x y*].

Data Types: `single` | `double`

`radius` — Search radius associated with center points
scalar | *M*1-element vector

Search radius associated with the center points, specified as a scalar or an *M*1-element vector. When you specify the `radius` as a scalar value, the function uses the same search radius for all center points.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'Metric','SSD'` specifies the sum of squared differences metric for feature matching.

`MatchThreshold` — Matching threshold
`10.0` or `1.0` (default) | scalar value in the range (0, 100]

Matching threshold, specified as a scalar value in the range (0,100]. The default values are `10.0` for binary feature vectors or `1.0` for nonbinary feature vectors. You can use the matching threshold to select the strongest matches. The threshold represents a percent of the distance from a perfect match.

Two feature vectors match when the distance between them is less than the threshold set by '`MatchThreshold`'. The function rejects a match when the distance between the features is greater than the value of '`MatchThreshold`'. Increase the value to return more matches.

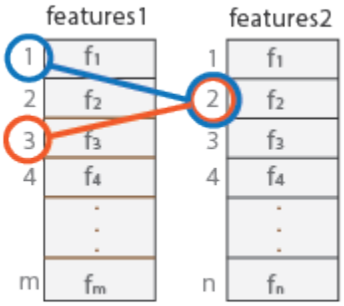
Inputs that are `binaryFeatures` objects typically require a larger value for the match threshold. The `extractFeatures` function returns a `binaryFeatures` object when extracting FREAK, ORB, or BRISK descriptors.

`MaxRatio` — Ratio threshold
`0.6` (default) | scalar value in the range (0, 1]

Ratio threshold, specified as a scalar value in the range (0, 1]. Use the ratio to reject ambiguous matches. Increase this value to return more matches.

`Metric` — Feature matching metric
`'SSD'` (default) | `'SAD'`

Feature matching metric, specified as either `'SAD'` or `'SSD'`.



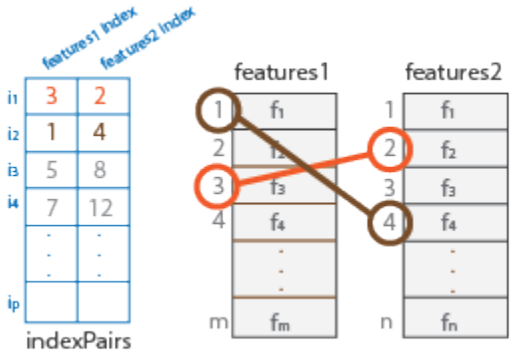
`'SAD'`	Sum of absolute differences
`'SSD'`	Sum of squared differences

This property applies when you specify the input feature sets, `features1` and `features2`, as matrices. When you specify the features as `binaryFeatures` objects, the function uses the Hamming distance to compute the similarity metric.

`Unique` — Unique matches
`false` or `0` (default) | `true` or `1`

Unique matches, specified as a logical `0` (`false`) or `1` (`true`). Set this value to `true` to return only unique matches between `features1` and `features2`.

When you set `Unique` to `false`, the function returns all matches between `features1` and `features2`. Multiple features in `features1` can match to one feature in `features2`.



When you set `Unique` to `true`, the function performs a forward-backward match to select a unique match. After matching `features1` to `features2`, it matches `features2` to `features1` and keeps the best match.

Output Arguments

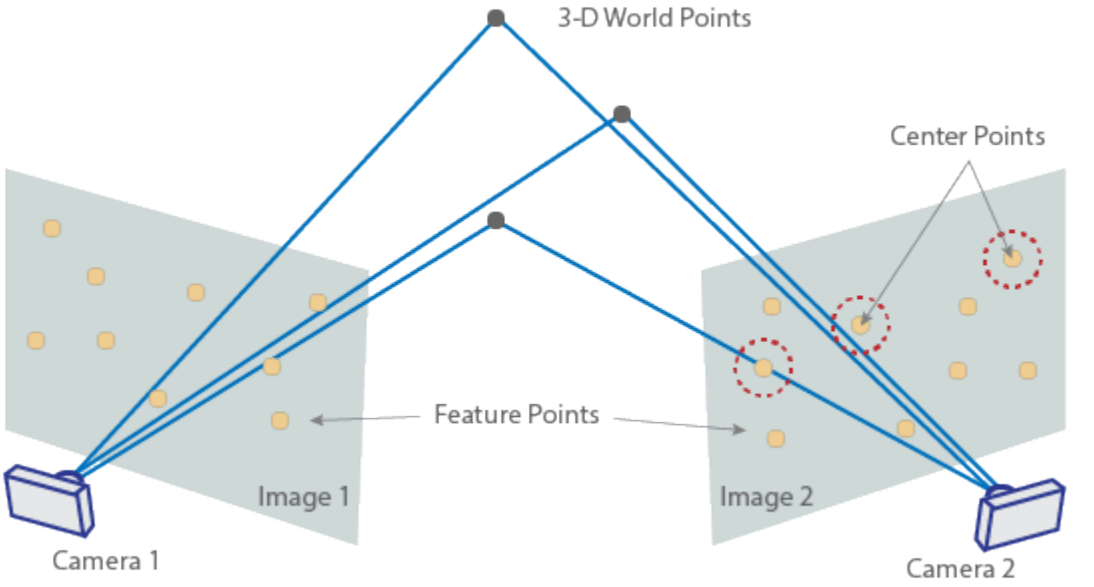
`indexPairs` — Indices of corresponding features
P-by-2 matrix

Indices of corresponding features between the two input feature sets, returned as a *P*-by-2 matrix. *P* is the number of matched pairs of features. Each index pair corresponds to a matched feature between

the `features1` and `features2` inputs. The first element indexes the feature in `features1`. The second element indexes the matching feature in `features2`.

`matchMetric` — Distance between matching features
P-by-1 vector

Distance between matching features, returned as a *P*-by-1 vector. The *i*th element in `matchMetric` corresponds to the *i*th row in the `indexPairs` output matrix. The values of the distances are based on the metric selected, but a perfect match is always `0`. When `Metric` is set to either `SAD` or `SSD`, the feature vectors are normalized to unit vectors before computation. The function returns `matchMetric` as a `double` data type when `features1` and `features2` are of type `double`. Otherwise, the returned vector is of type `single`.



Metric	Range
SAD	`[0, 2*sqrt(size(features1,2))]`.
SSD	`[0, 4]`
Hamming	`[0, features1.NumBits]`

Note You cannot select the Hamming metric. The metric is selected automatically when the `features1` and `features2` inputs are `binaryFeatures`.

Data Types: `single` | `double`

Tips

- Use this function when the 3-D world points that correspond to feature set one `features1`, are known. `centerPoints` can be obtained by projecting a 3-D world point onto the second image. You can obtain the 3-D world points by triangulating matched image points from two stereo images.
- You can specify a circular area of points in feature set two to match with feature set one. Specify the origin as `centerPoints` with a radius specified by `radius`. Specify the points to match from feature set two as `points2`

mrdivide, /

Transformation or rotation right division

Syntax

```
transformationC = transformationA/transformationB
rotationC = rotationA/rotationB
```

Description

`transformationC = transformationA/transformationB` right divides transformation `transformationA` by transformation `transformationB` and returns the quotient, transformation `transformationC`. `transformationC` is the same value as `transformationA*inv(transformationB)`.

You can use division to compose a sequence of transformations, so that `transformationC` represents a transformation where the inverse of `transformationB` is applied first, followed by `transformationA`.

`rotationC = rotationA/rotationB` right divides transformation `rotationA` by transformation `rotationB` and returns the quotient, transformation `rotationC`. `rotationC` is the same value as `rotationA*inv(rotationB)`.

Input Arguments

`transformationA` — First transformation

`se3` object | *N*-element array of transformation objects

First transformation, specified as a scalar `se3` object or as an *N*-element array of transformation objects. *N* is the total number of transformations.

If you specify `transformationA` as an array, each element must be of the same type.

Either `transformationA` or `transformationB` must be a scalar transformation object of the same type. For example, if `transformationA` is an array of `se3` objects, `transformationB` must be a scalar `se3` object.

`transformationB` — Last transformation

`se3` object | *N*-element array of transformation objects

Last transformation, specified as a scalar `se3` object or as an *N*-element array of transformation objects. *N* is the total number of transformations.

If you specify `transformationB` as an array, each element must be of the same type.

Either `transformationA` or `transformationB` must be a scalar transformation object of the same type. For example, if `transformationA` is an array of `se3` objects, `transformationB` must be a scalar `se3` object.

`rotationA` — First rotation
`so3` object | *N*-element array of rotation objects

First rotation, specified as a scalar `so3` object or as an *N*-element array of rotation objects. *N* is the total number of rotations.

If you specify `rotationA` as an array, each element must be of the same type.

Either `rotationA` or `rotationB` must be a scalar rotation object of the same type. For example, if `rotationA` is an array of `so3` objects, `rotationB` must be a scalar `so3` object.

`rotationB` — Last rotation
`so3` object | *N*-element array of rotation objects

Last rotation, specified as a scalar `so3` object or as an *N*-element array of rotation objects. *N* is the total number of rotations.

If you specify `rotationB` as an array, each element must be of the same type.

Either `rotationA` or `rotationB` must be a scalar rotation object of the same type. For example, if `rotationA` is an array of `se3` objects, `rotationB` must be a scalar `se3` object.

Output Arguments

`transformationC` — Transformation quotient
`se3` object | *N*-element array of transformation objects

Transformation quotient, returned as a scalar `se3` object or as an *N*-element array of the same transformation type as `transformationA` and `transformationB`. *N* is the length of the longer argument between `transformationA` and `transformationB` and each row represents the quotient between `transformationA` and `transformationB`.

`rotationC` — Rotation quotient
`so3` object | *N*-element array of rotation objects

Rotation quotient, returned as a scalar `so3` object or as an *N*-element array of the same rotation type as `rotationA` and `rotationB`. *N* is the length of the longer argument between `rotationA` and `rotationB` and each row represents the quotient between `rotationA` and `rotationB`.

Objects
`se3` | `so3`

mtimes, *

Transformation or rotation multiplication

Syntax

```
transformationC = transformationA*transformationB
rotationC = rotationA*rotationB
```

Description

`transformationC = transformationA*transformationB` performs transformation multiplication between transformation `transformationA` and transformation `transformationB` and returns the product, transformation `transformationC`.

You can use transformation multiplication to compose a sequence of transformations, so that `transformationC` represents a transformation where `transformationB` is applied first, followed by `transformationA`.

`rotationC = rotationA*rotationB` performs rotation multiplication between rotation `rotationA` and rotation `rotationB` and returns the product, rotation `rotationC`.

You can use rotation multiplication to compose a sequence of rotations, so that `rotationC` represents a rotation where `rotationB` is applied first, followed by `rotationA`.

Input Arguments

`transformationA` — First transformation

`se3` object | *N*-element array of transformation objects

First transformation, specified as a scalar `se3` object or as an *N*-element array of transformation objects. *N* is the total number of transformations.

If you specify `transformationA` as an array, each element must be of the same type.

Either `transformationA` or `transformationB` must be a scalar transformation object of the same type. For example, if `transformationA` is an array of `se3` objects, `transformationB` must be a scalar `se3` object.

`transformationB` — Last transformation

`se3` object | *N*-element array of transformation objects

Last transformation, specified as a scalar `se3` object or as an *N*-element array of transformation objects. *N* is the total number of transformations.

If you specify `transformationB` as an array, each element must be of the same type.

Either `transformationA` or `transformationB` must be a scalar transformation object of the same type. For example, if `transformationA` is an array of `se3` objects, `transformationB` must be a scalar `se3` object.

`rotationA` — First rotation
`so3` object | *N*-element array of rotation objects

First rotation, specified as a scalar `so3` object or as an *N*-element array of rotation objects. *N* is the total number of rotations.

If you specify `rotationA` as an array, each element must be of the same type.

Either `rotationA` or `rotationB` must be a scalar rotation object of the same type. For example, if `rotationA` is an array of `so3` objects, `rotationB` must be a scalar `so3` object.

`rotationB` — Last rotation
`so3` object | *N*-element array of rotation objects

Last rotation, specified as a scalar `so3` object or as an *N*-element array of rotation objects. *N* is the total number of rotations.

If you specify `rotationB` as an array, each element must be of the same type.

Either `rotationA` or `rotationB` must be a scalar rotation object of the same type. For example, if `rotationA` is an array of `se3` objects, `rotationB` must be a scalar `se3` object.

Output Arguments

`transformationC` — Transformation product
`se3` object | *N*-element array of transformation objects

Transformation product, returned as a scalar `se3` object or as an *N*-element array of the same transformation type as `transformationA` and `transformationB`. *N* is the length of the longer argument between `transformationA` and `transformationB` and each row represents the product between `transformationA` and `transformationB`.

`rotationC` — Rotation product
`so3` object | *N*-element array of rotation objects

Rotation product, returned as a scalar `so3` object or as an *N*-element array of the same rotation type as `rotationA` and `rotationB`. *N* is the length of the longer argument between `rotationA` and `rotationB` and each row represents the product between `rotationA` and `rotationB`.

normalize

Normalize transformation or rotation matrix

Syntax

```
transformationN = normalize(transformation)
rotationN = normalize(rotation)
___ = normalize( ___ ,Method=normMethod)
```

Description

`transformationN = normalize(transformation)` normalizes the rotation of the transformation `transformation` and returns a transformation, `transformationN`, that is equivalent to `transformation`, but with normalized rotation.

`rotationN = normalize(rotation)` normalizes the rotation of the rotation `rotation` and returns a rotation, `rotationN`, that is equivalent to `rotation`, but with normalized rotation.

Note The transformation and rotation objects do not automatically normalize their rotations. You must use `normalize` each time you need to normalize a transformation or rotation. You may need to do this if:

- You specified an unnormalized input transformation or rotation at the creation of the transformation or rotation object.
- You performed many operations on the transformation or rotation objects such as `mtimes, *`, which may cause the transformation or rotation to become unnormalized due to data type precision.

`___ = normalize( ___ ,Method=normMethod)` specifies the normalization method `normMethod` that the `normalize` function uses to normalize the specified transformation or rotation.

Input Arguments

`transformation` — Transformation

`se3` object | *N*-element array of transformation objects

Transformation, specified as a scalar `se3` object or an *N*-element array of transformation objects. *N* is the total number of transformations.

If you specify `transformation` as an array, each element must be of the same type.

`rotation` — Rotation

`so3` object | *N*-element array of rotation objects

Rotation, specified as a scalar `so3` object or as an *N*-element array of rotation objects. *N* is the total number of rotations.

If you specify `rotation` as an array, each element must be of the same type.

`normMethod` — Normalization method
`"quat"` (default) | `"cross"` | `"svd"`

Normalization method, specified as one of these options:

- `"quat"` — Convert the rotation submatrix into a normalized quaternion and then convert the normalized quaternion back to a transformation or rotation object. For more information, see the `normalize` of the `quaternion` object.
- `"cross"` — Normalize the third column of the rotation submatrix and then determine the other two columns through cross products.
- `"svd"` — Use singular value decomposition to find the closest orthonormal matrix by setting singular values to `1`. This solves the orthogonal Procrustes problem.

Data Types: `char` | `string`

Output Arguments

`transformationN` — Normalized transformation
`se3` object

Normalized transformation, returned as an `se3` object.

`rotationN` — Normalized rotation
`so3` object

Normalized rotation, returned as an `so3` object.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

ocrTrainingData

Create training data for OCR from ground truth

Syntax

```
[imds,boxds,txtds] = ocrTrainingData(gTruth,labelName,attributeName)
```

Description

`[imds,boxds,txtds] = ocrTrainingData(gTruth,labelName,attributeName)` creates datastores for loading images, bounding boxes, and image text from ground truth.

`ocrTrainingData` creates training data that you can use to train and evaluate an optical character recognition (OCR) model from ground truth data. Use the `trainOCR` function to train an OCR model and the `evaluateOCR` function to evaluate the model.

Examples

Analyze OCR Ground Truth Data

This example shows how to analyze an OCR ground truth data to identify its character set and to understand the class distribution.

Load the ground truth data and then extract text labels.

```
ld = load("14SegmentGtruth.mat");
gTruth = ld.gTruth;
[~,~,txtds] = ocrTrainingData(gTruth,"Text","Word");
```

Read all ground truth text corresponding to each image and combine them.

```
allImagesText = txtds.readall;
allText = strjoin([allImagesText{:}], "");
```

Find the unique set of characters in the ground truth text.

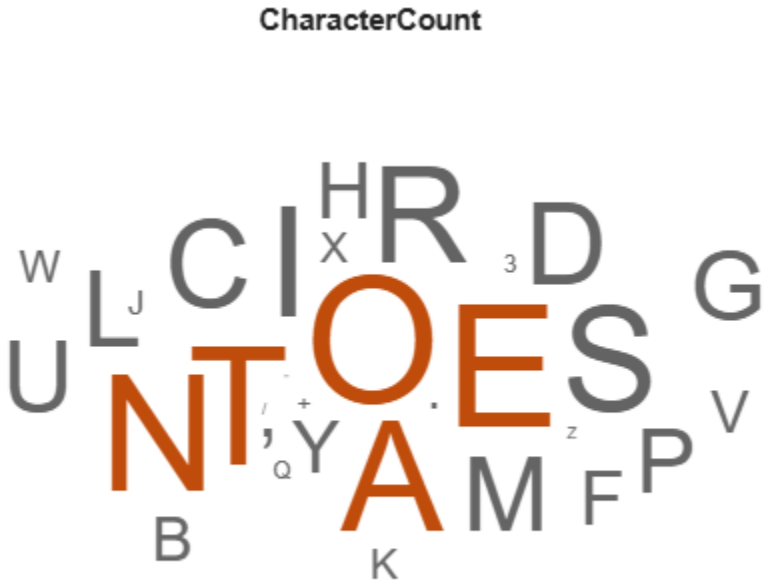
```
[characterSet, ~, idx] = unique(char(allText));
```

Display the ground truth character set.

```
disp("Ground Character Set: " + string(characterSet))
```

```
Ground Character Set: +,-./3ABCDEFGHIJKLMNOPQRSTUVWXYZ
```

The ground truth data contains all the 26 alphabets of English language in capital case, the digit 3 and five special characters: +,-./.

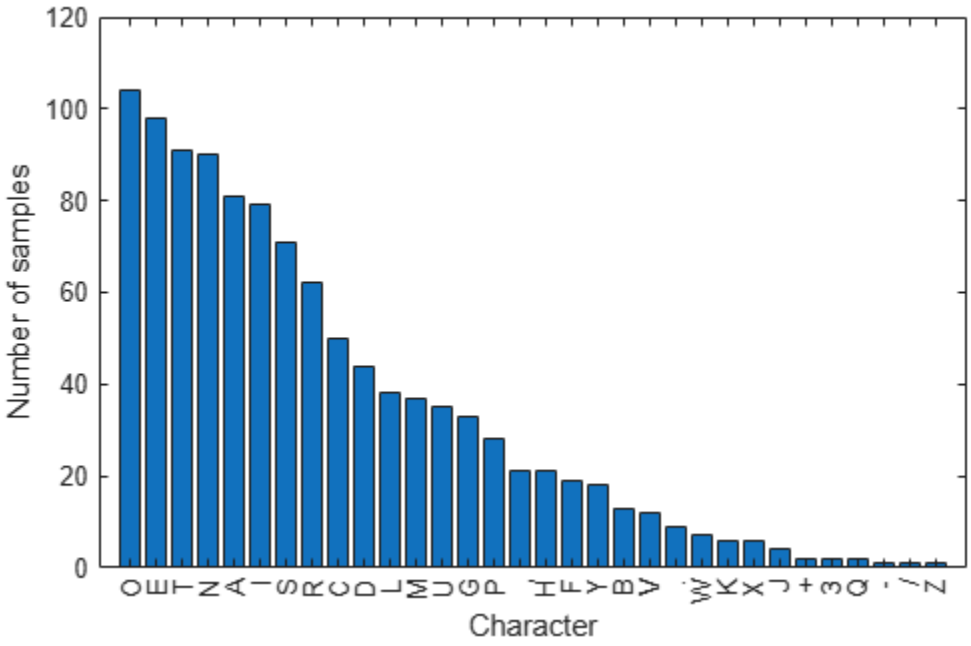


To understand the class distribution, count the character occurrences and tabulate the character count.

```
characterSet = cellstr(characterSet');
characterCount = accumarray(idx,1);
```

```
characterCountTbl = table(characterSet, characterCount, ...
    VariableNames=["Character", "CharacterCount"]);
characterCountTbl = sortrows(characterCountTbl, ...
    "CharacterCount", "descend");
```

Visualize the character count with a word cloud chart.

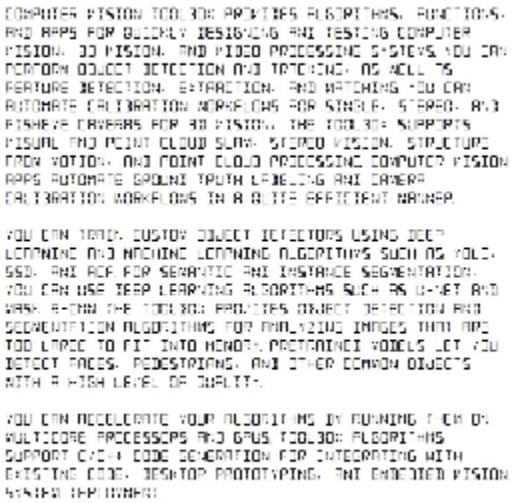


```
wordcloud(characterCountTbl, "Character", "CharacterCount")
```

The characters O, E, T, N and A have the highest character count and the characters -, +, /, . , 3 have the least character count.

Visualize the class distribution with a bar graph.

```
figure
numCharacters = numel(characterSet);
bar(1:numCharacters, characterCountTbl.CharacterCount)
xticks(1:numCharacters)
xticklabels(characterCountTbl.Character)
xlabel("Character")
ylabel("Number of samples")
```



Prepare Data for OCR Training

This example shows preparing data to train an OCR model that can recognize fourteen-segment characters.

The training data contains word samples of fourteen-segment characters from a page of text. Read the training image and display it.

```
I = imread("CVT-DSEG14.jpg");
imshow(I)
```

This image was annotated with bounding boxes containing words and text labels were added to these bounding boxes as an attribute using the Image Labeler. To learn more about labeling images for OCR training, see “Train Custom OCR Model”. The labels were exported from the app as groundTruth object and saved in 14SegmentGtruth.mat file.

```
ld = load("14SegmentGtruth.mat");
gTruth = ld.gTruth;
```

Create datastores that contain images, bounding boxes and text labels from the `groundTruth` object using the `ocrTrainingData` function with the label and attribute names used during labeling.

```
labelName = "Text";
attributeName = "Word";
[imds,boxds,txtds] = ocrTrainingData(gTruth,labelName,attributeName);
```

Combine the datastores.

```
cds = combine(imds,boxds,txtds);
```

The combined datastore can be used for training an OCR model using the `trainOCR` function.

Input Arguments

`gTruth` — Ground truth data

`groundTruth` object | *M*-by-1 array of `groundTruth` objects

Ground truth data, specified as a `groundTruth` object or an *M*-by-1 array of `groundTruth` objects exported from the Image Labeler app.

`labelName` — Name of rectangular ROI label

string scalar | character vector

Name of the rectangular ROI label used for labeling ground truth, specified as a string scalar or character vector. You must use the `Rectangle` label type for OCR ground truth labeling.

Use the Image Labeler app to label ground truth data. After loading your images into the app, select **Label** from the toolbar, then select `Rectangle`. A dialog box appears that provides the field for entering the label name.

`attributeName` — Attribute name
string scalar | character vector

Attribute name that corresponds to the label name, specified as a string scalar or character vector. The attribute identifies what the OCR detects in the specified ROI `labelName`. For example, `word`. To name an attribute in Image Labeler, after creating the ROI, select **Attribute** from the toolbar. A dialog box appears that provides the field for entering the attribute name.

Output Arguments

`imds` — Image datastore
`imageDatastore` object

Image datastore, returned as an `imageDatastore` object that contains images extracted from specified `groundTruth` object or objects.

`boxds` — Bounding box label datastore
`arrayDatastore` object

Bounding box label datastore associated with the ground truth images, returned as an `arrayDatastore` object.

`txtds` — Text label datastore
`arrayDatastore` object

Text label datastore that corresponds to the attribute name input, returned as an `arrayDatastore` object.

evaluateOCR

Evaluate OCR results against ground truth

Syntax

```
metrics = evaluateOCR(resultTxt,groundTruthTxt)
metrics = evaluateOCR( ___ ,Name=Value)
```

Description

`metrics = evaluateOCR(resultTxt,groundTruthTxt)` evaluates the optical character recognition (OCR) results `resultTxt` against the ground truth `groundTruthTxt`. The function evaluates the quality of the OCR results by computing the character error rate and word error rate metrics across images and the entire data set.

`metrics = evaluateOCR( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `Metrics="word-error-rate"` specifies to evaluate results using only the word error rate metric.

Examples

Evaluate Accuracy of OCR Model

This example shows how to evaluate the accuracy of an OCR model that can recognize seven-segment numerals on a dataset. The evaluation dataset contain images of energy meter displays that have seven-segment numerals in them.

Download and extract dataset.

```
datasetURL = "https://ssd.mathworks.com/supportfiles/vision/data/7SegmentImages.zip";
datasetZip = "7SegmentImages.zip";
if ~exist(datasetZip,"file")
    disp("Downloading evaluation dataset (" + datasetZip + " - 96 MB) ...");
    websave(datasetZip,datasetURL);
end

datasetFiles = unzip(datasetZip);
```

Load the evaluation ground truth.

```
ld = load("7SegmentGtruth.mat");
gTruth = ld.gTruth;
```

Create datastores that contain images, bounding boxes and text labels from the `groundTruth` object using the `ocrTrainingData` function with the label and attribute names used during labeling.

```
labelName = "Text";
attributeName = "Digits";
[imds,boxds,txtds] = ocrTrainingData(gTruth,labelName,attributeName);
```

Combine the datastores.

```
cds = combine(imds,boxds,txtds);
```

Run OCR on the evaluation dataset.

```
results = ocr(cds, Model="seven-segment");
```

Evaluate the OCR results against the ground truth.

```
metrics = evaluateOCR(results,cds);
```

```
Evaluating ocr results
----------------------
* Selected metrics: character error rate, word error rate.
* Processed 119 images.
* Finalizing... Done.
* Data set metrics:

    CharacterErrorRate    WordErrorRate
    __________________    _____________

         0.082195             0.19958
```

Display accuracy of the OCR model.

```
modelAccuracy = 100*(1-metrics.DataSetMetrics.CharacterErrorRate);
disp("Accuracy of the OCR model= " + modelAccuracy + "%")
```

```
Accuracy of the OCR model= 91.7805%
```

Input Arguments

`resultTxt` — Prediction from OCR model

`ocrText` object | datastore

Prediction from OCR model, specified as a cell array of `ocrText` objects, or any datastore object that returns a cell array with at least two elements, such that the last two cells contain:

- Cell 1 — *N*-by-4 matrix, where *N* is the number of ROIs [in the original ground truth data.] text line bounding boxes.
- Cell 2 — *N*-element vector of strings, where *N* is the number of ROIs [in the original ground truth data.] of text predictions.

If specified as a cell array, `resultTxt` must contain one element for each image in the original ground truth data.

`groundTruthTxt` — Ground truth text

datastore object

Ground truth text, specified as a datastore object that returns a cell array with at least two elements, such that the last two cells contain:

- Cell 1 — *N*-by-4 matrix, where *N* is the number of ROIs [in the original ground truth data.] text line bounding boxes.
- Cell 2 — *N*-element vector of strings, where *N* is the number of ROIs [in the original ground truth data.] of text predictions.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `metrics = evaluateOCR(resultTxt,groundTruthTxt,Metrics="word-error-rate")` specifies to evaluate results using only the word error rate metric.

`Metrics` — Metrics to compute
`"all"` (default) | `"word-error-rate"` | `"character-error-rate"`

Metrics to compute, specified as `"all"`, `"word-error-rate"`, or `"character-error-rate"`.

`Verbose` — Progress information display
`true` or `1` (default) | `false` or `0`

Progress information display, specified as a numeric or logical `1` (`true`) or `0` (`false`).

Output Arguments

`metrics` — OCR metrics
`ocrMetrics` object

OCR metrics, returned as an `ocrMetrics` object.

Tips

- Error rates are a percentage of characters (words) in the input `groundTruthTxt` that have been incorrectly predicted in `resultTxt`.
- To compute the number of incorrect predictions to use in the error rate calculation, the function uses the Levenshtein distance, which is defined as the minimum number of edits (such as insertions, deletions, or substitutions) required to change one word (or sentence) into another one.

  Error rate = $(S + D + I)/N$ where,

  - S — Number of substitutions
  - D — Number of deletions
  - I — Number of insertions
  - N — Maximum number of characters (words) between `groundTruthTxt` or `resultTxt`

quantizeOCR

Quantize OCR model

Syntax

```
outputFileName = quantizeOCR(inputFileName,outputModelName)
outputFileName = quantizeOCR( ___ ,OutputLocation=location)
```

Description

`outputFileName = quantizeOCR(inputFileName,outputModelName)` quantizes the specified optical character recognition (OCR) model `inputFileName` and stores it in the present working directory, specified by `outputModelName`.

`quantizeOCR` quantizes the weights of an OCR model to produce a new OCR model that is faster and use less memory, but at the cost of reduced accuracy in results.

`outputFileName = quantizeOCR( ___ ,OutputLocation=location)` specifies the location to store the returned quantized model, in addition to the input arguments from the previous syntax.. By default, `location` is set to the present working directory. Specify `location` as a character vector or string scalar of the absolute or relative path for the desired output location

Examples

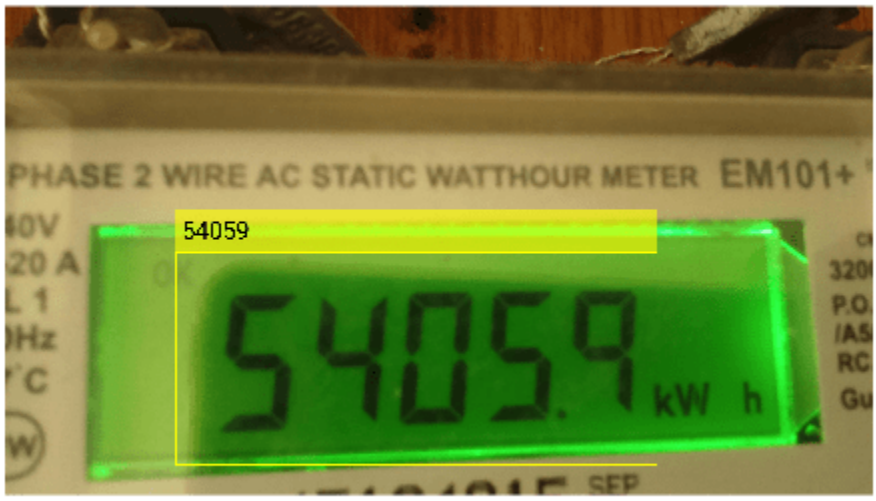
Quantize OCR Model

This example shows how to quantize the seven-segment OCR model that ships with the Computer Vision Toolbox™.

Specify the fullpath to the OCR model.

```
model = fullfile(toolboxdir("vision"),"visionutilities",...
    "tessdata_best","seven_segment.traineddata");
```

Specify a filename to save the quantized OCR model.



```
outputModelName = "quantizedModel";
```

Quantize the OCR model.

```
outputModel = quantizeOCR(model,outputModelName);
```

Use the quantized model to perform OCR on a test image and visualize the results.

```
I = imread("sevSegDisp.jpg");
roi = [506 725 1418 626];
ocrResults = ocr(I,roi,Model=outputModel,LayoutAnalysis="block");
Iocr = insertObjectAnnotation(I,"rectangle",...
            ocrResults.WordBoundingBoxes,ocrResults.Words,...
            LineWidth=5,FontSize=72);
imshow(Iocr)
```

Improve Runtime Performance of OCR Model with Quantization

This example shows how to improve runtime performance of an OCR model with quantization. This can be useful when deploying an OCR model in resource constrained systems.

Specify the fullpath to the OCR model.

```
originalModel = fullfile(toolboxdir("vision"),"visionutilities",...
    "tessdata_best","seven_segment.traineddata");
```

Specify a filename to save the quantized OCR model.

```
outputModelName = "quantizedModel";
```

Quantize the OCR model.

```
quantizedModel = quantizeOCR(originalModel,outputModelName);
```

Compare the runtime performance of the quantized model against the original model.

```
I = imread("sevSegDisp.jpg");
roi = [506 725 1418 626];
fOCR = @() ocr(I, roi, Model=originalModel, LayoutAnalysis="block");
tOCR = timeit(fOCR);

fQuantizedOCR = @() ocr(I, roi, Model=quantizedModel, LayoutAnalysis="block");
tQuantizedOCR = timeit(fQuantizedOCR);

perfRatio = tOCR/tQuantizedOCR;
disp("Quantized model is " + perfRatio + "x faster");
```

```
Quantized model is 1.7521x faster
```

Compare file size of the quantized model with that of the original model.

```
originalModelFile     = dir(originalModel);
originalModelFileSizeInMB = originalModelFile.bytes/1000000;

quantizedModelFile     = dir(quantizedModel);
quantizedModelFileSizeInMB = quantizedModelFile.bytes/1000000;

sizeRatio = originalModelFileSizeInMB/quantizedModelFileSizeInMB;
disp("Quantized model is " + sizeRatio + "x smaller");
```

```
Quantized model is 7.8483x smaller
```

While the quantized model is smaller and faster than the original model, these advantages of quantization comes at the expense of accuracy. To understand this trade-off, compare the accuracy of the two models by evaluating them against the YUVA EB dataset.

Download the dataset.

```
datasetURL = "https://ssd.mathworks.com/supportfiles/vision/data/7SegmentImages.zip";
datasetZip = "7SegmentImages.zip";
if ~exist(datasetZip,"file")
    disp("Downloading evaluation data set (" + datasetZip + " - 96 MB)...");
    websave(datasetZip,datasetURL);
end
```

```
Downloading evaluation data set (7SegmentImages.zip - 96 MB)...
```

```
datasetFiles = unzip(datasetZip);
```

Load ground truth to be used for evaluation.

```
ld = load("7SegmentGtruth.mat");
gTruth = ld.gTruth;
```

Create datastores that contain images, bounding boxes and text labels from the `groundTruth` object using the `ocrTrainingData` function with the label and attribute names used during labeling.

```
labelName = "Text";
attributeName = "Digits";
[imds,boxds,txtds] = ocrTrainingData(gTruth,labelName,attributeName);
cds = combine(imds,boxds,txtds);
```

Run the two models on the dataset and evaluate recognition accuracy using `evaluateOCR`.

```
originalResult  = ocr(cds, Model=originalModel);
quantizedResult = ocr(cds, Model=quantizedModel);

metricsOriginal = evaluateOCR(originalResult, cds);
```

```
Evaluating ocr results

    91.7805    86.9816
    11.2969     1.4394
     0.1057     0.0604
```

Input Arguments

`inputFileName` — Name of OCR model file

string scalar | character vector

Name of the OCR model file, specified as a string scalar or a character vector. If `inputFileName` does not include the full path, the function searches for the file in the current folder and along the MATLAB path. If you do not specify a file extension, the function appends `.traineddata`.

`outputModelName` — Output quantized model name

string scalar | character vector

Output quantized model name, specified as a string scalar or character vector.

Output Arguments

`outputFileName` — Name of quantized OCR model file
string scalar | character vector

Name of quantized OCR model file, specified as a string scalar or character vector.

quat

Convert transformation or rotation to numeric quaternion

Syntax

```
q = quat(transformation)
q = quat(rotation)
```

Description

`q = quat(transformation)` creates a quaternion `q` from the rotation of the transformation `transformation`.

`q = quat(rotation)` creates a quaternion `q` from the rotation `rotation`.

Examples

Convert SE(3) Transformation to Numeric Quaternion

Create SE(3) transformation with zero translation and a rotation defined by a numeric quaternion.

```
quat1 = [0.9659 0.2588 0 0]
```

```
quat1 = 1×4

    0.9659    0.2588         0         0
```

```
T = se3(quat1,"quat")
```

```
T = se3
    1.0000         0         0         0
         0    0.8660   -0.5000         0
         0    0.5000    0.8660         0
         0         0         0    1.0000
```

Convert the transformation back into a numeric quaternion.

```
quat2 = quat(T)
```

```
quat2 = 1×4

    0.9659    0.2588         0         0
```

Convert SO(3) Rotation to Numeric Quaternion

Create SO(3) rotation defined by a numeric quaternion. Use the `eul2quat` function to create the numeric quaternion.

```
quat1 = [0.9659 0.2588 0 0]
```

```
quat1 = 1×4

    0.9659    0.2588         0         0
```

```
R = so3(quat1,"quat")
```

```
R = so3
    1.0000         0         0
         0    0.8660   -0.5000
         0    0.5000    0.8660
```

Convert the rotation into a numeric quaternion.

```
quat2 = quat(R)
```

```
quat2 = 1×4

    0.9659    0.2588         0         0
```

Input Arguments

`transformation` — Transformation

`se3` object | *N*-element array of `se3` objects

Transformation, specified as an `se3` object or as an *N*-element array of `se3` objects. *N* is the total number of transformations.

`rotation` — Rotation

`so3` object | *N*-element array of `so3` objects

Rotation, specified as an `so3` object or as an *N*-element array of `so3` objects. *N* is the total number of rotations.

Output Arguments

`q` — Quaternion rotation angles

M-by-4 matrix

Quaternion rotation angles, returned as an *M*-by-4 matrix, where each row is of the form [*qw qx qy qz*]. *M* is the total number of transformations or rotations specified.

See Also

`se3` | `so3` | `quaternion`

trainOCR

Train OCR model to recognize text in image

Syntax

```
modelFileName = trainOCR(trainingData,modelName,baseModel,ocrOptions)
[modelFileName,info] = trainOCR( ___ )

[modelFileName,info] = trainOCR(trainingData,modelName,checkpoint,ocrOptions)
```

Description

Training

`modelFileName = trainOCR(trainingData,modelName,baseModel,ocrOptions)` trains a new OCR model by fine-tuning a pretrained base model using the hyperparameters specified in `ocrOptions`.

`[modelFileName,info] = trainOCR( ___ )` returns a structure that contains information on training progress, such as the training root mean squared error (RMSE) and learning rate for each iteration, using the input arguments from the previous syntax. For a list of the returned error rates, see the modelFileName on page 3-0 output argument.

Resume training

`[modelFileName,info] = trainOCR(trainingData,modelName,checkpoint,ocrOptions)` resumes training from an OCR training checkpoint. Use this syntax to improve the accuracy of your OCR model by using additional training data or to perform more training iterations.

Examples

Train OCR Model

This example shows how to train an OCR model that can recognize fourteen-segment characters. The training data contains word samples of fourteen-segment characters.

Unzip and extract training images.

```
datasetZip = 'dseg14.zip';
evalfiles = unzip(datasetZip);
```

The training images was annotated with bounding boxes containing words and text labels were added to these bounding boxes as an attribute using the Image Labeler. The labels were exported from the app as `groundTruth` object and saved in dseg14Gtruth.mat file.

```
ld = load("dseg14Gtruth.mat");
gTruth = ld.gTruth;
```

Create datastores that contain images, bounding boxes and text labels from the `groundTruth` object using the `ocrTrainingData` function with the label and attribute names used during labeling.

```
labelName = "Text";
attributeName = "Word";
[imds,boxds,txtds] = ocrTrainingData(gTruth,labelName,attributeName);
```

Combine the datastores.

```
cds = combine(imds,boxds,txtds);
```

Split the data for training and validation with a training-to-validation ratio of 0.9

```
% Set the random number seed for reproducibility.
rng(0);

% Compute number of training and validation samples.
trainingToValidationRatio = 0.9;
numSamples = height(ld.gTruth.LabelData);
numTrainSamples = ceil(trainingToValidationRatio*numSamples);

% Divide the dataset into training and validation.
indices = randperm(numSamples);
trainIndices = indices(1:numTrainSamples);
validationIndices = indices(numTrainSamples+1:end);

cdsTrain = subset(cds, trainIndices);
cdsValidation = subset(cds, validationIndices);
```

Specify training options. Set the gradient decay factor for ADAM optimization to 0.9, and use an initial learning rate of 40e-4. Set the verbose frequency to 160 iterations and the maximum number of epochs for training to 5. Specify the checkpoint path to enable saving checkpoints and specify the validation data to enable validation.

```
outputDir = "OCRModel";
if ~exist(outputDir, "dir")
    mkdir(outputDir);
end

checkpointsDir = "Checkpoints";
if ~exist(checkpointsDir, "dir")
    mkdir(checkpointsDir);
end

ocrOptions = ocrTrainingOptions(GradientDecayFactor=0.9, ...
    InitialLearnRate=40e-4, MaxEpochs=5, VerboseFrequency=160, ...
    CheckpointPath=checkpointsDir, ValidationData=cdsValidation, ...
    OutputLocation=outputDir);
```

Train a new OCR model by fine-tuning the pretrained "english" model. The training will take about 3-4 minutes.

```
outputModelName = "fourteenSegment";
baseModel = "english";
outputModel = trainOCR(cdsTrain, outputModelName, baseModel, ocrOptions);
```

```
*************************************************************************
Starting OCR training

Model Name: fourteenSegment
Base Model: english
```

OCR training complete.
Exit condition: Reached maximum epochs.

Model file name: OCRModel\fourteenSegment.traineddata
************************************************************************
```

Use the trained model to perform OCR on a test image and visualize the results.

```
I = imread("DSEG14.png");
ocrResults = ocr(I,Model=outputModel);
Iocr = insertObjectAnnotation(I,"rectangle",...
            ocrResults.WordBoundingBoxes,ocrResults.Words,...
            LineWidth=2,FontSize=17);
imshow(Iocr)
```

Input Arguments

`trainingData` — Ground truth data

datastore

Ground truth data, specified as a `datastore` that returns a cell array or a table when input to the `read` function. The table must contain at least these three columns:

- 1st column — A cell vector of logical, grayscale, or RGB images.
- 2nd column — A cell vector in which each cell corresponds to an image and contains an *M*-by-4 matrix. *M* is the number of bounding boxes in the image, and each row of the matrix specifies a bounding box in the form [*x*,*y*,*width*,*height*]. cell vector that contains *M*-by-4 matrices with *M* bounding boxes of the form [*x*,*y*,*width*,*height*].
- 3rd column — A cell vector in which each cell corresponds to an image and contains *N* strings. *N* is the number of lines of text in the image, and each line must contain only text without newline characters.

`modelName` — New model name

string scalar | character vector

New model name, specified as a string scalar or character vector. If the folder already contains a file with the name specified by the `modelName` argument, then the `trainOCR` function overwrites it during training.

`baseModel` — Pretrained base model

string scalar | character vector

Pretrained base model, specified as a string scalar or character vector. You can specify any of these options:

- Language models shipped in the Computer Vision Toolbox, such as `"english"`, `"seven-segment"`, or `"japanese"`.
- One of the supported languages described in the “`Model” on page 3-0` argument of the `ocr` function. You cannot use quantized models, such as `"english-fast"`, `"seven-segment-fast"`, or `"japanese-fast"`, as base models.
- Full path to a custom trained model with a `.traineddata` extension.

`ocrOptions` — Hyperparameters for training

`ocrTrainingOptions` object

Hyperparameters for training, specified as an `ocrTrainingOptions` object.

`checkpoint` — OCR training checkpoint

string scalar | character vector | `CheckpointPath`

OCR training checkpoint, specified as a string scalar or character vector. You must specify a path to a file with a `.checkpoint.traineddata` extension, such as the path specified by the `CheckpointPath` property of an `ocrTrainingOptions` object. When you specify a value for the `CheckpointPath` argument of an `ocrTrainingOptions` object, the `trainOCR` function saves checkpoints at regular intervals during training. You can resume training from any one of these saved checkpoints.

Output Arguments

`modelFileName` — Model filename
string scalar

Model filename, returned as a string scalar.

`info` — Information on training progress
structure

Information on training progress, returned as a structure containing these fields:

- `BaseLearnRate` — Learning rate at each iteration.
- `TrainingRMSE` — Training RMSE at each iteration.
- `TrainingCharError` — Training character error rate at each iteration.
- `TrainingWordError` — Training word error rate at each iteration.
- `ValidationRMSE` — Validation RMSE at each iteration.
- `ValidationCharError` — Validation character error rate at each iteration.
- `ValidationWordError` — Validation word error rate at each iteration.
- `FinalValidationRMSE` — Final validation RMSE at the end of the training.
- `OutputModelIteration` — Iteration number of the returned model.

If you do not specify validation data , the structure contains empty `ValidationRMSE`, `ValidationCharError`, `ValidationWordError`, and `FinalValidationRMSE` fields.

Limitations

- Training OCR models with right-to-left scripts such as Arabic and Hebrew are not supported.

Algorithms

- The `trainOCR` function creates a temporary folder, "`<`*`modelName`*`>Training/`, where `<`*`modelName`*`>` is the value of the `modelName` argument, in the location specified by the `OutputLocation` property of the `ocrTrainingOptions` object. The folder contains training artifacts. If the folder does not already exist before you run the `trainOCR` function, the function deletes it at the end of training. If the folder already exists prior to training, the function does not delete the folder.
- Images read from `trainingData` must contain text of at least one-word length and up to a maximum of one-line length. The `trainOCR` function does not support images that contain multiple lines of text.
- The `trainOCR` function does not support on-the-fly data augmentation using a datastore transform. All the image data is read once from the training datastores at the start of training.

Version History

Introduced in R2023a

R2025a: MATLAB Compiler support will be removed
Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

ocr

Recognize text using optical character recognition

Syntax

```
txt = ocr(I)
txt = ocr(I,roi)
txt = ocr(ds)
txt = ocr( ___ ,Name=Value)
```

Description

`txt = ocr(I)` returns an `ocrText` object that contains optical character recognition (OCR) information from the input image `I`. The object contains recognized characters, words, text lines, the locations of recognized words, and a metric indicating the confidence of each recognition result.

`txt = ocr(I,roi)` recognizes text in `I` within one or more rectangular regions.

`txt = ocr(ds)` returns a cell array of `ocrText` objects, each containing the recognition results for the ROIs specified in the datastore, `ds`, for the corresponding image. Use this syntax to perform OCR on a collection of images. By default, the `ocr` function assumes that each ROI contains only a single line of text. To process ROIs that may contain multiple lines of text, set the `LayoutAnalysis` name-value argument to `"block"`.

`txt = ocr( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `LayoutAnalysis="page"` treats the image as a page containing blocks of text.

Examples

Recognize Text Within an Image

Load an image with text into workspace.

```
businessCard = imread("businessCard.png");
ocrResults = ocr(businessCard)
```

```
ocrResults =
  ocrText with properties:

                     Text: '4 MathWorks:↵↵ ↵↵The MathWorks, Inc.↵↵-3 Apple Hill Drive↵Natick, MA
    CharacterBoundingBoxes: [107×4 double]
      CharacterConfidences: [107×1 single]
                     Words: {16×1 cell}
         WordBoundingBoxes: [16×4 double]
           WordConfidences: [16×1 single]
                 TextLines: {8×1 cell}
     TextLineBoundingBoxes: [8×4 double]
       TextLineConfidences: [8×1 single]
```

```
recognizedText = ocrResults.Text;
figure
imshow(businessCard)
text(600,150,recognizedText,BackgroundColor=[1 1 1]);
```

Recognize Text in Regions of Interest (ROIs)

Read an image into the workspace.

```
I = imread("handicapSign.jpg");
```

Define one or more rectangular regions of interest in which to recognize text within input image.

```
roi = [370 246 363 423];
```

Alternatively, you can use `drawrectangle` to select a region using a mouse.

For example,

```
figure;imshow(I)
```

```
roi = round(getPosition(drawrectangle))
```

Recognize text within the ROI.

```
ocrResults = ocr(I,roi);
```

Insert the recognized text into the original image. Display the image with the inserted recognized text.

```
Iocr = insertText(I,roi(1:2),ocrResults.Text,AnchorPoint="RightTop",FontSize=16);
figure
imshow(Iocr)
```

Recognize Digits from Seven-Segment Display

Read an image containing a seven-segment display into the workspace.

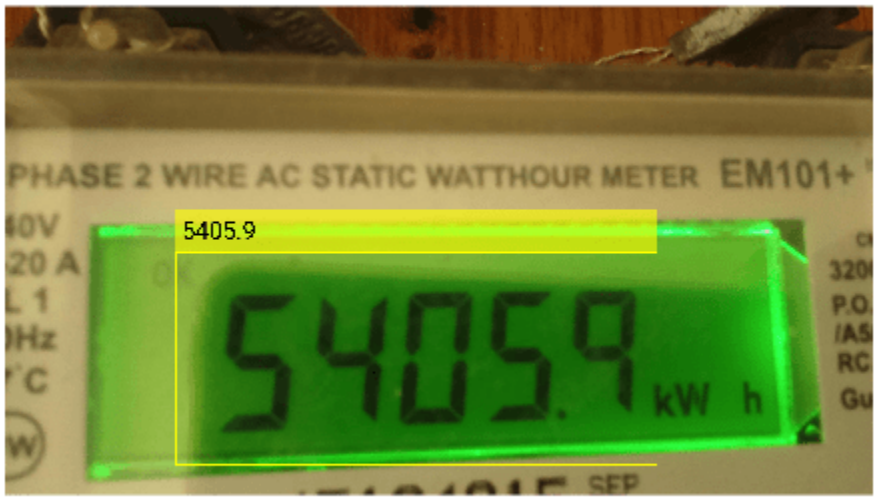
```
I = imread("sevSegDisp.jpg");
```

Specify the ROI that contains the seven-segment display.

```
roi = [506 725 1418 626];
```

To recognize the digits from the seven-segment display, specify the Model argument as "`seven-segment`".

```
ocrResults = ocr(I,roi,Model="seven-segment");
```



Display the recognized digits and detection confidence.

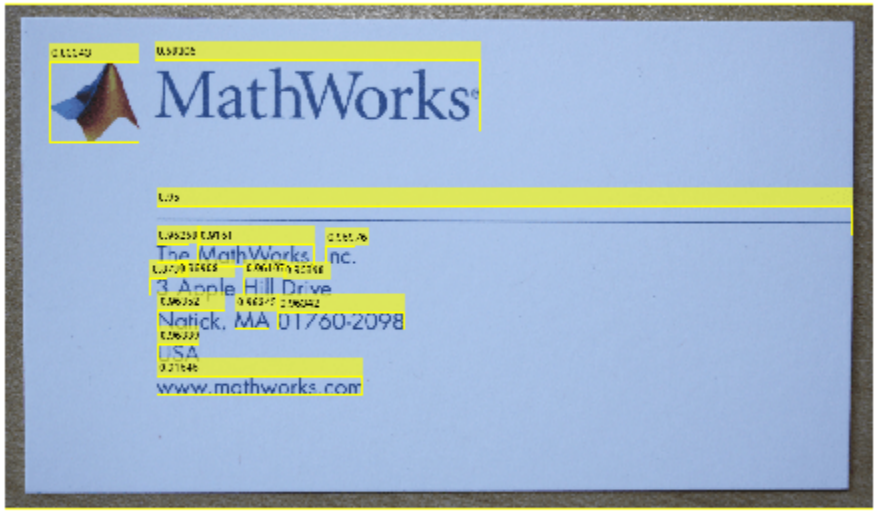
```
fprintf("Recognized seven-segment digits: ""%s""\nDetection confidence: %0.4f",cell2mat(ocrResul
```

```
Recognized seven-segment digits: "5405.9"
Detection confidence: 0.7948
```

Insert the recognized digits into the image.

```
Iocr = insertObjectAnnotation(I,"rectangle", ...
            ocrResults.WordBoundingBoxes,ocrResults.Words,LineWidth=5,FontSize=72);
figure
imshow(Iocr)
```

Display Bounding Boxes of Words and Recognition Confidences



Read an image containing text into the workspace.

```
businessCard = imread("businessCard.png");
ocrResults = ocr(businessCard)
```

```
ocrResults =
  ocrText with properties:

                     Text: '4 MathWorks:↵↵ ↵↵The MathWorks, Inc.↵↵-3 Apple Hill Drive↵Natick, MA
    CharacterBoundingBoxes: [107×4 double]
      CharacterConfidences: [107×1 single]
                     Words: {16×1 cell}
         WordBoundingBoxes: [16×4 double]
           WordConfidences: [16×1 single]
                 TextLines: {8×1 cell}
     TextLineBoundingBoxes: [8×4 double]
       TextLineConfidences: [8×1 single]
```

```
Iocr = insertObjectAnnotation(businessCard,"rectangle", ...
                              ocrResults.WordBoundingBoxes, ...
                              ocrResults.WordConfidences);
figure
imshow(Iocr)
```

Find and Highlight Text in Image

Load an image containing text into the workspace.

```
businessCard = imread("businessCard.png");
ocrResults = ocr(businessCard);
bboxes = locateText(ocrResults,"Math",IgnoreCase=true);
Iocr = insertShape(businessCard,"FilledRectangle",bboxes);
figure
imshow(Iocr)
```

Evaluate Accuracy of OCR Model

This example shows how to evaluate the accuracy of an OCR model that can recognize seven-segment numerals on a dataset. The evaluation dataset contain images of energy meter displays that have seven-segment numerals in them.

Download and extract dataset.

```
datasetURL = "https://ssd.mathworks.com/supportfiles/vision/data/7SegmentImages.zip";
datasetZip = "7SegmentImages.zip";
if ~exist(datasetZip,"file")
    disp("Downloading evaluation dataset (" + datasetZip + " - 96 MB) ...");
    websave(datasetZip,datasetURL);
end

datasetFiles = unzip(datasetZip);
```

Load the evaluation ground truth.

```
ld = load("7SegmentGtruth.mat");
gTruth = ld.gTruth;
```

Create datastores that contain images, bounding boxes and text labels from the `groundTruth` object using the `ocrTrainingData` function with the label and attribute names used during labeling.

```
labelName = "Text";
attributeName = "Digits";
[imds,boxds,txtds] = ocrTrainingData(gTruth,labelName,attributeName);
```

Combine the datastores.

```
cds = combine(imds,boxds,txtds);
```

Run OCR on the evaluation dataset.

```
results = ocr(cds, Model="seven-segment");
```

Evaluate the OCR results against the ground truth.

```
metrics = evaluateOCR(results,cds);
```

```
Evaluating ocr results
----------------------
* Selected metrics: character error rate, word error rate.
* Processed 119 images.
* Finalizing... Done.
* Data set metrics:

    CharacterErrorRate    WordErrorRate
    __________________    _____________

         0.082195             0.19958
```

Display accuracy of the OCR model.

```
modelAccuracy = 100*(1-metrics.DataSetMetrics.CharacterErrorRate);
disp("Accuracy of the OCR model= " + modelAccuracy + "%")
```

```
Accuracy of the OCR model= 91.7805%
```

Input Arguments

`I` — Input image

M-by-*N*-by-3 truecolor image | *M*-by-*N* 2-D grayscale image | *M*-by-*N* binary image

Input image, specified as an *M*-by-*N*-by-3 truecolor image, *M*-by-*N* grayscale, or *M*-by-*N* binary image. The input image must consist of real, nonsparse values. The function converts truecolor or grayscale input images into a binary image using Otsu's thresholding technique, before performing character recognition. For best OCR results, specify an image in which the height of a lowercase *x*, or comparable character, is greater than 20 pixels. To improve results, remove any text rotations from the horizontal or vertical axes of greater than 10 degrees in either direction. The input image must be less than 2^16 (32,768) pixels in width or height.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

`roi` — Rectangular regions of interest

M-by-4 element matrix

Rectangular regions of interest, specified as an *M*-by-4 matrix. Each row specifies a region of interest within the input image in the form [*x y width height*], where [*x y*] specifies the upper-left corner location, and [*width height*] specifies the size of the rectangular region of interest, in pixels. Each rectangle must be fully contained within the input image `I`. Before the recognition process, the function uses Otsu’s thresholding technique to convert truecolor and grayscale input regions of interest to binary regions.

To obtain best results when using `ocr` to recognize seven-segment digits, specify an `roi` that encloses only the part of the image that contains seven-segment digits.

ds — Evaluation data
datastore object

Evaluation data, specified as a datastore that returns a cell array or a table when input to the `read` function. The datastore must return a cell array or a table on the `read` functions with at least these two columns:

- 1st Column — A cell vector of logicals, grayscale images, or RGB images.
- 2nd Column — A cell vector that contains *numROIs*-by-4 matrices of bounding boxes of the form [*x y width height*], which specify text locations within each image.

When using a datastore input, the `LayoutAnalysis` name-value argument value must be either `"auto"` or `"none"`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `txt = ocr(I,LayoutAnalysis="page")` treats the text in the image as a page containing blocks of text.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

LayoutAnalysis — Type of layout analysis to perform for text segmentation
`"auto"` (default) | `"page"` | `"block"` | `"line"` | `"word"` | `"character"` | `"none"`

Type of layout analysis to perform for text segmentation, specified as one of these options:

LayoutAnalysis Value	Text Treatment
`"auto"`	If the `Model` argument value is `"seven-segment"`, treats the text in the image as though the `LayoutAnalysis` value is `"block"`. If you specify the `ds` input argument, treats the text in the image as though the `LayoutAnalysis` value is `"none"`. Otherwise, the function treats the text in the image as `"page"`.
`"page"`	Treats the text in the image as a page containing blocks of text.
`"block"`	Treats the text in the image as a single block of text.
`"line"`	Treats the text in the image as a single line of text.
`"word"`	Treats the text in the image as a single word of text.
`"character"`	Treats the text in the image as a single character.
`"none"`	Do not perform layout analysis. Best used for images with a single line of text.

You can use the `LayoutAnalysis` argument to determine the layout of the text within the input image. For example, you can set `LayoutAnalysis` to `"page"` to recognize text from a scanned

document that contains a specific format, such as a double column. This setting preserves the reading order in the returned text.

If your input image contains a few regions of text, or the text is located in a cluttered scene, the `ocr` function can return poor quality results. If you get poor OCR results, try a different layout that better matches the text in your image. If the text is located in a cluttered scene, try specifying an ROI around the text in your image in addition to trying a different layout.

`Model` — Model to use for recognition

`"english"` (default) | `"japanese"` | `"seven-segment"` | `<"ModelName">-fast"` | character vector | string scalar | cell array of character vectors | string array

Model to use for recognition, specified as one of these options;

- `"english"`, `"japanese"`, `"seven-segment"` — These specify the built-in models for detecting English text, Japanese text, or seven-segment digits, respectively.
- Character vector or string scalar — Use this option to specify a custom model or one of the additional language models included in the OCR Language Data Files support package.
- Cell array of character vectors or string array — Use this option to specify multiple models to use for detection simultaneously.

For faster performance using the built-in models (including any additional installed language models), you can append `-fast` to the language model string. For example, `"english-fast"`, `"japanese-fast"`, or `"seven-segment-fast"`.

You can also install additional models or add a custom model. For details, see “Install OCR Language Data Files”.

Specifying multiple languages enables simultaneous recognition of all the selected languages. However, selecting more than one language can reduce the accuracy of the `ocr` function and increase its processing time. To specify any of the additional languages that are contained in the “Install OCR Language Data Files” package, specify them the same way as the built-in languages. You do not need to specify the path. For example, to specify Finnish text recognition:

```
txt = ocr(img,Model="finnish");
```

List of Support Package OCR Languages

- `"afrikaans"`
- `"albanian"`
- `"ancientgreek"`
- `"arabic"`
- `"azerbaijani"`
- `"basque"`
- `"belarusian"`
- `"bengali"`
- `"bulgarian"`
- `"catalan"`
- `"cherokee"`

- "chinesesimplified"
- "chinesetraditional"
- "croatian"
- "czech"
- "danish"
- "dutch"
- "english"
- "esperanto"
- "esperantoalternative"
- "estonian"
- "finnish"
- "frankish"
- "french"
- "galician"
- "german"
- "greek"
- "hebrew"
- "hindi"
- "hungarian"
- "icelandic"
- "indonesian"
- "italian"
- "italianold"
- "japanese"
- "kannada"
- "korean"
- "latvian"
- "lithuanian"
- "macedonian"
- "malay"
- "malayalam"
- "maltese"
- "mathequation"
- "middleenglish"
- "middlefrench"
- "norwegian"
- "polish"
- "portuguese"
- "romanian"

- "russian"
- "serbianlatin"
- "slovakian"
- "slovenian"
- "spanish"
- "spanishold"
- "swahili"
- "swedish"
- "tagalog"
- "tamil"
- "telugu"
- "thai"
- "turkish"
- "ukrainian"

To use your own custom model for a `trainOCR` output, you can use this syntax:

```
ocrResults = ocr(I,Model=ocrModel);
```

where `ocrModel` contains the full path of the model.

For deployment targets generated by MATLAB Coder: The generated OCR executable and language model file folder must be colocated.

- For English: `C:/path/to/eng.traineddata`
- For Japanese: `C:/path/to/jpn.traineddata`
- For Seven-segment: `C:/path/to/seven_segment.traineddata`
- For custom data files: `C:/path/to/customlang.traineddata`
- `C:/path/ocr_app.exe`

You can copy the English, Japanese and seven-segment trained data files from this folder:

```
fullfile(matlabroot,"toolbox","vision","visionutilities","tessdata_best");
```

`CharacterSet` — Character subset

"" (default) | character vector | string scalar

Character subset, specified as a character vector or string scalar. By default, `CharacterSet` is set to the empty character vector `""`, which specifies the function to search for all characters in the language model specified by the `Model` name-value argument. You can set this value to a smaller set of known characters to constrain the classification process.

The `ocr` function selects the best match for detected text from the `CharacterSet`. Using deducible knowledge about the characters in the input image helps to improve text recognition accuracy. For example, if you set `CharacterSet` to all numeric digits, `"0123456789"`, the function attempts to match each character to only digits. In this case, the `ocr` function can incorrectly recognize a non-digit character as a digit.

If you specify the `Model` as `seven-segment`, the `ocr` function uses the `CharacterSet` value `"0123456789.:-"`.

Output Arguments

`txt` — Recognized text and metrics

`ocrText` object | array of `ocrText` objects | cell array of `ocrText` objects

Recognized text and metrics, returned as an `ocrText` object, array of `ocrText` objects, or a cell array of `ocrText` objects. Each object contains the recognized text and the location of the recognized text for an input image, as well as metrics indicating the confidence of the results. Confidence values are in the range [0,1], representing a percent probability. The shape of the `txt` output depends on whether you specify an entire single image or single image with one ROI, a single image with multiple ROIs, or a datastore to the `ocr` function.

Tips

Optical character recognition (OCR) language data files provide pretrained language models for the Tesseract OCR engine, enabling accurate and efficient text extraction in various languages. These files are designed for integration with Computer Vision Toolbox, allowing you to leverage advanced OCR capabilities across multiple languages. For step-by-step guidance on installing these language data files, enabling third-party language support, and using the pretrained models with the `ocr` function for multilingual text recognition, see “Install OCR Language Data Files”. For an overview of OCR workflows and basic usage, see “Getting Started with OCR”.

If your OCR results are not what you expect, try one or more of these options:

- Increase the image size by 2– 4 times.
- If the characters in the image are too close together or their edges are touching, use morphology to thin out the characters. Using morphology to thin out the characters helps create space between them.
- Use binarization to check for non-uniform lighting issues. Use the `graythresh` and `imbinarize` functions to binarize the image. If the characters are not visible in the results of the binarization, then the image has a potential non-uniform lighting issue. Try top-hat filtering, using the `imtophat` function, or other techniques that deal with removing non-uniform illumination.
- Use the `roi` argument to isolate the text. You can specify the `roi` manually or use text detection.
- If your image looks like a natural scene containing words, such as a street scene, rather than a scanned document, try setting the `LayoutAnalysis` argument to either `"Block"` or `"Word"`.
- Ensure that the image contains dark text on a light background. To achieve this, you can binarize the image and invert it before passing it to the `ocr` function.

Version History

Introduced in R2014a

R2024b: Generate optimized C/C++ code using Embedded Coder

Starting in R2024b, you can generate optimized C/C++ code for ARM processors using Embedded Coder.

R2023a: `Language` and `TextLayout` name-value arguments removed

The `Language` and `TextLayout` name-value arguments have been removed. Use the `Model` and `LayoutAnalysis`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- `LayoutAnalysis`, `Model`, and `CharacterSet` must be compile-time constants.
- Generated code for this function requires that the target platform has Tesseract and Leptonica installed. By default, generated code uses precompiled, platform-specific shared libraries. To generate portable code without relying on precompiled libraries, configure MATLAB Coder as follows:

  ```
  cfg = coder.config("lib");
  cfg.TargetLang = "C++";
  cfg.UsePrecompiledLibraries = "Avoid";
  ```

- You can also generate optimized C/C++ code using Embedded Coder, provided Tesseract and Leptonica are installed on the target platform.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

detectTextCRAFT

Detect texts in images by using CRAFT deep learning model

Syntax

```
bboxes = detectTextCRAFT(I)
bboxes = detectTextCRAFT(I,roi)
bboxes = detectTextCRAFT( ___ ,Name=Value)
```

Description

`bboxes = detectTextCRAFT(I)` detects texts in images by using character region awareness for text detection (CRAFT) deep learning model. The `detectTextCRAFT` function uses a pretrained CRAFT deep learning model to detect texts in an image. The pretrained CRAFT model can detect 9 languages that include Chinese, Japanese, Korean, Italian, English, French, Arabic, German, and Bangla (Indian).

Note To use the pretrained CRAFT model, you must install the Computer Vision Toolbox Model for Text Detection. You can download and install the Computer Vision Toolbox Model for Text Detection from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons. To run this function, you will require the Deep Learning Toolbox.

`bboxes = detectTextCRAFT(I,roi)` detects texts within a region-of-interest (ROI) in the image.

`bboxes = detectTextCRAFT( ___ ,Name=Value)` specifies additional options by using name-value pair arguments. You can use the name-value pair arguments to fine-tune the detection results.

Examples

Detect Texts in Images by Using CRAFT Model

Read an input image into the MATLAB workspace.

```
I = imread("handicapSign.jpg");
```

Compute the text detection results by using the `detectTextCRAFT` function. The region and the affinity thresholds are set to default values. The output is a set of bounding boxes that contain the detected text regions.

```
bboxes = detectTextCRAFT(I);
```

Draw the output bounding boxes on the image by using the `insertShape` function.

```
Iout = insertShape(I,"rectangle",bboxes,LineWidth=3);
```

Display the text detection results.

```
figure
imshow(Iout)
```

Detect Texts in ROI by Using CRAFT

Read an input image into the MATLAB workspace.

```
visiondatadir = fullfile(toolboxdir('vision'),'visiondata');
I = imread(fullfile(visiondatadir,'imageSets','books','pairOfBooks.jpg'));
```

Specify a region of interest (ROI) within the input image.

```
roi = [120,80,250,200];
```

Detect texts within the specified ROI by using the `detectTextCRAFT` function. The region and affinity thresholds are set to default values. The output is a set of bounding boxes that contain the detected text regions.

```
bboxes = detectTextCRAFT(I,roi);
```

Draw the ROI and the output bounding boxes on the input image. Display the text detection results.

```
I = insertObjectAnnotation(I,"rectangle",roi,"ROI",Color="green");
Iout = insertShape(I,"rectangle",bboxes,LineWidth=3);
figure
imshow(Iout)
```

Detect Characters by Modifying Affinity Threshold

This example shows how to detect each character in the text regions of an input image by using the CRAFT model. You can achieve this by modifying the affinity threshold. This example also demonstrates the effect of different affinity threshold values on the detection results.

Read an input image into the MATLAB workspace.

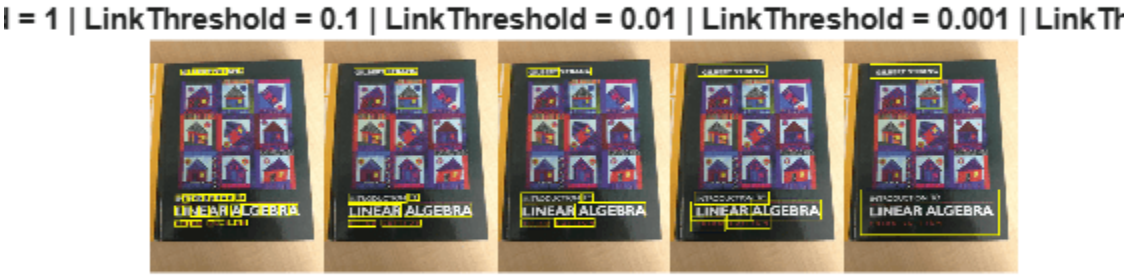
```
visiondatadir = fullfile(toolboxdir('vision'),'visiondata');
I = imread(fullfile(visiondatadir,'bookCovers','book27.jpg'));
```

Specify the affinity threshold values to consider for detecting the text regions in the image.

```
threshold = [1 0.1 0.01 0.001 0.0004];
```

Preallocate a 4-D array `Iout` to store the output image with detection results.

```
Iout = zeros(size(I,1),size(I,2),size(I,3),length(threshold));
```



Compute the output for each affinity threshold value specified at the input. The output is a set of bounding boxes that contain the detected text regions. Draw the output bounding boxes on the image by using the `insertShape` function. The region threshold is set to the default value, 0.4.

```
for cnt = 1:length(threshold)
    bboxes = detectTextCRAFT(I,LinkThreshold=threshold(cnt));
    Iout(:,:,:,cnt) = insertShape(I,"rectangle",bboxes,LineWidth=3);
end
```

Display the text detection results obtained for different values of affinity threshold. You can notice that as the affinity threshold value decrease, the characters with less affinity scores are considered as

connected components and are grouped as a single instance. For good localization and detection results, the affinity threshold must be greater than zero.

```
figure
montage(uint8(Iout),Size=[1 5],BackgroundColor="white");
title(['LinkThreshold = ' num2str(threshold(1)) ' | LinkThreshold = ' num2str(threshold(2)) ' | L
    ' | LinkThreshold = ' num2str(threshold(4)) ' | LinkThreshold = ' num2str(threshold(5))]);
```

Input Arguments

`I` — Input image

2-D grayscale image | 2-D color image

Input image, specified as a 2-D grayscale image or 2-D color image.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

`roi` — Search rectangular region-of-interest

four-element vector

Search a rectangular region-of-interest in an image, specified as a four-element vector of the form [*x y width height*]. The vector specifies the upper left corner and size of a rectangular region in pixels. The region must be fully contained in the image.

When you specify this value, the `detectTextCRAFT` function detects texts that are present only within this ROI.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `bboxes = detectTextCRAFT(I,MaxSize=[10,10])` specifies the maximum size of the text region to detect in the input image

`CharacterThreshold` — Region threshold for characters
0.4 (default) | positive scalar

Region threshold for localizing each character in the image, specified as a positive scalar in the range [0, 1]. To increase the number of detections, lower the region threshold value. However, this will also result in false-positives. To reduce the number of false-positives, increase the region threshold value.

Data Types: `single` | `double`

`LinkThreshold` — Link threshold
0.4 (default) | positive scalar

Link threshold for grouping adjacent characters into a word, specified as a positive scalar in the range [0, 1]. You can increase the number of character level detections by increasing the link threshold. To detect each character in the image, set this value to 1. For good localization and detection results, the link threshold must be greater than zero.

Data Types: `single` | `double`

`MinSize` — Size of smallest detectable text region
[6,6] (default) | two-element vector

Size of smallest detectable text region in the image, specified as a two-element vector of form [*height width*].

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`MaxSize` — Size of largest detectable text region
size of input image (default) | two-element vector

Size of largest detectable text region in the image, specified as a two-element vector of form [*height width*]. By default, this value is set to the height and width of the input image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"cpu"` | `"gpu"`

Hardware resource for processing images with the CRAFT model, specified as `"auto"`, `"gpu"`, or `"cpu"`.

ExecutionEnvironment	Description
`"auto"`	Use a GPU if available. Otherwise, use the CPU. The use of GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
`"gpu"`	Use the GPU. If a suitable GPU is not available, the function returns an error message.
`"cpu"`	Use the CPU.

Data Types: `char` | `string`

`Acceleration` — Performance optimization
`"auto"` (default) | `"mex"` | `"none"`

Performance optimization, specified as `"auto"`, `"mex"`, or `"none"`.

Acceleration	Description
`"auto"`	Automatically apply a number of optimizations suitable for the input network and hardware resource.
`"mex"`	Compile and execute a MEX function. This option is available when using a GPU only. You must also have a C/C++ compiler installed. For setup instructions, see “Set Up Compiler” (GPU Coder).
`"none"`	Disable all acceleration.

The default option is `"auto"`. If you use the `"auto"` option, MATLAB does not ever generate a MEX function.

Using the `"Acceleration"` options `"auto"` and `"mex"` can offer performance benefits, but at the expense of an increased initial run time. Subsequent calls with compatible parameters are faster. Use performance optimization when you plan to call the function multiple times using new input data.

The `"mex"` option generates and executes a MEX function based on the network and parameters used in the function call. You can have several MEX functions associated with a single network at one time. Clearing the network variable also clears any MEX functions associated with that network.

The `"mex"` option is only available when you are using a GPU. Using a GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox). If Parallel Computing Toolbox or a suitable GPU is not available, then the function returns an error.

Output Arguments

`bboxes` — Bounding boxes for detected text regions
M-by-4 matrix

Bounding boxes specifying the detected text regions, returned as an *M*-by-4 matrix. *M* is the number of detected text regions. Each row in the matrix is a vector of form [*x y width height*]. The vector specifies the upper left corner and size of the detected region in pixels.

Version History

Introduced in R2022a

R2024a: Generate CUDA code using GPU Coder

`detectTextCRAFT` now supports the generation of optimized CUDA code (requires GPU Coder).

R2024a: Generate C/C++ code using MATLAB Coder

`detectTextCRAFT` now supports the generation of C/C++ code (requires MATLAB Coder).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `roi` argument must be a code generation constant (`coder.const()`) and a 1-by-4 vector.
- Code generation does not support variable-size data for the input argument `I`.
- Only the `CharacterThreshold`, `LinkThreshold`, `MinSize`, and `MaxSize` name-value arguments are supported.
- When you set `build_type` argument of `coder.config` object to `dll`, for generating code that does not use any third-party library, the `DynamicMemoryAllocationForFixedSizeArrays` property of the `coder.CodeConfig` object must be set to `true`.
- To avoid memory allocation error during library free C++ code generation on Windows platform, the `cfg.DynamicMemoryAllocationForFixedSizeArrays` property of the `coder.CodeConfig` object must be set to `true`.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- The `roi` argument must be a code generation constant (`coder.const()`) and a 1-by-4 vector.
- Code generation does not support variable-size data for the input argument `I`.
- Only the `CharacterThreshold`, `LinkThreshold`, `MinSize`, and `MaxSize` name-value arguments are supported.

pcdenoise

Remove noise from 3-D point cloud

Syntax

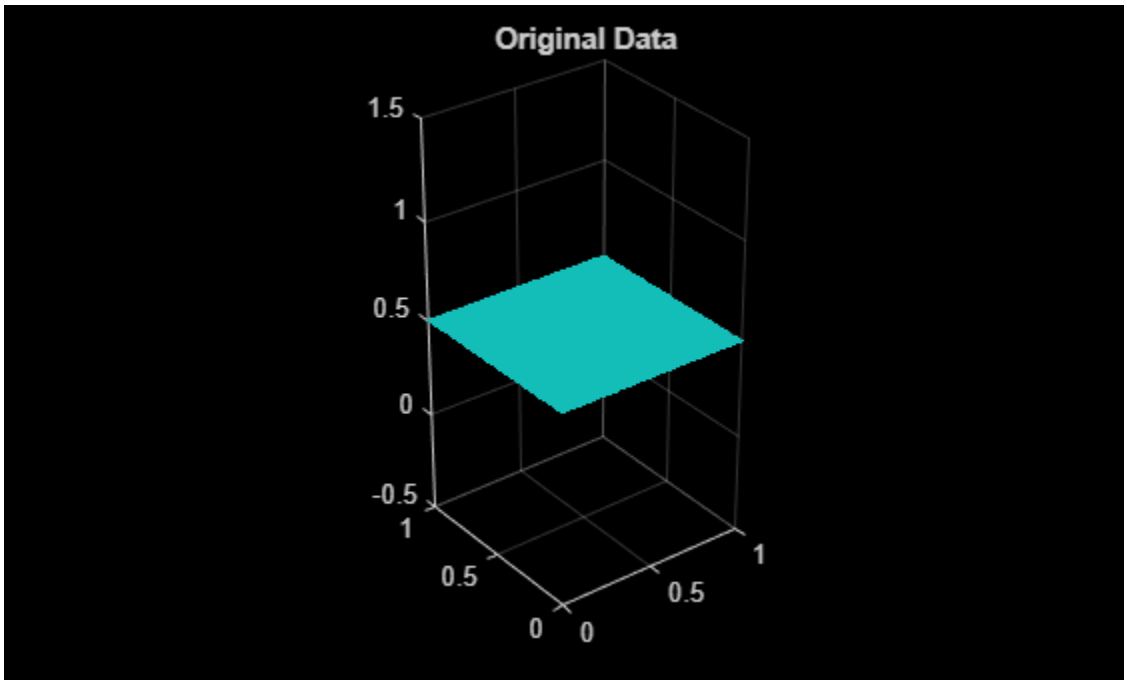
```
ptCloudOut = pcdenoise(ptCloudIn)
[ptCloudOut,inlierIndices,outlierIndices] = pcdenoise(ptCloudIn)
[ptCloudOut, ___ ] = pcdenoise( ___ Name=Value)
```

Description

`ptCloudOut = pcdenoise(ptCloudIn)` returns a filtered point cloud that removes outliers.

`[ptCloudOut,inlierIndices,outlierIndices] = pcdenoise(ptCloudIn)` additionally returns the linear indices to the points that are identified as inliers and outliers.

`[ptCloudOut, ___ ] = pcdenoise( ___ Name=Value)` specifies a name-value argument in addition to any combination of arguments from previous syntaxes. For example, `Threshold=1.0` sets the outlier threshold to `1.0`.



Examples

Remove Outliers from Noisy Point Cloud

Create a plane point cloud.

```
gv = 0:0.01:1;
[X,Y] = meshgrid(gv,gv);
ptCloud = pointCloud([X(:),Y(:),0.5*ones(numel(X),1)]);

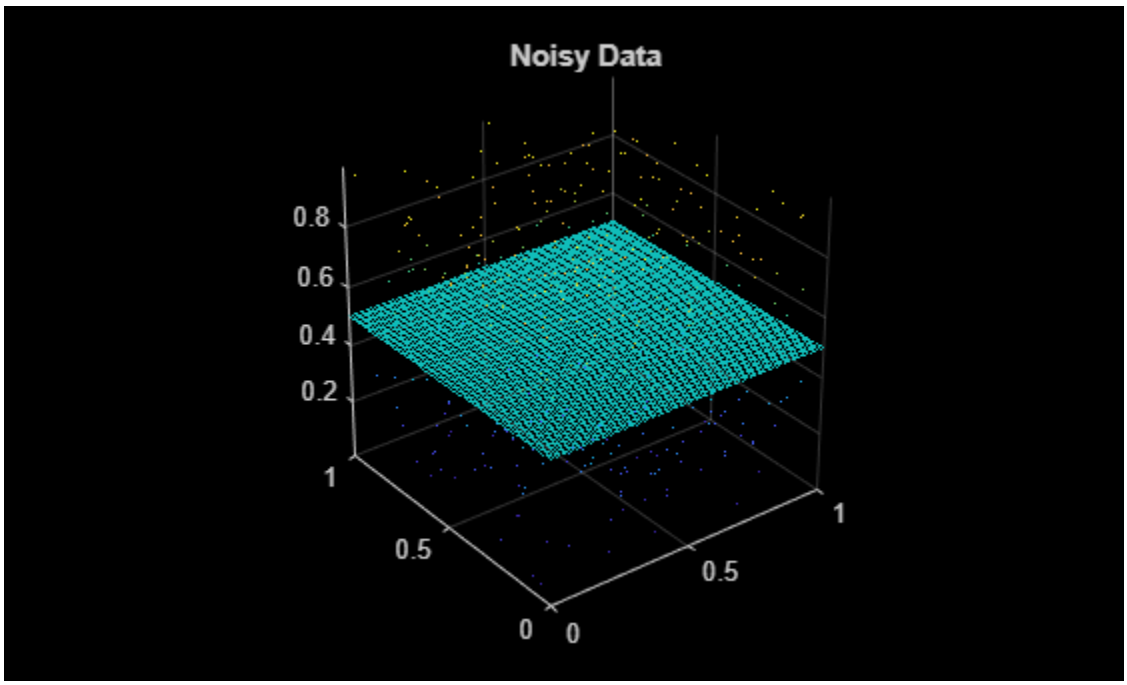


figure
pcshow(ptCloud);
title('Original Data');
```

Add uniformly distributed random noise.

```
noise = rand(500, 3);
ptCloudA = pointCloud([ptCloud.Location; noise]);

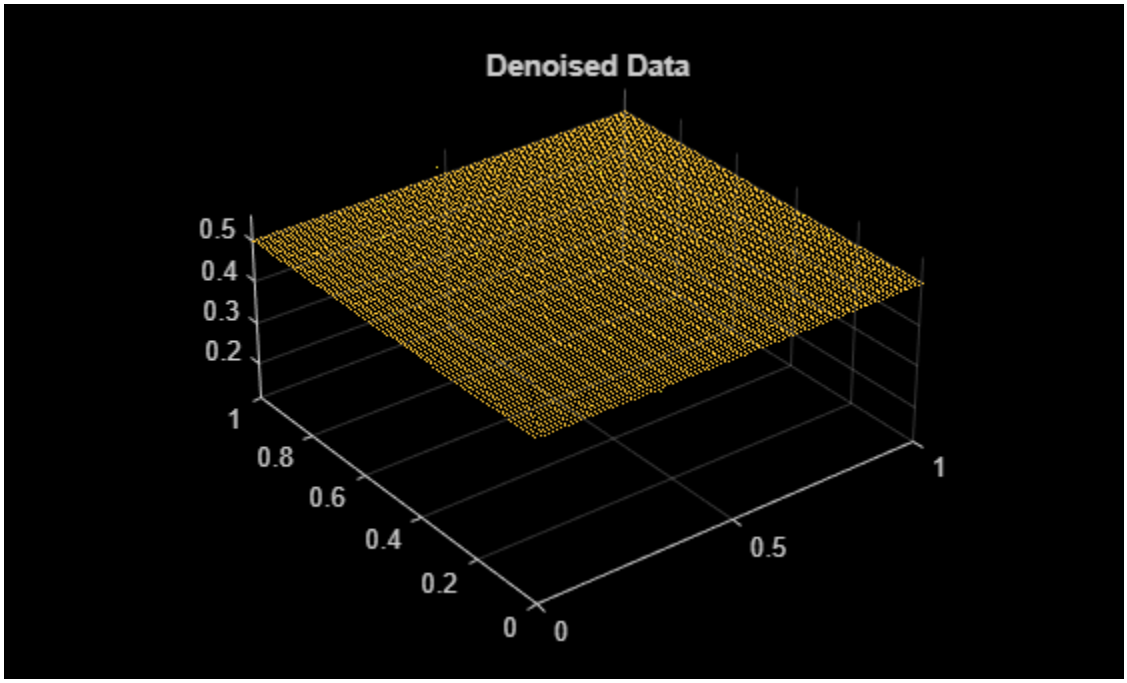


figure
pcshow(ptCloudA);
title('Noisy Data');
```

Remove outliers.

```
ptCloudB = pcdenoise(ptCloudA);

figure;
pcshow(ptCloudB);
title('Denoised Data');
```

Preserve Organized Structure of Point Cloud After Denoising

Load an organized point cloud from a saved MAT file.

```
ld = load('drivingLidarPoints.mat');
orgPtCloud = ld.ptCloud;
```

Remove noise from the point cloud.

```
orgPtCloudOut = pcdenoise(orgPtCloud,PreserveStructure=true);
```

Input Arguments

`ptCloudIn` — Point cloud

`pointCloud` object

Point cloud, specified as a `pointCloud` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Threshold=1.0` sets the threshold to `1.0`.

`NumNeighbors` — Number of nearest neighbor points

4 (default) | positive integer

Number of nearest neighbor points, specified as the comma-separated pair consisting of '`NumNeighbors`' and a positive integer in pixels. The value is used to estimate the mean of the average distance to neighbors of all points. Decreasing this value makes the filter more sensitive to noise. Increasing this value increases the number of computations.

Data Types: `single` | `double`

`Threshold` — Outlier threshold

`1.0` (default) | positive scalar

Outlier threshold, specified as the comma-separated pair consisting of '`Threshold`' and a positive scalar. By default, the threshold is one standard deviation from the mean of the average distance to neighbors of all points. A point is considered to be an outlier if the average distance to its *k*-nearest neighbors is above the specified threshold.

Data Types: `single` | `double`

`PreserveStructure` — Preserve the organized structure of a point cloud

`false` (default) | `true`

Preserve the organized structure of a point cloud as an *M*-by-*N*-by-3 location matrix, specified as `true` or `false`. The table describes the point cloud structure according to the value of `PreserveStructure`.

`PreserveStructure`	The function returns
`true`	An organized, denoised, point cloud. The “Location” on page 2-0 property that describes the structure of the point cloud, contains an *M*-by-*N*-by-3 matrix. Points that are not selected in the denoised point cloud are filled with `NaN`, and the corresponding color is set to `[0 0 0]`. To return an organized point cloud, the input must be an organized point cloud.

PreserveStructure	The function returns
false	An unorganized, denoised, point cloud. The “Location” on page 2-0 property that describes the structure of the point cloud, contains an *M*-by-3 matrix.

Output Arguments

ptCloudOut — Filtered point cloud
pointCloud object

Filtered point cloud, returned as a pointCloud object.

inlierIndices — Linear index of inlier points
1-by-*N* vector

Linear index of inlier points, returned as a 1-by-*N* vector.

Data Types: uint32

outlierIndices — Linear index of outlier points
1-by-*N* vector

Linear index of outlier points, returned as a 1-by-*N* vector.

Data Types: uint32

Version History

Introduced in R2015a

pcmerge

Merge two 3-D point clouds

Syntax

```
ptCloudOut = pcmerge(ptCloudA,ptCloudB,gridStep)
ptCloudOut = pcmerge( ___ ,GridFilter=gridFilterMethod)
```

Description

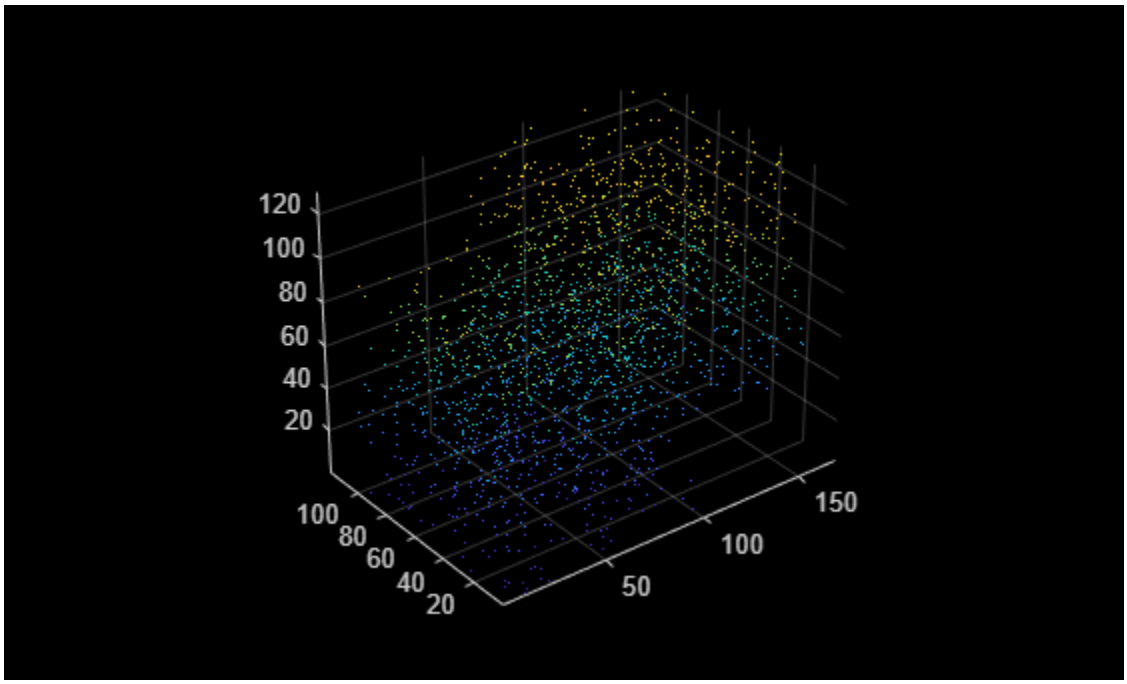
`ptCloudOut = pcmerge(ptCloudA,ptCloudB,gridStep)` returns a merged point cloud using a box grid filter in the region of overlap. `gridStep` specifies the size of the 3-D box for the filter.

`ptCloudOut = pcmerge( ___ ,GridFilter=gridFilterMethod)` sets the method to downsample the region of overlap between the merged point clouds.

Examples

Merge Two Identical Point Clouds Using Box Grid Filter

Create a point cloud with X, Y, Z points in [0, 100].



```
ptCloudA = pointCloud(100*rand(1000,3));
```

Create a partially overlapping point cloud.

```
ptCloudB = pointCloud([70 20 30] + 100*rand(1000,3));
```

Merge the two point clouds using a box filter.

```
ptCloudOut = pcmerge(ptCloudA, ptCloudB, 1);
pcshow(ptCloudOut);
```

Input Arguments

`ptCloudA` — Point cloud A
`pointCloud` object

Point cloud A, specified as a `pointCloud` object.

`ptCloudB` — Point cloud B
`pointCloud` object

Point cloud B, specified as a `pointCloud` object.

`gridStep` — Size of 3-D box for grid filter
positive scalar

Size of 3-D box for grid filter, specified as a positive scalar. Increasing the value of `gridStep` can reduce memory usage by merging more points, but it can also reduce the amount of detail captured. The grid filter returns a single point per 3-D box.

Data Types: `single` | `double`

`gridFilterMethod` — Method to downsample region of overlap
`"average"` | `"nearest"`

Method to downsample region of overlap between the merged point clouds, specified as one of:

- `"average"` (default) — Selects a point in the voxel by averaging the location, color, intensity, and normal of all points within the voxel.
- `"nearest"` — Selects the voxel's location, color, intensity, and normal based on the point nearest to the centroid of the voxel.

Output Arguments

`ptCloudOut` — Merged point cloud

`pointCloud` object

Merged point cloud, returned as a `pointCloud` object. The function computes the axis-aligned bounding box for the overlapped region between two point clouds. The bounding box is divided into grid boxes of the size specified by `gridStep`. Points within each grid box are downsampled using the specified grid filter type. Points outside the overlapped region are untouched.

Tips

- If the two point clouds do not have the same set of properties filled, such as `Color` or `Normal`, these properties will be cleared in the returned point cloud. For example, if `ptCloudA` has color but `ptCloudB` does not, then `ptCloudOut` will not contain color.
- The function filters out points with `NaN` or `Inf` values.

Version History

pcdownsample

Downsample 3-D point cloud

Syntax

```
ptCloudOut = pcdownsample(ptCloudIn,"random",percentage)
ptCloudOut = pcdownsample(ptCloudIn,"gridAverage",gridStep)
ptCloudOut = pcdownsample(ptCloudIn,"gridNearest",gridStep)
ptCloudOut = pcdownsample(ptCloudIn,"nonuniformGridSample",maxNumPoints)

[ptCloudOut,indices] = pcdownsample( ___ )
 ___  = pcdownsample( ___ ,Name=Value)
```

Description

`ptCloudOut = pcdownsample(ptCloudIn,"random",percentage)` returns a downsampled point cloud. Use this syntax for random sampling without replacement. The `percentage` input specifies the portion of the input to return to the output.

`ptCloudOut = pcdownsample(ptCloudIn,"gridAverage",gridStep)` returns a downsampled point cloud using a box grid filter. The `gridStep` input specifies the size of a 3-D box.

`ptCloudOut = pcdownsample(ptCloudIn,"gridNearest",gridStep)` returns a downsampled point cloud by selecting points closest to the centroid in each grid, using a box grid filter. The `gridStep` input specifies the size of a 3-D box.

`ptCloudOut = pcdownsample(ptCloudIn,"nonuniformGridSample",maxNumPoints)` returns a downsampled point cloud using nonuniform box grid filter. You must set the maximum number of points in the grid box, `maxNumPoints`, to at least `6`.

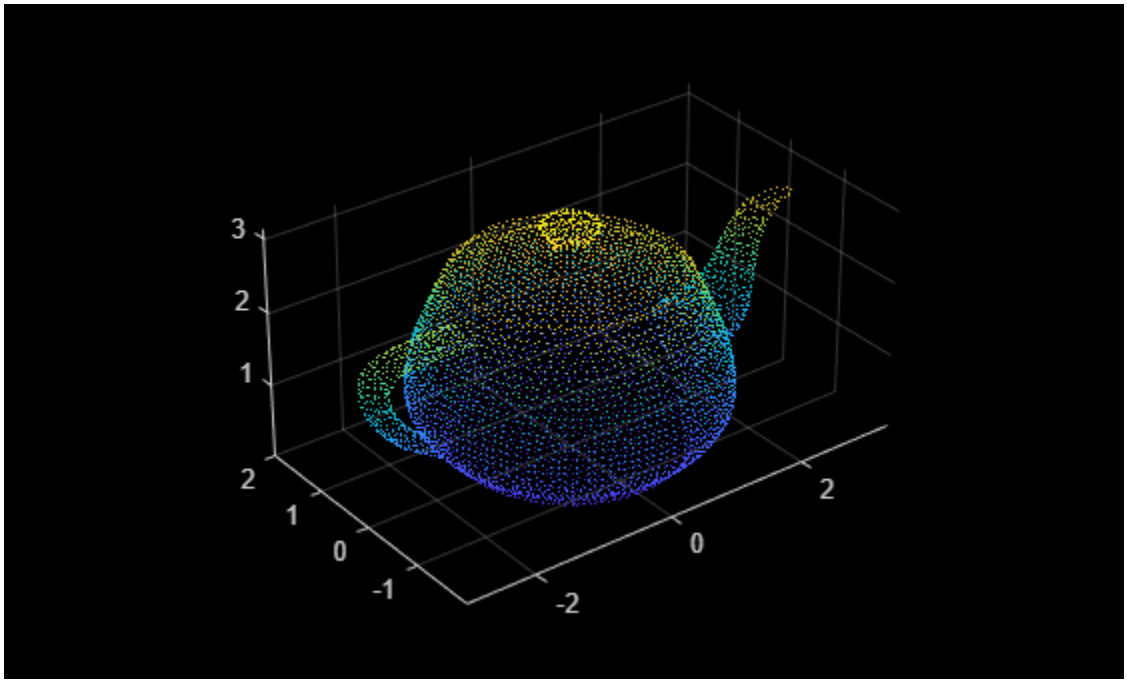
`[ptCloudOut,indices] = pcdownsample( ___ )` returns the linear indices for the points that are included in the downsampled point cloud. This syntax applies only when you use the `"random"`, `"gridNearest"`, or `"nonuniformGridSample"` downsampling methods.

` ___  = pcdownsample( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `pcdownsample(PtCloud,"random",percentage,PreserveStructure=true)` preserves the organized structure of a point cloud.

Examples

Downsample Point Cloud Using Box Grid Filter

Read a point cloud.



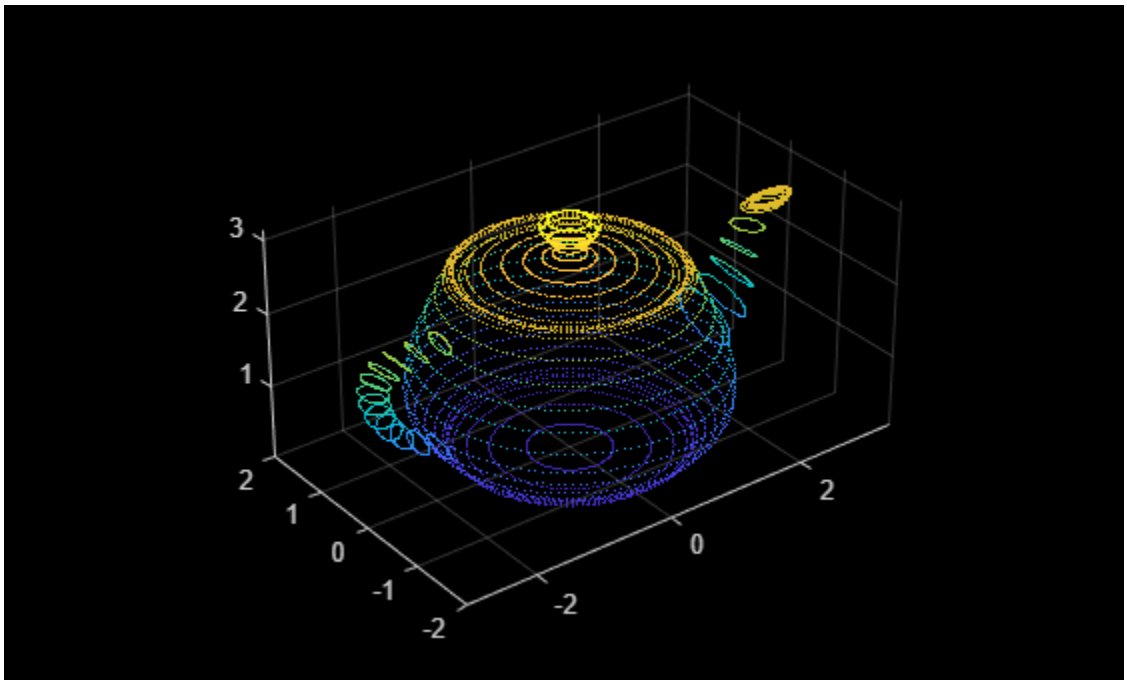
```
ptCloud = pcread("teapot.ply");
```

Set the 3-D resolution to be (0.1 x 0.1 x 0.1).

```
gridStep = 0.1;
ptCloudA = pcdownsample(ptCloud,'gridAverage',gridStep);
```

Visualize the downsampled data.

```
figure
pcshow(ptCloudA);
```



Compare the point cloud to data that is downsampled using a fixed step size.

```
stepSize = floor(ptCloud.Count/ptCloudA.Count);
indices = 1:stepSize:ptCloud.Count;
ptCloudB = select(ptCloud,indices);
```

Visualize the downsampled point cloud.

```
figure
pcshow(ptCloudB);
```

Remove Redundant Points from Point Cloud

Create a point cloud with all points sharing the same coordinates.

```
ptCloud = pointCloud(ones(100,3));
```

Set the 3-D resolution to a small value.

```
gridStep = 0.01;
```

The output now contains only one unique point.

```
ptCloudOut = pcdownsample(ptCloud,'gridAverage',gridStep)
```

```
ptCloudOut =
  pointCloud with properties:

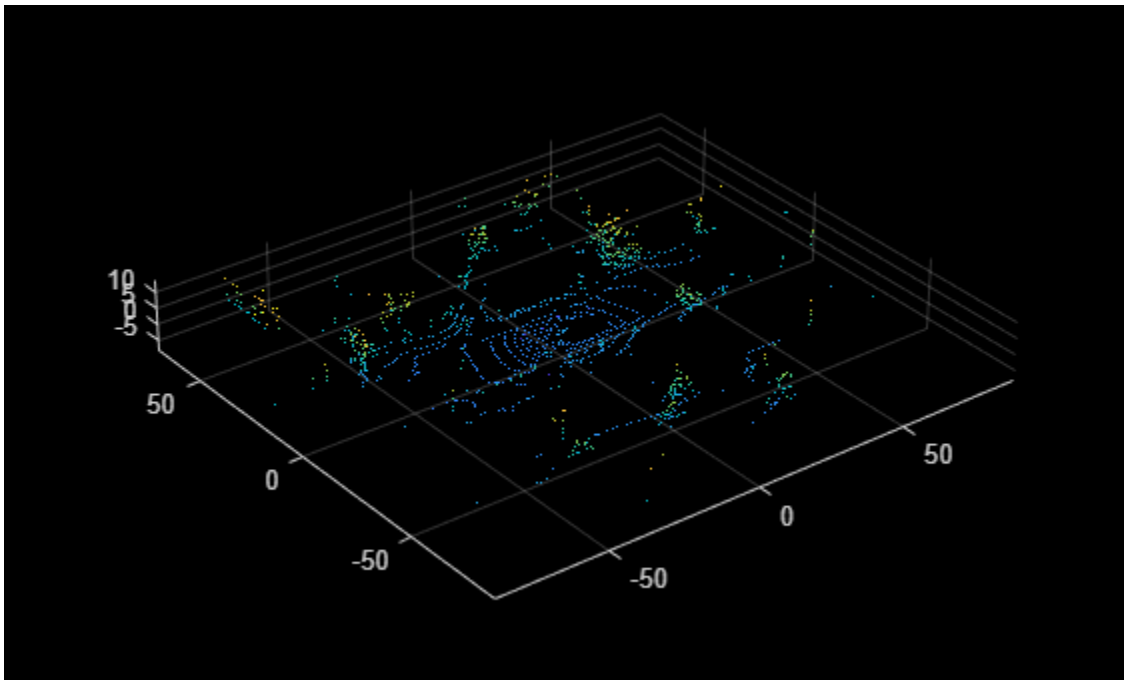
     Location: [1 1 1]
        Count: 1
      XLimits: [1 1]
      YLimits: [1 1]
      ZLimits: [1 1]
        Color: [0×3 uint8]
       Normal: [0×3 double]
    Intensity: [0×1 double]
```

Preserve Organized Structure of Point Cloud After Downsampling

Load an organized point cloud from a saved MAT file.

```
ld = load('drivingLidarPoints.mat');
orgPtCloud = ld.ptCloud;
```

Downsample the point cloud. The output point cloud preserves the organized structure. Its location property is of size M-by-N-by-3.



```
gridStep = 2;
orgPtCloudOut = pcdownsample(orgPtCloud,'gridNearest',gridStep,PreserveStructure=true)
```

```
orgPtCloudOut =
  pointCloud with properties:

     Location: [32×1083×3 double]
        Count: 34656
      XLimits: [-86.7523 90.5514]
      YLimits: [-85.8353 70.7870]
      ZLimits: [-8.2440 13.9009]
        Color: []
       Normal: []
    Intensity: [32×1083 double]
```

Visualize the downsampled point cloud.

```
figure
pcshow(orgPtCloudOut)
```

Input Arguments

`ptCloudIn` — Point cloud

`pointCloud` object

Point cloud, specified as a `pointCloud` object.

`"random"` — Random downsample method

`"random"`

Random downsample method, specified as `"random"`. The `"random"` method is more efficient than the `"gridAverage"` downsample method, especially when it is applied before point cloud registration.

`percentage` — Percentage of input

nonnegative scalar

Percentage of input, specified as a nonnegative scalar in the range [0, 1]. The `percentage` input specifies the portion of the input for the function to return.

`"gridAverage"` — Grid average downsample method

`"gridAverage"`

Grid average downsample method, specified as `"gridAverage"`. Points within the same voxel are merged to a single point in the output voxel. Their color and normal properties are averaged accordingly. This method preserves the shape of the point cloud better than the `"random"` downsample method.

The function computes the axis-aligned bounding box for the entire point cloud. The bounding box is divided into a grid of voxels of size specified by `gridStep`. Points within each voxel are merged by averaging their locations, colors, and normals.

`"gridNearest"` — Nearest to centroid downsample method

`"gridNearest"`

Nearest to centroid downsample method, specified as `"gridNearest"`. Points are selected that are closest to the centroid in each voxel. Use the `gridNearest` downsampling technique to achieve a more precise depiction of color, intensity, and normal data in the downsampled point cloud.

The function computes the axis-aligned bounding box for the entire point cloud. The bounding box is divided into grid of voxels of size specified by `gridStep`.

`gridStep` — Size of 3-D box for grid filter

numeric value

Size of 3-D box for grid filter, specified as a numeric value. Increase the size of `gridStep` when there are not enough resources to construct a large fine-grained grid of voxels.

Data Types: `single` | `double`

`"nonuniformGridSample"` — Nonuniform grid sample method

`"nonuniformGridSample"`

Nonuniform grid sample method, specified as `"nonuniformGridSample"`. When you use the `"nonuniformGridSample"` algorithm, the normals are computed on the original data prior to downsampling. The downsampled output preserves more accurate normals.

`maxNumPoints` — Maximum number of points in grid box
integer

Maximum number of points in grid voxel, specified as an integer greater than `6`. The method randomly selects a single point from each voxel. If the normal was not provided in the input point cloud, this method automatically fills in the normal property in the `ptCloudOut` output.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PreserveStructure=true` preserves the organized structure of a point cloud.

`PreserveStructure` — Preserve the organized structure of a point cloud
`false` (default) | `true`

Preserve the organized structure of a point cloud, specified as `true` or `false`. The table describes the point cloud structure according to the value of `PreserveStructure`.

`PreserveStructure`	The function returns
`true`	An organized, downsampled, point cloud. The "Location" on page 2-0 property that describes the structure of the point cloud, contains an *M*-by-*N*-by-3 matrix. Points that are not selected in the downsampled point cloud are filled with `NaN`, and the corresponding color is set to `[0 0 0]`. To return an organized point cloud, the input must be an organized point cloud, and the downsampling method must be `"random"`, `"nonuniformGridSample"`, or `"gridNearest"`.
`false`	An unorganized, downsampled, point cloud. The "Location" on page 2-0 property that describes the structure of the point cloud, contains an *M*-by-3 matrix.

Output Arguments

`ptCloudOut` — Downsampled point cloud
`pointCloud` object

Downsampled point cloud, returned as a `pointCloud` object.

`indices` — Indices of points in the downsampled point cloud
N-element vector

Indices of points in the downsampled point cloud, returned as a *N*-element vector.

Version History

Introduced in R2015a

R2024b: Specify `gridNearest` downsampling method

Use the `gridNearest` downsampling method, which selects the nearest point to the centroid of each grid.

R2025a: Generate C/C++ code for "`gridNearest`" method

The function now supports C/C++ code generation for the "`gridNearest`" method for downsampling point clouds.

References

[1] Pomerleau, F., F. Colas, R. Siegwart, and S. Magnenat. “Comparing ICP variants on real-world data sets.” *Autonomous Robots*. Vol. 34, Issue 3, April 2013, pp. 133–148.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- GPU code generation for nonuniform grid sample method is not optimized.
- For the random downsample method, GPU Coder uses the NVIDIA CUDA random library (cuRAND) to generate the random numbers. Because of architectural and implementation differences between the random number generators on the GPU and CPU, numerical verification does not always match.
- The `PreserveStructure` name-value argument is not supported for GPU code generation.
- GPU code generation does not support the "`gridNearest`" method for downsampling point clouds.

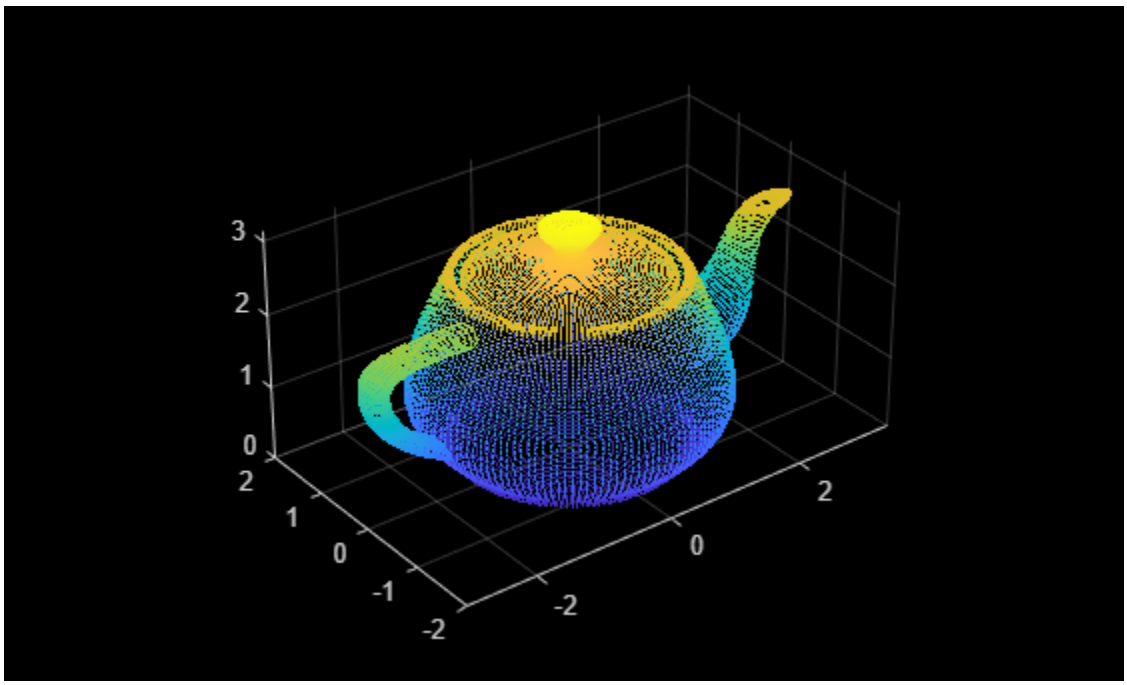
pcread

Read 3-D point cloud from PLY or PCD file

Syntax

```
ptCloud = pcread(filename)
```

Description



`ptCloud = pcread(filename)` reads a point cloud from the PLY or PCD file specified by the input `filename`. The function returns a `pointCloud` object, `ptCloud`.

Examples

Read Point Cloud from a PLY File

Load a PLY-format point cloud into the workspace.

```
ptCloud = pcread('teapot.ply');
pcshow(ptCloud);
```

Input Arguments

`filename` — File name
character vector | string scalar

File name, specified as a character vector or a string scalar. The input file type must be a PLY or a PCD format file.

The polygon (PLY) file format , also known as the Stanford triangle format stores three-dimensional data from 3-D scanners. It is a format for storing graphical objects that are described as a collection of polygons. A PLY file consists of a header, followed by a list of vertices and then, a list of polygons. The header specifies how many vertices and polygons are in the file. It also states what properties are associated with each vertex, such as (*x*,*y*,*z*) coordinates, normals, and color. The file format has two sub-formats: an ASCII representation and a binary version for compact storage and for rapid saving and loading. The header of both ASCII and binary files is ASCII text. Only the numeric data that follows the header is different between the two versions. See “The PLY Format” for details on the contents of a PLY file.

The point cloud data (PCD) file format also stores three-dimensional data. It was created by the authors of the widely used point cloud library (PCL) to accommodate additional point cloud data requirements. See The PCD (Point Cloud Data) file format.

Note This function only supports PCD file formats saved in version 0.7 (PCD_V7). It also only supports the header entries with the `COUNT` entry set to `1`. It does not support the `COUNT` entry set to a feature descriptor.

Output Arguments

`ptCloud` — Object for storing point cloud

`pointCloud` object

Object for storing point cloud, returned as a `pointCloud` object that contains the following PLY or PCD fields:

- `Location` property, stores the *x*, *y*, and *z* values.
- `Color` property, stores the red, green, and blue values.
- `Normal` property, stores the normal vectors for each point.
- `Intensity` property, stores the grayscale intensity for each point.

The PCD (Point Cloud Data) file format

pcregistericp

Register two point clouds using ICP algorithm

Syntax

```
tform = pcregistericp(moving,fixed)
[tform,movingReg] = pcregistericp(moving,fixed)
[tform,movingReg,rmse] = pcregistericp(moving,fixed)
[___] = pcregistericp(moving,fixed,Name=Value)
```

Description

`tform = pcregistericp(moving,fixed)` returns a rigid transformation that registers a moving point cloud to a fixed point cloud.

The registration algorithm is based on the iterative closest point (ICP) algorithm. Best performance of this iterative process requires adjusting properties for your data. To improve the accuracy and efficiency of registration, consider downsampling point clouds using `pcdownsample` before using `pcregistericp`.

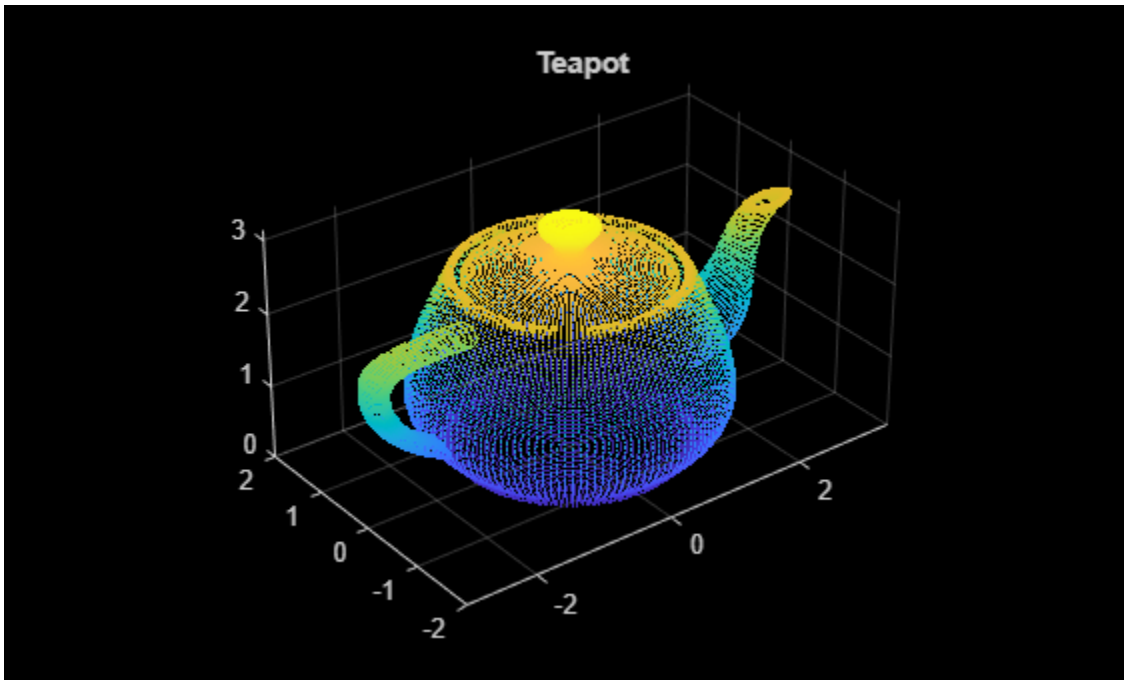
The registration algorithm requires point cloud normals when you select the `"pointToPlane"` or the `"planeToPlane"` (also known as Generalized-ICP or G-ICP) metric. If the `Normal` property of the input point cloud is empty, the function fills it.

`[tform,movingReg] = pcregistericp(moving,fixed)` additionally returns the transformed point cloud that aligns with the fixed point cloud.

`[tform,movingReg,rmse] = pcregistericp(moving,fixed)` additionally returns the root mean square error of the Euclidean distance between the aligned points, using any of the preceding syntaxes.

`[___] = pcregistericp(moving,fixed,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `pcregistericp(moving,fixed,Metric="planeToPlane")` sets the minimization metric to `"planeToPlane"`.

Examples



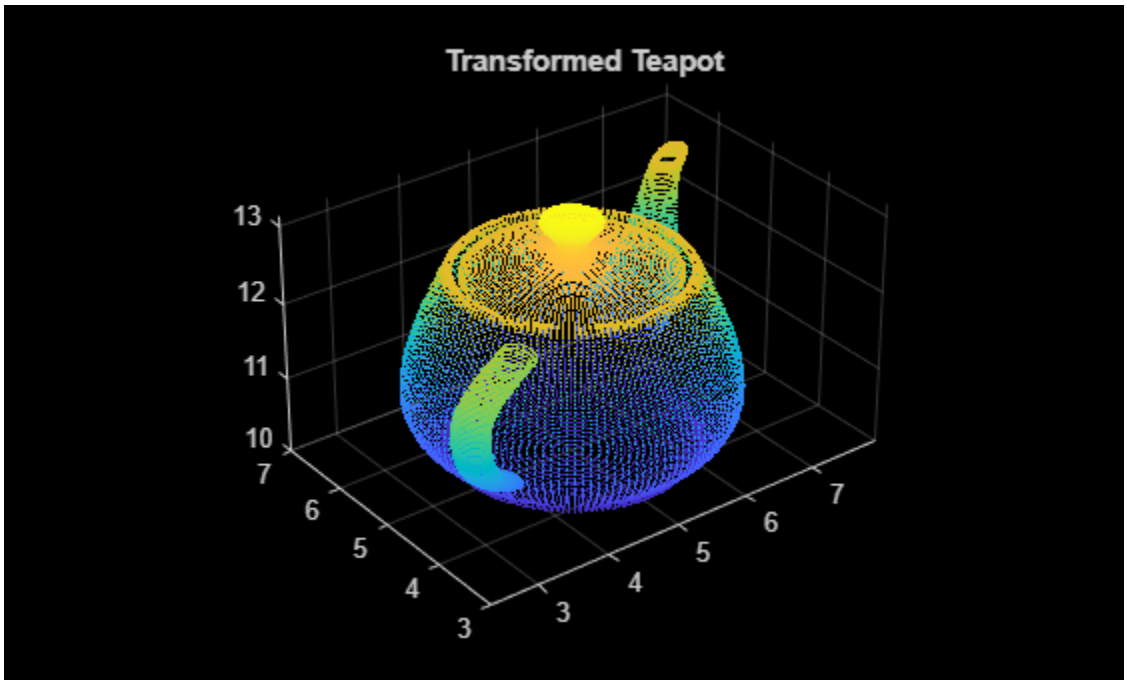
Align Two Point Clouds Using ICP Algorithm

Load point cloud data into the workspace.

```
ptCloud = pcread("teapot.ply");
```

Display the loaded point cloud.

```
pcshow(ptCloud)
title("Teapot")
```



Create a transformation object with 30 degree rotation along the Z-axis and with a translation of [5 5 10].

```
rotationAngles = [0 0 30];
translation = [5 5 10];
tform1 = rigidtform3d(rotationAngles,translation);
```

Transform the point cloud and visualize the result.

```
ptCloudTformed = pctransform(ptCloud,tform1);

pcshow(ptCloudTformed)
title("Transformed Teapot")
```

Register the point clouds.

```
tform = pcregistericp(ptCloudTformed,ptCloud);
```

Compare the result with the true transformation.

```
disp(tform1.A);
```

```
    0.8660   -0.5000         0    5.0000
    0.5000    0.8660         0    5.0000

```

Align Two Point Clouds Using Plane-to-Plane ICP Registration

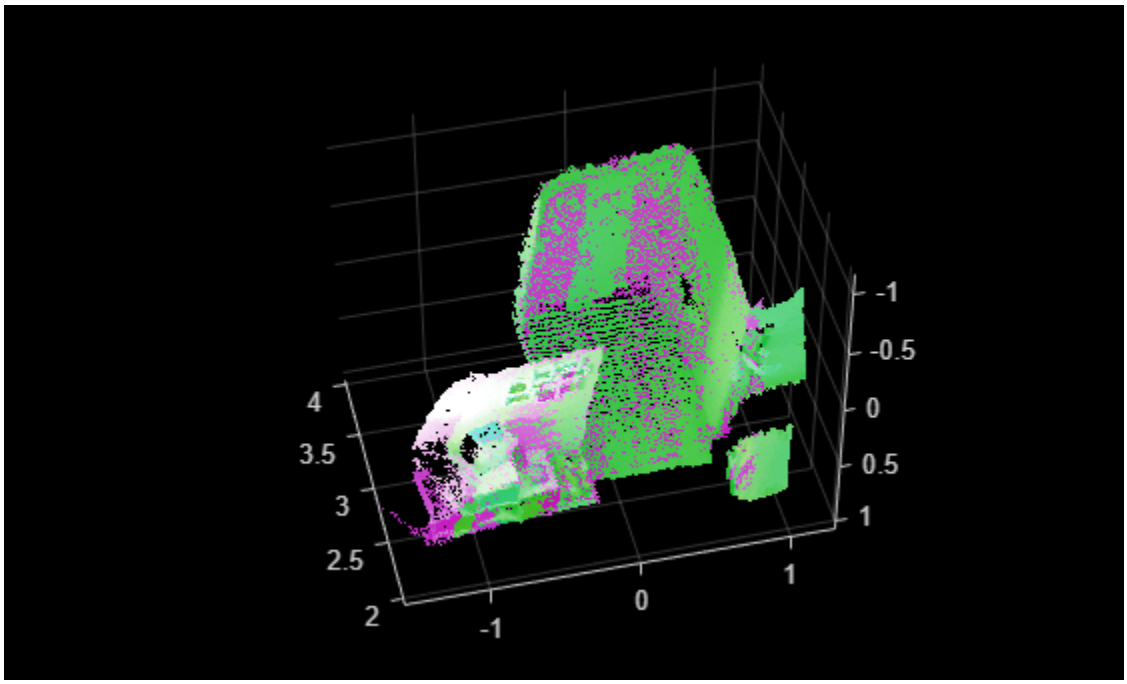
Load point cloud data into the workspace.

```
ld = load("livingRoom.mat");
moving = ld.livingRoomData{1};
fixed  = ld.livingRoomData{2};
```

Visualize the point cloud and set the direction to display the *y*-axis.

```
figure
pcshowpair(moving,fixed,VerticalAxis="Y",VerticalAxisDir="Down")
```

Downsample the point clouds using `nonuniformGridSample` method to improve the efficiency and accuracy of registration.



```
maxNumPoints = 12;
fixedDownsampled = pcdownsample(fixed,"nonuniformGridSample",maxNumPoints);
movingDownsampled = pcdownsample(moving,"nonuniformGridSample",maxNumPoints);
```

Align the point clouds using plane-to-plane (Generalized-ICP) registration.

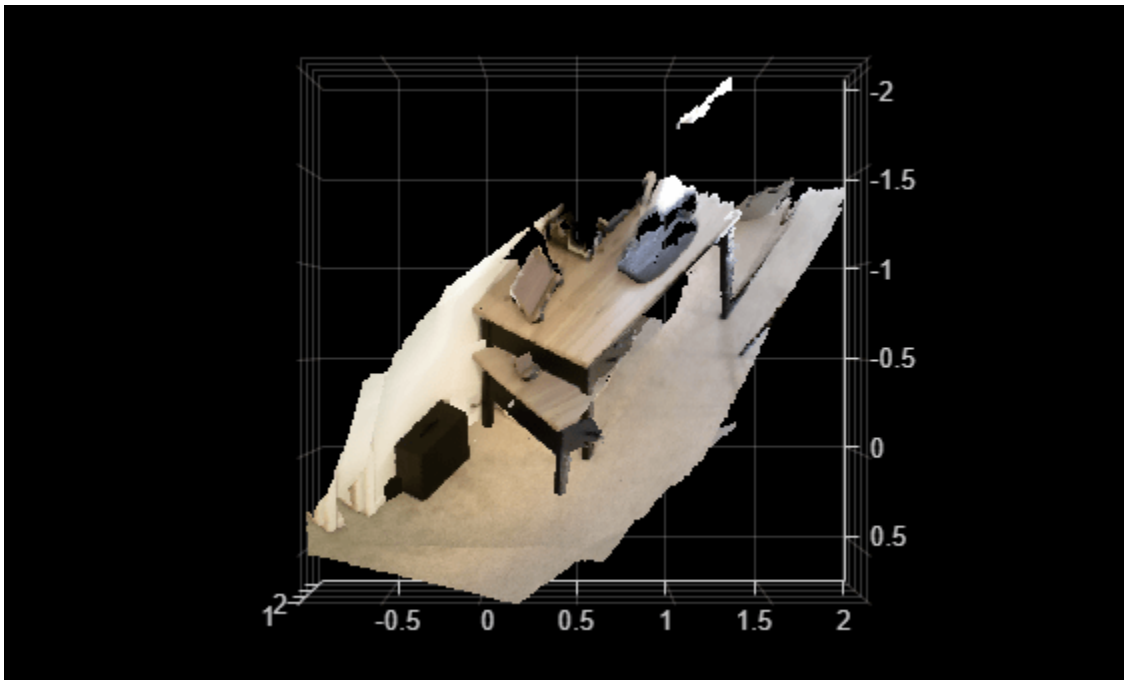
```
[~,movingReg] = pcregistericp(movingDownsampled,fixedDownsampled,Metric="planeToPlane");
```

Visualize the point cloud alignment and set the direction to display the *y*-axis.

```
figure
pcshowpair(movingReg,fixed,VerticalAxis="Y",VerticalAxisDir="Down")
```

Align Two Colored Point Clouds

Load moving point cloud data having color information into the workspace.



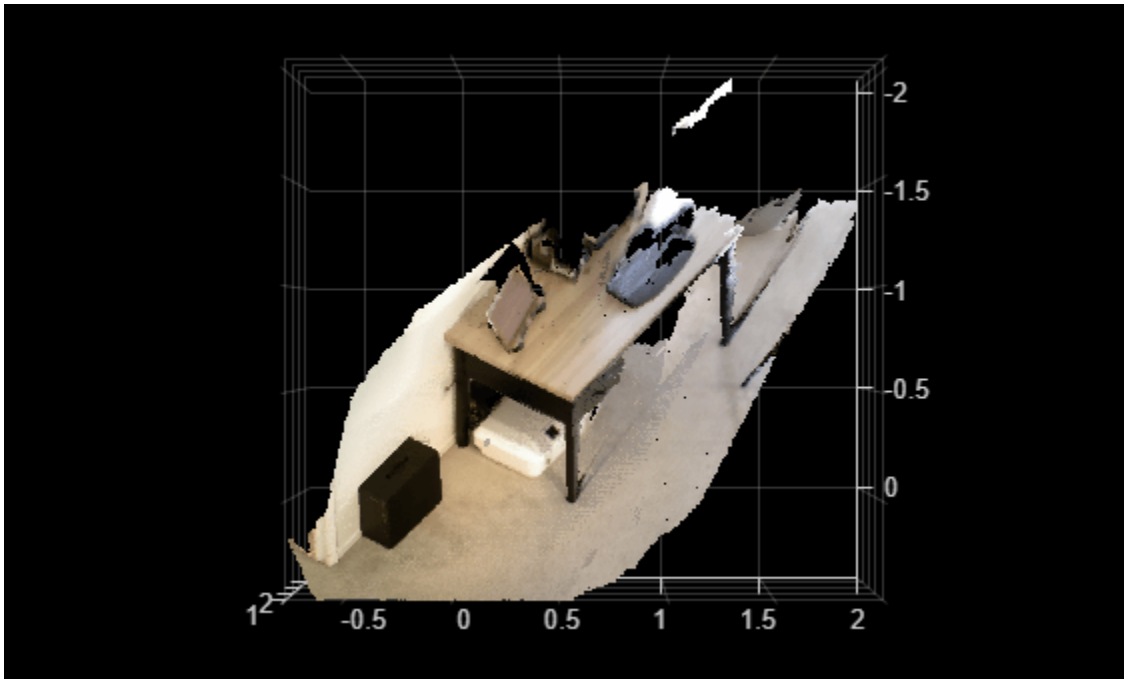
```
moving = pcread("apartmentMoving.pcd");
```

Load fixed point cloud data having color information into the workspace.

```
fixed  = pcread("apartmentFixed.pcd");
```

Visualize the colored point clouds and set the direction to display the *yx*-plane.

```
figure
pcshowpair(moving,fixed,"ViewPlane","YX","ColorSource","Color")
```



Align the colored point clouds using plane-to-plane (Generalized-ICP) registration and color information. Set the value to the `Metric` argument as `planeToPlaneWithColor`.

```
[~,movingReg] = pcregistericp(moving,fixed,Metric="planeToPlaneWithColor");
```

Visualize the point cloud alignment and set the direction to display the *yx*-plane.

```
figure
pcshowpair(movingReg,fixed,"ViewPlane","YX","ColorSource","Color")
```

Input Arguments

`moving` — Moving point cloud

`pointCloud` object

Moving point cloud, specified as a `pointCloud` object.

`fixed` — Fixed point cloud

`pointCloud` object

Fixed point cloud, specified as a `pointCloud` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Metric="planeToPlane"` sets the minimization metric for the ICP algorithm to `"planeToPlane"`.

`Metric` — Minimization metric

`"pointToPoint"` (default) | `"pointToPlane"` | `"planeToPlane"` | `"pointToPlaneWithColor"` | `"planeToPlaneWithColor"`

Minimization metric, specified as `"pointToPoint"`, `"pointToPlane"`, `"planeToPlane"`, `"planeToPlaneWithColor"`, or `"pointToPlaneWithColor"`. The iterative closest point (ICP) algorithm estimates the rigid transformation between the moving and fixed point clouds by minimizing the distance between the two point clouds according to the specified metric.

The normal based metrics `"pointToPlane"` and `"planeToPlane"` (also known as the Generalized ICP algorithm) can reduce the number of iterations required for registration, although they involve additional computation within each iteration. These metrics provide improved performance when registering planar surfaces. For point clouds that include color information, the `"pointToPlaneWithColor"` and `"planeToPlaneWithColor"` metrics provide further improvements in registration accuracy.

Downsample Method Selection

Downsample the point clouds using the `pcdownsample` function. If you select the `"pointToPlane"` or `"planeToPlane"` metric, the registration algorithm requires point cloud normals. The `"nonuniformGridSample"` metric computes normals on the original (pre-downsampled) data, which produces more accurate normals. As a result, using `"nonuniformGridSample"` can also improve accuracy for `"pointToPoint"` and `"pointToPlane"` ICP registration methods.

Use the `"random"`, `"gridAverage"`, or `"nonuniformGridSample"` downsampling methods with `pcdownsample`, as summarized in the table.

Metric	Moving Point Cloud Downsample Method	Fixed Point Cloud Downsample Method
"pointToPoint"	"random"	"random"
	"gridAverage"	"gridAverage"
"pointToPlane"	"gridAverage"	"gridAverage"
	"random"	"nonuniformGridSample"
"planeToPlane"	"gridAverage"	"gridAverage"
	"nonuniformGridSample"	"nonuniformGridSample"
"planeToPlaneWithColor"	"gridAverage"	"gridAverage"
	"nonuniformGridSample"	"nonuniformGridSample"

The "pointToPlaneWithColor" metric uses a multiscale registration approach where the point clouds are registered from coarser registration to finer registration. The result of the coarser registration is fed to the next finer registration step as the initial transformation. Therefore, the pcregistericp function does not use the normals in the input point clouds and thus the downsampling method does not affect its registration accuracy.

InlierRatio — Inlier percentage of matched pairs
1 (default) | scalar in the range (0, 1]

Inlier percentage of matched pairs, specified as a scalar between (0, 1]. This value specifies the percentage of matched pairs to use as inliers. The function considers a pair of matched points to be an inlier if the Euclidean distance between the two points is less than the specified percentage of the maximum Euclidean distance between any two points in a matched pair of the point clouds. By default, the function uses all matching pairs as inliers.

Specify only the InlierRatio or the InlierDistance name-value argument to exclude outliers. If you do not specify either argument, the function uses all matching pairs which is equivalent to setting the InlierRatio value to 1.

InlierDistance — Inlier distance threshold
scalar

Inlier distance threshold, specified as a scalar. This value sets the maximum distance between a point in the fixed point cloud and a matched point in the moving point cloud for the function to consider them as inliers. Decrease this value when you have a more accurate initial transformation, InitialTransform. Increase this value when there is more uncertainty in the initial transformation. Note that, increasing this value can decrease the speed of registration.

Specify only the InlierRatio or the InlierDistance name-value argument to exclude outliers. If you do not specify either argument, the function uses all matching pairs which is equivalent to setting the InlierRatio value to 1.

MaxIterations — Maximum number of iterations
30 (default) | positive integer

Maximum number of iterations, specified as a positive integer. This value specifies the maximum number of iterations over which the function attempts to make the two point clouds converge.

Tolerance — Tolerance between consecutive ICP iterations
[0.01 0.5] (default) | two-element vector

Tolerance between consecutive ICP iterations, specified as a two-element vector of the form [*Tdiff Rdiff*], where *Tdiff* and *Rdiff* represent the tolerances of absolute difference in translation and in rotation, respectively, estimated in consecutive ICP iterations. *Tdiff* measures the Euclidean distance between two translation vectors. *Rdiff* measures the angular difference in degrees. The algorithm stops when the average difference between estimated rigid transformations in the three most recent consecutive iterations is less than the specified tolerance values.

`InitialTransform` — Initial rigid transformation
`rigidtform3d` object

Initial rigid transformation, specified as a `rigidtform3d` object. This transformation must align the moving point cloud to the fixed point cloud. If not provided, the function uses a default translation that moves the centroid of the moving point cloud to the centroid of the fixed point cloud. The initial rigid transformation is useful when you have an external coarse estimation.

Note For the `"pointToPlaneWithColor"` metric, the default value of the `InitialTransform` name-value argument is a `rigidtform3d` object that performs an identity transformation.

`Verbose` — Display progress information
`false` or `0` (default) | `true` or `1`

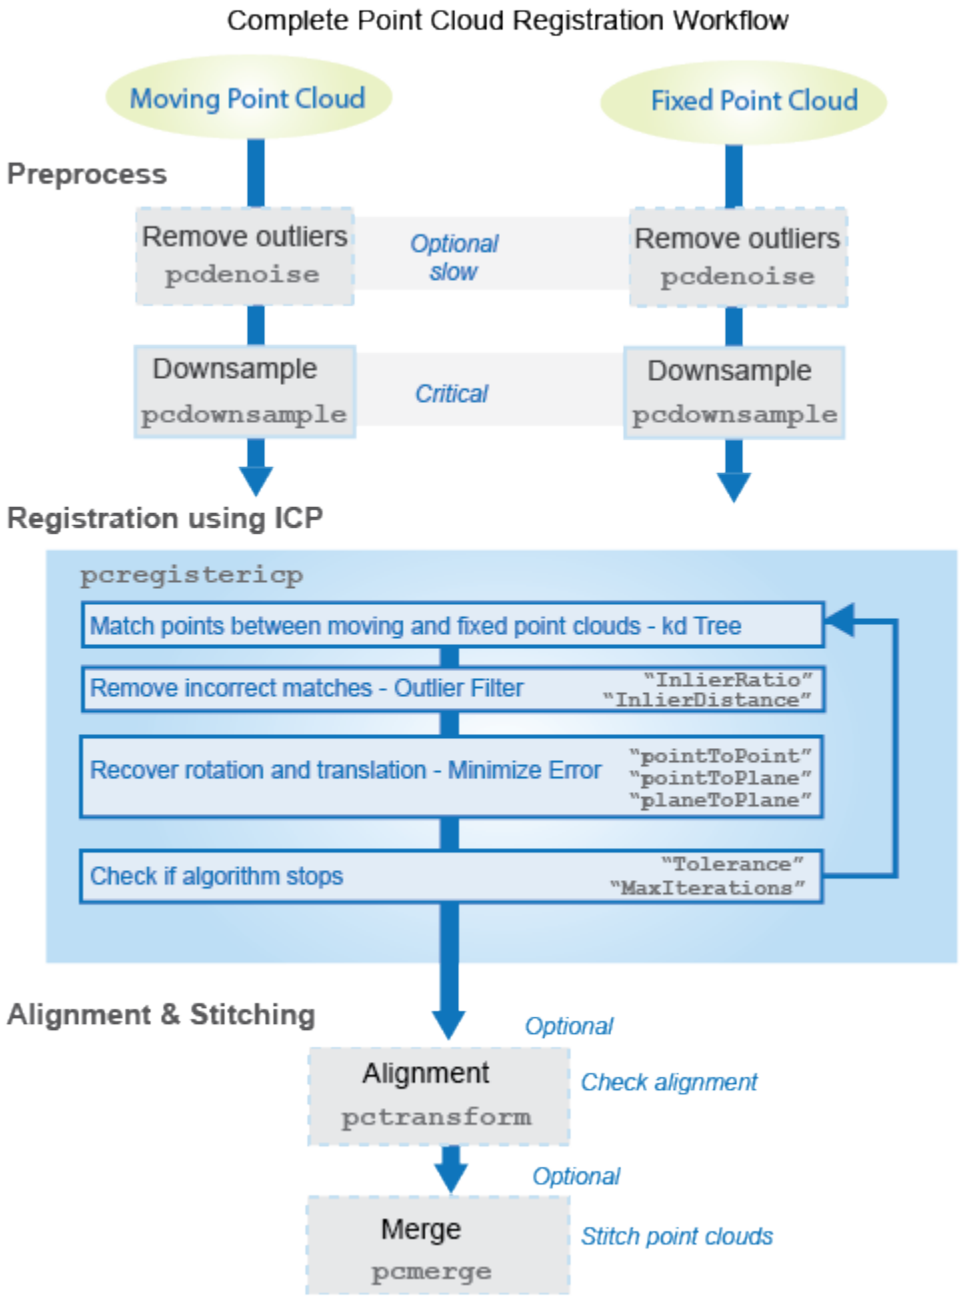
Display progress information, specified as a logical `0` (`false`) or `1` (`true`). Specify `Verbose` as `true` to display progress information.

Output Arguments

`tform` — Rigid transformation
`rigidtform3d` object

Rigid transformation, returned as a `rigidtform3d` object. The rigid transformation registers a moving point cloud to a fixed point cloud. The `rigidtform3d` object describes the rigid 3-D transform. The iterative closest point (ICP) algorithm estimates the rigid transformation between the moving and fixed point clouds.

`movingReg` — Transformed point cloud
`pointCloud` object



Transformed point cloud, returned as a `pointCloud` object. The transformed point cloud is aligned with the fixed point cloud.

`rmse` — Root mean square error
positive numeric scalar

Root mean square error, returned as a positive numeric scalar that represents the Euclidean distance between the aligned points. The aligned points is a result of the moving point cloud transformed by the `tform` output and the fixed point cloud. For each point in the fixed point cloud, the algorithm finds the closest point in the transformed point cloud, `movingReg`, then computes the Euclidean distance between the points, and then computes the `rmse`. A low `rmse` value indicates a more accurate registration. The `rmse` calculation is:

```
rmse = sqrt(sum(distance.^2,'all')/numel(distance));
```

Algorithms

Tips

- For ground vehicle point clouds, you can improve performance and accuracy by removing the ground using the `pcfitplane` or `segmentGroundFromLidarData` function before registration. For details on how to do this, see the `helperProcessPointCloud` helper function in the “Build a Map from Lidar Data” (Automated Driving Toolbox) example.

- To merge more than two point clouds, you can use the `pccat` function instead of the `pcmerge` function.

Version History

Introduced in R2018a

R2025a: `Extrapolate` name-value argument removed

Errors starting in R2025a

The `Extrapolate` name-value argument of the `pcregistericp` function has been removed. You can increase the `MaxIterations` argument or use the `pointToPlane` or `planeToPlane` values for the `Metric` name-value argument for similar accuracy.

R2024b: Generate optimized C/C++ code using Embedded Coder

Starting in R2024b, you can generate optimized C/C++ code for ARM processors using Embedded Coder.

R2024a: `InitialTransform` name-value argument default value changed for `"pointToPlaneWithColor"` metric

Behavior changed in R2024a

Starting in R2024a, for the `"pointToPlaneWithColor"` metric, the default value of the `InitialTransform` name-value argument is changed to a `rigidtform3d` object that performs an identity transformation. Prior to R2024a, the default value is a `rigidtform3d` object that contains the translation between the centroids of the moving and the fixed point clouds.

R2023b: Register point clouds with color information

Behavior changed in R2023b

Starting in R2023b, the `pcregistericp` function now supports the point cloud registration using color information. To include color information for registration, specify the `Metric` name-value argument as `"pointToPlaneWithColor"` or `"planeToPlaneWithColor"`. The `"pointToPlaneWithColor"` and `"planeToPlaneWithColor"` algorithm metrics do not support code generation.

R2023b: `Extrapolate` name-value argument will be removed in a future release

Not recommended starting in R2023b

The `Extrapolate` name-value argument of the `pcregistericp` function will be removed in a future release. You can increase the `MaxIterations` argument or use the `pointToPlane` or `planeToPlane` values for the `Metric` name-value argument for similar accuracy.

R2023b: `MaxIterations` name-value argument default value changed

Behavior changed in R2023b

The default value for the `MaxIterations` name-value argument was changed from `20` to `30` for `pointToPoint` and `pointToPlane` metrics.

R2023a: Returns RMSE of all points

Behavior changed in R2023a

Starting in R2023a, the `pcregistericp` function now returns the RMSE of all points. Previously, the function returned the RMSE of only the inliers. The function still outputs the RMSE of the inliers at each iteration when you set the `Verbose` argument to `true`.

R2023a: Default value modified for `InitialTransform` argument
Behavior changed in R2023a

Starting in R2023a, the `pcregistericp` function now uses a modified default value for the `InitialTransform` name-value argument. The default value is now a `rigidtform3d` object that contains a translation aligning the centroid of the moving point cloud to that of the fixed point cloud. Prior to R2023a, the default value is `rigidtform3d()`.

R2022b: Returns `rigidtform3d` object
Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, the `pcregistericp` function now returns the output argument `tform` a `rigidtform3d` object, which uses the premultiply convention. Before, the function returned `tform` as a `rigid3d` object, which uses the postmultiply convention.

You can now specify the `InitialTransform` name-value argument as a `rigidtform3d` object. Although you can still specify `InitialTransform` as a `rigid3d` object, this object is not recommended because it uses the postmultiply convention. You can streamline your geometric transformation workflows by switching to new premultiply geometric transformation objects. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

R2022b: Generalized-ICP registration algorithm
Behavior changed in R2022b

The `pcregistericp` function now supports the Generalized-ICP (G-ICP), or plane-to-plane, minimization metric. To use this registration algorithm, specify the `Metric` name-value argument as `"planeToPlane"`. The `"planeToPlane"` algorithm metric does not support code generation.

R2020a: Returns a `rigid3d` object
Behavior changed in R2020a

Starting in R2020a, the `pcregistericp` function returns a `rigid3d` object. Prior to R2020a, the function returned an `affine3d` object.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The values for the `Extrapolate` and `Metric` arguments must be compile time constants.
- For C/C++ code generation on Windows platforms, only the Microsoft Visual C++ compiler is supported.

You can also generate optimized C/C++ code for ARM processors using Embedded Coder.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- The `"pointToPlaneWithColor"` and `"planeToPlaneWithColor"` algorithm metrics do not support GPU code generation.
- The point cloud output locations of the GPU-generated code differ from simulation by an order of `10e-3`, and the RMSE output differs by an order of `10e-4`, due to precision errors. However, the simulation and GPU code generation outputs have no notable visual differences.
- To ensure similar outputs from GPU code generation and simulation, the `Extrapolate` argument must be `false` or `0`.
- For enhanced GPU code generation performance, specify `"Location"`property of input point clouds of type `single`.
- For enhanced GPU code generation performance of `"planeToPlane"` metric, disable calls to cuBLAS and cuFFT CUDA libraries.

pcregisterndt

Register two point clouds using NDT algorithm

Syntax

```
tform = pcregisterndt(moving,fixed,gridStep)
[tform,movingReg] = pcregisterndt( ___ )
[tform,movingReg,rmse] = pcregisterndt( ___ )
[ ___ ] = pcregisterndt( ___ ,Name=Value)
```

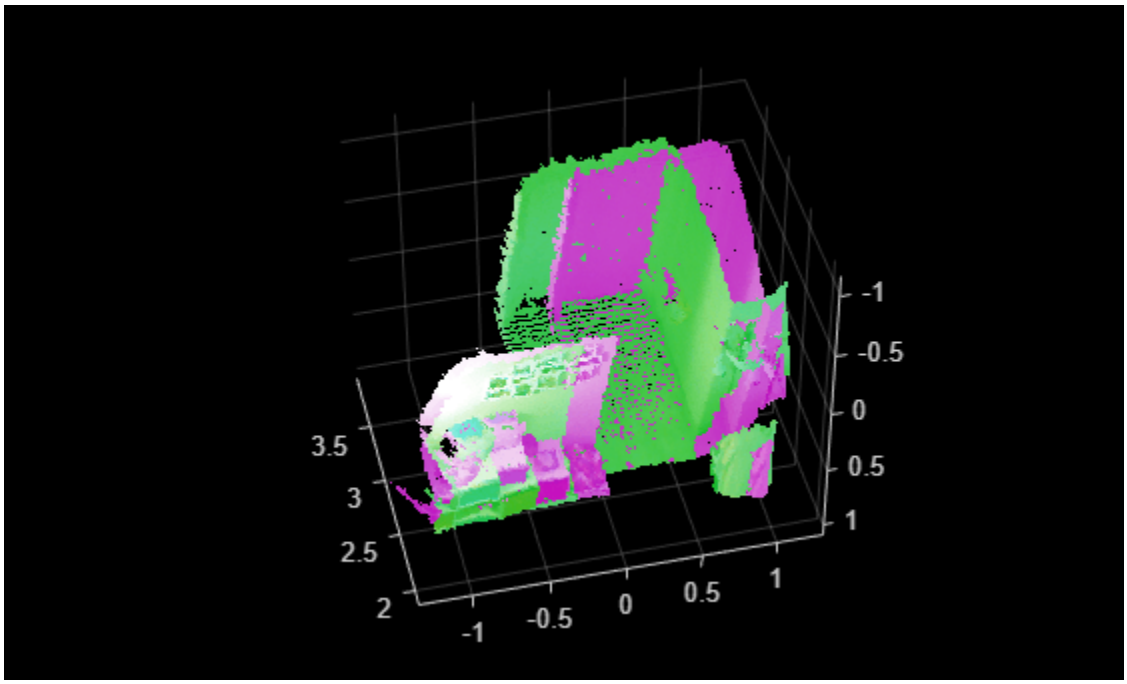
Description

`tform = pcregisterndt(moving,fixed,gridStep)` returns the rigid transformation that registers the moving point cloud with the fixed point cloud. The fixed point cloud is voxelized into cubes of size `gridStep`.

The registration algorithm is based on the normal-distributions transform (NDT) algorithm [1] [2]. Best performance of this iterative process requires adjusting properties for your data. To improve accuracy and efficiency of registration, consider downsampling the moving point cloud by using `pcdownsample` before using `pcregisterndt`.

`[tform,movingReg] = pcregisterndt( ___ )` also returns the transformed point cloud that aligns with the fixed point cloud.

`[tform,movingReg,rmse] = pcregisterndt( ___ )` also returns the root mean square error of the Euclidean distance between the aligned point clouds.



`[ ___ ] = pcregisterndt( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `MaxIterations=20` stops the NDT algorithm after 20 iterations.

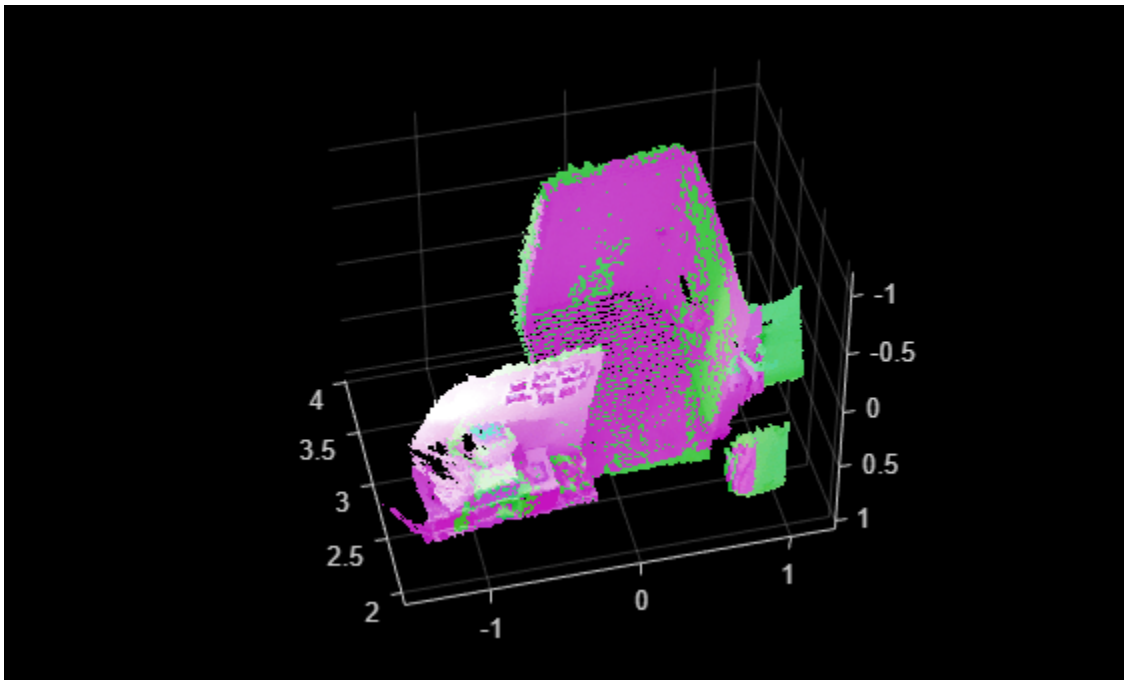
Examples

Align Two Point Clouds Using NDT Algorithm

Load point cloud data.

```
ld = load('livingRoom.mat');
moving = ld.livingRoomData{1};
fixed = ld.livingRoomData{2};
figure
pcshowpair(moving,fixed,VerticalAxis='Y',VerticalAxisDir='Down')
```

To improve the efficiency and accuracy of the NDT registration algorithm, downsample the moving point cloud.



```
movingDownsampled = pcdownsample(moving,'gridAverage',0.1);
```

Voxelize the point cloud into cubes of sidelength 0.5. Apply the rigid registration using the NDT algorithm.

```
gridStep = 0.5;
tform = pcregisterndt(movingDownsampled,fixed,gridStep);
```

Visualize the alignment.

```
movingReg = pctransform(moving,tform);
figure
pcshowpair(movingReg,fixed,VerticalAxis='Y',VerticalAxisDir='Down')
```

Align Two Lidar Point Clouds

Construct a `velodyneFileReader` object.

```
veloReader = velodyneFileReader('lidarData_ConstructionRoad.pcap','HDL32E');
```

Read and visualize two lidar point clouds.

```
frameNumber = 1;
skipFrame   = 5;
fixed = readFrame(veloReader,frameNumber);
moving = readFrame(veloReader,frameNumber + skipFrame);
```

Segment the ground plane and remove it from the fixed point cloud.

```
groundPtsIdxFixed = segmentGroundFromLidarData(fixed);
fixedSeg = select(fixed,~groundPtsIdxFixed,OutputSize='full');
```

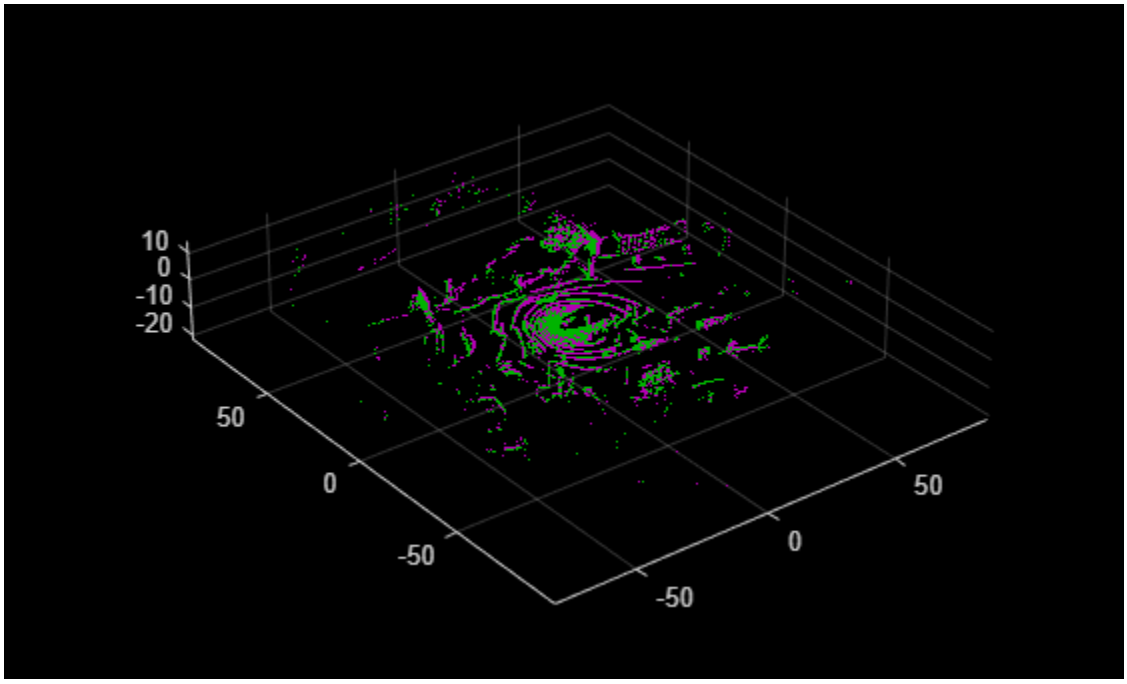
Segment the ground plane and remove it from the moving point cloud.

```
groundPtsIdxMoving = segmentGroundFromLidarData(moving);
movingSeg = select(moving,~groundPtsIdxMoving,OutputSize='full');
```

Downsample the moving point cloud to improve accuracy and the efficiency of processing the points.

```
movingDownsampled = pcdownsample(movingSeg,gridAverage=0.2);
```

Register the moving point cloud with respect to the fixed point cloud.



```
gridStep = 5;
tform = pcregisterndt(movingDownsampled,fixedSeg,gridStep);
```

Transform the moving point cloud using an estimated rigid transformation.

```
movingReg = pctransform(moving,tform);
```

Visualize the alignment of the point clouds.

```
figure
pcshowpair(movingReg,fixed)
```

Input Arguments

`moving` — Moving point cloud

`pointCloud` object

Moving point cloud, specified as a `pointCloud` object.

`fixed` — Fixed point cloud

`pointCloud` object

Fixed point cloud, specified as a `pointCloud` object.

`gridStep` — Size of voxels

positive scalar

Size of the 3-D cube that voxelizes the fixed point cloud, specified as a positive scalar.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `MaxIterations=20` stops the NDT algorithm after 20 iterations.

`InitialTransform` — Initial rigid transformation
`rigidtform3d` object

Initial rigid transformation, specified as a `rigidtform3d` object. This transformation must align the moving point cloud to the fixed point cloud. If not provided, the function uses a default translation that moves the centroid of the moving point cloud to the centroid of the fixed point cloud.

`OutlierRatio` — Percentage of outliers
`0.55` (default) | scalar in the range [0, 1)

Expected percentage of outliers with respect to a normal distribution, specified as a scalar in the range [0, 1). The NDT algorithm assumes a point is generated by a mixture of a normal distribution for inliers and a uniform distribution for outliers. A larger value of `OutlierRatio` reduces the influence of outliers.

Data Types: `single` | `double`

`MaxIterations` — Maximum number of iterations
`30` (default) | positive integer

Maximum number of iterations before NDT stops, specified as a positive integer.

Data Types: `single` | `double`

`Tolerance` — Tolerance between consecutive NDT iterations
`[0.01 0.5]` (default) | 2-element vector

Tolerance between consecutive NDT iterations, specified as a 2-element vector with nonnegative values. The vector, [*Tdiff Rdiff*], represents the tolerance of absolute difference in translation and rotation estimated in consecutive NDT iterations. *Tdiff* measures the Euclidean distance between two translation vectors. *Rdiff* measures the angular difference in degrees. The algorithm stops when the difference between estimated rigid transformations in the most recent consecutive iterations falls below the specified tolerance value.

Data Types: `single` | `double`

`Verbose` — Display progress information
`false` (default) | `true`

Display progress information, specified as a numeric or logical `0` (`false`) or `1` (`true`). To display the progress information, set `Verbose` to `true`.

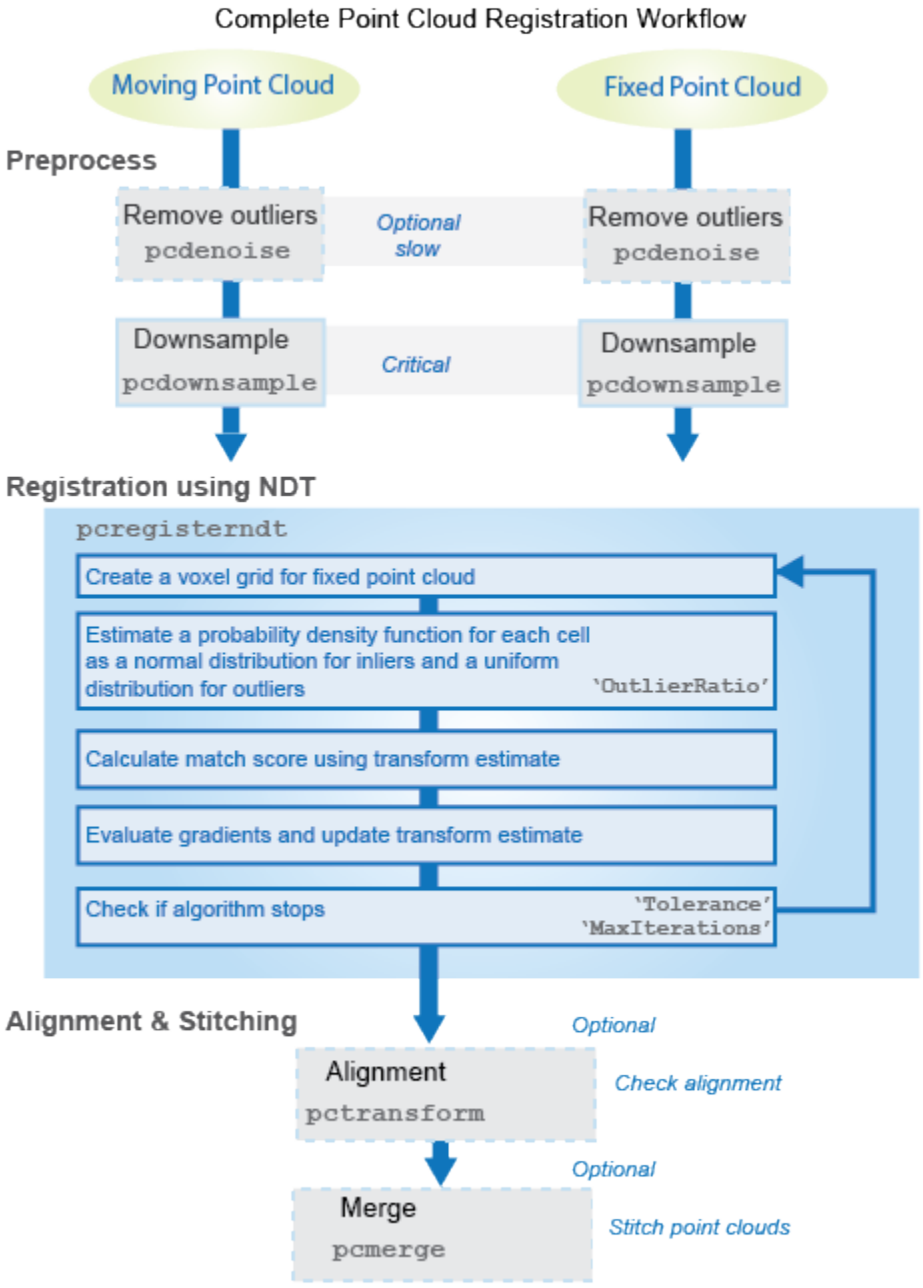
Output Arguments

`tform` — Rigid transformation
`rigidtform3d` object

Rigid transformation, returned as a `rigidtform3d` object. `tform` describes the rigid 3-D transformation that registers the moving point cloud, `moving`, to the fixed point cloud, `fixed`.

`movingReg` — Transformed point cloud
`pointCloud` object

Transformed point cloud, returned as a `pointCloud` object. The transformed point cloud is aligned with the fixed point cloud, `fixed`.



`rmse` — Root mean square error
positive number

Root mean square error, returned as a positive numeric scalar that represents the Euclidean distance between the aligned points. The aligned points is a result of the moving point cloud transformed by the `tform` output and the fixed point cloud. For each point in the fixed point cloud, the algorithm finds the closest point in the transformed point cloud, `movingReg`, then computes the Euclidean distance between the points, and then computes the `rmse`. A low `rmse` value indicates a more accurate registration. The `rmse` calculation is:

```
rmse = sqrt(sum(distance.^2,'all')/numel(distance));
```

Data Types: `single` | `double`

Algorithms

Tips

- For ground vehicle point clouds, you can improve performance and accuracy by removing the ground using `pcfitplane` or `segmentGroundFromLidarData` before registration. For details on how to do this, see the helper function, `helperProcessPointCloud` in the “Build a Map from Lidar Data” (Automated Driving Toolbox) example.

- To merge more than two point clouds, you can use `pccat` function instead of the `pcmerge` function.
- Prior to registration, the `pcregisterndt` function voxelizes the fixed point cloud using the specified `gridStep`. Decrease the grid step to capture distinct structures within the point cloud. However, decreasing this value can lead to an increase of the effect of the local noise from the sensor. Use the `pcdownsample` function to determine the effect of voxelization with this syntax:

  ```
  pcdownsample(fixed,"gridAverage",gridStep)
  ```

NDT Registration Overview

The NDT registration is based on normal distributions rather than other types of registration which match points or lines in order to find the transformation between two point clouds. The NDT approach uses statistical models with 3-D boxes, called voxels.

To register two point clouds, a moving point cloud and a fixed point cloud, using the NDT approach, the algorithm performs the following:

1. Computes the normal distributions for the fixed point cloud by dividing the area covered by the point cloud scan into 3-D boxes of constant size, referred to as "voxels". Each voxel contains a set of points. The algorithm computes the mean and covariance matrix for the points in each voxel.
2. Starting with an initial guess of the transformation, the algorithm aligns the moving point cloud to the fixed point cloud. It then finds the sum of the statistical likelihood of each aligned point to be located in the voxel that surrounds the point (in the moving point cloud), based on the normal distribution of the fixed point cloud.
3. To improve the registration, the algorithm maximizes the probability score of the moving point cloud on the normal distributions of the fixed point cloud. This is done by iteratively optimizing angular and translational estimations.
4. Repeats the alignment of the moving point cloud with the fixed point cloud using the new transformation from the previous step and then repeats the optimization.
5. The algorithm stops once the maximum iterations or the tolerance parameters, are met. The tolerance is a measure of how much the angular and translational estimations change from one iteration to another.

Version History

Introduced in R2018a

R2022b: Supports premultiply geometric transformation convention

Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, the `pcregisterndt` function now returns the output argument `tform` as `rigidtform3d` object, which uses the premultiply convention. Before, the function returned `tform` as a `rigid3d` object, which uses the postmultiply convention.

You can now specify the `InitialTransform` name-value argument as a `rigidtform3d` object. Although you can still specify `InitialTransform` as a `rigid3d` object, this object is not recommended because it uses the postmultiply convention. You can streamline your geometric transformation workflows by switching to new premultiply geometric transformation objects. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

R2020a: Returns `rigid3d` object
Behavior changed in R2020a

Starting in R2020a, the `pcregisterndt` function returns a `rigid3d` object. Prior to R2020a, the function returned an `affine3d` object.

pcregrigid

(To be removed) Register two point clouds using ICP algorithm

Note The `pcregrigid` function will be removed in a future release. Use `pcregistericp` instead.

Syntax

```
tform = pcregrigid(moving,fixed)
[tform,movingReg] = pcregrigid(moving,fixed)
[tform,movingReg,rmse] = pcregrigid(moving,fixed)
[___] = pcregrigid(moving,fixed,Name,Value)
```

Description

`tform = pcregrigid(moving,fixed)` returns a rigid transformation that registers a moving point cloud to a fixed point cloud.

The registration algorithm is based on the "iterative closest point" (ICP) algorithm. Best performance of this iterative process requires adjusting properties for your data. Consider downsampling point clouds using `pcdownsample` before using `pcregrigid` to improve accuracy and efficiency of registration.

Point cloud normals are required by the registration algorithm when you select the `'pointToPlane'` metric. Therefore, if the input point cloud's `Normal` property is empty, the function fills it. When the function fills the `Normal` property, it uses 6 points to fit the local plane. Six points may not work under all circumstances. If registration with the `'pointToPlane'` metric fails, consider calling the `pcnormals` function which allows you to select the number of points to use.

`[tform,movingReg] = pcregrigid(moving,fixed)` additionally returns the transformed point cloud that aligns with the fixed point cloud.

`[tform,movingReg,rmse] = pcregrigid(moving,fixed)` additionally returns the root mean squared error of the Euclidean distance between the aligned point clouds, using any of the preceding syntaxes.

`[___] = pcregrigid(moving,fixed,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`moving` — Moving point cloud

`pointCloud` object

Moving point cloud, specified as a `pointCloud` object.

`fixed` — Fixed point cloud

`pointCloud` object

Fixed point cloud, specified as a `pointCloud` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'Metric','pointToPoint'` sets the metric for the ICP algorithm to the `'pointToPoint'`.

`Metric` — Minimization metric
`'pointToPoint'` (default) | `'pointToPlane'`

Minimization metric, specified as the comma-separated pair consisting of '`Metric`' and `'pointToPoint'` or `'pointToPlane'`. The rigid transformation between the moving and fixed point clouds are estimated by the iterative closest point (ICP) algorithm. The ICP algorithm minimizes the distance between the two point clouds according to the given metric.

Setting '`Metric`' to `'pointToPlane'` can reduce the number of iterations to process. However, this metric requires extra algorithmic steps within each iteration. The `'pointToPlane'` metric improves the registration of planar surfaces.

Downsample Method Selection:
Downsample the point clouds using the `pcdownsample` function. Use either the `'random'` or `'gridAverage'` input for the `pcdownsample` function according to the `Metric` table below.

Metric	Point Cloud A Downsample Method	Point Cloud B Downsample Method
`'pointToPoint'`	`'random'`	`'random'`
	`'gridAverage'`	`'gridAverage'`
`'pointToPlane'`	`'gridAverage'`	`'gridAverage'`
	`'random'`	`'nonuniformGridSample'`

`Extrapolate` — Extrapolation
`false` (default) | `true`

Extrapolation, specified as the comma-separated pair consisting of '`Extrapolate`' and the boolean `true` or `false`. When you set this property to `true`, the function adds an extrapolation step that traces out a path in the registration state space, that is described in [2]. Setting this property to `true` can reduce the number of iterations to converge.

`InlierRatio` — Percentage of inliers
`1` (default) | scalar

Percentage of inliers, specified as the comma-separated pair consisting of '`InlierRatio`' and a scalar value. Use this value to set a percentage of matched pairs as inliers. A pair of matched points is considered an inlier if its Euclidean distance falls within the percentage set of matching distances. By default, all matching pairs are used.

`MaxIterations` — Maximum number of iterations
`20` (default) | positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of 'MaxIterations' and a positive integer. This value specifies the maximum number of iterations before ICP stops.

`Tolerance` — Tolerance between consecutive ICP iterations
`[0.01, 0.009]` (default) | 2-element vector

Tolerance between consecutive ICP iterations, specified as the comma-separated pair consisting of 'Tolerance' and a 2-element vector. The 2-element vector, [*Tdiff*, *Rdiff*], represents the tolerance of absolute difference in translation and rotation estimated in consecutive ICP iterations. *Tdiff* measures the Euclidean distance between two translation vectors. *Rdiff* measures the angular difference in radians. The algorithm stops when the average difference between estimated rigid transformations in the three most recent consecutive iterations falls below the specified tolerance value.

`InitialTransform` — Initial rigid transformation
`affine3d()` object (default)

Initial rigid transformation, specified as the comma-separated pair consisting of 'InitialTransform' and an `affine3d` object. The initial rigid transformation is useful when you provide an external coarse estimation.

`Verbose` — Display progress information
`true` (default) | `false`

Display progress information, specified as the comma-separated pair consisting of 'Verbose' and a logical scalar. Set `Verbose` to `true` to display progress information.

Output Arguments

`tform` — Rigid transformation
`affine3d` object

Rigid transformation, returned as an `affine3d` object. The rigid transformation registers a moving point cloud to a fixed point cloud. The `affine3d` object describes the rigid 3-D transform. The iterative closest point (ICP) algorithm estimates the rigid transformation between the moving and fixed point clouds.

`movingReg` — Transformed point cloud
`pointCloud` object

Transformed point cloud, returned as a `pointCloud` object. The transformed point cloud is aligned with the fixed point cloud.

`rmse` — Root mean square error
positive numeric

Root mean square error, returned as the Euclidean distance between the aligned point clouds.

Version History

Introduced in R2015a

R2024a: Warns
Warns starting in R2024a

The `pcregrigid` function issues a warning that it will be removed in a future release. Use the `pcregistericp` object to perform ICP point cloud registration, instead.

R2023b: To be removed
Not recommended starting in R2023b

The `pcregrigid` function will be removed in a future release.

pcsegdist

Segment point cloud into clusters based on Euclidean distance

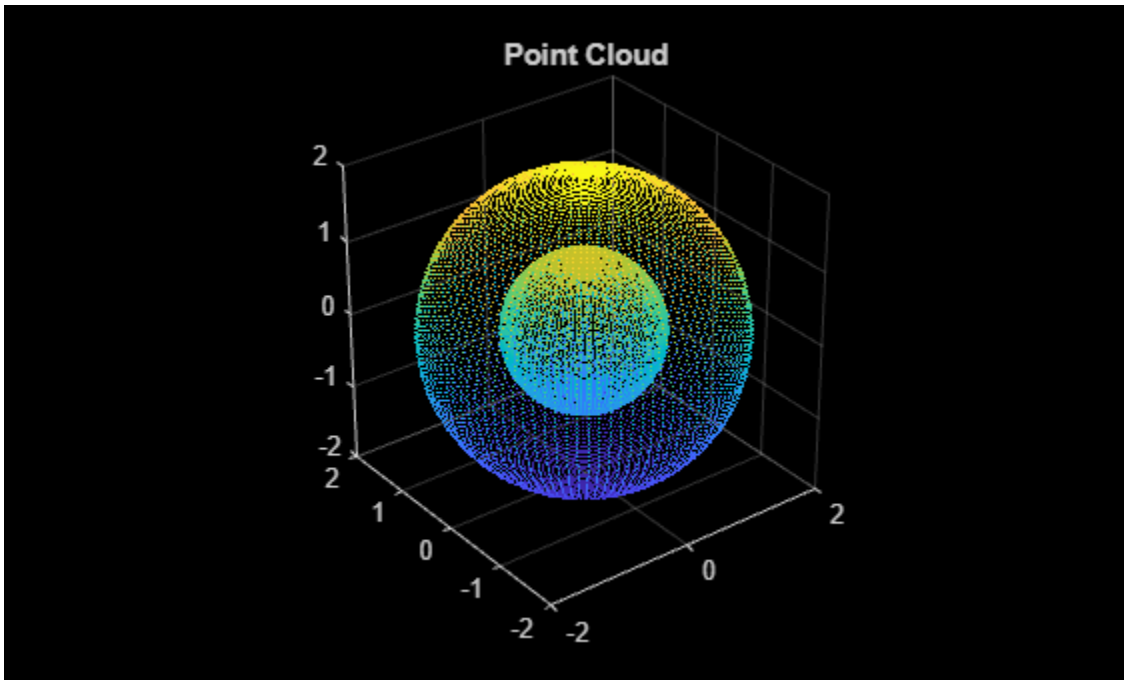
Syntax

```
labels = pcsegdist(ptCloud,minDistance)
[labels,numClusters] = pcsegdist(ptCloud,minDistance)
[___] = pcsegdist(___,Name=Value)
```

Description

`labels = pcsegdist(ptCloud,minDistance)` segments a point cloud into clusters, with a minimum Euclidean distance of `minDistance` between points from different clusters. `pcsegdist` assigns an integer cluster label to each point in the point cloud, and returns the `labels` of all points.

`[labels,numClusters] = pcsegdist(ptCloud,minDistance)` also returns the number of clusters.



`[___] = pcsegdist(___,Name=Value)` sets properties using name-value arguments. For example, `labels = pcsegdist(ptCloud,minDistance,NumClusterPoints=[1,Inf])` sets the minimum and maximum number of points in each cluster to `[1,Inf]`.

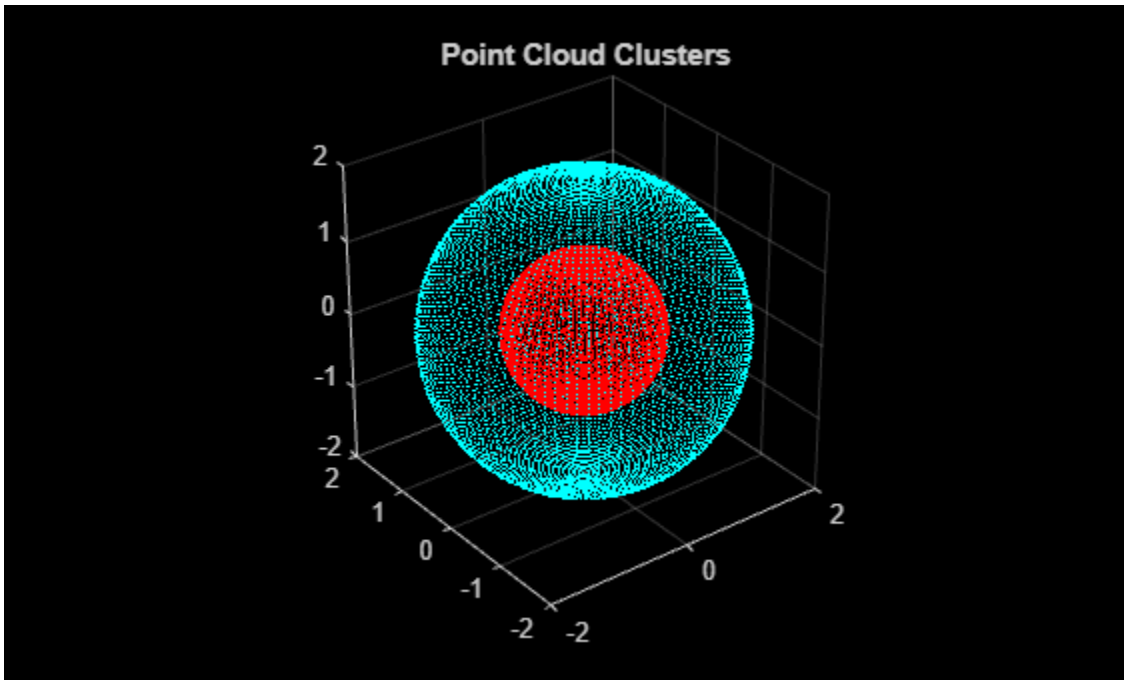
Examples

Cluster Point Cloud Based on Euclidean Distance

Create two concentric spheres and combine them.

```
[X,Y,Z] = sphere(100);
loc1 = [X(:),Y(:),Z(:)];
loc2 = 2*loc1;
ptCloud = pointCloud([loc1;loc2]);
pcshow(ptCloud)
title('Point Cloud')
```

Set the minimum Euclidean distance between clusters.



```
minDistance = 0.5;
```

Segment the point cloud.

```
[labels,numClusters] = pcsegdist(ptCloud,minDistance);
```

Plot the labeled results. The points are grouped into two clusters.

```
pcshow(ptCloud.Location,labels)
colormap(hsv(numClusters))
title('Point Cloud Clusters')
```

Cluster Lidar Point Cloud Based on Euclidean Distance

Load an organized lidar point cloud to the workspace.

```
ld = load('drivingLidarPoints.mat');
```

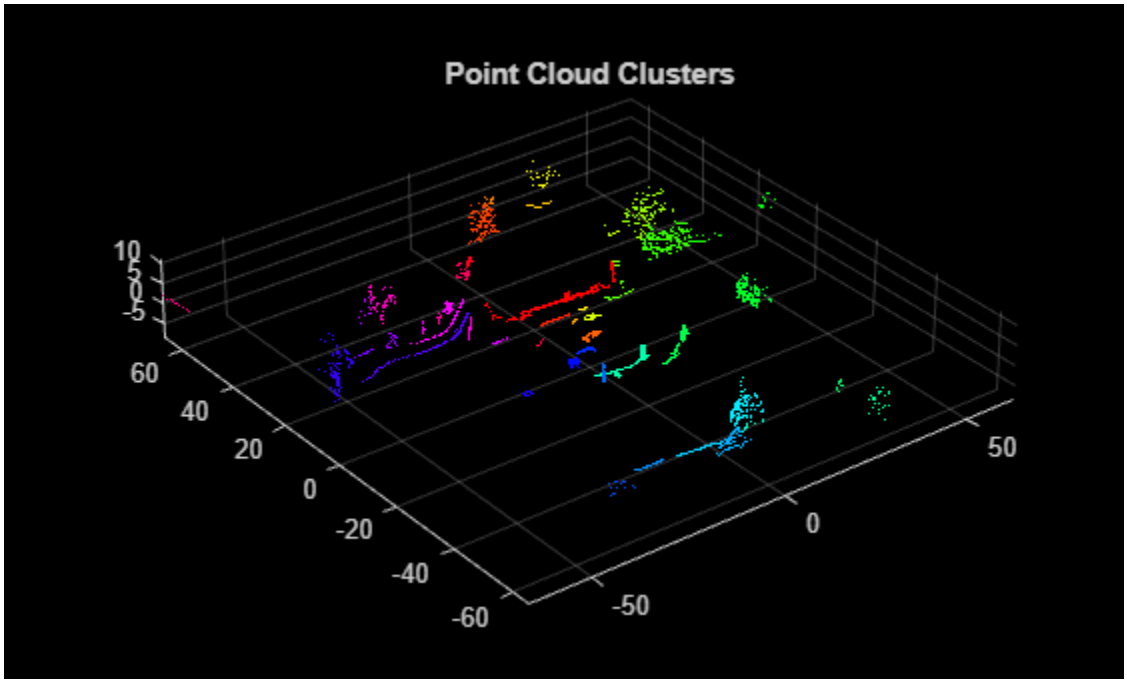
Detect the ground plane. Distance is measured in meters.

```
maxDistance = 0.9;
referenceVector = [0 0 1];
[~,inliers,outliers] = pcfitplane(ld.ptCloud,maxDistance,referenceVector);
```

Remove the ground plane points.

```
ptCloudWithoutGround = select(ld.ptCloud,outliers);
```

Cluster the point cloud with a minimum of 10 points per cluster using the exhaustive method.



```
minDistance = 2;
minPoints = 10;
[labels,numClusters] = pcsegdist(ptCloudWithoutGround,minDistance,Method="exhaustive",...
    NumClusterPoints=minPoints);
```

Remove the points with a label value of `0`.

```
idxValidPoints = find(labels);
labelColorIndex = labels(idxValidPoints);
segmentedPtCloud = select(ptCloudWithoutGround,idxValidPoints);
```

Plot the labeled results.

```
figure
colormap(hsv(numClusters))
pcshow(segmentedPtCloud.Location,labelColorIndex)
title('Point Cloud Clusters')
```

Input Arguments

`ptCloud` — Point cloud
`pointCloud` object

Point cloud, specified as a `pointCloud` object.

`minDistance` — Minimum Euclidean distance
positive scalar

Minimum Euclidean distance between points from two different clusters, specified as a positive scalar.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `ParallelNeighborSearch=false` sets the `ParallelNeighborSearch` to `false`.

`NumClusterPoints` — Minimum and maximum number of points in each cluster
`[1,Inf]` (default) | 2-element vector | scalar

Minimum and maximum number of points in each cluster, specified as a scalar or a 2-element vector of the form [*minPoints*,*maxPoints*]. When you specify `NumClusterPoints` as a scalar, the maximum number of points in the cluster is unrestricted. The function sets `labels` to `0` when clusters are outside of the specified range.

`Method` — Method to segment the point cloud
`"approximate"` (default) | `"exhaustive"`

Method to segment the point cloud, specified as `"approximate"` or `"exhaustive"`. Set `Method` to `"exhaustive"` to ensure that no points outside of each cluster are less than `minDistance` away. This approach uses the density-based spatial clustering of applications with noise (DBSCAN) algorithm. Set `Method` to `"approximate"` for faster segmentation, but at the expense of accuracy.

`ParallelNeighborSearch` — Parallel neighbor search to segment point cloud data
`false` (default) | `true`

Parallel neighbor search to segment point cloud data, specified as `true` or `false`. Set this property to `true` when you expect there to be approximately 50 clusters or more with fewer than 100 points per cluster.

A parallel neighbor search can improve segmentation speed for some datasets. Improved speed depends on the dataset and the value of the `minDistance` input. This argument is not supported when you set the `Method` name-value argument to `"exhaustive"`.

Output Arguments

`labels` — Cluster labels
M-by-1 vector | *M*-by-*N* matrix

Cluster labels, returned as one of the following.

- If the point cloud, `ptCloud`, stores point locations as an unorganized *M*-by-3 matrix, then `labels` is an *M*-by-1 vector.
- If the point cloud, `ptCloud`, stores point locations as an organized *M*-by-*N*-by-3 matrix, then `labels` is an *M*-by-*N* matrix.

Each point in the point cloud has a cluster label, specified by the corresponding element in `labels`. The value of each label is an integer from `0` to the number of clusters of valid points, `numClusters`. The value `0` is reserved for invalid points, such as points with `Inf` or `NaN` coordinates.

Data Types: `uint32`

`numClusters` — Number of clusters
positive integer

Number of clusters, returned as a positive integer. The number of clusters excludes the label value `0`, which is reserved for invalid points. The function returns `numClusters` as a `single` data type when the value of the `Location` property of the `ptCloud` object is `single`. Otherwise, the function returns the value as a `double` data type.

Data Types: `single` | `double`

Version History

Introduced in R2018a

R2026a: Support for `NumClusterPoints` in GPU Code Generation

Starting in R2026a, `pcsegdist` function supports the `NumClusterPoints` name-value argument for GPU code generation.

R2024b: New `Method` name-value argument for segmenting point cloud

Configure the `Method` name-value argument to choose between `"exhaustive"` or `"approximate"` segmentation methods. The `ParallelNeighborhood` name-value argument does not support the `"exhaustive"` method.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

The `"exhaustive"` segmentation method, which can be set by using the `Method` name-value argument, does not support C/C++ code generation.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- The generated CUDA code segments the point cloud into clusters by using a combination of algorithms described in [1] and [2]. The output from the generated code can differ slightly with results from MATLAB simulation.
- The `"exhaustive"` segmentation method, which can be set by using the `Method` name-value argument, does not support GPU code generation.

pcwrite

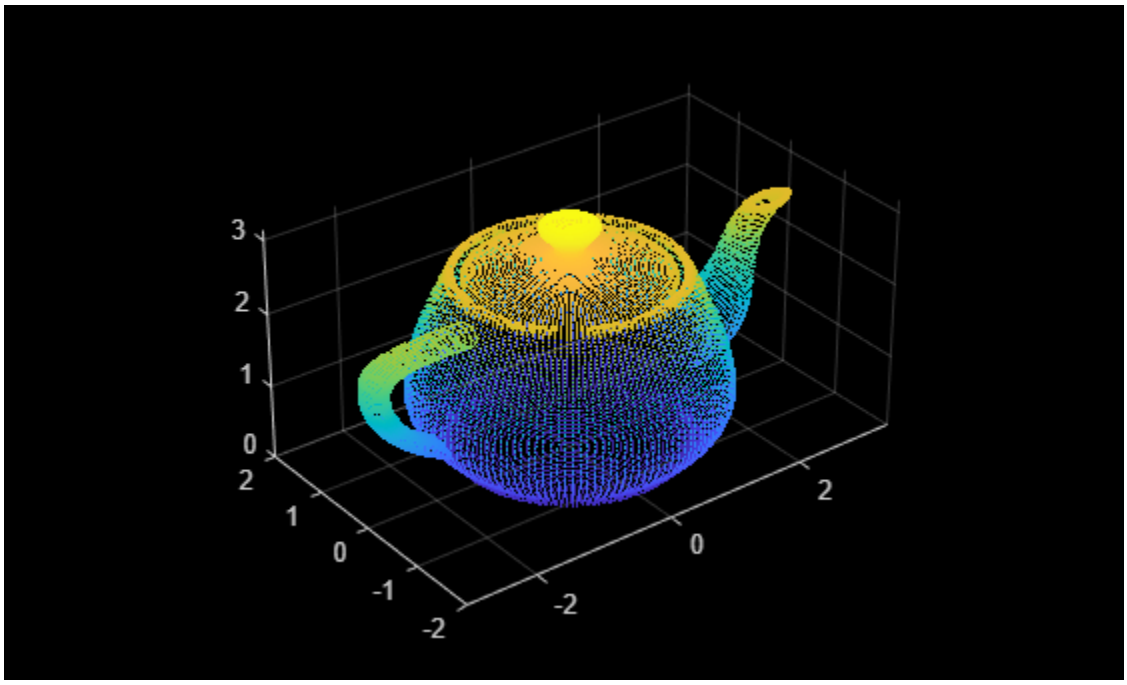
Write 3-D point cloud to PLY or PCD file

Syntax

```
pcwrite(ptCloud,filename)
pcwrite(ptCloud,filename,Encoding=encodingType)
```

Description

`pcwrite(ptCloud,filename)` writes the point cloud object, `ptCloud`, to the PLY or PCD file specified by the input `filename`.



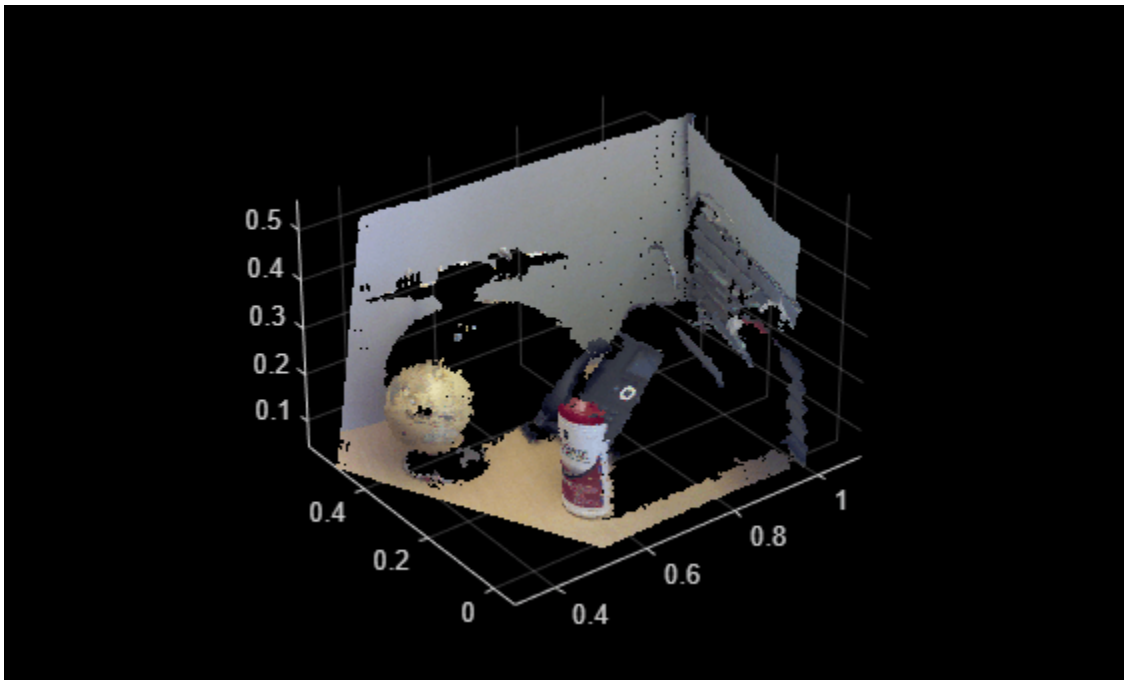
`pcwrite(ptCloud,filename,Encoding=encodingType)` writes a `pointCloud` object, `ptCloud`, to a PLY file that is in the specified format.

Examples

Write 3-D Point Cloud to PLY File

Load a point cloud into the workspace.

```
ptCloud = pcread("teapot.ply");
pcshow(ptCloud);
```



```
pcwrite(ptCloud,"teapotOut",Encoding="binary");
```

Write 3-D Organized Point Cloud to PCD File

Load a MAT file containing point cloud data into the workspace.

```
load("object3d.mat");
pcwrite(ptCloud,"object3d.pcd",Encoding="ascii");
pc = pcread("object3d.pcd");
pcshow(pc);
```

Input Arguments

`filename` — File name

character vector | string scalar

File name, specified as a character vector or string scalar. The input file type must be a PLY or PCD format file.

For a PLY-file, the `pcwrite` function converts an organized *M*-by-*N*-by-3 point cloud to an unorganized *M*-by-3 format. It converts the format because PLY files do not support organized point clouds. To preserve the organized format, you can save the point cloud as a PCD-file.

If you do not specify the file name with an extension, the function writes the file in a PLY-format. All `NaN` or `Inf` values will be skipped when writing to a PLY file.

`ptCloud` — Object for storing point cloud

`pointCloud` object

Object for storing point cloud, specified as a `pointCloud` object.

encodingType — Encoding type for output file
`"ascii"` | `"binary"` | `"compressed"`

Encoding type for the output file, specified as `"ascii"`, `"binary"`, or `"compressed"`. This table summarizes the valid and default encoding types for PLY and PCD file formats.

File Format	Valid Encodings
PLY	`"ascii"` `"binary"` (default)

PCD	`"ascii"`
	
	`"binary"`
	
	`"compressed"` (default)

To improve performance when writing large point clouds, use the `"compressed"` or `"binary"` encoding type.

Version History

Introduced in R2015a

R2026a: Write point clouds with additional Color property data types

You can now write a `pointCloud` object with a `Color` property of data type `uint8`, `uint16`, `single`, or `double` to a PLY or PCD file. In previous releases, the valid data types for the `Color` property depends on the file format you write to.

Valid Color Data Types

File Format	R2025b	R2026a
PLY	`uint8`, `uint16`	`uint8`, `uint16`, `single`, `double`
PCD	`uint8`	`uint8`, `uint16`, `single`, `double`

R2026a: Change in default encoding type
Behavior changed in R2026a

The default value of the `encodingType` argument is now `"binary"` for PLY files and `"compressed"` for PCD files. Before R2026a, the default value is `"ascii"` for both file formats.

In most cases, you do not need to make any changes to your code. However, if you specifically want to write point cloud data to a PLY or PCD file with ASCII encoding, you must specify the `encodingType` argument as `"ascii"`, as shown in this command:
`pcwrite(ptCloud,"sample.ply",Encoding="ascii")`.

R2026a: Improved performance

When you use the `pcwrite` function with the default encoding type, the function shows improved performance. When you use the `pcread` function to read a file generated by the `pcwrite` function, the `pcread` function also shows improved performance. The performance improvement increases as the number of points stored in the point cloud increases. For example, writing and then reading a point cloud using this code is about 17x and 11x faster, respectively, than in the previous release.

```
function [tWrite,tRead] = timingTest
    % Create a large point cloud
    rng("default");
    N = 1e6; % Number of points

    x = -50 + 100*rand(N,1);        % range [-50, 50]
    y = -50 + 100*rand(N,1);        % range [-50, 50]
    z = 10*rand(N,1);               % range [0, 10]

    ptCloud = pointCloud([x y z]);

    % Measure execution time of the operations
    tWrite = timeit(@()pcwrite(ptCloud,"temp.ply"));
    tRead = timeit(@()pcread("temp.ply"));
end
```

This table shows the approximate execution times required to write and read point cloud data to and from a PLY file.

Release	`pcwrite` Execution Time	`pcread` Execution Time
R2025b	2.19 s	0.56 s
R2026a	0.13 s	0.05 s

The code was timed on a Debian® 12, Intel® Xeon® CPU W-2133 @ 3.60 GHz test system by calling the function `timingTest`.

pctransform

Transform 3-D point cloud

Syntax

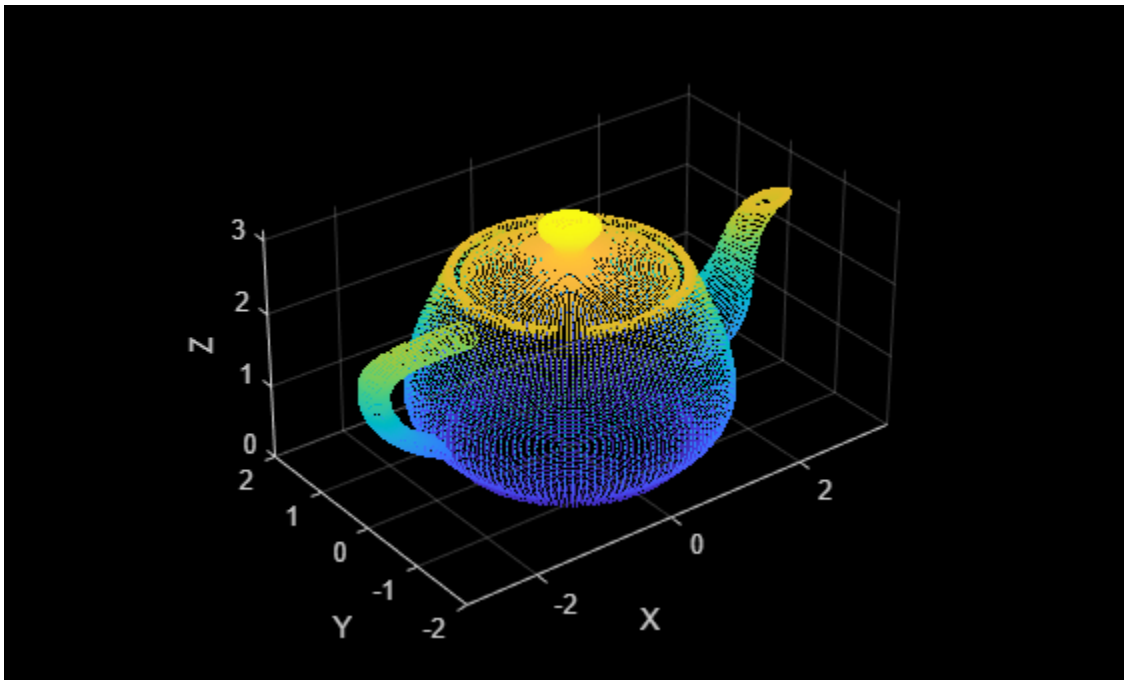
```
ptCloudOut = pctransform(ptCloudIn,tform)
ptCloudOut = pctransform(ptCloudIn,D)
```

Description

`ptCloudOut = pctransform(ptCloudIn,tform)` applies the specified 3-D affine transform, `tform` to the point cloud, `ptCloudIn`. The transformation can be a rigid, similarity, or affine transformation.

`ptCloudOut = pctransform(ptCloudIn,D)` applies the displacement field `D` to the point cloud. Point cloud transformation using a displacement field define translations with respect to each point in the point cloud.

Examples



Rotate 3-D Point Cloud Using Rigid Transformation

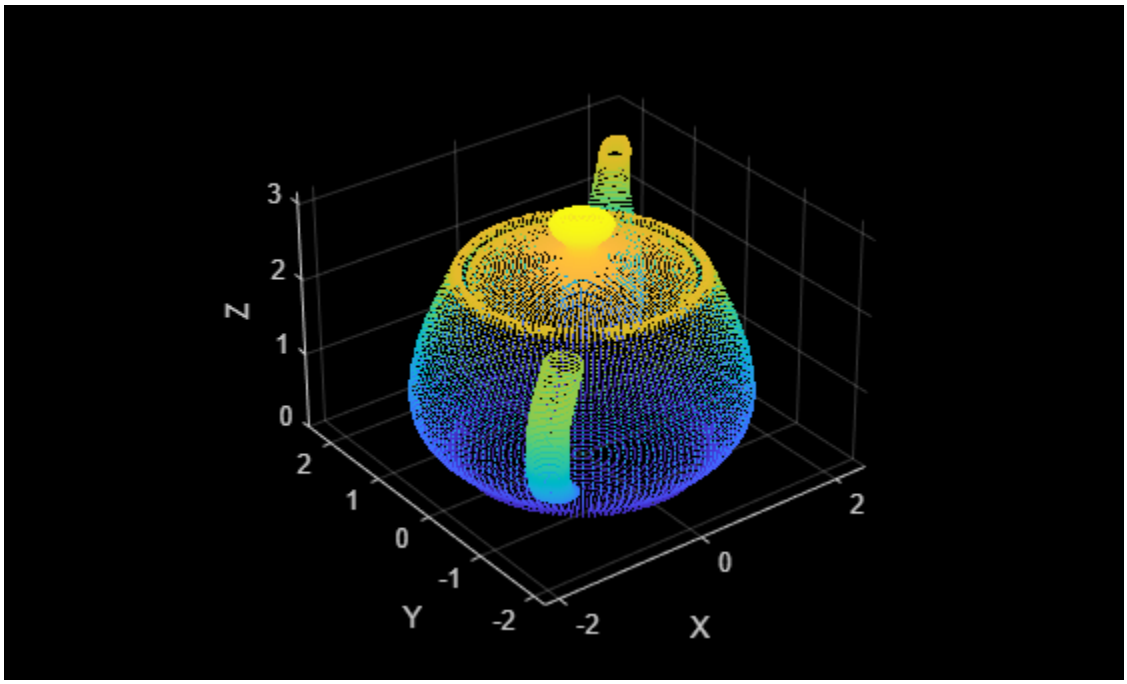
Read a point cloud.

```
ptCloud = pcread('teapot.ply');
```

Plot the point cloud.

```
figure
pcshow(ptCloud)
xlabel('X')
ylabel('Y')
zlabel('Z')
```

Create a transformation object with a 45 degree rotation along the z-axis.



```
rotationAngles = [0 0 45];
translation = [0 0 0];
tform = rigidtform3d(rotationAngles,translation);
```

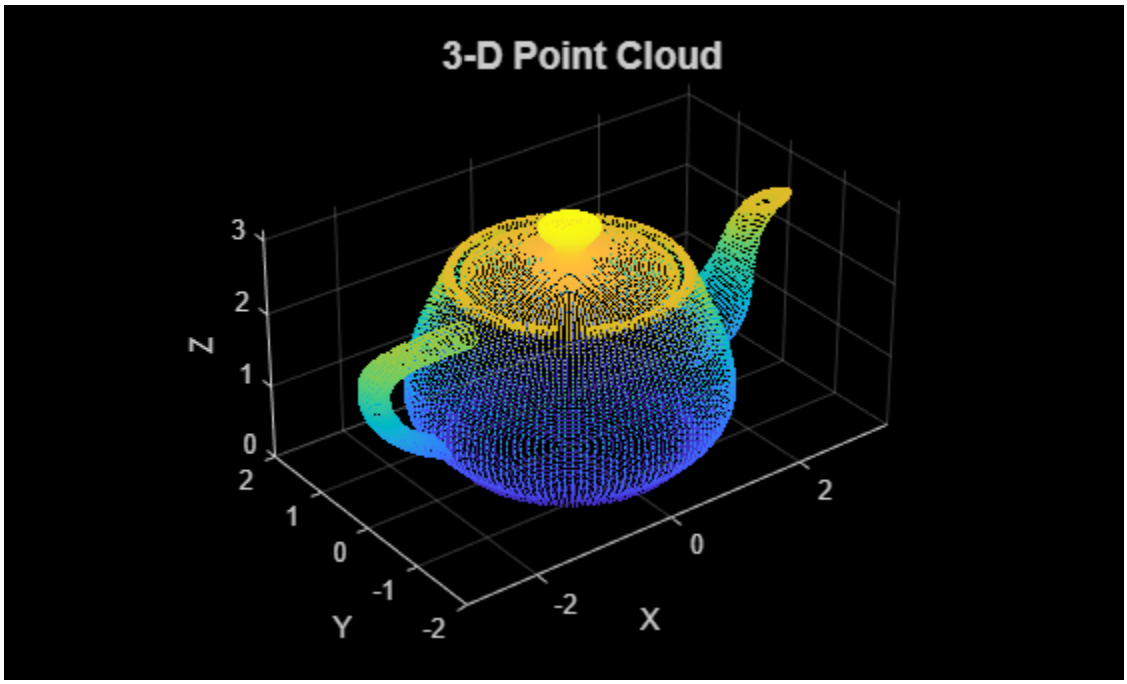
Transform the point cloud.

```
ptCloudOut = pctransform(ptCloud,tform);
```

Plot the transformed point cloud.

```
figure
pcshow(ptCloudOut)
xlabel('X')
ylabel('Y')
zlabel('Z')
```

Rigid and Nonrigid Transformations of 3-D Point Cloud



This example applies a rigid transformation (rotation) and a nonrigid transformation (shear) to a 3-D point cloud.

Read a point cloud into the workspace.

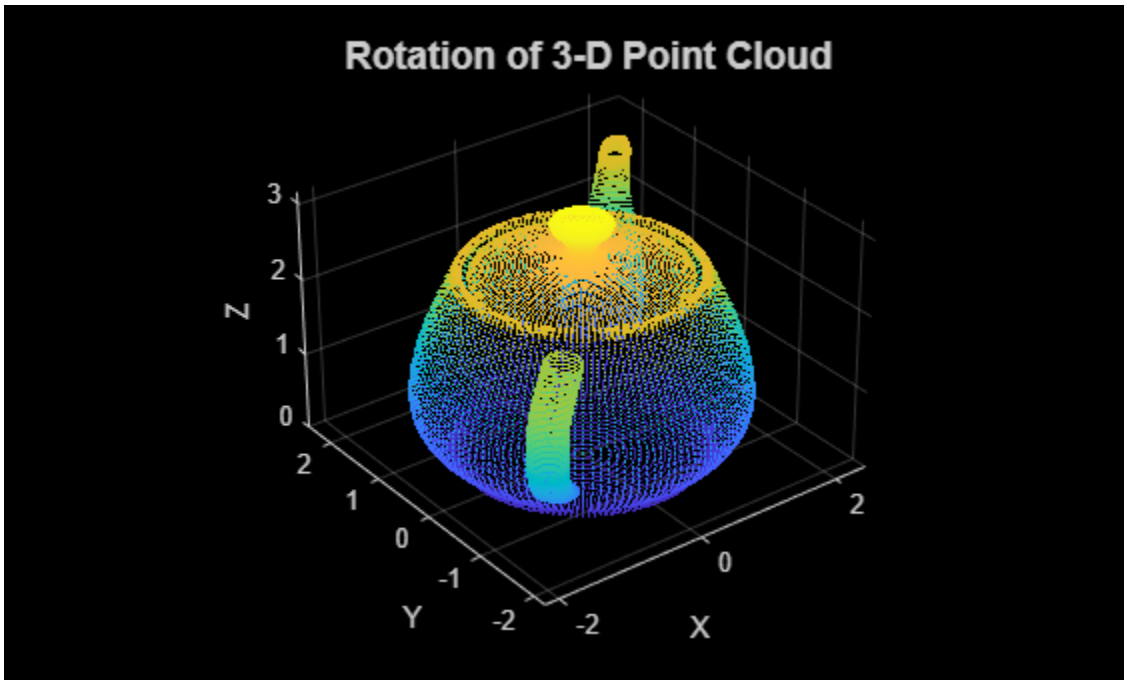
```
ptCloud = pcread('teapot.ply');
```

Plot the original 3-D point cloud.

```
figure1 = figure;
axes1 = axes(Parent=figure1);
pcshow(ptCloud,Parent=axes1,AxesVisibility='on');
xlabel('X');
ylabel('Y');
zlabel('Z');
title('3-D Point Cloud',FontSize=14)
```

Rotation of 3-D Point Cloud

Create a rigid transformation object that defines a 45 degree rotation along the *z*-axis.



```
rotationAngles = [0 0 45];
translation = [0 0 0];
tform = rigidtform3d(rotationAngles,translation);
```

Transform the point cloud.

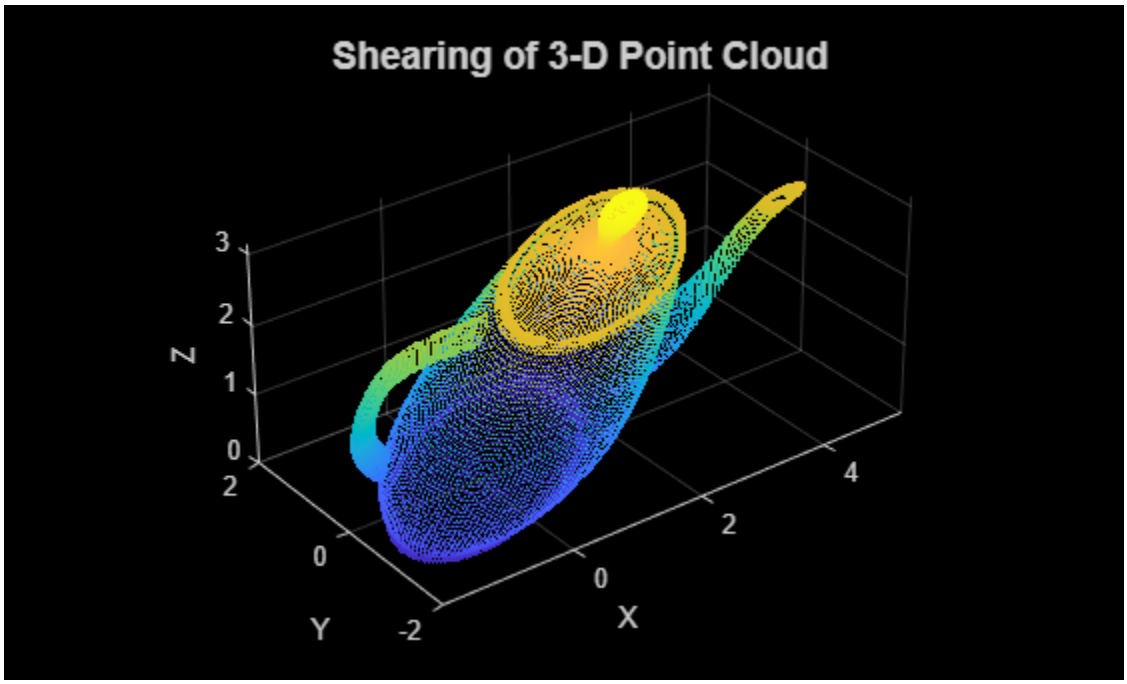
```
ptCloudOut1 = pctransform(ptCloud,tform);
```

Plot the rotated point cloud.

```
figure2 = figure;
axes2 = axes(Parent=figure2);
pcshow(ptCloudOut1,Parent=axes2,AxesVisibility='on');
xlabel('X');
ylabel('Y');
zlabel('Z');
title({'Rotation of 3-D Point Cloud'},FontSize=14)
```

Shearing of 3-D Point Cloud

Create an affine transformation object that defines shearing along the *x*-axis.



```
A = [1 0.75 0.75 0; ...
     0   1    0  0; ...
     0   0    1  0; ...
     0   0    0  1];
tform = affinetform3d(A);
```

Transform the point cloud.

```
ptCloudOut2 = pctransform(ptCloud,tform);
```

Plot the transformed point cloud.

```
figure3 = figure;
axes3 = axes(Parent=figure3);
pcshow(ptCloudOut2,Parent=axes3,AxesVisibility='on');
xlabel('X');
ylabel('Y');
zlabel('Z');
title({'Shearing of 3-D Point Cloud'},FontSize=14)
```

Point Cloud Transformation Using Displacement Field

Read a point cloud into the workspace.

```
ptCloud = pcread('teapot.ply');
```

Create a displacement field `D` of same size as the point cloud.

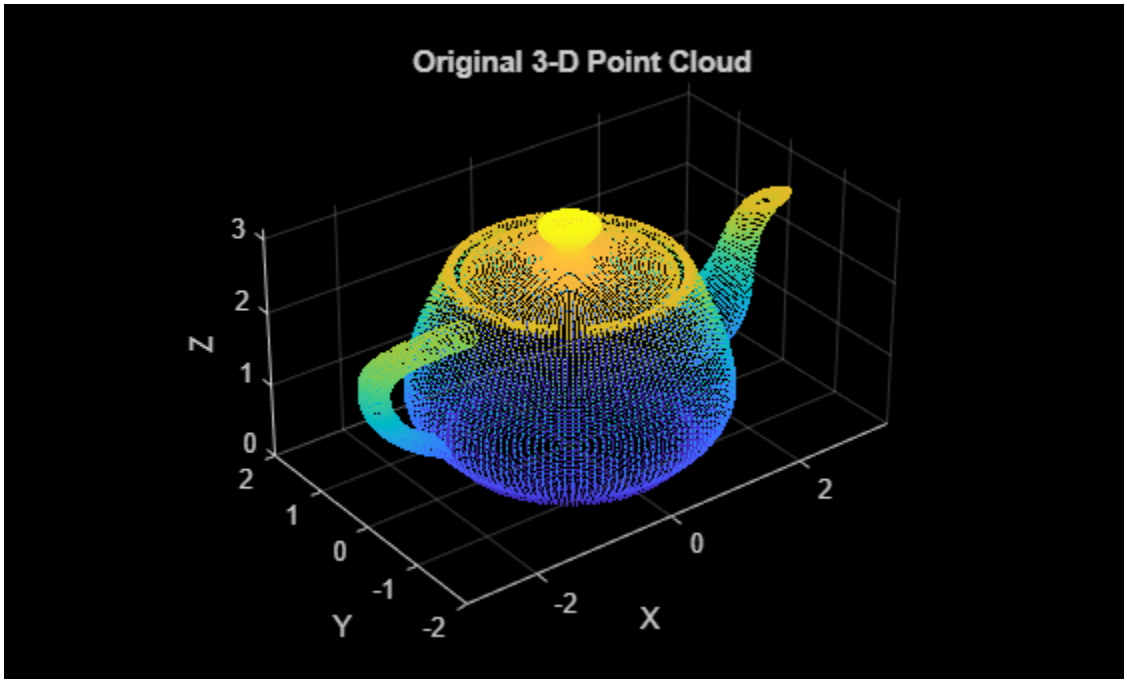
```
D = zeros(size(ptCloud.Location));
```

Set the displacement field value along *x*-axis for the first half of the points to 7.

```
pthalf = ptCloud.Count/2;
D(1:pthalf,1) = 7;
```

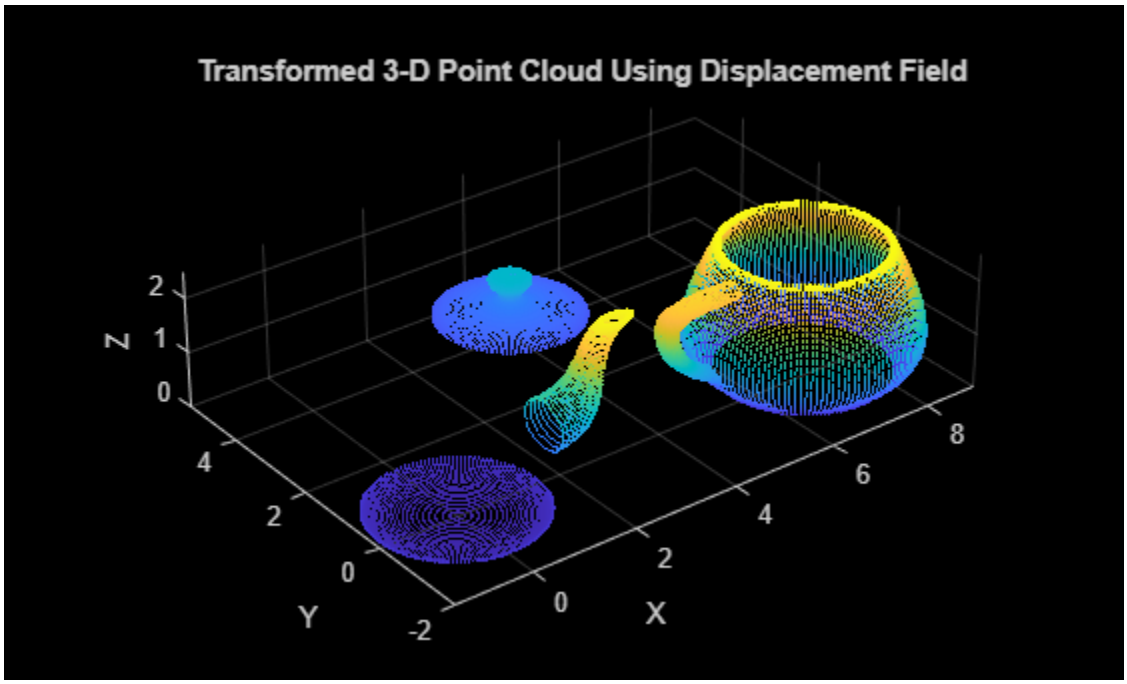
Extract the indices of points within a region-of-interest (ROI) using the `pointCloud` method `findNeighborsInRadius`. Set the displacement field value along the *x*-, *y*-, and *z*-axis for points within the ROI to 4, 4, and -2, respectively.

```
indices = findNeighborsInRadius(ptCloud,[0 0 3.1],1.5);
D(indices,1:2) = 4;
D(indices,3) = -2;
```



Transform the point cloud using the displacement field.

```
ptCloudOut = pctransform(ptCloud,D);
```



Display the original and transformed point cloud.

```
figure
pcshow(ptCloud)
xlabel('X');
```

```
ylabel('Y');
zlabel('Z');
title('Original 3-D Point Cloud')
```

```
figure
pcshow(ptCloudOut)
xlabel('X');
ylabel('Y');
zlabel('Z');
title('Transformed 3-D Point Cloud Using Displacement Field')
```

Input Arguments

`ptCloudIn` — Point cloud
`pointCloud` object

Point cloud, specified as a `pointCloud` object.

`tform` — 3-D geometric transformation
`rigidtform3d` object | `simtform3d` object | `affinetform3d` object

3-D geometric transformation, specified as a `rigidtform3d`, `simtform3d`, or `affinetform3d` object. See “Specify Transformation Matrix” for details on how to set up an affine 3-D `tform` input.

`D` — Displacement field
M-by-3 matrix | *M*-by-*N*-by-3 array

Displacement field, specified as either *M*-by-3 or an *M*-by-*N*-by-3 array. The displacement field is a set of displacement vectors that specify the magnitude and direction of translation for each point in the point cloud. The size of the displacement field must be the same as the size of the `Location` property of the `pointCloud` object.

Data Types: `single` | `double`

Output Arguments

`ptCloudOut` — Transformed point cloud
`pointCloud` object

Transformed point cloud, returned as a `pointCloud` object. The transformation applies to the coordinates of points and their normal vectors.

Version History

Introduced in R2015a

R2022b: Supports new geometric transformation objects

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, you can now specify `tform` as a `rigidtform3d`, `simtform3d`, or `affinetform3d` object, which use the premultiply convention.

Although you can still specify `tform` as a `rigid3d` object or an `affine3d` object, these objects are not recommended because they use the postmultiply convention. You can streamline your geometric transformation workflows by switching to the new premultiply geometric transformation objects. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- Because of architectural and implementation differences between the GPU and CPU, the selection of neighboring points may differ during the computation of normal vectors. As a result, there may be numerical mismatches between MATLAB simulation and the output from code generation.

pcnormals

Estimate normals for point cloud

Syntax

```
normals = pcnormals(ptCloud)
normals = pcnormals(ptCloud,k)
```

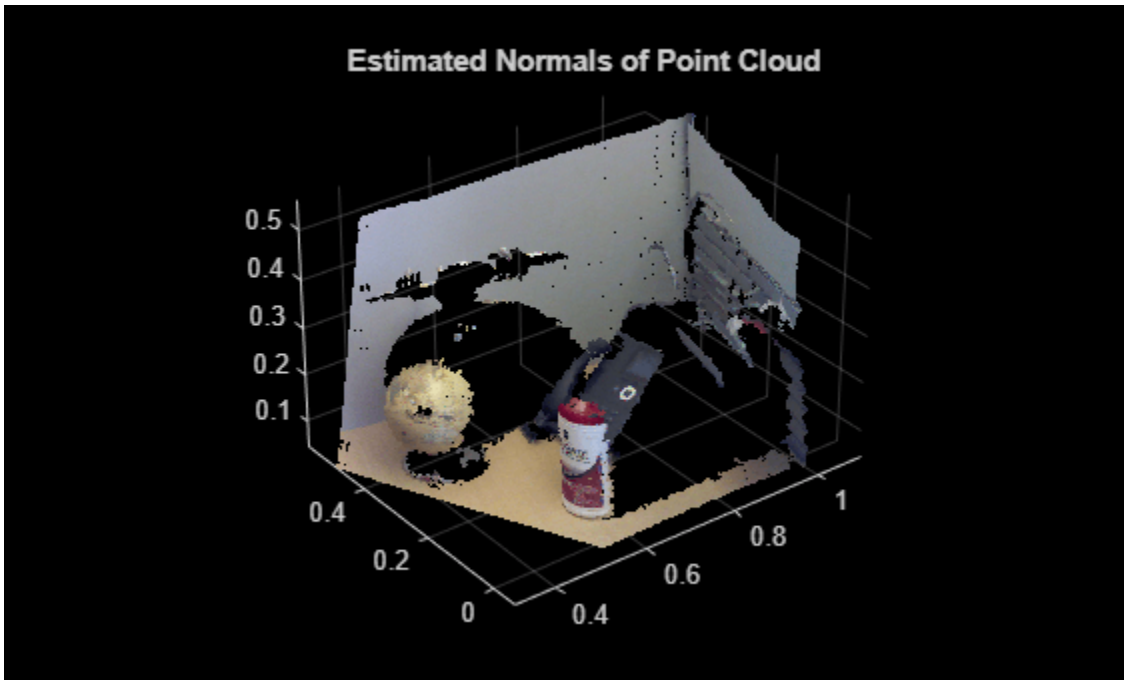
Description

`normals = pcnormals(ptCloud)` returns a matrix that stores a normal for each point in the input `ptCloud`. The function uses six neighboring points to fit a local plane to determine each normal vector.

`normals = pcnormals(ptCloud,k)` additionally specifies `k`, the number of points used for local plane fitting. The function uses this value rather than the six neighboring points as described in the first syntax.

Examples

Estimate Normals of Point Cloud



Load a point cloud.

```
load('object3d.mat');
```

Estimate the normal vectors.

```
normals = pcnormals(ptCloud);

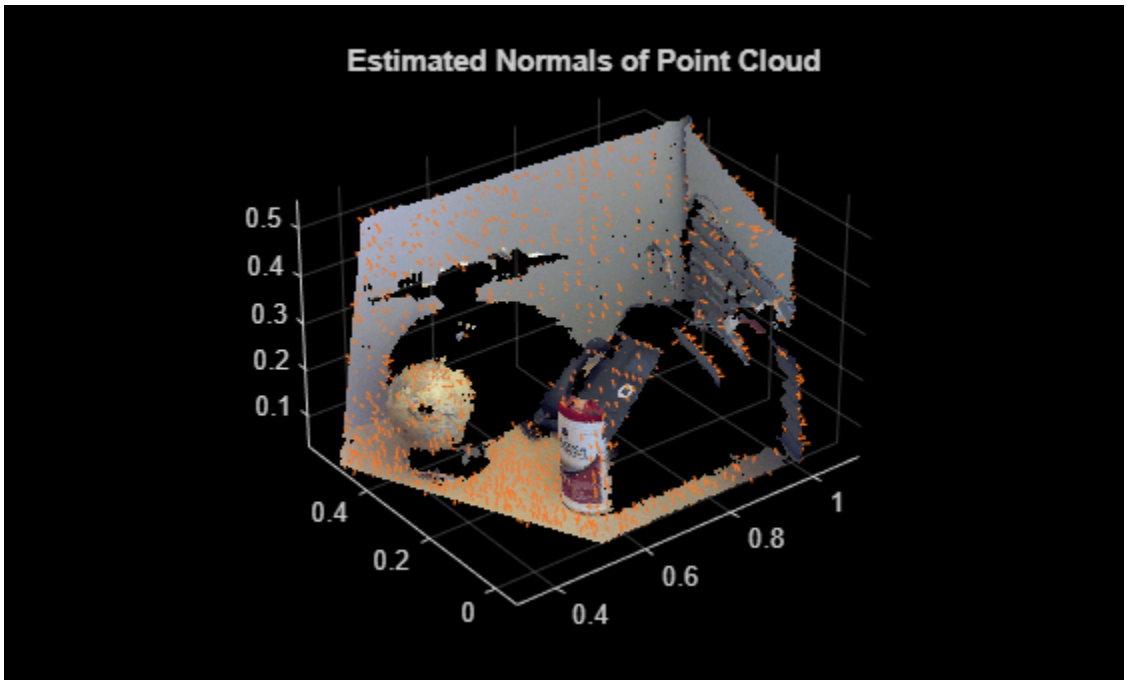
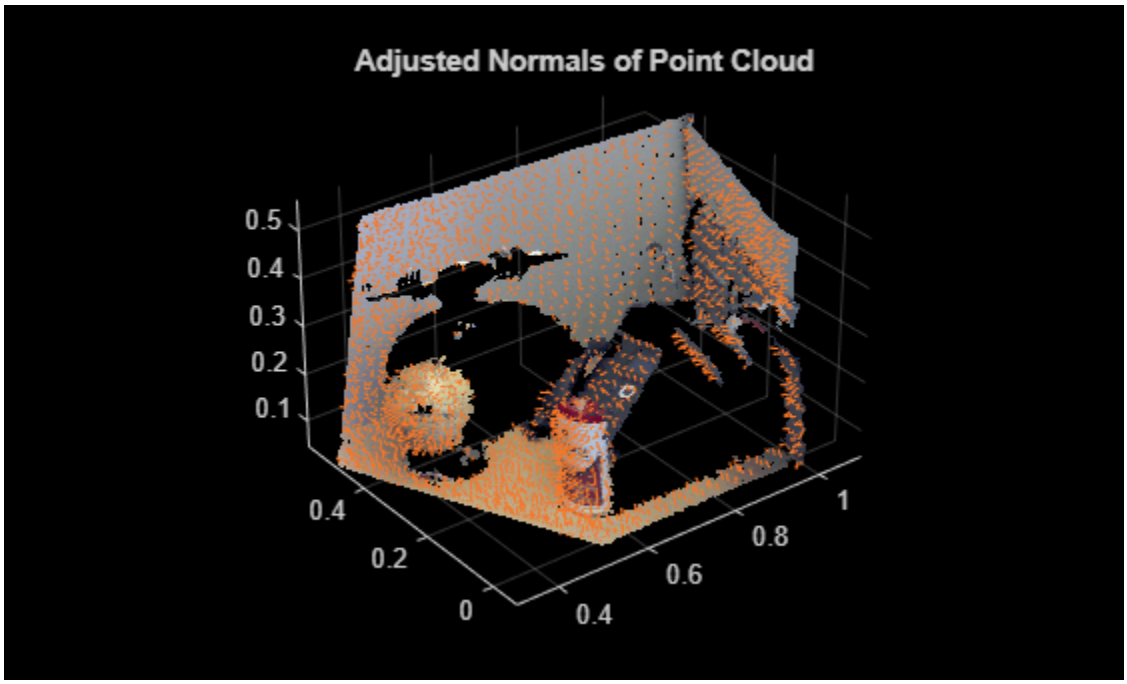


figure
pcshow(ptCloud)
title('Estimated Normals of Point Cloud')
hold on
```

```
x = ptCloud.Location(1:10:end,1:10:end,1);
y = ptCloud.Location(1:10:end,1:10:end,2);
z = ptCloud.Location(1:10:end,1:10:end,3);
u = normals(1:10:end,1:10:end,1);
v = normals(1:10:end,1:10:end,2);
w = normals(1:10:end,1:10:end,3);
```

Plot the normal vectors.

```
quiver3(x,y,z,u,v,w);
hold off
```



Flip the normals to point towards the sensor location. This step is necessary only for determining the inward or outward direction of the surface. The sensor center is set in *x* , *y* , *z* coordinates.

```
sensorCenter = [0,-0.3,0.3];
for k = 1 : numel(x)
   p1 = sensorCenter - [x(k),y(k),z(k)];
   p2 = [u(k),v(k),w(k)];
   % Flip the normal vector if it is not pointing towards the sensor.
   angle = atan2(norm(cross(p1,p2)),p1*p2');
   if angle > pi/2 || angle < -pi/2
       u(k) = -u(k);
       v(k) = -v(k);
       w(k) = -w(k);
   end
end
```

Plot the adjusted normals.

```
figure
pcshow(ptCloud)
title('Adjusted Normals of Point Cloud')
hold on
quiver3(x, y, z, u, v, w);
hold off
```

Input Arguments

`ptCloud` — Object for storing point cloud
`pointCloud` object

Object for storing point cloud, returned as a `pointCloud` object.

k — Number of points used for local plane fitting
integer greater than or equal to 3

Number of points used for local plane fitting, specified as an integer greater than or equal to 3. Increasing this value improves accuracy but slows down computation time. If you do not specify `k`, the function uses six neighboring points to fit a local plane to determine each normal vector.

Output Arguments

`normals` — Normals used to fit a local plane
M-by-3 matrix | *M*-by-*N*-by-3 matrix

Normals used to fit a local plane, returned as an *M*-by-3 or an *M*-by-*N*-by-3 matrix. The normal vectors are computed locally using the number of neighbors defined by the value of `k`. If `k` is not an input, it uses six neighboring points. The direction of each normal vector can be set based on how you acquired the points. The “Estimate Normals of Point Cloud” on page 3-1071 example, shows how to set the direction when the normal vectors are pointing towards the sensor.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- For GPU code generation, the number of neighbors must be a compile-time constant.
- Because of architectural and implementation differences between the GPU and CPU, the choice of neighboring points may differ during computation of normal vectors. As a result, there may be numerical mismatch between MATLAB simulation and the output from code generation.

pcfitcylinder

Fit cylinder to 3-D point cloud

Syntax

```
model = pcfitcylinder(ptCloudIn,maxDistance)
model = pcfitcylinder(ptCloudIn,maxDistance,referenceVector)
model = pcfitcylinder(ptCloudIn,maxDistance,referenceVector,
maxAngularDistance)

[model,inlierIndices,outlierIndices] = pcfitcylinder( ___ )
[model,inlierIndices,outlierIndices,meanError] = pcfitcylinder( ___ )
[ ___ ] = pcfitcylinder( ___ ,Name=Value)
```

Description

`model = pcfitcylinder(ptCloudIn,maxDistance)` fits a cylinder to a point cloud with a maximum allowable distance from an inlier point to the cylinder. This function uses the M-estimator SAmple Consensus (MSAC) algorithm to find the cylinder.

`model = pcfitcylinder(ptCloudIn,maxDistance,referenceVector)` fits a cylinder to the point cloud with additional orientation constraints specified by the 1-by-3 reference orientation input vector.

`model = pcfitcylinder(ptCloudIn,maxDistance,referenceVector, maxAngularDistance)` additionally specifies the maximum allowed absolute angular distance.

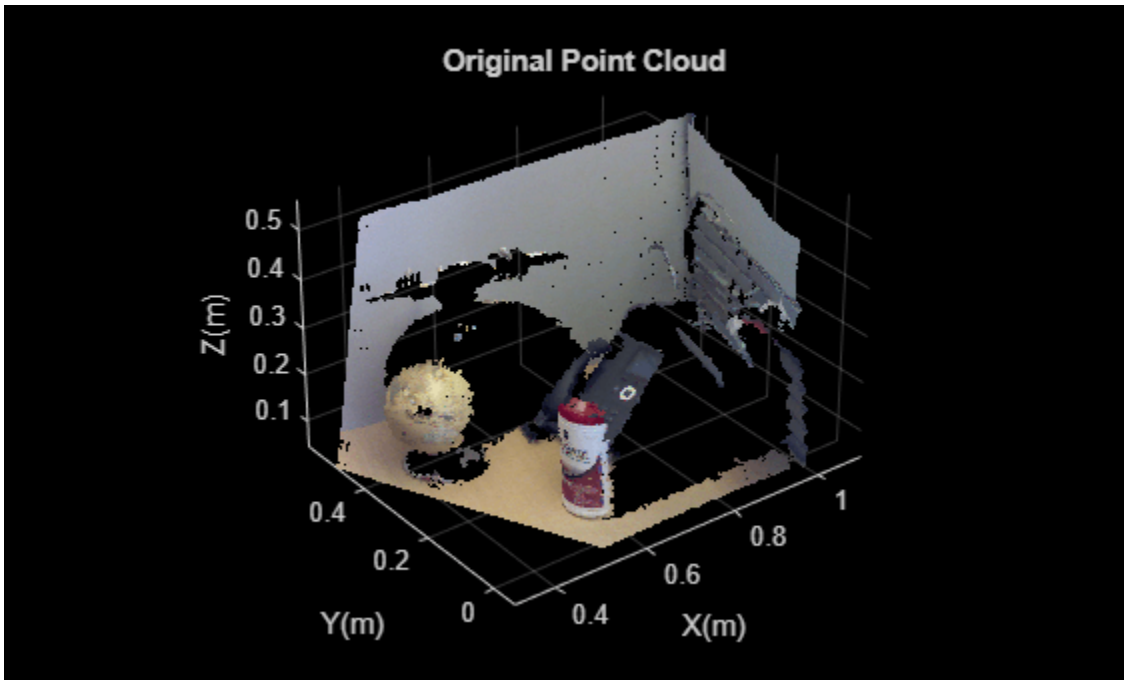
`[model,inlierIndices,outlierIndices] = pcfitcylinder( ___ )` additionally returns linear indices to the inlier and outlier points in the point cloud input.

`[model,inlierIndices,outlierIndices,meanError] = pcfitcylinder( ___ )` additionally returns the mean error of the distance of the inlier points to the model.

`[ ___ ] = pcfitcylinder( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `MaxNumTrials=1000` sets the maximum number of random trials to 1000.

Examples

Extract Cylinder from Point Cloud



Load the point cloud.

```
load("object3d.mat");
```

Display the point cloud.

```
figure
pcshow(ptCloud)
```

```
xlabel("X(m)")
ylabel("Y(m)")
zlabel("Z(m)")
title("Original Point Cloud")
```

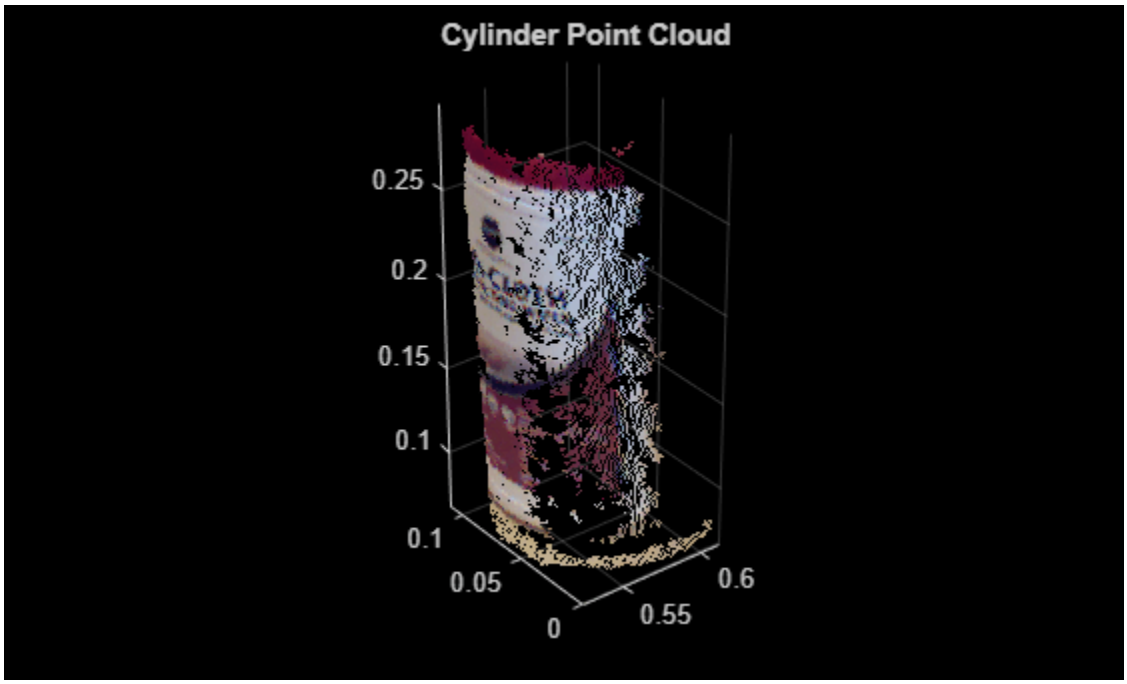
Set the maximum point-to-cylinder distance (5 mm) for cylinder fitting.

```
maxDistance = 0.005;
```

Set the region of interest to constrain the search.

```
roi = [0.4 0.6 -Inf 0.2 0.1 Inf];
sampleIndices = findPointsInROI(ptCloud,roi);
```

Set the orientation constraint.



```
referenceVector = [0 0 1];
```

Detect the cylinder and extract it from the point cloud by specifying the inlier points.

```
[model,inlierIndices] = pcfitcylinder(ptCloud,maxDistance,...
        referenceVector,SampleIndices=sampleIndices);
pc = select(ptCloud,inlierIndices);
```

Plot the extracted cylinder.

```
figure
pcshow(pc)
title("Cylinder Point Cloud")
```

Detect Cylinder in Point Cloud

Load a MAT file containing a point cloud into the workspace.

```
load("object3d.mat");
```

Display the point cloud.

```
figure
pcshow(ptCloud)
title("Detect a Cylinder in a Point Cloud")
```

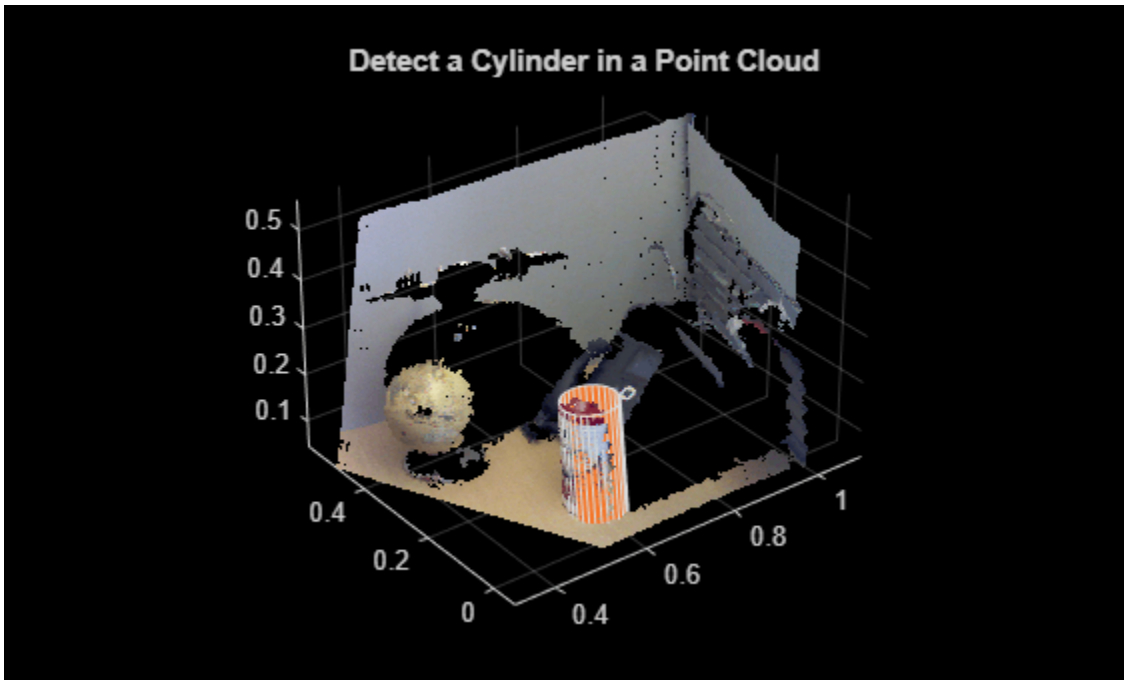
Set the maximum point-to-cylinder distance for cylinder fitting to 5mm.

```
maxDistance = 0.005;
```

Specify a region of interest (ROI) to constrain the fitting function.

```
roi = [0.4 0.6; -inf 0.2; 0.1 inf];
sampleIndices = findPointsInROI(ptCloud,roi);
```

Set the orientation constraint for the fitting function



```
referenceVector = [0 0 1];
```

Detect the cylinder in the specified ROI of the point cloud and extract it.

```
model = pcfitcylinder(ptCloud,maxDistance,referenceVector, ...
        SampleIndices=sampleIndices);
```

Plot the model of the detected cylinder.

```
hold on
plot(model)
```

Input Arguments

`ptCloudIn` — Point cloud

`pointCloud` object

Point cloud, specified as a `pointCloud` object. If the `Normal` property of the input `ptCloud` is empty, the function populates it with values to meet the requirements of the fitting algorithm.

`maxDistance` — Maximum distance from an inlier point to the cylinder

scalar value

Maximum distance from an inlier point to the cylinder, specified as a scalar value. Specify the distance in units that are consistent with the units you are using for the point cloud.

Data Types: `single` | `double`

`referenceVector` — Reference orientation constraint

1-by-3 vector

Reference orientation constraint, specified as a 1-by-3 vector.

`maxAngularDistance` — Maximum absolute angular distance

5 (default) | scalar value

Maximum absolute angular distance, specified as a scalar value. The maximum angular distance is measured in degrees between the direction of the fitted cylinder and the reference orientation.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'SampleIndices',[]`.

`SampleIndices` — Linear indices of points to sample
`[]` (default) | column vector

Linear indices of points to sample in the input point cloud, specified as the comma-separated pair consisting of '`SampleIndices`' and a column vector. An empty vector means that all points are candidates to sample when fitting the cylinder during the RANSAC iteration. If you specify a subset of points, the function fits the model by sampling only those points in the subset. Providing a subset of points can significantly speed up the process by reducing the number of trials. You can generate the indices vector using the `findPointsInROI` method of the `pointCloud` object.

`MaxNumTrials` — Maximum number of random trials
`1000` (default) | positive integer

Maximum number of random trials for finding inliers, specified as the comma-separated pair consisting of '`MaxNumTrials`' and a positive integer. To improve robustness of the output, increase this value. However, doing so adds additional computations.

`Confidence` — Percentage for finding maximum number of inliers
`99` (default) | numeric scalar in the range (0 100)

Percentage for finding maximum number of inliers, specified as the comma-separated pair consisting of '`Confidence`' and a numeric scalar, in the range (0 100). To improve the robustness of the output, increase this value. However, doing so adds additional computations.

Output Arguments

`model` — Geometric model of cylinder
`cylinderModel` object.

Geometric model of cylinder, returned as a `cylinderModel` object.

The coefficients for the output model are set to zero when:

- The input point cloud does not contain enough valid points.
- The algorithm cannot find enough inlier points.

`inlierIndices` — Linear indices of inlier points
column vector

Linear indices of the inlier points in the input point cloud, returned as a column vector.

`outlierIndices` — Linear indices of outlier points
column vector

Linear indices of the outlier points in the input point cloud returned as a column vector.

`meanError` — Mean square error
scalar value

Mean error of the distance of inlier points to the model, returned as a scalar value.

Algorithms

The function returns a geometric model that describes the cylinder. This function uses the M-estimator SAmple Consensus (MSAC) algorithm to find the cylinder. The MSAC algorithm is a variant of the RANdom SAmple Consensus (RANSAC) algorithm.

The fitting algorithm for the `pcfitcylinder` function requires point cloud normals. Therefore, if the `Normal` property for the input point cloud is empty, the function fills it. When the function fills the `Normal` property, it uses six points to fit the local cylinder. If six points do not work and the fitting fails, consider calling the `pcnormals` function which enables you to select the number of points to use.

Version History

Introduced in R2015b

pcfitplane

Fit plane to 3-D point cloud

Syntax

```
model = pcfitplane(ptCloudIn,maxDistance)
model = pcfitplane(ptCloudIn,maxDistance,referenceVector)
model = pcfitplane(ptCloudIn,maxDistance,referenceVector,maxAngularDistance)

[model,inlierIndices,outlierIndices] = pcfitplane( ___ )
[model,inlierIndices,outlierIndices,meanError] = pcfitplane( ___ )
[ ___ ] = pcfitplane( ___ ,Name=Value)
```

Description

`model = pcfitplane(ptCloudIn,maxDistance)` fits a plane to a point cloud that has a maximum allowable distance from an inlier point to the plane. The function returns a geometrical model that describes the plane.

This function uses the M-estimator SAmple Consensus (MSAC) algorithm to find the plane. The MSAC algorithm is a variant of the RANdom SAmple Consensus (RANSAC) algorithm.

`model = pcfitplane(ptCloudIn,maxDistance,referenceVector)` fits a plane to a point cloud that has additional orientation constraints specified by the 1-by-3 `referenceVector` input.

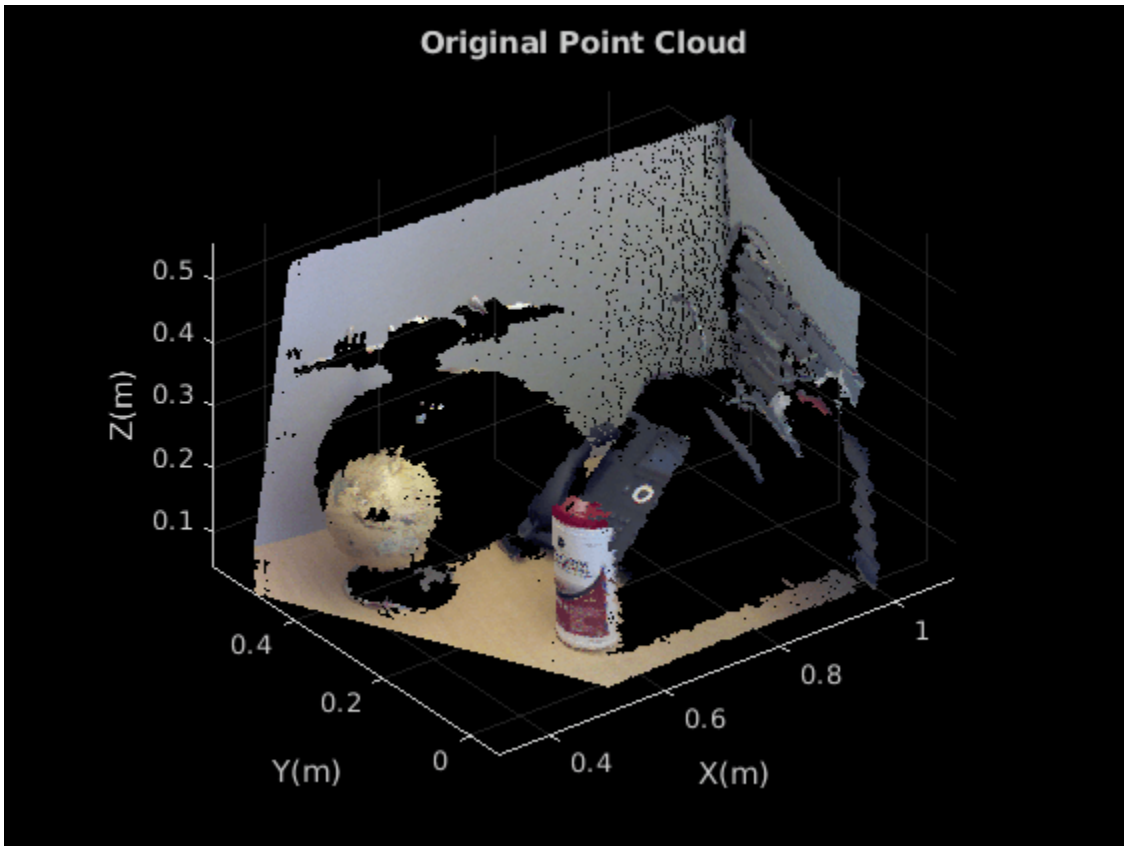
`model = pcfitplane(ptCloudIn,maxDistance,referenceVector,maxAngularDistance)` fits a plane to a point cloud that has a specified maximum angular distance.

`[model,inlierIndices,outlierIndices] = pcfitplane( ___ )` additionally returns the linear indices to the inlier and outlier points in the point cloud input.

`[model,inlierIndices,outlierIndices,meanError] = pcfitplane( ___ )` additionally returns the mean error of the distance of inlier points to the model, using any of the preceding syntaxes.

`[ ___ ] = pcfitplane( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `pcfitplane(ptCloud,maxDistance,referenceVector,maxAngularDistance,Confidence=95)` sets the confidence percentage for finding maximum number of inlier to `95`.

Examples



Detect Multiple Planes from Point Cloud

Load the point cloud.

```
load("object3d.mat")
```

Display the point cloud and label the figure.

```
figure
pcshow(ptCloud)
xlabel("X(m)")
ylabel("Y(m)")
zlabel("Z(m)")
title("Original Point Cloud")
```

Set the maximum point-to-plane distance (2cm) for plane fitting.

```
maxDistance = 0.02;
```

Set the normal vector of the plane.

```
referenceVector = [0,0,1];
```

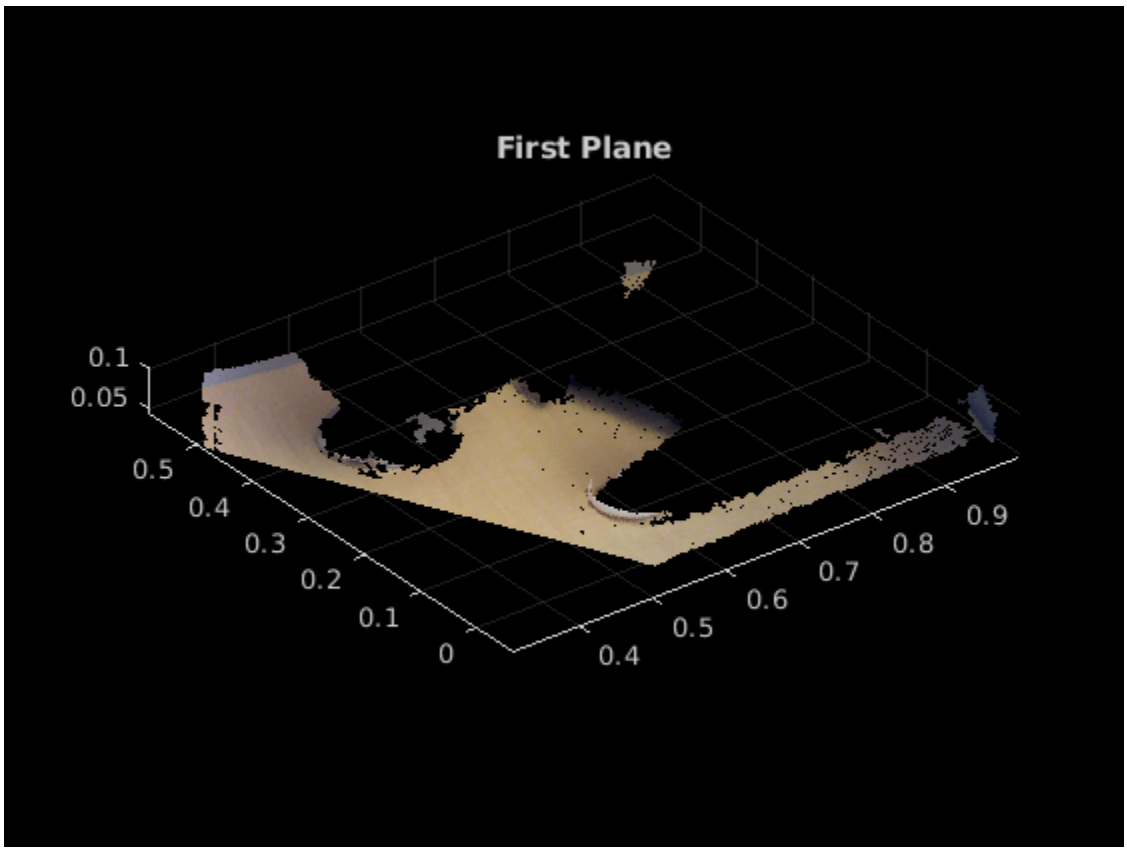
Set the maximum angular distance to 5 degrees.

```
maxAngularDistance = 5;
```

Detect the first plane, the table, and extract it from the point cloud.

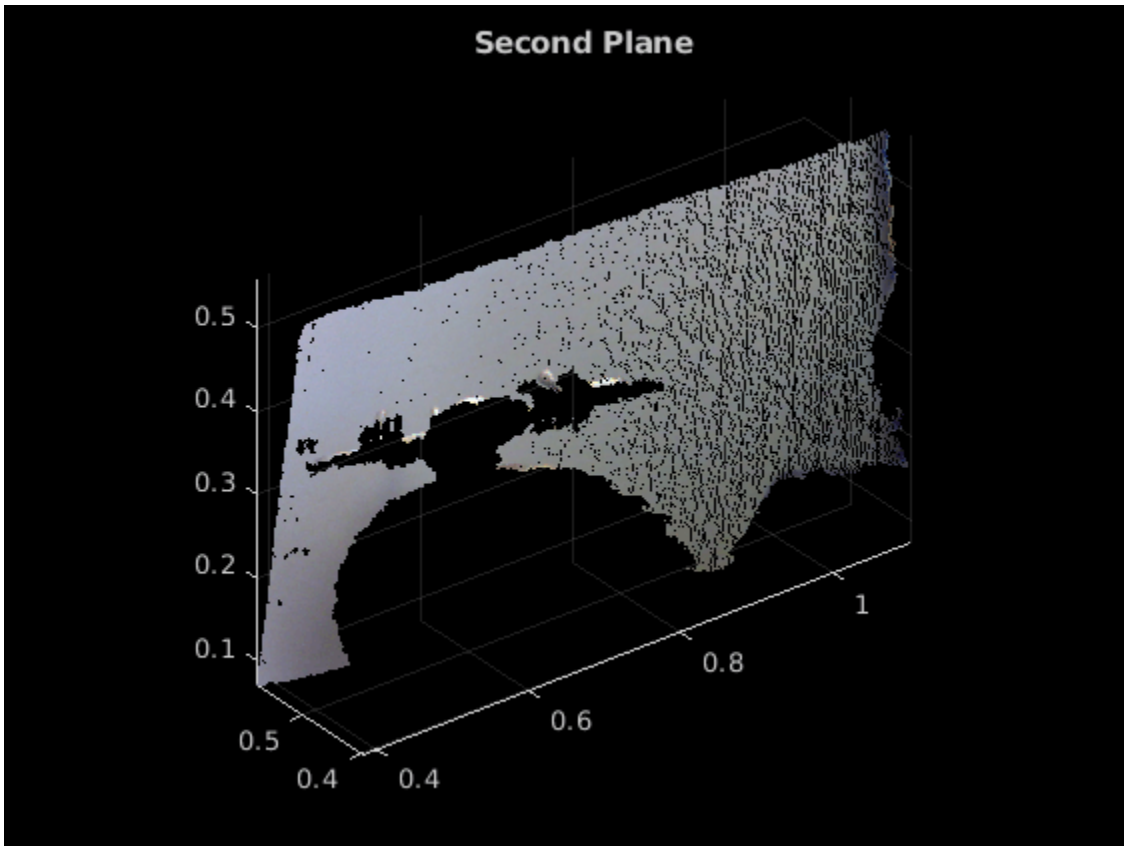
```
[model1,inlierIndices,outlierIndices] = pcfitplane(ptCloud,...
            maxDistance,referenceVector,maxAngularDistance);
plane1 = select(ptCloud,inlierIndices);
remainPtCloud = select(ptCloud,outlierIndices);
```

Set the region of interest to constrain the search for the second plane, left wall.



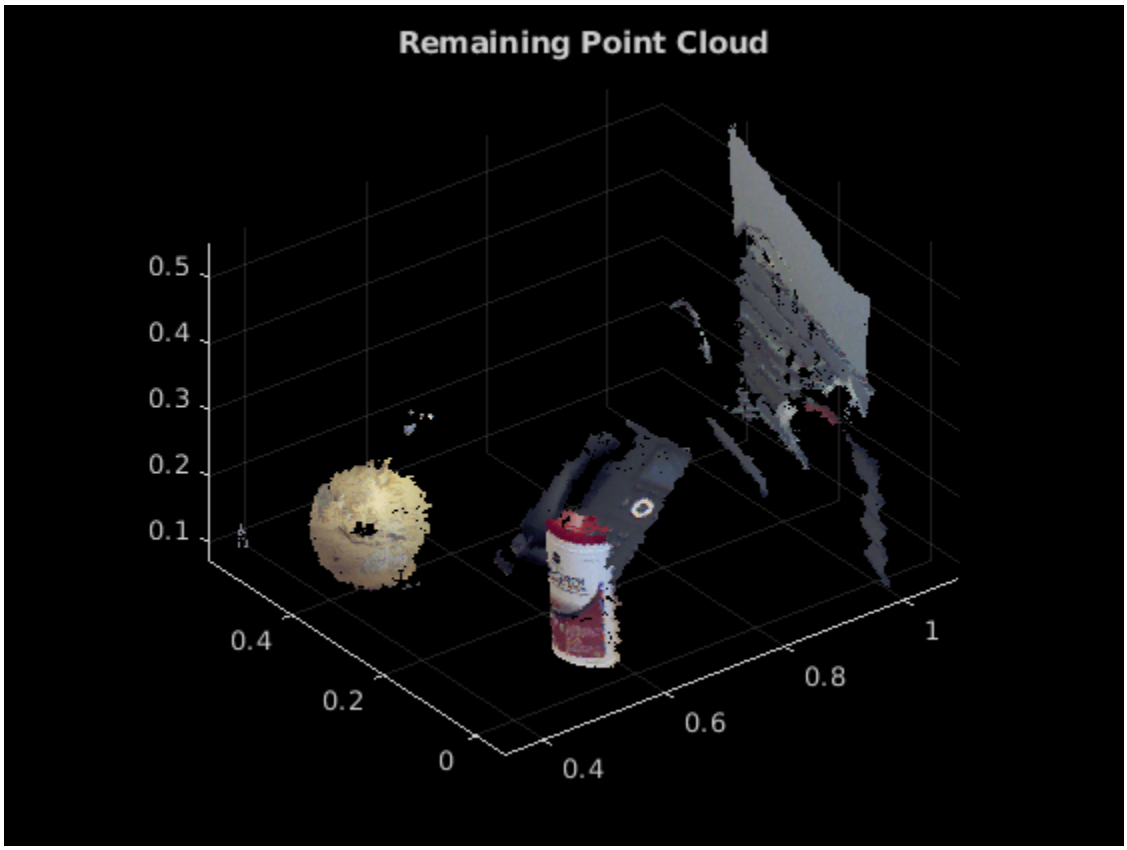
```
roi = [-inf,inf;0.4,inf;-inf,inf];
sampleIndices = findPointsInROI(remainPtCloud,roi);
```

Detect the left wall and extract it from the remaining point cloud.



```
[model2,inlierIndices,outlierIndices] = pcfitplane(remainPtCloud,...
            maxDistance,SampleIndices=sampleIndices);
plane2 = select(remainPtCloud,inlierIndices);
remainPtCloud = select(remainPtCloud,outlierIndices);
```

Plot the two planes and the remaining points.



```
figure
pcshow(plane1)
title("First Plane")
```

```
figure
pcshow(plane2)
title("Second Plane")
```

```
figure
pcshow(remainPtCloud)
title("Remaining Point Cloud")
```

Input Arguments

`ptCloudIn` — Point cloud
`pointCloud` object

Point cloud, specified as a `pointCloud` object.

`maxDistance` — Maximum distance from an inlier point to the plane
scalar value

Maximum distance from an inlier point to the plane, specified as a scalar value. Specify the distance in units that are consistent with the units you are using for the point cloud.

Data Types: `single` | `double`

`referenceVector` — Reference orientation constraint
1-by-3 vector

Reference orientation constraint, specified as a 1-by-3 vector. You must specify this argument for the function to apply an orientation constraint to fit a plane to the input point cloud. If you do not specify the reference vector, the function fits the model using the plane equation, $ax + by + cz + d = 0$.

Data Types: `single` | `double`

`maxAngularDistance` — Maximum absolute angular distance
5 degrees (default) | scalar value

Maximum absolute angular distance between the normal vector of the fitted plane and the reference orientation, specified as a scalar value in degrees.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `pcfitplane(ptCloud,maxDistance,referenceVector,maxAngularDistance,Confidence=95)` sets the confidence percentage for finding maximum number of inlier to 95.

`SampleIndices` — Linear indices of points to be sampled
`[]` (default) | column vector

Linear indices of points to sample in the input point cloud, specified as a column vector. An empty vector means that all points are candidates to sample in the RANSAC iteration to fit the plane. When you specify a subset, only points in the subset are sampled to fit a model.

Providing a subset of points can significantly speed up the process and reduce the number of trials. You can generate the indices vector using the `findPointsInROI` object function of the `pointCloud` object.

`MaxNumTrials` — Maximum number of random trials
`1000` (default) | positive integer

Maximum number of random trials for finding inliers, specified as a positive integer. Increasing this value makes the output more robust but adds additional computations.

`Confidence` — Confidence percentage for finding maximum number of inliers
`99` (default) | numeric scalar in the range (0, 100)

Confidence percentage for finding maximum number of inliers, specified as a numeric scalar in the range (0 100). Increasing this value makes the output more robust but adds additional computations.

Output Arguments

`model` — Geometric model of plane
`planeModel` object

Geometric model of plane, returned as a `planeModel` object.

When the input point cloud does not contain enough valid points, or when the function cannot find enough inlier points, the coefficients for the output model are set to zero.

`inlierIndices` — Linear indices of inlier points
column vector

Linear indices of inlier points within the input point cloud, returned as a column vector.

`outlierIndices` — Linear indices of outlier points
column vector

Linear indices of outlier points within the input point cloud, returned as a column vector.

`meanError` — Mean square error
scalar value

Mean error of the distance of inlier points to the model, returned as a scalar value.

Version History

Introduced in R2015b

pcfitsphere

Fit sphere to 3-D point cloud

Syntax

```
model = pcfitsphere(ptCloudIn,maxDistance)
[model,inlierIndices,outlierIndices] = pcfitsphere( ___ )
[model,inlierIndices,outlierIndices,meanError] = pcfitsphere( ___ )
[ ___ ] = pcfitsphere( ___ ,Name=Value)
```

Description

`model = pcfitsphere(ptCloudIn,maxDistance)` fits a sphere to a point cloud that has a maximum allowable distance from an inlier point to the sphere. The function returns a geometrical model that describes the sphere.

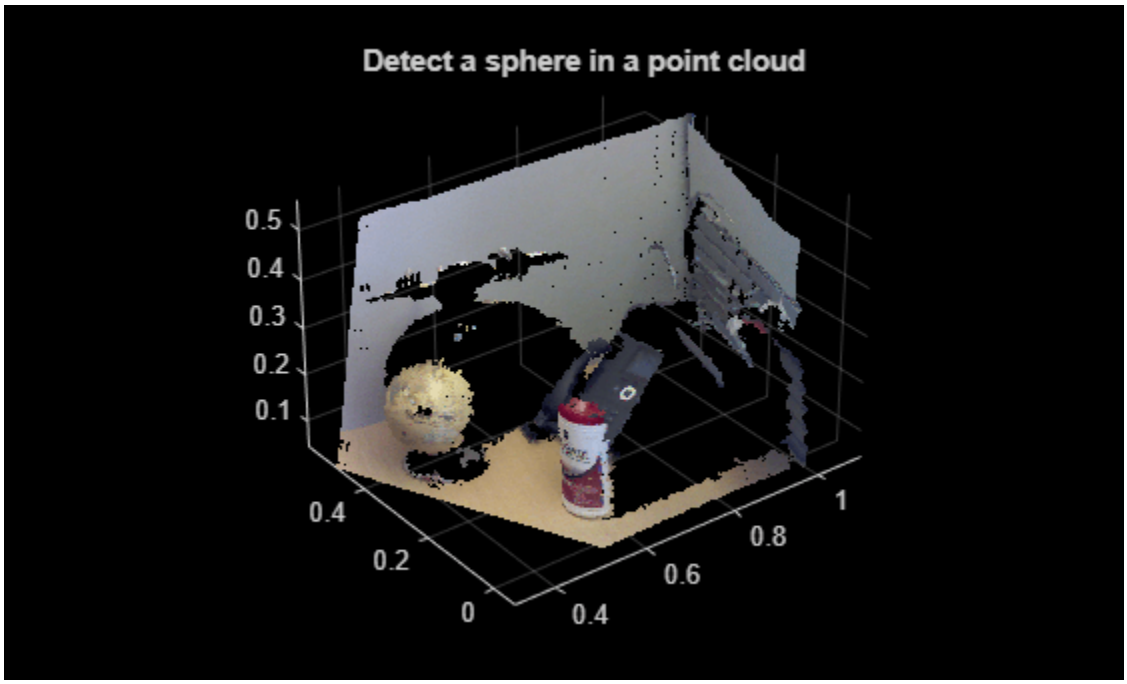
This function uses the M-estimator SAmple Consensus (MSAC) algorithm to find the sphere. The MSAC algorithm is a variant of the RANdom SAmple Consensus (RANSAC) algorithm.

`[model,inlierIndices,outlierIndices] = pcfitsphere( ___ )` additionally returns linear indices to the inlier and outlier points in the point cloud input.

`[model,inlierIndices,outlierIndices,meanError] = pcfitsphere( ___ )` additionally returns the mean error of the distance of inlier points to the model, using any of the preceding syntaxes.

`[ ___ ] = pcfitsphere( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `MaxNumTrials=1000` sets the maximum number of random trials to 1000.

Examples



Detect Sphere in Point Cloud

Load a point cloud into the workspace.

```
load("object3d.mat");
```

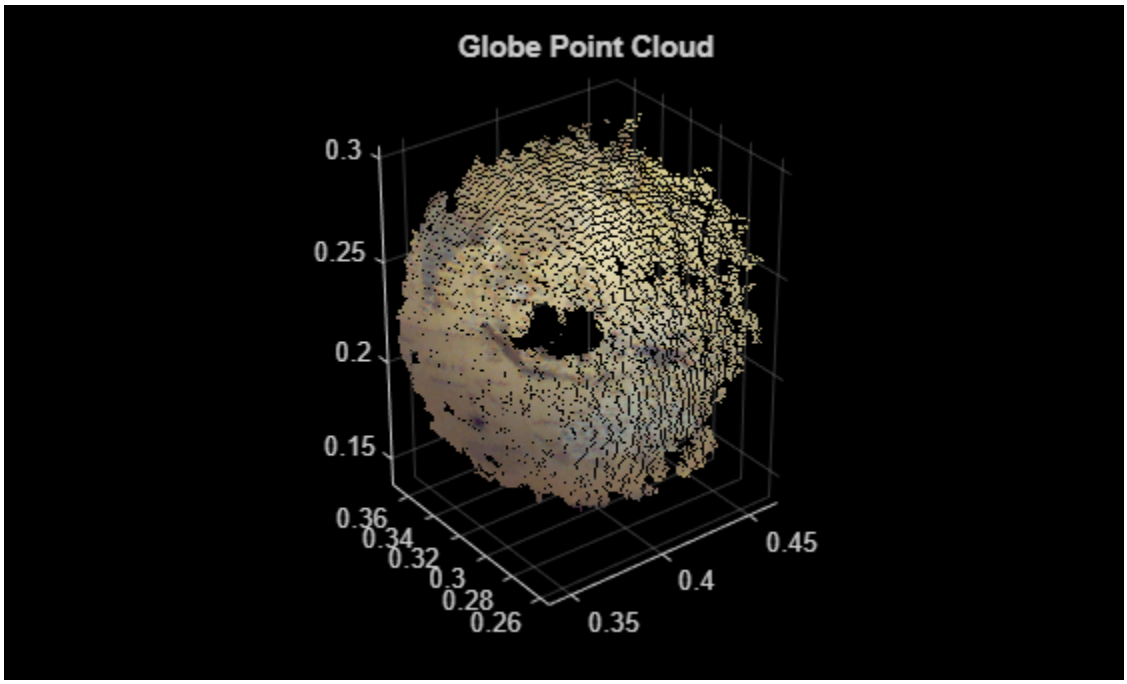
Display the point cloud and label the figure.

```
figure
pcshow(ptCloud)
title("Detect a sphere in a point cloud")
```

Set the maximum point-to-sphere distance for sphere fitting to 1cm.

```
maxDistance = 0.01;
```

Set the region of interest to constrain the search.



```
roi = [-inf,0.5;0.2,0.4;0.1,inf];
sampleIndices = findPointsInROI(ptCloud,roi);
```

Detect the globe in the point cloud and extract it.

```
[model,inlierIndices] = pcfitsphere(ptCloud,maxDistance,SampleIndices=sampleIndices);
globe = select(ptCloud,inlierIndices);
```

Plot the extracted globe.

```
figure
pcshow(globe)
title("Globe Point Cloud")
```

Input Arguments

`ptCloudIn` — Point cloud
`pointCloud` object

Point cloud, specified as a `pointCloud` object.

`maxDistance` — Maximum distance from an inlier point to the sphere
scalar value

Maximum distance from an inlier point to the sphere, specified as a scalar value. Specify the distance in units that are consistent with the units you are using for the point cloud.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `MaxNumTrials=1000` sets the maximum number of random trials to 1000.

`SampleIndices` — Linear indices of points to be sampled
`[]` (default) | column vector

Linear indices of points to sample in the input point cloud, specified as a column vector. An empty vector means that all points are candidates to sample in the RANSAC iteration to fit the sphere. When you specify a subset, only points in the subset are sampled to fit a model. Providing a subset of points

can significantly speed up the process and reduce the number of trials. You can generate the indices vector using the `findPointsInROI` object function of the `pointCloud` object.

`MaxNumTrials` — Maximum number of random trials
`1000` (default) | positive integer

Maximum number of random trials for finding inliers, specified as a positive integer. Increasing this value makes the output more robust but adds additional computations.

`Confidence` — Confidence percentage for finding maximum number of inliers
`99` (default) | numeric scalar in the range (0 100)

Confidence percentage for finding maximum number of inliers, specified as a numeric scalar representing percentage, in the range (0 100). Increasing this value makes the output more robust but adds additional computations.

Output Arguments

`model` — Geometric model of sphere
`sphereModel` object

Geometric model of sphere, returned as a `sphereModel` object.

When the input point cloud does not contain enough valid points, or when the function cannot find enough inlier points, the coefficients for the output model are set to zero.

`inlierIndices` — Linear indices of inlier points
column vector

Linear indices of inlier points within the input point cloud, returned as a column vector.

`outlierIndices` — Linear indices of outlier points
column vector

Linear indices of outlier points within the input point cloud, returned as a column vector.

`meanError` — Mean square error
scalar value

Mean error of the distance of inlier points to the model, returned as a scalar value.

pixelLabelTrainingData

Create training data for semantic segmentation from ground truth

Syntax

```
[imds,pxds] = pixelLabelTrainingData(gTruth)
[imds,pxds] = pixelLabelTrainingData(gTruth,Name,Value)
```

Description

`[imds,pxds] = pixelLabelTrainingData(gTruth)` creates image datastore `imds` and pixel label datastore `pxds` from the specified ground truth. You can combine the returned datastores using the `combine` function and use the `trainnet` function to train deep learning segmentation networks. You can also use these datastores with the `evaluateSemanticSegmentation` function to evaluate the result from deep learning or classical segmentation methods.

This function supports parallel computing using multiple MATLAB workers. Enable parallel computing using the “Computer Vision Toolbox Preferences” dialog box.

`[imds,pxds] = pixelLabelTrainingData(gTruth,Name,Value)` returns image and pixel label datastores with additional options specified by one or more name-value arguments.

- If the `groundTruth` objects in `gTruth` were created using a video file, a custom data source, or an `imageDatastore` with different custom read functions, then you can specify any combination of name-value pair arguments.
- If the `groundTruth` objects were created from an image collection or image sequence data source, then you can specify only the `SamplingFactor` name-value pair argument

Examples

Prepare Data for Evaluating Semantic Segmentation Algorithm

Load a `groundTruth` object named `gTruth`. The ground truth contains pixel labels for triangles and background, annotated on a video with 100 frames.

```
visiondataPath = fullfile(matlabroot, 'toolbox', 'vision', 'visiondata');
addpath(fullfile(visiondataPath, 'triangleImages'));
addpath(fullfile(visiondataPath, 'triangleImages', 'testLabels'));
loadedData = load(fullfile(visiondataPath, 'triangleImages', 'triangleGroundTruth.mat'));
gTruth = loadedData.gTruth;
```

Create a folder in the current directory.

```
foldername = fullfile(tempdir,"videoFrames");
mkdir(foldername)
```

Create an `imageDatastore` and a `pixelLabelDatastore` from the video file and corresponding pixel labels. Write every fifth image to disk.

```
[imds,pxdsTruth] = pixelLabelTrainingData(gTruth,...
    'SamplingFactor',5,'WriteLocation',foldername);

Write images extracted for training to folder:
    /tmp/videoFrames

Writing 20 images extracted from triangleVideo.avi...Completed.
```

Confirm that the temporary folder contains every fifth image.

```
imds.Files

ans = 20×1 cell array
    "'/tmp/videoFrames/triangleVideo01.png'"
    "'/tmp/videoFrames/triangleVideo06.png'"
    "'/tmp/videoFrames/triangleVideo11.png'"
    "'/tmp/videoFrames/triangleVideo16.png'"
    "'/tmp/videoFrames/triangleVideo21.png'"
    "'/tmp/videoFrames/triangleVideo26.png'"
    "'/tmp/videoFrames/triangleVideo31.png'"
    "'/tmp/videoFrames/triangleVideo36.png'"
    "'/tmp/videoFrames/triangleVideo41.png'"
    "'/tmp/videoFrames/triangleVideo46.png'"
```

Remove the video and images from the path.

```
rmpath(fullfile(visiondataPath, 'triangleImages'));
rmpath(fullfile(visiondataPath, 'triangleImages', 'testLabels'));
```

Input Arguments

`gTruth` — Ground truth data

scalar `groundTruth` object | array of `groundTruth` objects

Ground truth data, specified as a scalar `groundTruth` object or an array of `groundTruth` objects. When `gTruth` is an array of `groundTruth` objects, the `LabelDefinitions` property of each object must contain the same pixel label names.

If you use custom data sources in `gTruth` with parallel computing enabled, then the reader function is expected to work with a pool of MATLAB workers to read images from the data source in parallel.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `"SamplingFactor",5`

`SamplingFactor` — Factor for subsampling images

1 (default) | integer | vector of integers

Factor for subsampling images in the ground truth data source, specified an integer or a vector of integers. For a sampling factor of *N*, the returned training data includes every *N*th image in the ground truth data source. The function ignores ground truth images with empty label data.

Use sampled data to reduce repeated data, such as a sequence of images with the same scene and labels. It can also help in reducing training time.

Value	Sampling Factor
Integer	Manually set the sampling factor to apply to all data.
Vector of integers	When you input a vector of ground truth objects, the function uses the sampling factor specified by the corresponding vector element.

`ImageFormat` — Image file format
PNG (default) | string scalar | character vector

Image file format, specified as a string scalar or character vector. File formats must be supported by `imwrite`. This argument applies only for `groundTruth` objects created using a video file or a custom data source.

`WriteLocation` — Name of folder
`pwd` (current working folder) (default) | string scalar | character vector

Folder name to write extracted images to, specified as a string scalar or character vector. The specified folder must exist and have write permissions.

This argument applies only for:

- `groundTruth` objects created using a video file or a custom data source.
- An array of `groundTruth` objects created using `imageDatastore` with different custom `read` functions.

The function ignores this argument when:

- The input `groundTruth` object was created from an image sequence data source.
- The array of input `groundTruth` objects all contain image datastores using the same custom `read` function.
- Any of the input `groundTruth` objects containing datastores, use the default `read` functions.

`ImageFormat` — Image file format
PNG (default) | string scalar | character vector

Image file format, specified as a string scalar or character vector. File formats must be supported by `imwrite`.

This argument applies only for:

- `groundTruth` objects created using a video file or a custom data source.
- An array of `groundTruth` objects created using `imageDatastore` with different custom `read` functions.

The function ignores this argument when:

- The input `groundTruth` object was created from an image sequence data source.
- The array of input `groundTruth` objects all contain image datastores using the same custom `read` function.
- Any of the input `groundTruth` objects containing datastores, use the default `read` functions.

`NamePrefix` — Prefix for output image file names
string scalar | character vector

Prefix for output image file names, specified as a string scalar or character vector. The image files are named as:

```
<name_prefix><source_number>_<image_number>.<image_format>
```

The default value uses the name of the data source that the images were extracted from, `strcat(sourceName,"_")` for video and custom data source, or `"datastore"` for image datastore.

This argument applies only for:

- `groundTruth` objects created using a video file or a custom data source.
- An array of `groundTruth` objects created using `imageDatastore` with custom `read` functions.

The function ignores this argument when:

- The input `groundTruth` object was created from an image sequence data source.
- The array of input `groundTruth` objects all contain image datastores using the same custom `read` function.
- Any of the input `groundTruth` objects containing datastores, use the default `read` functions.

`Verbose` — Display training progress
`true` (default) | `false`

Display training progress on the MATLAB command line, specified as `true` or `false`. This argument applies only for `groundTruth` objects created using a video file or a custom data source.

Output Arguments

`imds` — Collection of images
`ImageDatastore` object

Collection of images extracted from the ground truth, `gTruth`, returned as an `ImageDatastore` object. Each image in `imds` has annotations with at least one class of pixel labels. `imds` ignores images that with no annotations.

`pxds` — Collection of pixel-labeled data
`PixelLabelDatastore` object

Collection of pixel-labeled data extracted from the ground truth, `gTruth`, returned as a `PixelLabelDatastore` object. The object contains a categorical matrix of pixel labels for each image contained in the image datastore, `imds`. Labels that do not correspond to pixel labels are ignored.

plotCamera

Plot camera in 3-D coordinates

Syntax

```
cam = plotCamera
cam = plotCamera(camPoses)
cam = plotCamera(cameraTable)
cam = plotCamera(Name=Value)
```

Description

`cam = plotCamera` plots a default camera in 3-D coordinates in the current axes. The function returns `cam`, a `Camera` object that contains the properties of the plotted camera.

`cam = plotCamera(camPoses)` plots an array of camera visualization objects `camPoses`, in the current axes.

`cam = plotCamera(cameraTable)` plots one or more cameras specified by `cameraTable`.

`cam = plotCamera(Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `Opacity=0.4` sets the opacity of the plotted camera to `0.4`.

The name-value pair arguments set the associated properties of the plotted camera visualization object.

Examples

Plot Animated Camera Using Absolute Pose

Create a `rigidtform3d` object.

```
initialRotation = [1  0  0;
                   0  0  1;
                   0 -1  0];
initialTranslation = [10 0 20];
pose = rigidtform3d(initialRotation,initialTranslation);
```

Plot a camera with an opacity of zero and an absolute pose based on the created `rigidtform3d` object.

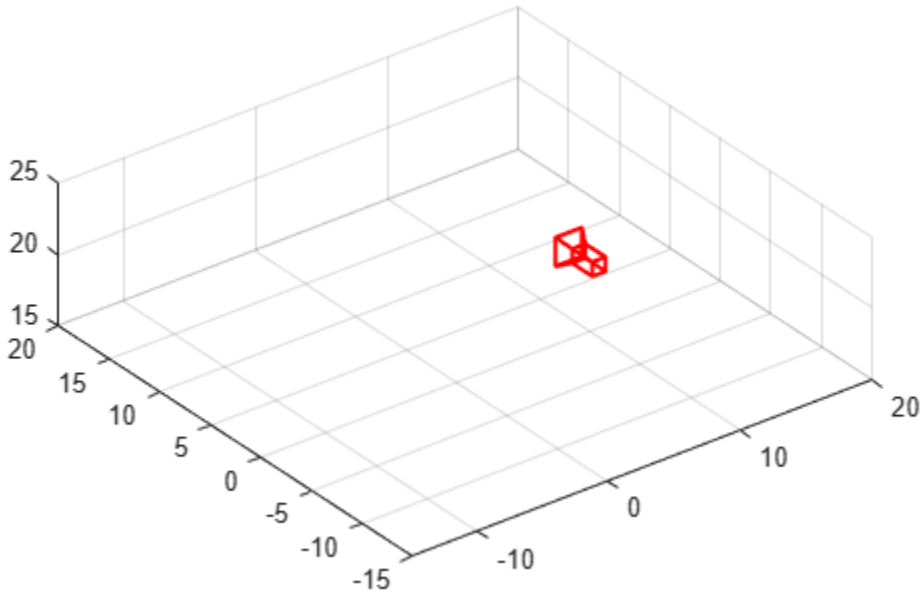
```
cam = plotCamera(AbsolutePose=pose,Opacity=0)
```

```
cam =
  Camera with properties:

           Parent: [1×1 Axes]
             Size: 1
     AbsolutePose: [1×1 rigidtform3d]
```

```
          Visible: 1
        AxesVisible: 0
      ButtonDownFcn: ''
              Color: [1 0 0]
            Opacity: 0
              Label: ''
```

Set viewing properties for the current axes.



```
grid on
axis equal
axis manual
```

Expand the viewable limits of each axis. These changes enable the entire animation to be visible in the next step.

```
xlim([-15 20]);
ylim([-15 20]);
zlim([15 25]);
```

Rotate the camera around the *y*-axis.

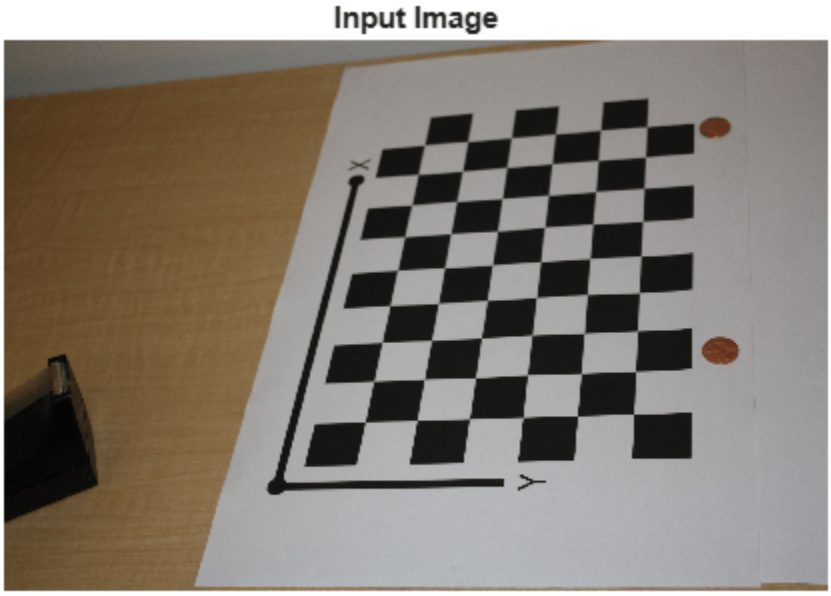
```
for theta = 0:10:1800
    updateAngles = [0 -theta 0];
    updateTranslation = [10*cosd(theta) 10*sind(theta) 20];
    updateTform = rigidtform3d(updateAngles, updateTranslation);
    cam.AbsolutePose = rigidtform3d(initialRotation * updateTform.R, updateTform.Translation);
    drawnow();
end
```

Visualize Camera Extrinsics

Create a set of calibration images.

```
imds = imageDatastore(fullfile(toolboxdir("vision"),"visiondata","calibration","slr"));
```

Detect the checkerboard corners in the images.



```
[imagePoints,patternDims] = detectCheckerboardPoints(imds.Files);
```

Generate the world coordinates of the checkerboard corners in the pattern-centric coordinate system, with the upper-left corner at (0,0). Set the square size to 29 mm.

```
squareSize = 29; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Load an image at its new location.

```
imOrig = imread(fullfile(toolboxdir("vision"),"visiondata","calibration","slr","image9.jpg"));
figure;
imshow(imOrig);
title("Input Image");
```

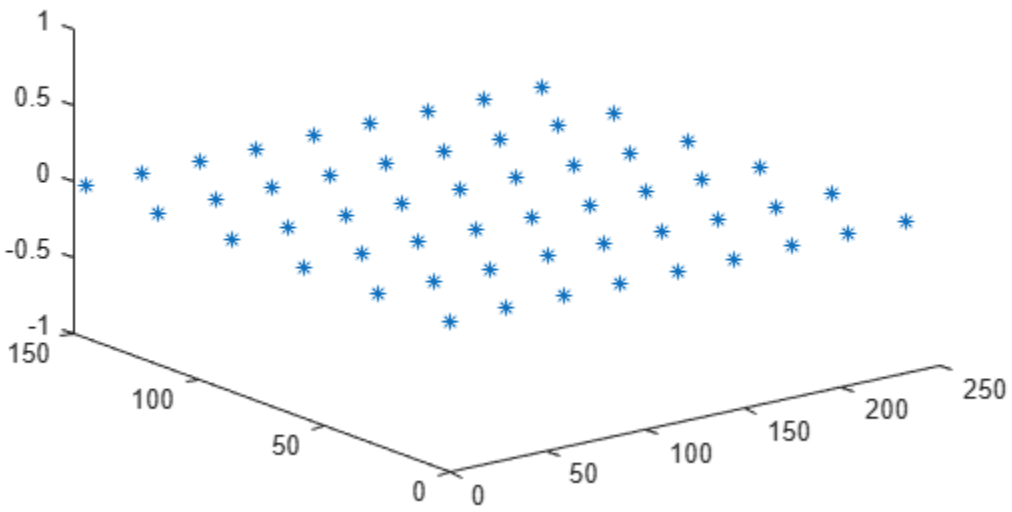
Calibrate the camera.

```
cameraParams = estimateCameraParameters(imagePoints,worldPoints,ImageSize=size(imOrig,1:2));
```

Undistort the image.

```
im = undistortImage(imOrig,cameraParams.Intrinsics);
```

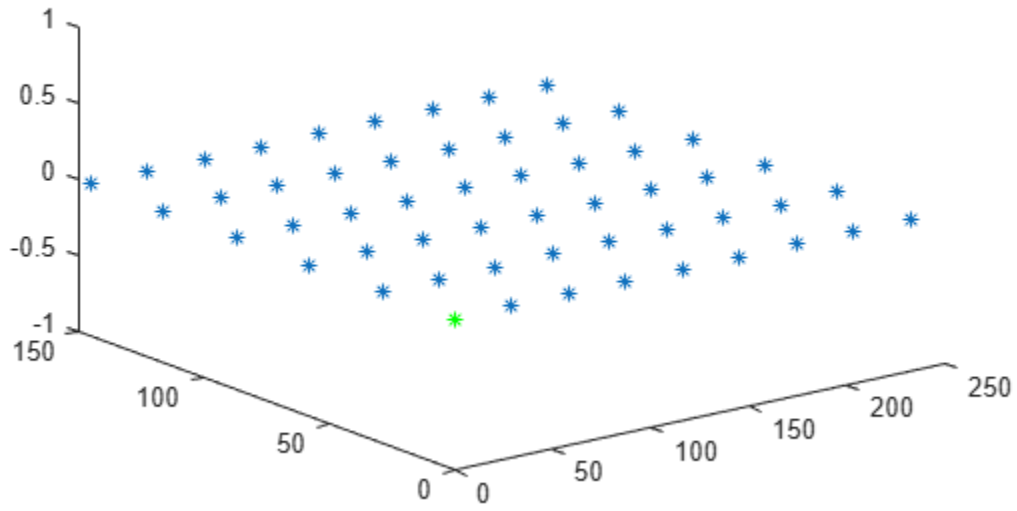
Find the reference object in the new image.



```
[imagePoints,patternDims] = detectCheckerboardPoints(im);
```

Compute the new extrinsics.

```
camExtrinsics = estimateExtrinsics(imagePoints,worldPoints,cameraParams.Intrinsics);
```

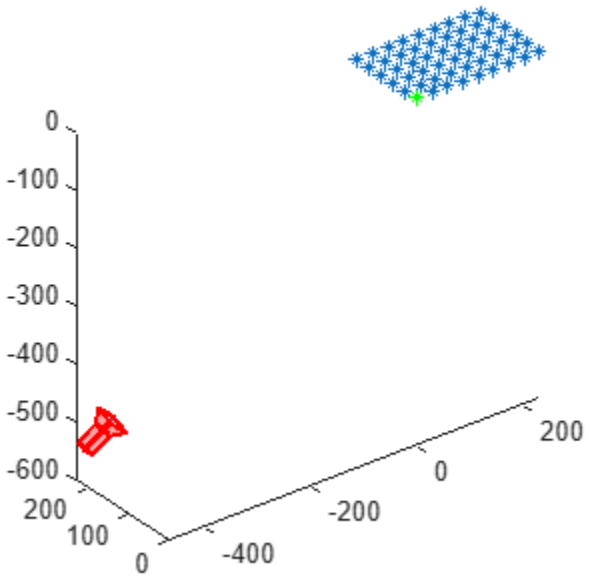


Plot the world points.

```
figure;
plot3(worldPoints(:,1),worldPoints(:,2),zeros(size(worldPoints, 1),1),"*");
hold on
```

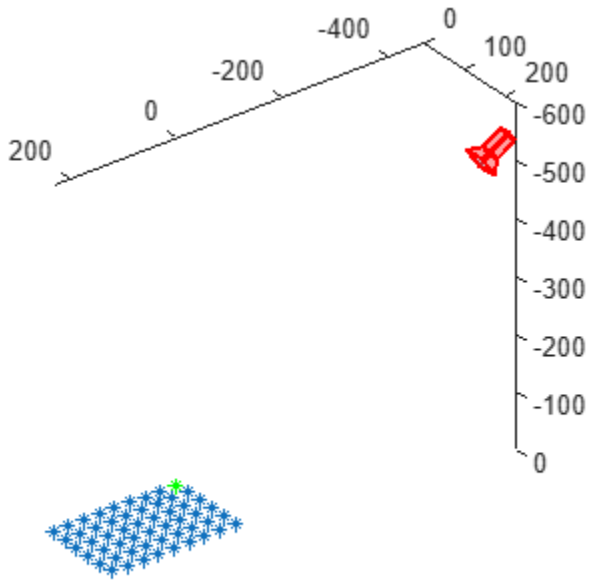
Mark the origin.

```
plot3(0,0,0,"g*");
```



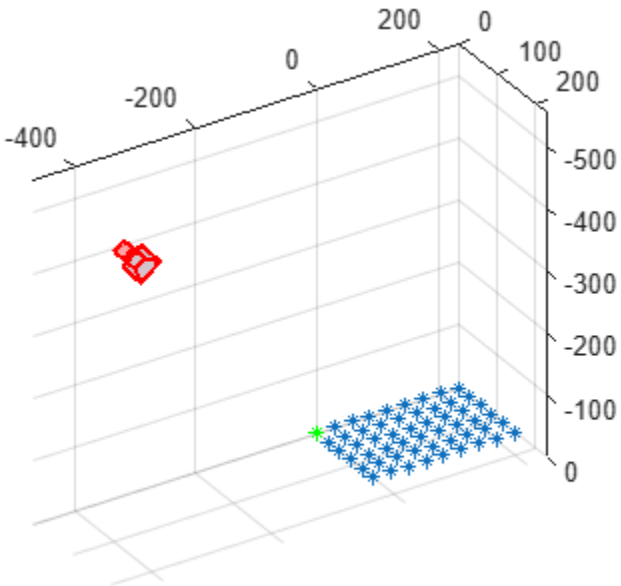
Compute the camera location and orientation.

```
absPose = extr2pose(camExtrinsics);
```



Plot the camera.

```
cam = plotCamera(AbsolutePose=absPose,Size=20);
```

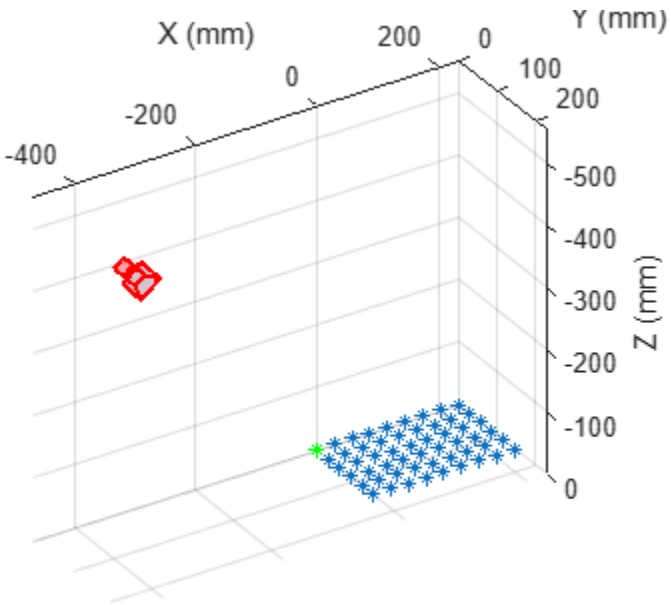


Make the z -axis point down.

```
set(gca,CameraUpVector=[0 0 -1]);
```

Set the view parameters.

```
camorbit(gca,-110,60,data=[0 0 1]);
axis equal
grid on
```

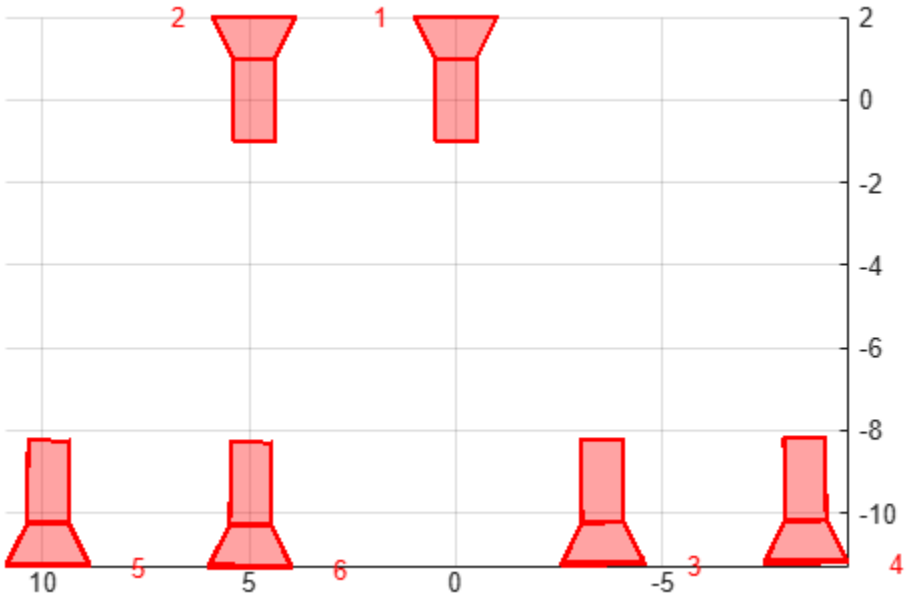


Turn on 3-D rotation.

```
cameratoolbar('SetMode','orbit');
```

Label the axes.

```
xlabel("X (mm)");
ylabel("Y (mm)");
zlabel("Z (mm)");
```



Plot Poses of Multiple Cameras

Load the poses of multiple cameras as a vector of `rigidtform3d` objects.

```
load("multiCameraPoses.mat")
```

Plot the cameras and show the results in a top-down view.

```
plotCamera(poses);
axis equal
view([0 1 0])
grid on
```

Input Arguments

`cameraTable` — Properties of cameras for visualization

table

Properties of cameras for visualization, specified as a table. Each row represents a single camera. Each column title must match the name-part of a name-value pair argument. The *n*th-row values set the properties for the *n*th element of `cam`. You cannot specify values for `Parent`. If the table contains a `ViewId` column, then the view IDs are used to set the `Label` values of the cameras.

`camPoses` — Camera visualization

scalar | array of `rigidtform3d` objects

Camera visualization, specified as a scalar or an array of `rigidtform3d` objects. These objects represent the camera poses in world coordinates.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Size=0.3` specifies the camera-base width as `0.3`.

`AbsolutePose` — Camera absolute pose

`rigidtform3d` object

Camera absolute pose in the world coordinate system, specified as a `rigidtform3d` object.

`Size` — Camera-base width
`1` (default) | positive real number

Camera-base width, specified as a positive real number.

`Label` — Camera label
`''` (default) | cell array of character vectors | array of strings

Camera label, specified as an array of strings or a cell array of character vectors. When camera poses are the initial input, the size of `Label` must match the size of `camPoses`.

`Color` — Camera color
`[1 0 0]` (red) (default) | RGB triplet

Camera color, specified as an RGB triplet. An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1].

`Opacity` — Camera opacity
`0.2` (default) | scalar in the range [0, 1]

Camera opacity, specified as a scalar in the range [0, 1].

`Visible` — Camera visibility
`true` or `1` (default) | `false` or `0`

Camera visibility, specified as a numeric or logical `1` (`true`) or `0` (`false`).

`AxesVisible` — Camera axes visibility
`false` or `0` (default) | `true` or `1`

Camera axes visibility, specified as a numeric or logical `1` (`true`) or `0` (`false`).

`ButtonDownFcn` — Callback function
`''` (default) | function handle

Callback function, specified as a function handle that executes when you click the camera.

`Parent` — Output axes
`axes` handle

Output axes, specified as an axes handle. By default, `plotCamera` uses the current axes handle. To return the current axes, use the `gca` function.

Output Arguments

`cam` — Camera visualization object
`Camera` object | row vector of `Camera` objects

Camera visualization object, returned as one of these options.

- `Camera` object — The function returns this option when plotting a single camera. Name-value arguments or `cameraTable` input elements set the corresponding `Camera` object properties.

- Row vector of `Camera` objects — The function returns this option when plotting multiple cameras. The *n*th -row values of the `cameraTable` input set the properties for the *n*th `Camera` object in this vector.

Camera objects are created using the `vision.graphics.Camera` class, which contains the following properties:

- “Parent” on page 3-0
- “Size” on page 3-0
- “AbsolutePose” on page 3-0
- “Visible” on page 3-0
- “AxesVisible” on page 3-0
- “ButtonDownFcn” on page 3-0
- “Color” on page 3-0
- “Opacity” on page 3-0
- “Label” on page 3-0

Version History

Introduced in R2015a

R2026a: Support for multiple camera poses

Added a new syntax to specify camera poses in world coordinates as a vector of `rigidtform3d` objects and enhanced the `Label` name-value argument to support multiple camera poses.

R2022b: Specify `AbsolutePose` as a `rigidtform3d` object

Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, you can now specify the `AbsolutePose` name-value argument as a `rigidtform3d` object, which uses the premultiply convention.

Although you can still specify `AbsolutePose` as a `rigid3d` object, this object is not recommended because it uses the postmultiply convention. You can streamline your geometric transformation workflows by switching to the new premultiply geometric transformation objects. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

R2020a: The `Location` and `Orientation` properties belonging to the `plotCamera` function are removed

The `plotCamera` function now accepts a `rigid3d` object to specify a camera pose. Starting in R2020a, you must use the `rigid3d` object instead of the `Location` and `Orientation` properties to specify the pose.

pose2extr

Convert camera pose to extrinsics

Syntax

```
camExtrinsics = pose2extr(cameraPose)
```

Description

`camExtrinsics = pose2extr(cameraPose)` returns the camera extrinsics, or the transformation from world coordinates to camera coordinates, for a camera with pose `cameraPose` in world coordinates.

Examples

Convert World Coordinates to Camera Coordinates

Create a camera pose from a 3-D orientation matrix and location vector.

```
orientation = eye(3);
location = [0 0 10];
cameraPose = rigidtform3d(orientation,location);
```

Compute the transformation from world coordinates to camera coordinates.

```
tform = pose2extr(cameraPose)
```

```
tform =
  rigidtform3d with properties:

    Dimensionality: 3
       Translation: [0 0 -10]
                 R: [3×3 double]

                 A: [1     0     0     0
                     0     1     0     0
                     0     0     1   -10
                     0     0     0     1]
```

Input Arguments

cameraPose — Orientation and location of camera

`rigidtform3d` object | `se3`

Orientation and location of the camera in world coordinates, specified as a `rigidtform3d` or `se3` object.

Output Arguments

`camExtrinsics` — Camera extrinsics
`rigidtform3d` object | `se3` object

Camera extrinsics, returned as a `rigidtform3d` or `se3` object. The extrinsics are a transformation from world coordinates to camera coordinates that enables you to transform points from the world coordinate system to the camera coordinate system. `camExtrinsics` is the inverse of `cameraPose` as calculated using the `invert` function.

Version History

Introduced in R2022b

R2022b: Recommended over `cameraPoseToExtrinsics`

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `cameraPoseToExtrinsics` function uses the postmultiply convention. Although there are no plans to remove `cameraPoseToExtrinsics` at this time, you can streamline your geometric transformation workflows by switching to the `pose2extr` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

ransac

Fit model to noisy data

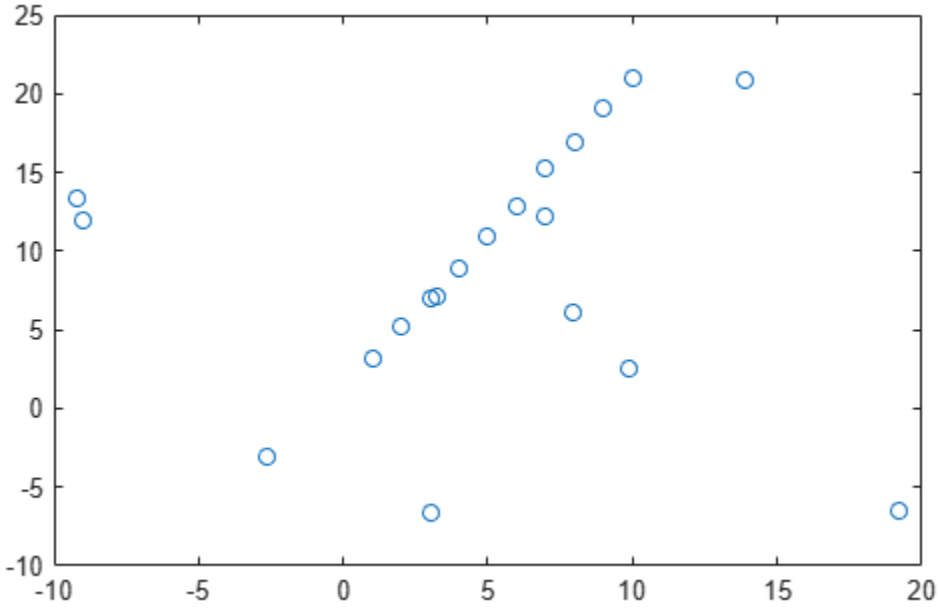
Syntax

```
[model,inlierIdx] = ransac(data,fitFcn,distFcn,sampleSize,maxDistance)
[___] = ransac(___,Name,Value)
```

Description

`[model,inlierIdx] = ransac(data,fitFcn,distFcn,sampleSize,maxDistance)` fits a model to noisy data using the M-estimator sample consensus (MSAC) algorithm, a version of the random sample consensus (RANSAC) algorithm.

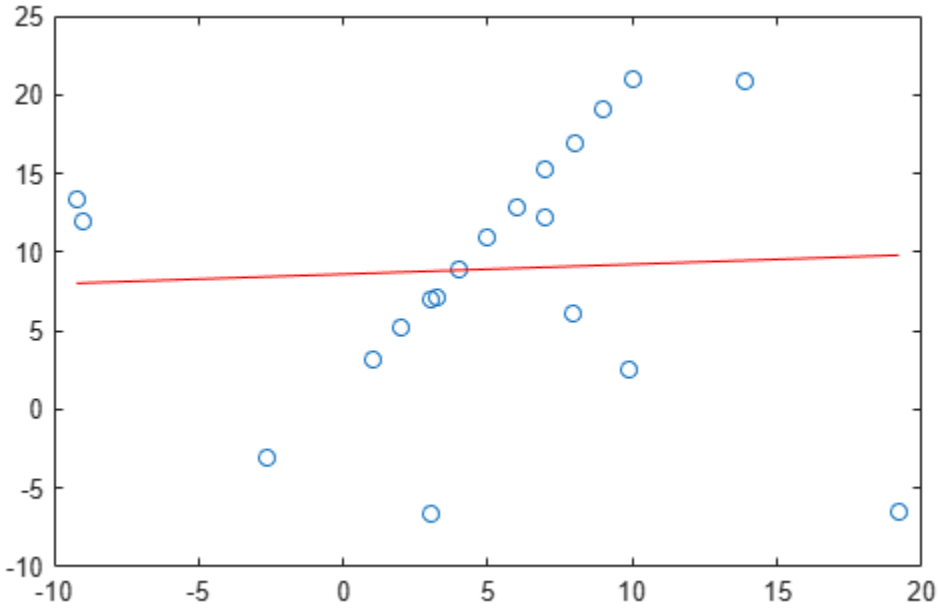
Specify your function for fitting a model, `fitFcn`, and your function for calculating distances from the model to your data, `distFcn`. The `ransac` function takes random samples from your `data` using `sampleSize` and uses the fit function to maximize the number of inliers within `maxDistance`.



`[___] = ransac(___,Name,Value)` additionally specifies one or more `Name,Value` pair arguments.

Examples

Fit Line to 2-D Points Using Least Squares and RANSAC Algorithms



Load and plot a set of noisy 2-D points.

```
load pointsForLineFitting.mat
plot(points(:,1),points(:,2),'o');
hold on
```

Fit a line using linear least squares. Due to outliers, the line is not a good fit.

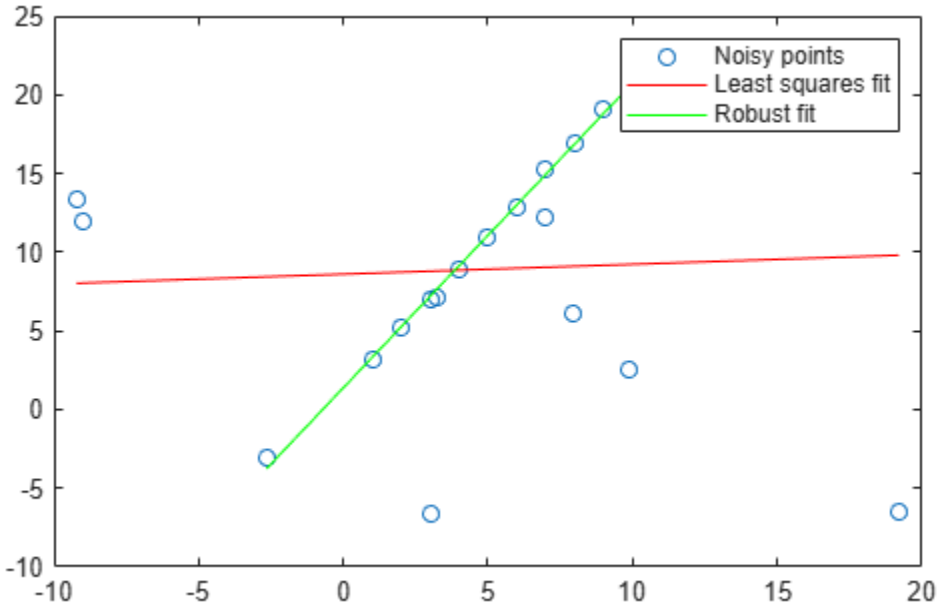
```
modelLeastSquares = polyfit(points(:,1),points(:,2),1);
x = [min(points(:,1)) max(points(:,1))];
y = modelLeastSquares(1)*x + modelLeastSquares(2);
plot(x,y,'r-')
```

Fit a line to the points using the MSAC algorithm. Define the sample size, the maximum distance for inliers, the fit function, and the distance evaluation function. Call `ransac` to run the MSAC algorithm.

```
sampleSize = 2; % number of points to sample per trial
maxDistance = 2; % max allowable distance for inliers

% Define the fit function using polyfit.
fitLineFcn = @(points)polyfit(points(:,1),points(:,2),1);

% Define the distance function to classify each point as an inlier or outlier
% based on the maxDistance threshold.
distLineFcn = @(model,points)(points(:, 2) - polyval(model, points(:,1))).^2;



[modelRANSAC,inlierIdx] = ransac(points,fitLineFcn,distLineFcn, ...
  sampleSize,maxDistance);
```

Refit a line to the inliers using `polyfit`.

```
modelInliers = polyfit(points(inlierIdx,1),points(inlierIdx,2),1);
```

Display the final fit line. This line is robust to the outliers that `ransac` identified and ignored.

```
inlierPts = points(inlierIdx,:);
x = [min(inlierPts(:,1)) max(inlierPts(:,1))];
y = modelInliers(1)*x + modelInliers(2);
plot(x, y, 'g-')
legend('Noisy points','Least squares fit','Robust fit');
hold off
```

Input Arguments

data — Data to be modeled

m-by-*n* matrix

Data to be modeled, specified as an *m*-by-*n* matrix. Each row corresponds to a data point in the set to be modeled. For example, to model a set of 2-D points, specify the point data as an *m*-by-*2* matrix.

Data Types: `single` | `double`

`fitFcn` — Function to fit a subset of `data`
function handle

Function to fit a subset of `data`, specified as a function handle. The function must be of the form:

```
model = fitFcn(data)
```

If it is possible to fit multiple models to the data, then `fitFcn` returns the model parameters as a cell array.

`distFcn` — Function to compute distances from model
function handle

Function to compute distances from the model to the data, specified as a function handle. The function must be of the form:

```
distances = distFcn(model,data)
```

If `model` is an *n*-element array, then distances must be an *m*-by-*n* matrix. Otherwise, `distances` must be an *m*-by-1 vector.

`sampleSize` — Minimum sample size
positive scalar integer

Minimum sample size from `data` that is required by `fitFcn`, specified as a positive scalar integer.

`maxDistance` — Maximum distance for inlier points
positive scalar

Maximum distance from the fit curve to an inlier point, specified as a positive scalar. Any points further away than this distance are considered outliers. The distance is defined by `distFcn`. The RANSAC algorithm creates a fit from a small sample of points, but tries to maximize the number of inlier points. Lowering the maximum distance improves the fit by putting a tighter tolerance on inlier points.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'MaxNumTrials',2000`

`ValidateModelFcn` — Function to validate model
function handle

Function to validate model, specified as the comma-separated pair consisting of '`ValidateModelFcn`' and a function handle. The function returns `true` if the model is accepted

based on criteria defined in the function. Use this function to reject specific fits. The function must be of the form:

```
isValid = validateModelFcn(model,varargin)
```

If no function is specified, all models are assumed to be valid.

`MaxSamplingAttempts` — Maximum number of sampling attempts
100 (default) | integer

Maximum number of attempts to find a sample that yields a valid model, specified as the comma-separated pair consisting of '`MaxSamplingAttempts`' and an integer.

`MaxNumTrials` — Maximum number of random trials
`1000` (default) | integer

Maximum number of random trials, specified as the comma-separated pair consisting of '`MaxNumTrials`' and an integer. A single trial uses a minimum number of random points from `data` to fit a model. Then, the trial checks the number of inliers within the `maxDistance` from the model. After all trials, the model with the highest number of inliers is selected. Increasing the number of trials improves the robustness of the output at the expense of additional computation.

`Confidence` — Confidence of final solution
`99` (default) | scalar from 0 to 100

Confidence that the final solution finds the maximum number of inliers for the model fit, specified as the comma-separated pair consisting of '`Confidence`' and a scalar from 0 to 100. Increasing this value improves the robustness of the output at the expense of additional computation.

Output Arguments

`model` — Best fit model
parameters defined in `fitFcn`

Best fit model, returned as the parameters defined in the `fitFcn` input. This model maximizes the number of inliers from all the sample attempts.

`inlierIdx` — Inlier points
logical vector

Inlier points, returned as a logical vector. The vector is the same length as `data`, and each element indicates if that point is an inlier for the model fit based on `maxDistance`.

`fitPolynomialRANSAC` | `polyfit` | `polyval`

rdivide, ./

Element-wise transformation or rotation right division

Syntax

```
transformationC = transformationA./transformationB
rotationC = rotationA./rotationB
```

Description

`transformationC = transformationA./transformationB` divides transformations element-by-element by dividing each element of transformation `transformationA` with the corresponding element of transformation `transformationB` and returns the quotient, transformation `transformationC`.

`rotationC = rotationA./rotationB` divides rotations element-by-element by dividing each element of rotation `rotationA` with the corresponding element of rotation `rotationB` and returns the quotient, rotation `rotationC`.

Input Arguments

`transformationA` — First transformation

`se3` object | *N*-element array of transformation objects

First transformation, specified as a scalar `se3` object or as an *N*-element array of transformation objects. *N* is the total number of transformations.

If you specify `transformationA` as an array, each element must be of the same type.

Either `transformationA` or `transformationB` must be a scalar transformation object of the same type. For example, if `transformationA` is an array of `se3` objects, `transformationB` must be a scalar `se3` object.

`transformationB` — Last transformation

`se3` object | *N*-element array of transformation objects

Last transformation, specified as a scalar `se3` object or as an *N*-element array of transformation objects. *N* is the total number of transformations.

If you specify `transformationB` as an array, each element must be of the same type.

Either `transformationA` or `transformationB` must be a scalar transformation object of the same type. For example, if `transformationA` is an array of `se3` objects, `transformationB` must be a scalar `se3` object.

`rotationA` — First rotation

`so3` object | *N*-element array of rotation objects

First rotation, specified as a scalar `so3` object or as an *N*-element array of rotation objects. *N* is the total number of rotations.

If you specify `rotationA` as an array, each element must be of the same type.

Either `rotationA` or `rotationB` must be a scalar rotation object of the same type. For example, if `rotationA` is an array of `so3` objects, `rotationB` must be a scalar `so3` object.

`rotationB` — Last rotation
`so2` object | `so3` object | *N*-element array of rotation objects

Last rotation, specified as a scalar `so3` object or as an *N*-element array of rotation objects. *N* is the total number of rotations.

If you specify `rotationB` as an array, each element must be of the same type.

Either `rotationA` or `rotationB` must be a scalar rotation object of the same type. For example, if `rotationA` is an array of `se3` objects, `rotationB` must be a scalar `se3` object.

Output Arguments

`transformationC` — Transformation quotient
`se3` object | *N*-element array of transformation objects

Transformation quotient, returned as a scalar `se3` object or as an *N*-element array of the same transformation type as `transformationA` and `transformationB`. *N* is the length of the longer argument between `transformationA` and `transformationB` and each row represents the quotient between `transformationA` and `transformationB`.

`rotationC` — Rotation quotient
`so3` object | *N*-element array of rotation objects

Rotation quotient, returned as a scalar `so3` object or as an *N*-element array of the same rotation type as `rotationA` and `rotationB`. *N* is the length of the longer argument between `rotationA` and `rotationB` and each row represents the quotient between `rotationA` and `rotationB`.

reconstructScene

Reconstruct 3-D scene from disparity map

Syntax

```
xyzPoints = reconstructScene(disparityMap,reprojectionMatrix)
```

Description

`xyzPoints = reconstructScene(disparityMap,reprojectionMatrix)` returns an array of 3-D world point coordinates that reconstruct a scene from a disparity map. The 3-D world coordinates are relative to the optical center of camera 1 in a stereo system. You can use the `rectifyStereoImages` function to obtain the `reprojectionMatrix` from a pair of stereo images.

Examples

Reconstruct 3-D Scene from Stereo Image Pair Using Semi-Global Matching

Reconstruct a 3-D scene from a pair of stereo images by using the disparity map computed through semi-global matching.

Load the stereo parameters.

```
load('webcamsSceneReconstruction.mat');
```

Read in the stereo pair of images.

```
I1 = imread('sceneReconstructionLeft.jpg');
I2 = imread('sceneReconstructionRight.jpg');
```

Rectify the images.

```
[J1, J2, reprojectionMatrix] = rectifyStereoImages(I1,I2,stereoParams);
```

Display the images after rectification.

```
figure
imshow(cat(3,J1(:,:,1),J2(:,:,2:3)));
```

Compute the disparity.

```
disparityMap = disparitySGM(im2gray(J1),im2gray(J2));
figure
imshow(disparityMap,[0,64]);
```

Reconstruct the 3-D world coordinates of points corresponding to each pixel from the disparity map.

```
xyzPoints = reconstructScene(disparityMap,reprojectionMatrix);
```

Segment out a person located between 3.2 and 3.7 meters away from the camera.

```
Z = xyzPoints(:,:,3);
mask = repmat(Z > 3200 & Z < 3700,[1,1,3]);
J1(~mask) = 0;
imshow(J1);
```

Input Arguments

`disparityMap` — Disparity image

2-*D* array

Disparity image, specified as a 2-D array of disparity values for pixels in image 1 of a stereo pair. You can use either `disparityBM` or `disparitySGM` functions to generate the disparity image.

The disparity image can contain invalid values marked as `NaN`. These values correspond to pixels in image 1 that did not match with image 2. The function sets the world coordinates corresponding to invalid disparity value to `NaN`.

Pixels with zero disparity correspond to world points that are too far away to measure, given the resolution of the camera. The function sets the world coordinates corresponding to zero disparity to `Inf`.

When you specify the `disparityMap` input as a `double`, the function returns the coordinates as `double`. Otherwise, the function returns the coordinates as `single`.

Data Types: `single` | `double`

`reprojectionMatrix` — Reprojection matrix

4-by-4 matrix

Reprojection matrix, specified as a 4-by-4 matrix. You can use the `rectifyStereoImages` function to obtain the `reprojectionMatrix` from a pair of stereo images.

The reprojection matrix is represented as:

$$\begin{bmatrix} 1 & 0 & 0 & -cx \\ 0 & 1 & 0 & -cy \\ 0 & 0 & 0 & f \\ 0 & 0 & 1/b & 0 \end{bmatrix}$$

where f and $[cx,cy]$ are the focal length and principal point of the rectified camera 1, respectively. b is the baseline of the virtual rectified stereo camera.

Data Types: `single` | `double`

Output Arguments

`xyzPoints` — Coordinates of world points

M-by-*N*-by-3 array

Coordinates of world points, returned as an *M*-by-*N*-by-3 array. The 3-D world coordinates are relative to the optical center of camera 1 in the stereo system represented by `stereoParams`.

The output array contains the $[x, y, z]$ coordinates of world points that correspond to the pixels in the `disparityMap` input. `xyzPoints`(:, :, 1) contains the x world coordinates of points corresponding to the pixels in the disparity map. `xyzPoints`(:, :, 2) contains the y world coordinates, and `xyzPoints`(:, :, 3) contains the z world coordinates. The 3-D world coordinates are relative to the optical center of camera 1 in the stereo system.

When you specify the `disparityMap` input as `double`, the function returns the `xyzPoints` output as `double`. Otherwise, the function returns it as `single`.

Data Types: `single` | `double`

Version History

Introduced in R2014a

rectifyStereoImages

Rectify pair of stereo images

Syntax

```
[J1,J2,reprojectionMatrix] = rectifyStereoImages(I1,I2,stereoParams)
[___,camMatrix1,camMatrix2,R1,R2] = rectifyStereoImages(I1,I2,stereoParams)
[J1,J2] = rectifyStereoImages(I1,I2,tform1,tform2)

[J1,J2] = rectifyStereoImages(___,interp)
[J1,J2] = rectifyStereoImages(___,Name=Value)
```

Description

`[J1,J2,reprojectionMatrix] = rectifyStereoImages(I1,I2,stereoParams)` undistorts and rectifies versions of `I1` and `I2` input images using the stereo parameters of a stereo camera system stored in the `stereoParams` object. Use the `reconstructScene` function with the `reprojectionMatrix` to reproject a 2-D point in a disparity map to a 3-D point in the rectified camera coordinate system of camera 1.

Stereo image rectification projects images onto a common image plane in such a way that the corresponding points have the same row coordinates. This image projection makes the image appear as though the two cameras are parallel. Use the `disparityBM` or `disparitySGM` functions to compute a disparity map from the rectified images for 3-D scene reconstruction.

`[___,camMatrix1,camMatrix2,R1,R2] = rectifyStereoImages(I1,I2,stereoParams)` returns the 3-by-4 camera projection matrices `camMatrix1` and `camMatrix2` for the rectified cameras, and the corresponding rectification rotation matrices, `R1` and `R2`.

`[J1,J2] = rectifyStereoImages(I1,I2,tform1,tform2)` returns rectified versions of `I1` and `I2` input images by applying projective transformations `tform1` and `tform2`.

`[J1,J2] = rectifyStereoImages(___,interp)` additionally specifies the interpolation method to use for rectified images. You can specify the method as `"nearest"`, `"linear"`, or `"cubic"`.

`[J1,J2] = rectifyStereoImages(___,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `OutputView="valid"` sets the `OutputView` argument to `"valid"`.

Examples

Rectify Stereo Images

Specify images containing a checkerboard for calibration.

```
imageDir = fullfile(toolboxdir("vision"),"visiondata", ...
    "calibration","stereo");
leftImages = imageDatastore(fullfile(imageDir,"left"));
rightImages = imageDatastore(fullfile(imageDir,"right"));
```

Detect the checkerboards.

```
[imagePoints,patternDims] = detectCheckerboardPoints(...
    leftImages.Files,rightImages.Files);
```

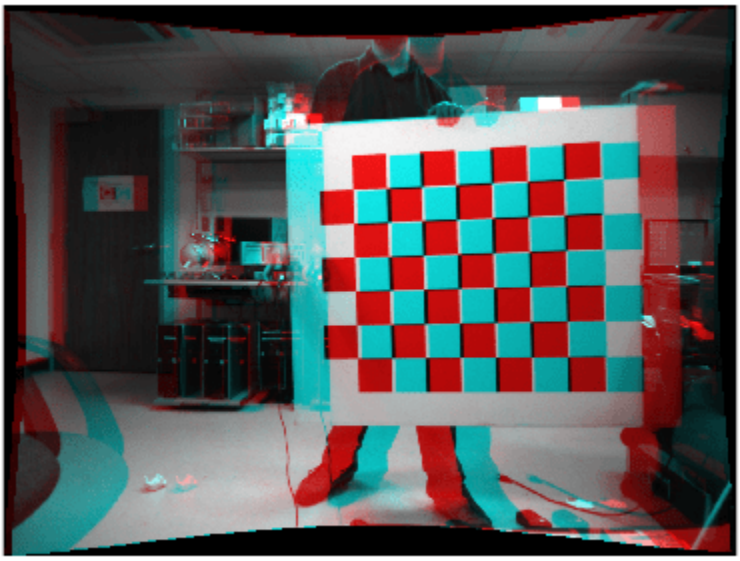
Specify world coordinates of checkerboard keypoints.

```
squareSize = 108; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Read in the images.

```
I1 = readimage(leftImages,1);
I2 = readimage(rightImages,1);
imageSize = [size(I1,1),size(I1,2)];
```

Calibrate the stereo camera system.



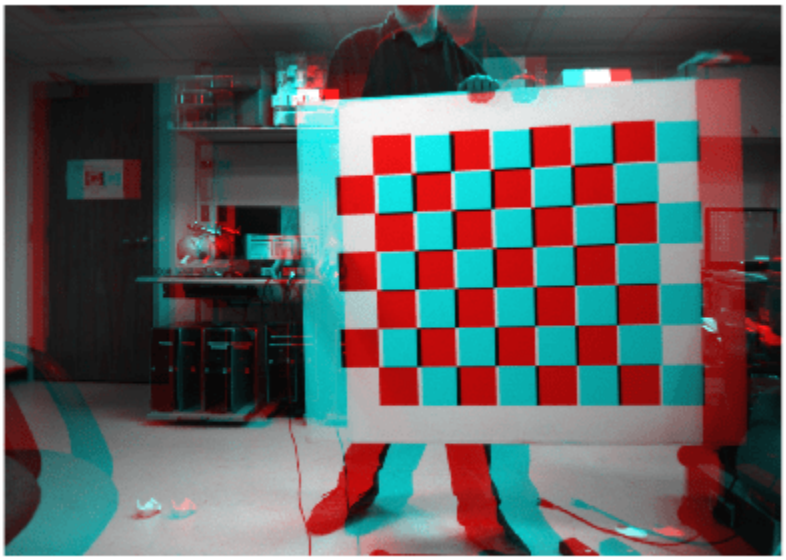
```
stereoParams = estimateCameraParameters(imagePoints,worldPoints,ImageSize=imageSize);
```

Rectify the images using "full" output view.

```
[J1_full,J2_full] = rectifyStereoImages(I1,I2,stereoParams,OutputView="full");
```

Display the result for "full" output view.

```
figure;
imshow(stereoAnaglyph(J1_full,J2_full));
```



Rectify the images using "valid" output view. This is most suitable for computing disparity.

```
[J1_valid,J2_valid] = rectifyStereoImages(I1,I2,stereoParams,OutputView="valid");
```

Display the result for "valid" output view.

```
figure;
imshow(stereoAnaglyph(J1_valid,J2_valid));
```

Input Arguments

`I1` — Input image 1

M-by-*N*-by-3 truecolor image | *M*-by-*N* 2-D grayscale image

Input image corresponding to camera 1, specified as an *M*-by-*N*-by-3 truecolor image or an *M*-by-*N* 2-D grayscale array. Input images `I1` and `I2` must also be real, finite, and nonsparse. The input images must be the same class.

Data Types: `uint8` | `uint16` | `int16` | `single` | `double` | `logical`

`I2` — Input image 2

M-by-*N*-by-3 truecolor image | *M*-by-*N* 2-D truecolor image

Input image corresponding to camera 2, specified as an *M*-by-*N*-by-3 truecolor image or an *M*-by-*N* 2-D grayscale array. Input images `I1` and `I2` must be real, finite, and nonsparse. The input images must also be the same class.

Data Types: `uint8` | `uint16` | `int16` | `single` | `double` | `logical`

`stereoParams` — Stereo camera system parameters

`stereoParameters` object

Stereo camera system parameters, specified as a `stereoParameters` object.

Data Types: `uint8` | `uint16` | `int16` | `single` | `double`

`tform1` — Projective transformation

`projtform2d` object

Projective transformations for image 1, specified as a `projtform2d` object. You can get a `projtform2d` object using the `estimateStereoRectification` function.

Data Types: `single` | `double`

`tform2` — Projective transformation
`projtform2d` object

Projective transformations for image 2, specified as a `projtform2d` object. You can get a `projtform2d` object using the `estimateStereoRectification` function.

Data Types: `single` | `double`

`interp` — Interpolation method
`"linear"` (default) | `"nearest"` | `"cubic"`

Interpolation method, specified as either `"linear"`, `"nearest"`, or `"cubic"`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `OutputView="valid"` sets the `OutputView` argument to `"valid"`.

`OutputView` — Size of rectified images
`"valid"` (default) | `"full"`

Size of rectified images, specified as `"full"` or `"valid"`. When you set this parameter to `"full"`, the rectified images include all pixels from the original images. When you set this value to `"valid"`, the output images are cropped to the size of the largest common rectangle containing valid pixels.

When there is no overlap between rectified images, set `OutputView` to `"full"`.

`FillValues` — Output pixel fill values
numeric scalar | three-element numeric vector

Output pixel fill values, specified as numeric scalar or three-element numeric vector. When the corresponding inverse-transformed location in the input image is completely outside the input image boundaries, use the fill values for output pixels. If `I1` and `I2` are 2-D grayscale images, then you must set `FillValues` to a numeric scalar. If `I1` and `I2` are truecolor images, then you can set `FillValues` to a scalar or a three-element vector of RGB values.

Output Arguments

`J1` — Undistorted and rectified image 1
M-by-*N*-by-3 truecolor image | *M*-by-*N* 2-D grayscale image

Undistorted and rectified version of `I1`, returned as an *M*-by-*N*-by-3 truecolor image or as an *M*-by-*N* 2-D grayscale image.

Stereo image rectification projects images onto a common image plane in such a way that the corresponding points have the same row coordinates. This image projection makes the image appear

as though the two cameras are parallel. Use the `disparityBM` or `disparitySGM` functions to compute a disparity map from the rectified images for 3-D scene reconstruction.

`J2` — Undistorted and rectified image 2

M-by-*N*-by-3 truecolor image | *M*-by-*N* 2-D grayscale image

Undistorted and rectified version of `I2`, returned as an *M*-by-*N*-by-3 truecolor image or as an *M*-by-*N* 2-D grayscale image.

Stereo image rectification projects images onto a common image plane in such a way that the corresponding points have the same row coordinates. This image projection makes the image appear as though the two cameras are parallel. Use the `disparityBM` or `disparitySGM` functions to compute a disparity map from the rectified images for 3-D scene reconstruction.

`reprojectionMatrix` — Reprojection matrix

4-by-4 matrix

Reprojection matrix, returned as a 4-by-4 matrix of the form:

$$\begin{bmatrix} 1 & 0 & 0 & -cx \\ 0 & 1 & 0 & -cy \\ 0 & 0 & 0 & f \\ 0 & 0 & 1/b & 0 \end{bmatrix},$$

where f and $[cx,cy]$ are the focal length and principal point of rectified camera 1, respectively. b is the baseline of the virtual rectified stereo camera.

Use the `reconstructScene` function with the `reprojectionMatrix` to reproject a 2-D point in a disparity map to a 3-D point in the rectified camera coordinate system of camera 1.

`camMatrix1` — Camera one rectified projection matrix

3-by-4 matrix

Rectified camera one projection matrix, returned as 3-by-4 matrix. Use `camMatrix1` and `camMatrix2` to project 3-D world points in camera one's coordinate system into the image plane of `J1` and `J2`, respectively.

Use `camMatrix1` to project 3-D world points in the rectified camera one coordinate system into the image plane of `J1`.

Data Types: `single` | `double`

`camMatrix2` — Camera two rectified projection matrix

3-by-4 matrix

Camera two rectified projection matrix, returned as 3-by-4 matrix. Use `camMatrix1` and `camMatrix2` to project 3-D world points in camera one's coordinate system into the image plane of `J1` and `J2`, respectively.

Use `camMatrix2` to project 3-D world points in the rectified camera two coordinate system into the image plane of `J2`.

Data Types: `single` | `double`

`R1` — Camera one rotation matrix

3-by-3 matrix

Camera one rotation matrix related to camera one rectified projection, returned as a 3-by-3 matrix. The `R1` rotation matrix relate 3-D points from the unrectified camera one coordinate system to points in the rectified camera one coordinate system.

Data Types: `single` | `double`

R2 — Camera two rotation matrix
3-by-3 matrix

Camera two rotation matrix related to camera one rectified projection, returned as a 3-by-3 matrix. The `R2` rotation matrix relate 3-D points from the unrectified camera two coordinate system to points in the rectified camera two coordinate system.

Data Types: `single` | `double`

Tips

- The Computer Vision Toolbox rectification algorithm requires that the epipole for each image lie outside of the image. If the epipole lies within the image, you can first transform the images into polar coordinates as described in the rectification method proposed by Marc Pollefeys, Reinhard Koch, and Luc Van Gool [2] on page 3-782.

Version History

Introduced in R2014a

R2022b: Supports premultiply geometric transformation convention

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, you can now specify the `tform1` and `tform2` as `projtform2d` objects, which use the premultiply convention.

Although you can still specify `tform1` and `tform2` as `projective2d` objects or 3-by-3 matrices returned by the `estimateUncalibratedRectification` function, these values are not recommended because they use the postmultiply convention. You can streamline your geometric transformation workflows by switching to the `projtform2d` objects. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

retrieveImages

Search image set for similar image

Syntax

```
imageIDs = retrieveImages(queryImage,imageIndex)
[imageIDs,scores] = retrieveImages(queryImage,imageIndex)
[imageIDs,scores,imageWords] = retrieveImages(queryImage,imageIndex)
[imageIDs, ___ ] = retrieveImages(queryImage,imageIndex,Name,Value)
```

Description

`imageIDs = retrieveImages(queryImage,imageIndex)` returns the image identifiers `imageIDs` that correspond to images within `imageIndex` that are visually similar to the query image. The `imageIDs` are returned in ranked order, from the most to least similar match.

`[imageIDs,scores] = retrieveImages(queryImage,imageIndex)` optionally returns the similarity scores used to rank the image retrieval results. The `scores` output contains the corresponding scores from 0 to 1.

`[imageIDs,scores,imageWords] = retrieveImages(queryImage,imageIndex)` optionally returns the visual words in `queryImage` that are used to search for similar images.

`[imageIDs, ___ ] = retrieveImages(queryImage,imageIndex,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments, using any of the preceding syntaxes.

Examples

Search Image Set Using Query Image

Create an image set of book covers.

```
dataDir = fullfile(toolboxdir('vision'),'visiondata','bookCovers');
bookCovers = imageDatastore(dataDir);
```

Display the data set.

```
thumbnailGallery = [];
for i = 1:length(bookCovers.Files)
    I = readimage(bookCovers,i);
    thumbnail = imresize(I,[300 300]);
    thumbnailGallery = cat(4,thumbnailGallery,thumbnail);
end

figure
montage(thumbnailGallery);
```

Index the image set. This step may take a few minutes.

```
imageIndex = indexImages(bookCovers);
```

```
Creating an inverted image index using Bag-Of-Features.

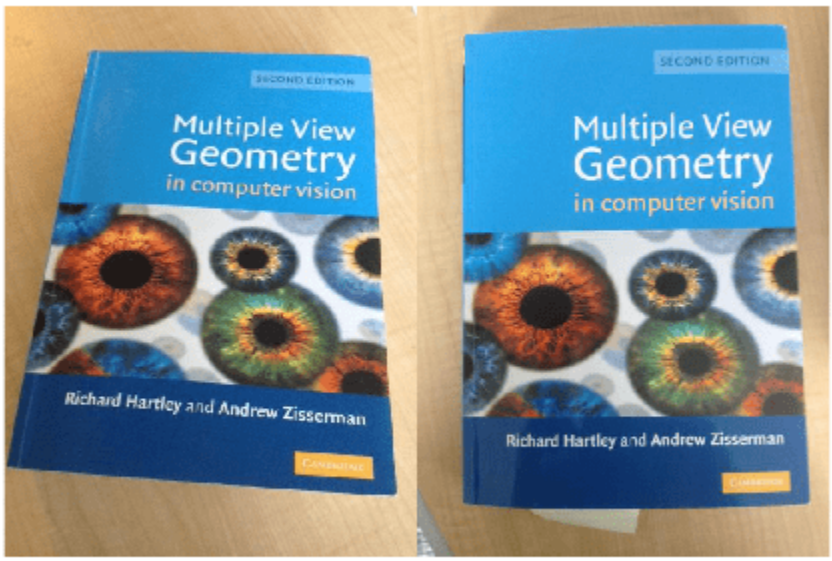
* Encoding 58 images...done.
Finished creating the image index.
```

Select and display the query image.



```
queryDir = fullfile(dataDir,'queries',filesep);
queryImage = imread([queryDir 'query3.jpg']);

imageIDs = retrieveImages(queryImage,imageIndex);
```

Show the query image and its best match, side-by-side.

```
bestMatch = imageIDs(1);
bestImage = imread(imageIndex.ImageLocation{bestMatch});

figure
imshowpair(queryImage,bestImage,'montage')
```

Search Image Set for Specific Object Using ROIs

Search an image set for an object using a region of interest (ROI) for the query image.

Define a set of images to search.

```
imageFiles = ...
  {'elephant.jpg', 'cameraman.tif', ...
```

```
  'peppers.png',  'saturn.png',...
  'pears.png',    'stapleRemover.jpg', ...
  'football.jpg', 'mandi.tif',...
  'kids.tif',     'liftingbody.png', ...
  'office_5.jpg', 'gantrycrane.png',...
  'moon.tif',     'circuit.tif', ...
  'tape.png',     'coins.png'};

imds = imageDatastore(imageFiles);
```

Create a search index.

```
 imageIndex = indexImages(imds);

Creating an inverted image index using Bag-Of-Features.

* Encoding 16 images...done.
Finished creating the image index.
```

Specify a query image and an ROI. The ROI outlines the object, an elephant, for the search.

```
queryImage = imread('clutteredDesk.jpg');
queryROI = [130 175 330 365];

figure
```

```
imshow(queryImage)
rectangle('Position',queryROI,'EdgeColor','yellow')
```

You can also use the `imrect` function to select an ROI interactively. For example, `queryROI = getPosition(imrect)`

Find images that contain the object.

```
imageIDs = retrieveImages(queryImage,imageIndex,'ROI',queryROI)
```

```
imageIDs = 12×1 uint32 column vector

    1
   11
    6
   12
    2
    3
    8
    5
   14
   13
   10
   16
```

Display the best match.

```
bestMatch = imageIDs(1);

figure
imshow(imageIndex.ImageLocation{bestMatch})
```

Geometric Verification Using `estgeotform2d` Function

Use the locations of visual words to verify the best search result. To rerank the search results based on geometric information, repeat this procedure for the top *N* search results.

Specify the location of the images.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata","bookCovers");
bookCovers = imageDatastore(dataDir);
```

Index the image set. This process can take a few minutes.

```
imageIndex = indexImages(bookCovers);
```

```
Creating an inverted image index using Bag-Of-Features.

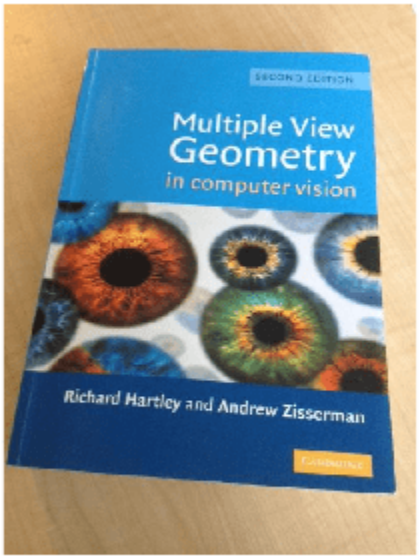
* Number of levels: 1
* Branching factor: 20000
* Number of clustering steps: 1

* [Step 1/1] Clustering vocabulary level 1.
* Number of features          : 23373
* Number of clusters          : 20000
* Initializing cluster centers...100.00%.
* Clustering...completed 5/100 iterations (~1.18 seconds/iteration)...converged in 5 iterations.

* Finished creating Bag-Of-Features



Encoding images using Bag-Of-Features.
---------------------------------------

* Encoding 58 images...done.
Finished creating the image index.
```

Select and display the query image.

```
queryDir = fullfile(dataDir,"queries",filesep);
queryImage = imread(queryDir+"query3.jpg");

figure
imshow(queryImage)
```

Retrieve the best matches. The `queryWords` output contains visual word locations information for the query image. Use this information to verify the search results.

```
[imageIDs, ~, queryWords] = retrieveImages(queryImage,imageIndex);
```

Find the best match for the query image by extracting the visual words from the image index. The image index contains the visual word information for all images in the index.

```
bestMatch = imageIDs(1);
bestImage = imread(imageIndex.ImageLocation{bestMatch});
bestMatchWords = imageIndex.ImageWords(bestMatch);
```

Generate a set of tentative matches based on visual word assignments. Each visual word in the query can have multiple matches due to the hard quantization used to assign visual words.

```
queryWordsIndex     = queryWords.WordIndex;
bestMatchWordIndex  = bestMatchWords.WordIndex;

tentativeMatches = [];
for i = 1:numel(queryWords.WordIndex)

    idx = find(queryWordsIndex(i) == bestMatchWordIndex);

    matches = [repmat(i, numel(idx), 1) idx];

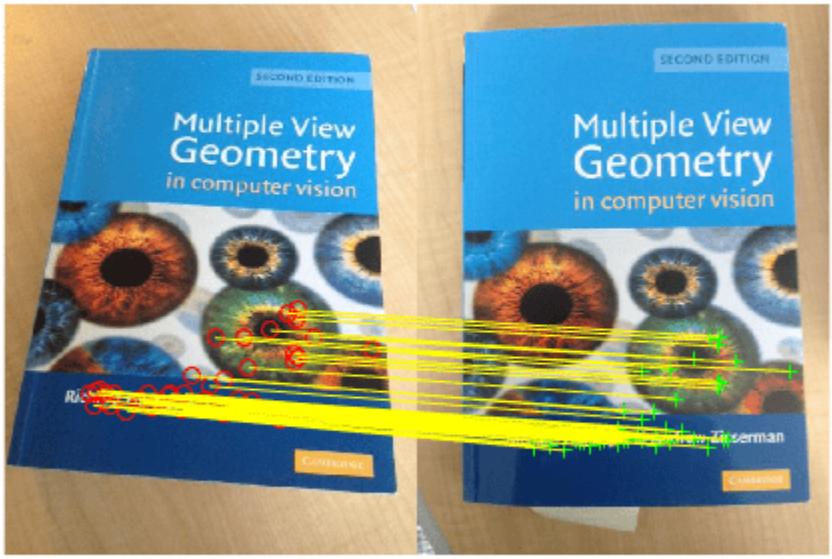
    tentativeMatches = [tentativeMatches; matches];

end
```

Show the point locations for the tentative matches. There are many poor matches.

```
points1 = queryWords.Location(tentativeMatches(:,1),:);
points2 = bestMatchWords.Location(tentativeMatches(:,2),:);

figure
showMatchedFeatures(queryImage,bestImage,points1,points2,"montage")
```



Remove poor visual word assignments using `estgeotform2d` function. Keep the assignments that fit a valid geometric transform.

```
[tform,inlierIdx] = estgeotform2d(points1,points2,"affine",MaxNumTrial=2000);
inlierPoints1 = points1(inlierIdx, :);
inlierPoints2 = points2(inlierIdx, :);
```

Rerank the search results by the percentage of inliers. Do this when the geometric verification procedure is applied to the top *N* search results. Those images with a higher percentage of inliers are more likely to be relevant.

```
percentageOfInliers = size(inlierPoints1,1)./size(points1,1);

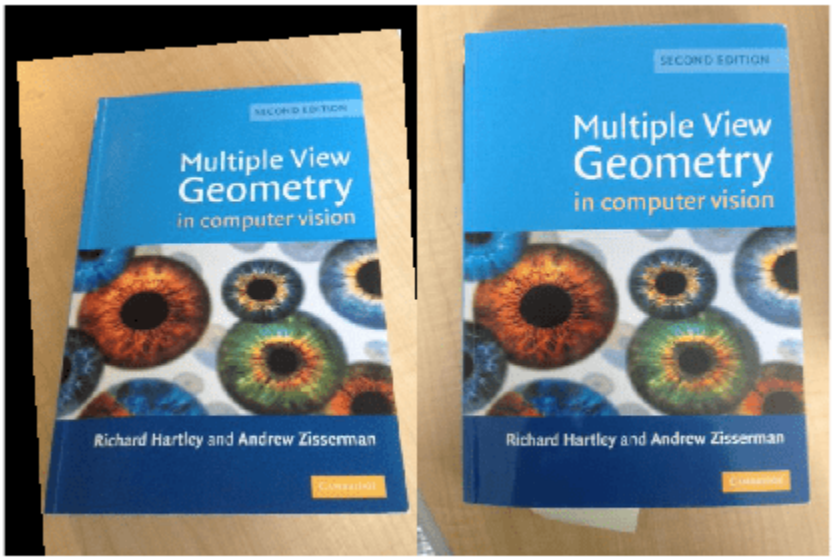


figure
showMatchedFeatures(queryImage,bestImage,inlierPoints1,...
    inlierPoints2,"montage")
```

Apply the estimated transform.

```
outputView = imref2d(size(bestImage));
Ir = imwarp(queryImage, tform, OutputView=outputView);

figure
imshowpair(Ir,bestImage,"montage")
```

Modify Search Parameters for Image Search

Use the `evaluateImageRetrieval` function to help select proper search parameters.

Create an image set.

```
setDir  = fullfile(toolboxdir('vision'),'visiondata','imageSets','cups');
imds = imageDatastore(setDir, 'IncludeSubfolders', true, 'LabelSource', 'foldernames');
```

Index the image set.

```
 imageIndex = indexImages(imds,'Verbose',false);
```

Tune image search parameters.

```
imageIndex.MatchThreshold = 0.2;
imageIndex.WordFrequencyRange = [0 1]
```

```
imageIndex =
  invertedImageIndex with properties:

         ImageLocation: {6×1 cell}
            ImageWords: [6×1 vision.internal.visualWords]
         WordFrequency: [0.1667 0.1667 0.1667 0.3333 0.1667 0.1667 0.1667 0.5000 0.3333 0.1667 0
         BagOfFeatures: [1×1 bagOfFeatures]
               ImageID: [1 2 3 4 5 6]
        MatchThreshold: 0.2000
    WordFrequencyRange: [0 1]
```

```
queryImage = readimage(imds, 1);
indices = retrieveImages(queryImage,imageIndex);
```

Input Arguments

`queryImage` — Input query image

M-by-*N*-by-3 truecolor image | *M*-by-*N* 2-D grayscale image

Input query image, specified as either an *M*-by-*N*-by-3 truecolor image or an *M*-by-*N* 2-D grayscale image.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

`imageIndex` — Image search index

`invertedImageIndex` object

Image search index, specified as an `invertedImageIndex` object. The `indexImages` function creates the `invertedImageIndex` object, which stores the data used for the image search.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'NumResults'`,25 sets the `'NumResults'` property to 25

`NumResults` — Maximum number of results

`20` (default) | numeric value

Maximum number of results to return, specified as the comma-separated pair consisting of '`NumResults`' and a numeric value. Set this value to `Inf` to return as many matching images as possible.

`ROI` — Query image search region

`[1 1 size(queryImage,2) size(queryImage,1)]` (default) | [*x y width height*] vector

Query image search region, specified as the comma-separated pair consisting of '`ROI`' and an [*x y width height*] vector.

`Metric` — Similarity metric

`'cosine'` (default) | `'L1'`

Similarity metric used to rank the image retrieval results, specified as `'cosine'` or `'L1'` [3] on page 3-1144.

Output Arguments

`imageIDs` — Ranked index of retrieved images

M-by-1 vector

Ranked index of retrieved images, returned as an *M*-by-1 vector. The image IDs are returned in ranked order, from the most to least similar matched image.

`scores` — Similarity metric
N-by-1 vector

Similarity metric, returned as an *N*-by-1 vector. This output contains the scores that correspond to the retrieved images in the `imageIDs` output. The scores are computed using the `Metric` property and a range from 0 to 1.

`imageWords` — Object for storing visual word assignments
`visualWords` object

Object for storing visual word assignments, returned as a `visualWords` object. The object stores the visual word assignments of `queryImage` and their locations within that image.

Version History

Introduced in R2015a

roialign

Non-quantized ROI pooling of `dlarray` data

Syntax

```
dlY = roialign(dlX,boxes,outputSize)
dlY = roialign(dlX,boxes,outputSize,Name=Value)
```

Description

The ROI align operation pools a rectangular ROI into fixed sized bins without quantizing the grid points to the nearest pixel. The function uses bilinear interpolation to infer the value at each grid point.

Given input data of size [*H W C N*], where *C* is the number of channels and *N* is the number of observations, the pooled deep learning data has size [*h w C* `sum`(*M*)], where *h* and *w* are the specified output size. *M* is a vector of length *N* and *M*(*i*) is the number of ROIs associated with the *i*-th observation.

Note To perform ROI pooling within a `Layer` array, use `roiAlignLayer`.

This function requires Deep Learning Toolbox.

`dlY = roialign(dlX,boxes,outputSize)` performs a pooling operation along the spatial dimensions of the input `X` for each bounding box in `boxes`. The outputs, `Y`, are of size `outputSize`.

`dlY = roialign(dlX,boxes,outputSize,Name=Value)` specifies additional name-value arguments.

Examples

Perform ROI Pooling

Create a 4-D formatted `dlarray` object that simulates a batch of two RGB images.

```
X = dlarray(rand(10,10,3,2),"SSCB");
```

Specify the position and batch index of one bounding box.

```
startXY = [2 2];
endXY = [4 4];
batchIdx = 1;
rois = [startXY endXY batchIdx]';
```

Perform ROI pooling with an output size of 3-by-3.

```
Y = roialign(X,rois,[3 3])
```

```
Y =
  3(S) × 3(S) × 3(C) × 1(B) single dlarray

(:,:,1) =

    0.7464    0.3069    0.1780
    0.9212    0.8491    0.4677
    0.7303    0.9057    0.3840

(:,:,2) =

    0.3024    0.6428    0.6594
    0.1542    0.0046    0.1228
    0.6295    0.5182    0.3304

(:,:,3) =

    0.4915    0.7590    0.5035
    0.4574    0.4302    0.5453
    0.2960    0.2666    0.5389
```

Input Arguments

`dlX` — Deep learning data to pool

4-D formatted `dlarray` object

Deep learning data to pool, specified as a 4-D formatted `dlarray` object with a data format of "SSCB".

`boxes` — Bounding boxes

5-by-*N* numeric matrix

Bounding boxes, specified as a 5-by-*N* numeric matrix, where *N* is the number of bounding boxes. Each bounding box is formatted as a column vector of the form [*x_start*; *y_start*; *x_end*; *y_end*; *batchIdx*], where:

- *x_start* and *y_start* specify the (x,y) coordinates of the upper-left corner of the rectangle.
- *x_end* and *y_end* specify the (x,y) coordinates of the bottom-right corner of the rectangle.
- *batchIdx* specifies the index of the observation corresponding to the rectangle.

By default, `boxes` are in the same coordinate space and scale as the input deep learning data `dlX`.

`outputSize` — Pooled output size

vector of two positive integers

Pooled output size, specified as a vector of two positive integers `[h w]`, where `h` is the height and `w` is the width.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `dlY = roialign(dlX,boxes,outputSize,ROIScale=2)` scales the input ROIs by a factor of 2

`ROIScale` — Ratio of scale of input feature map to ROI coordinates
`1` (default) | numeric scalar

Ratio of the scale of the input feature map to that of the ROI coordinates. This ratio specifies the factor used to scale input ROIs to the input feature map size.

`SamplingRatio` — Number of samples in each pooled bin
`"auto"` (default) | row vector of two positive integers

Number of samples in each pooled bin, specified as `"auto"` or a row vector of two positive integers. The two elements are the number of vertical and horizontal samples, respectively.

If you do not specify the sampling ratio, then the number of vertical samples has the default value `ceil(`*`roiHeight/outputHeight`*`)`. Likewise, the number of horizontal samples has the default value `ceil(`*`roiWidth/outputWidth`*`)`.

Data Types: `double` | `char`

Output Arguments

`dlY` — Pooled deep learning data
4-D formatted `dlarray` object

Pooled deep learning data, returned as a 4-D formatted `dlarray` object with a data format of "SSCB".

More About

ROI Align

An ROI align operation returns fixed size feature maps for every rectangular ROI within an input `dlarray`. The function first partitions an ROI into fixed sized bins of size `OutputSize` without quantizing the grid points. Each bin is further sampled at `SamplingRatio` locations. The value at each sampled point is inferred using bilinear interpolation. The average of the sampled values is returned as the output value of each pooled bin.

Version History

Introduced in R2021b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

When you specify a custom range of values for the `SamplingRatio` argument, you will observe a slight numerical discrepancy between the MATLAB simulation results and the generated code.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

rotationMatrixToVector

(Not recommended) Convert 3-D rotation matrix to rotation vector

Note `rotationMatrixToVector` is not recommended. Use the `rotmat2vec3d` function instead. For more information, see “Version History”.

Syntax

```
rotationVector = rotationMatrixToVector(rotationMatrix)
```

Description

`rotationVector = rotationMatrixToVector(rotationMatrix)` returns an axis-angle rotation vector that corresponds to the input 3-D rotation matrix. The function uses the Rodrigues formula for the conversion.

Examples

Convert Rotation Matrix to Rotation Vector

Create a matrix representing a 90-degree rotation about the *Z*-axis.

```
rotationMatrix = [0 1 0; -1 0 0; 0 0 1];
```

Find the equivalent rotation vector.

```
rotationVector = rotationMatrixToVector(rotationMatrix)
```

```
rotationVector = 1×3

         0         0    1.5708
```

Input Arguments

`rotationMatrix` — Rotation of camera

3-by-3 matrix

Rotation of camera, specified as a 3-by-3 matrix. You can obtain this matrix by using the `estimateExtrinsics` function.

Output Arguments

`rotationVector` — Rotation vector

three-element vector

Rotation vector, returned as a three-element vector. The vector represents the axis of rotation in 3-D, where the magnitude corresponds to the rotation angle in radians.

Data Types: `single` | `double`

Version History

Introduced in R2016a

R2022b: Not recommended

Not recommended starting in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `rotationMatrixToVector` function uses the postmultiply convention. Although there are no plans to remove `rotationMatrixToVector` at this time, you can streamline your geometric transformation workflows by switching to the `rotmat2vec3d` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

To update your code:

- Change instances of the function name `rotationMatrixToVector` to `rotmat2vec3d`.
- Specify the rotation matrix as the transpose of the `rotationMatrix` argument of the `rotationMatrixToVector` function. Alternatively, you can get a rotation matrix in the correct premultiply format by using the `estimateExtrinsics` function and querying the `R` property of the returned `rigidtform3d` object.

The table shows examples of how to update your code.

Discouraged Usage	Recommended Replacement

This example converts a 3-D rotation matrix in the postmultiply convention to a rotation vector using the `rotationMatrixToVector` function.
 	
`rotVectorOld = rotationMatrixToVector(rotMatrixOld);`
	This example converts a 3-D rotation matrix in the premultiply convention to a rotation vector using the `rotmat2vec2d` function. The 3-D rotation matrix is the transpose of `rotMatrixOld`.
	
	`rotMatrixNew = rotMatrixOld';`
	`rotVectorNew = rotmat2vec2d(rotMatrixNew);`

This example obtains a 3-D rotation matrix in the postmultiply convention using the `extrinsics` function, then converts the matrix to a rotation vector using the `rotationMatrixToVector` function.
 	
`[rotMatrixOld,transVector] = extrinsics( ...`
`    imagePoints,worldPoints,intrinsics);`
`rotVectorOld = rotationMatrixToVector(rotMatrixOld);`
	This example obtains a 3-D rotation matrix in the premultiply convention using the `estimateExtrinsics` function, then converts the matrix to a rotation vector using the `rotmat2vec2d` function.
	
	`camExtrinsics = estimateExtrinsics( ...`
	`    imagePoints,worldPoints,intrinsics);`
	`rotMatrixNew = camExtrinsics.R;`
	`rotVectorNew = rotmat2vec2d(rotMatrixNew);`

rotationVectorToMatrix

(Not recommended) Convert 3-D rotation vector to rotation matrix

Note `rotationVectorToMatrix` is not recommended. Use the `rotvec2mat3d` function instead. For more information, see “Version History”.

Syntax

```
rotationMatrix = rotationVectorToMatrix(rotationVector)
```

Description

`rotationMatrix = rotationVectorToMatrix(rotationVector)` returns a 3-D rotation matrix that corresponds to the input axis-angle rotation vector. The function uses the Rodrigues formula for the computation.

Examples

Convert Rotation Vector to Rotation Matrix

Create a vector representing a 90-degree rotation about the *Z*-axis.

```
rotationVector = pi/2 * [0, 0, 1];
```

Find the equivalent rotation matrix.

```
rotationMatrix = rotationVectorToMatrix(rotationVector)
```

```
rotationMatrix = 3×3

    0.0000    1.0000         0
   -1.0000    0.0000         0
         0         0    1.0000
```

Input Arguments

`rotationVector` — Rotation vector

three-element vector

Rotation vector, specified as a three-element vector. The vector represents the axis of rotation in 3-D, where the magnitude corresponds to the rotation angle in radians.

Data Types: `single` | `double`

Output Arguments

`rotationMatrix` — Rotation of camera
3-by-3 matrix

Rotation of camera, returned as a 3-by-3 matrix that corresponds to the input axis-angle rotation vector.

Version History

Introduced in R2016a

R2022b: Not recommended
Not recommended starting in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `rotationVectorToMatrix` function uses the postmultiply convention. Although there are no plans to remove `rotationVectorToMatrix` at this time, you can streamline your geometric transformation workflows by switching to the `rotvec2mat3d` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

To update your code:

- Change instances of the function name `rotationVectorToMatrix` to `rotvec2mat3d`.
- You do not need to change the input argument, `rotationVector`. The `rotvec2mat3d` function automatically returns the rotation matrix using the premultiply convention.

rotm

Extract rotation matrix

Syntax

```
rotationMatrix = rotm(transformation)
rotationMatrix = rotm(rotation)
```

Description

`rotationMatrix = rotm(transformation)` returns the rotation matrix `rotationMatrix` from the SE(3) transformation `transformation`.

`rotationMatrix = rotm(rotation)` returns the rotation matrix `rotationMatrix` from the SO(2) or SO(3) rotation `rotation`.

Input Arguments

`transformation` — Transformation

`se3` object | *N*-element array of transformation objects

Transformation, specified as a scalar `se3` object or an *N*-element array of transformation objects. *N* is the total number of transformations.

If you specify `transformation` as an array, each element must be of the same type.

`rotation` — Rotation

`so3` object | *N*-element array of rotation objects

Rotation, specified as a scalar `so3` object, or as an *N*-element array of rotation objects. *N* is the total number of rotations.

If you specify `rotation` as an array, each element must be of the same type.

Output Arguments

`rotationMatrix` — Rotation matrix

2-by-2-by-*N* array | 3-by-3-by-*N* array

Rotation matrix, returned as a 2-by-2-by-*N* array for 2-D transformations or a 3-by-3-by-*N* array for 3-D transformations. *N* is the total number of transformations.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

rotmat2vec3d

Convert 3-D rotation matrix to rotation vector

Syntax

```
rotationVector = rotmat2vec3d(rotationMatrix)
```

Description

`rotationVector = rotmat2vec3d(rotationMatrix)` returns an axis-angle rotation vector that corresponds to the input 3-D rotation matrix. The function uses the Rodrigues formula for the conversion.

Examples

Convert Rotation Matrix to Rotation Vector

Create a matrix representing a 90-degree rotation about the *Z-*axis.

```
rotationMatrix = [0 -1 0; 1 0 0; 0 0 1];
```

Find the equivalent rotation vector.

```
rotationVector = rotmat2vec3d(rotationMatrix)
```

```
rotationVector = 1×3

         0         0    1.5708
```

Input Arguments

`rotationMatrix` — Rotation of camera

3-by-3 matrix

Rotation of camera, specified as a 3-by-3 matrix. You can obtain this matrix by using the `estimateExtrinsics` function.

Output Arguments

`rotationVector` — Rotation vector

three-element vector

Rotation vector, returned as a three-element vector. The vector represents the axis of rotation in 3-D, where the magnitude corresponds to the rotation angle in radians.

Data Types: `single` | `double`

Version History

Introduced in R2022b

R2022b: Recommended over `rotationMatrixToVector`

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `rotationMatrixToVector` function uses the postmultiply convention. Although there are no plans to remove `rotationMatrixToVector` at this time, you can streamline your geometric transformation workflows by switching to the `rotmat2vec3d` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

sceneLabelTrainingData

Create training data for scene classification from ground truth

Syntax

```
imds = sceneLabelTrainingData(gTruth)
[imds,groupInfo] = sceneLabelTrainingData(gTruth)
```

Description

`imds = sceneLabelTrainingData(gTruth)` creates image datastore `imds` from the specified ground truth.

Note This function only supports ground truth exported by the Image Labeler app.

`[imds,groupInfo] = sceneLabelTrainingData(gTruth)` also returns information about the groups of scene labels.

Input Arguments

`gTruth` — Ground truth data

`groundTruth` object

Ground truth data, specified as a `groundTruth` object.

Output Arguments

`imds` — Collection of images

`ImageDatastore` object

Collection of images extracted from the ground truth object `gTruth`, returned as an `ImageDatastore` object. The `Labels` property of the datastore has a scalar valued scene label corresponding to each image.

`groupInfo` — Information about scene label groups

structure

Information about the scene label groups, returned as a structure. The names of the fields describe scene label groups. The values in the structure are string arrays that indicate which scene label names belong to the corresponding group.

Version History

Introduced in R2022b

See Also

`pixelLabelTrainingData` | `trainFCDDAnomalyDetector`

segmentationConfusionMatrix

Confusion matrix of multi-class pixel-level image segmentation

Syntax

```
confusionMatrix = segmentationConfusionMatrix(LPred,LTruth)
```

Description

`confusionMatrix = segmentationConfusionMatrix(LPred,LTruth)` computes a confusion matrix from the predicted pixel labels `LPred` and ground truth pixel labels `LTruth`.

Examples

Calculate Confusion Matrix from Labeled Images

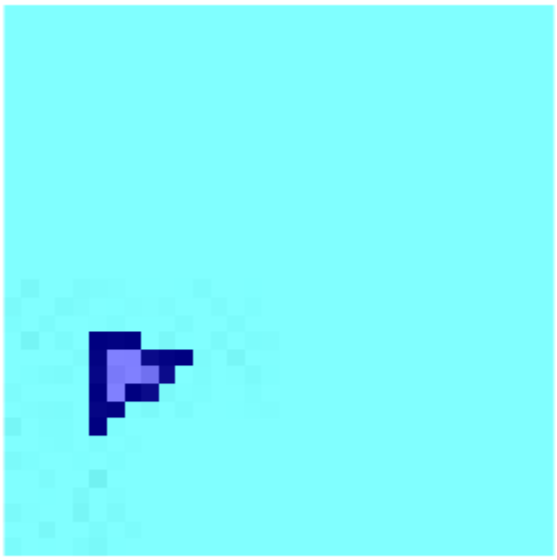
Load a pretrained network that performs binary segmentation of triangles against a background.

```
load("triangleSegmentationNetwork");
```

The `triangleImages` data set has 100 test images with ground truth labels. Define the location of the data set.

```
dataSetDir = fullfile(toolboxdir("vision"),"visiondata","triangleImages");
```

Get one test image and the corresponding ground truth label.



```
testImage = imread(fullfile(dataSetDir,"testImages","image_001.jpg"));
gtLabel   = imread(fullfile(dataSetDir,"testLabels","labeled_image_001.png"));
```

The label image is stored as a numeric image, so convert the ground truth label to a categorical image.

```
classNames = ["triangle" "background"];
labelIDs   = [255 0];
gtLabel = categorical(gtLabel,labelIDs,classNames);
```

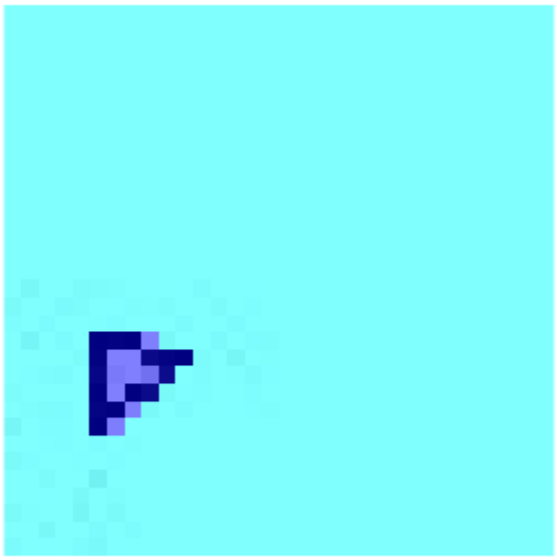
Display the ground truth labels over the test image.

```
imshow(labeloverlay(testImage,gtLabel))
```

Perform semantic image segmentation.

```
predLabel = semanticseg(testImage,net,Classes=classNames);
```

Get the confusion matrix of the predicted labels and ground truth labels. The confusion matrix shows the segmentation correctly classified 21 pixels as triangle and 939 pixels as background. The confusion matrix also shows that the segmentation misclassified 64 background pixels as triangle. No triangle pixels are misclassified as background.



```
confusionMatrix = segmentationConfusionMatrix(predLabel,gtLabel)
```

```
confusionMatrix = 2×2

          21           0
           3        1000
```

To check the accuracy of the confusion matrix, display the predicted labels over the test image. The overlay agrees with the values in the confusion matrix.

```
imshow(labeloverlay(testImage,predLabel))
```

Input Arguments

`LPred` — Predicted pixel labels

2-D label image | 3-D label image

Predicted pixel labels after semantic segmentation, specified as a 2-D label image or 3-D label image.

Data Types: `double` | `logical` | `categorical`

`LTruth` — Ground truth pixel labels

2-D label image | 3-D label image

Ground truth pixel labels, specified as a 2-D label image or 3-D label image of the same size as the predicted pixel labels, `LPred`.

Data Types: `double` | `logical` | `categorical`

Output Arguments

`confusionMatrix` — Confusion matrix

C-by-*C* numeric matrix

Confusion matrix for the classes in the segmented images, returned as a *C*-by-*C* numeric matrix, where *C* is the number of classes in the semantic segmentation. Element (*i*,*j*) is the count of pixels known to belong to class *i* but predicted to belong to class *j*.

Tips

- You can calculate semantic segmentation metrics such as the Jaccard score and classification accuracy from the confusion matrix by using the `evaluateSemanticSegmentation` function.

- You can use this function in block-based image processing workflows such as `blockedImage`. For example, you can perform semantic segmentation and calculate the confusion matrix for a block in the same call to the `apply` function.

Version History

Introduced in R2020b

segmentLidarData

Segment organized 3-D range data into clusters

Syntax

```
labels = segmentLidarData(ptCloud,distThreshold)
labels = segmentLidarData(ptCloud,distThreshold,angleThreshold)
[labels,numClusters] = segmentLidarData( ___ )
[ ___ ] = segmentLidarData( ___ ,NumClusterPoints=[1,Inf])
```

Description

`labels = segmentLidarData(ptCloud,distThreshold)` segments organized 3-D range data `ptCloud` into clusters. The function assigns an integer cluster label to each point in the point cloud and returns the cluster label of all points in `labels`.

The function groups two neighboring points into the same cluster if their Euclidean distance is less than `distThreshold` or if the angle between the sensor and two neighboring points is at least 5 degrees.

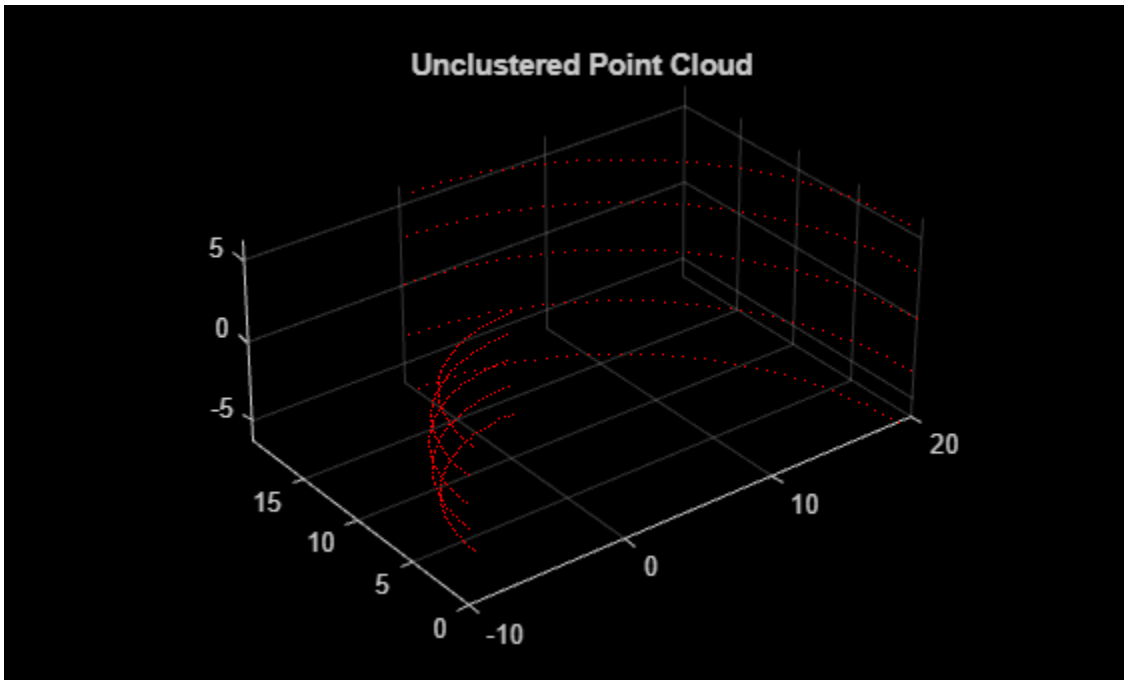
`labels = segmentLidarData(ptCloud,distThreshold,angleThreshold)` sets the angle constraint for grouping points into the same cluster to `angleThreshold`.

`[labels,numClusters] = segmentLidarData( ___ )` also returns the number of clusters.

`[ ___ ] = segmentLidarData( ___ ,NumClusterPoints=[1,Inf])` also sets the minimum and maximum number of points in each cluster, specified as a 2-element vector or as a scalar value. When you specify `NumClusterPoints` as a scalar, the maximum number of points in the cluster is unrestricted. The function sets the `labels` to `0` when clusters are outside of the specified range.

Examples

Cluster Organized Synthetic Lidar Data



Create organized synthetic lidar data containing two objects.

```
ldr = zeros(5,100);
ldr(:,1:50) = 10;
ldr(:,51:end) = 20;
pitch = linspace(-18,18,5);
pitch = repmat(pitch',1,100);
yaw = linspace(-90,90,100);
yaw = repmat(yaw,5,1);
```

Convert to Cartesian coordinates.

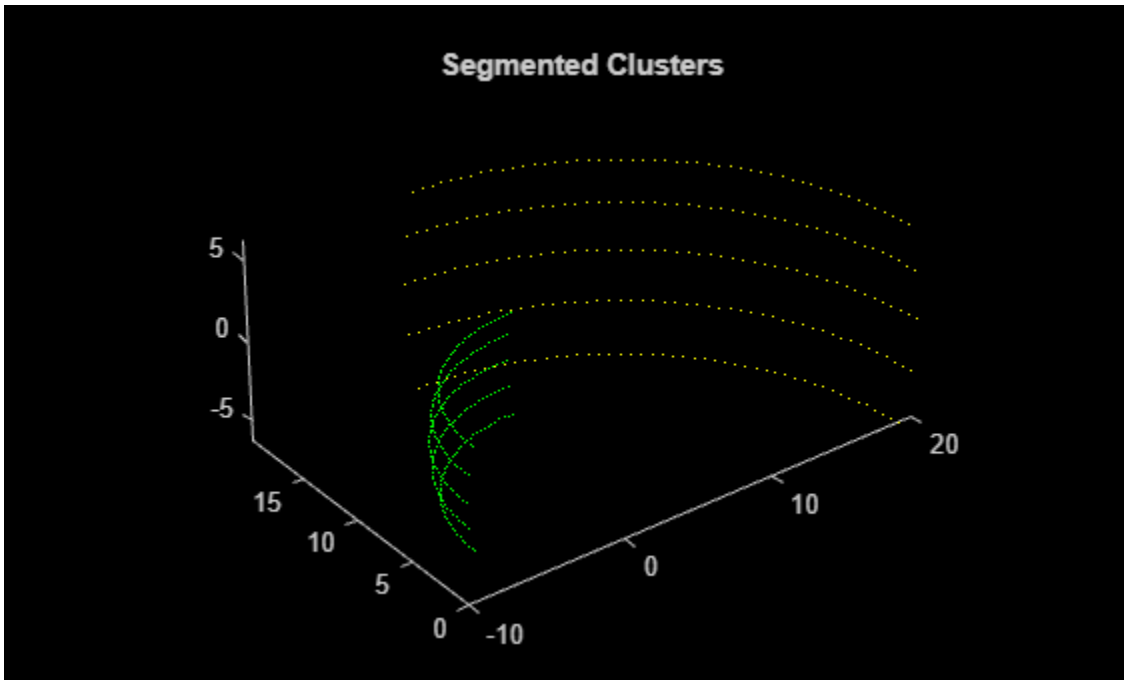
```
X = ldr .* cosd(pitch) .* sind(yaw);
Y = ldr .* cosd(pitch) .* cosd(yaw);
Z = ldr .* sind(pitch);
pc = pointCloud(cat(3,X,Y,Z));
```

```
figure
pcshow(pc.Location,'r')
title('Unclustered Point Cloud')
```

Set the threshold.

```
distThreshold = 5;
```

Segment the lidar data.



```
labels = segmentLidarData(pc,distThreshold);
```

Plot the results.

```
figure
hold on
title('Segmented Clusters')

pc1 = select(pc,find(labels == 1));
pcshow(pc1.Location,'g')

pc2 = select(pc,find(labels == 2));
pcshow(pc2.Location,'y')
```

Cluster Organized Lidar Point Cloud

Set up the PCAP file reader.

```
veloReader = velodyneFileReader('lidarData_ConstructionRoad.pcap','HDL32E');
```

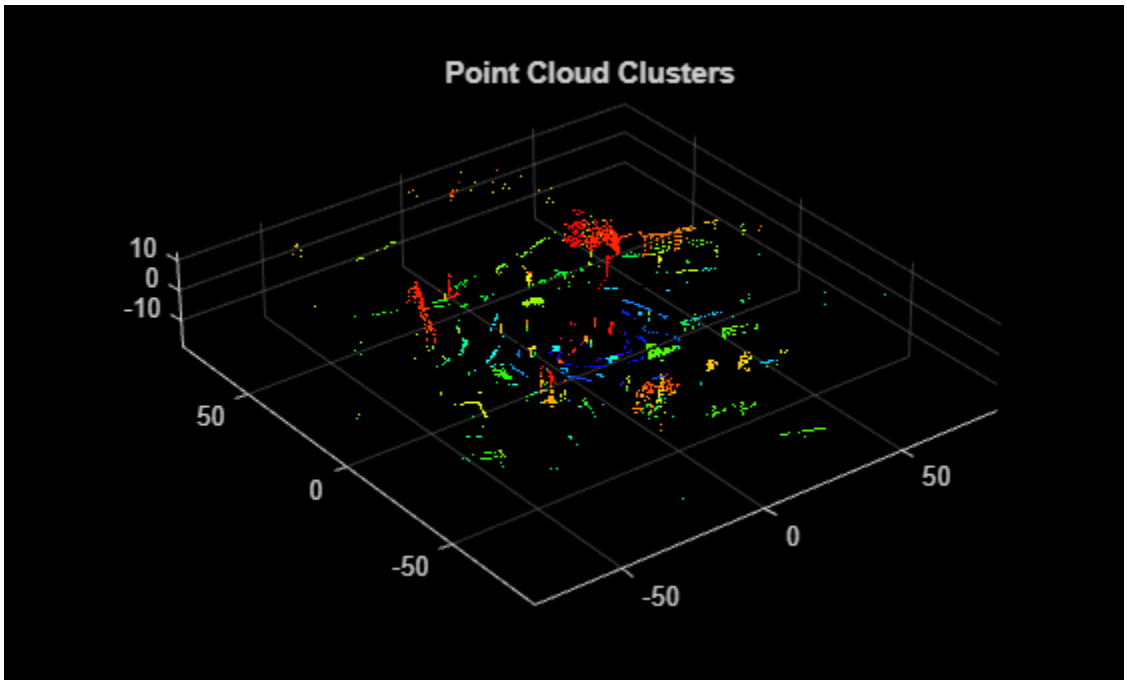
Wait for 0.3 seconds from the beginning of the file, then read the point cloud from the next frame.

```
veloReader.CurrentTime = veloReader.StartTime + seconds(0.3);
ptCloud = readFrame(veloReader);
```

Segment and remove the ground plane.

```
groundPtsIdx = segmentGroundFromLidarData(ptCloud);
ptCloudWithoutGround = select(ptCloud,~groundPtsIdx,'OutputSize','full');
```

Cluster the remaining points. Distance is in meters.



```
distThreshold = 0.5;
[labels,numClusters] = segmentLidarData(ptCloudWithoutGround,distThreshold);
```

Add an additional label for the ground plane.

```
numClusters = numClusters+1;
labels(groundPtsIdx) = numClusters;
```

Plot the labeled results. Display the ground plane in black.

```
labelColorIndex = labels+1;
pcshow(ptCloud.Location,labelColorIndex)
colormap([hsv(numClusters);[0 0 0]])
title('Point Cloud Clusters')
```

Input Arguments

`ptCloud` — Point cloud

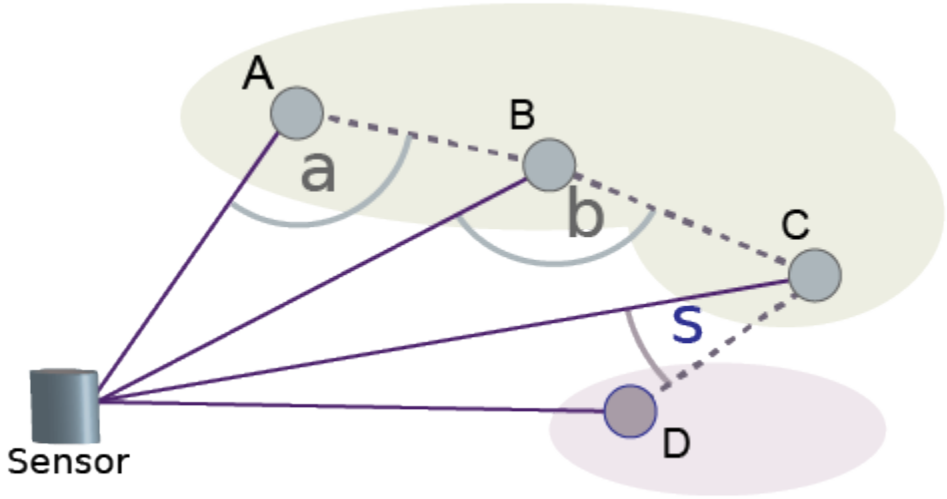
`pointCloud` object

Point cloud, specified as a `pointCloud` object. `ptCloud` is an organized point cloud that stores point coordinates in an *M*-by-*N*-by-3 matrix. The points must be organized by pitch and yaw angles in a sequential scanning order, which is typically obtained from laser range finders and the `velodyneFileReader`.

`distThreshold` — Distance threshold

nonnegative scalar

Distance threshold in world units, specified as a nonnegative scalar. Adjacent points are grouped into the same cluster if the distance between them is less than the distance threshold. To reduce the number of output clusters, increase the value of `distThreshold`.



Data Types: `single` | `double`

`angleThreshold` — Angle threshold

scalar in the range [0, 180]

Angle threshold, in degrees, specified as a scalar in the range [0, 180]. To reduce the number of output clusters, decrease the value of `angleThreshold`. The function groups adjacent points into the same cluster if the angle formed by the sensor and the points is greater than the angle threshold. For example, in the figure, the function groups points A and B into the same cluster if the angle formed by the sensor, point A, and point B, is greater than `angleThreshold`. For more details, see

“Algorithms” on page 3-1170.

Data Types: `single` | `double`

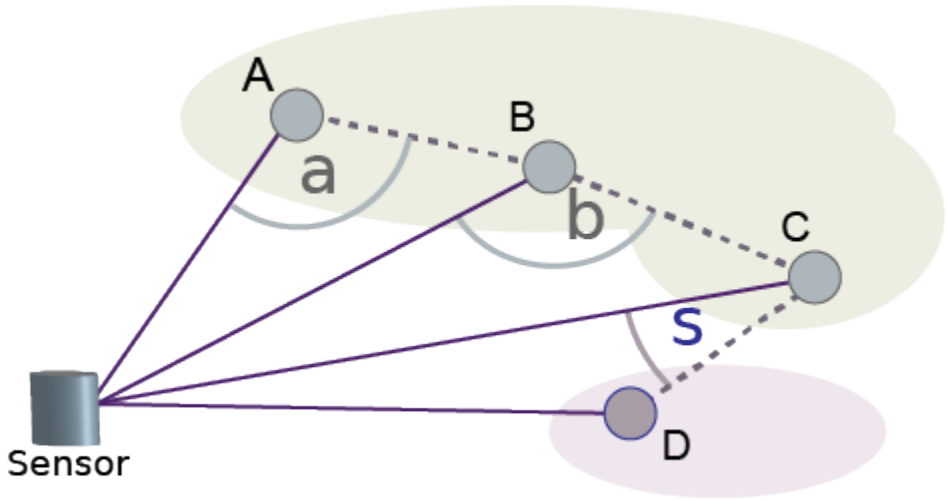
Output Arguments

`labels` — Cluster labels

M-by-*N* matrix

Cluster labels of all points in the point cloud `ptCloud`, returned as an *M*-by-*N* matrix of integers. Each valid point in `ptCloud` belongs to a cluster. All points in a cluster are assigned the same integer cluster label, ranging from `1` to `numClusters`. Invalid points, such as points with `Inf` or `NaN` coordinates, are assigned the label `0`.

`numClusters` — Number of clusters



nonnegative integer

Number of clusters, returned as a positive integer. The number of clusters does not include the cluster corresponding to invalid points and excludes the label value, `0`, which is reserved for invalid points.

Algorithms

The `segmentLidarData` function uses distance and angle thresholds to cluster neighboring points. The function groups two neighboring points into the same cluster if their Euclidean distance is less than the input `distThreshold` or if the angle between the sensor and neighboring points is greater than or equal to the input `angleThreshold`. If you do not specify `angleThreshold`, the function sets this angle to 5 degrees.

For example, suppose `angleThreshold` is set to `90`. Because angles α and β in the figure are both greater than the specified threshold of 90 degrees, the function groups points A, B, and C into the same cluster. Because angle σ is less than the 90-degree threshold, the function groups point D into a separate cluster. Each angle the function uses for clustering is formed by the line from a point to the sensor and the line from that same point to the neighboring point

selectStrongestBbox

Select strongest bounding boxes from overlapping clusters using nonmaximal suppression (NMS)

Syntax

```
[selectedBbox,selectedScore] = selectStrongestBbox(bbox,score)
[selectedBbox,selectedScore,index] = selectStrongestBbox(bbox,score)
[___] = selectStrongestBbox(___,Name,Value)
```

Description

`[selectedBbox,selectedScore] = selectStrongestBbox(bbox,score)` returns selected bounding boxes that have a high confidence score. The function uses nonmaximal suppression (NMS) to eliminate overlapping bounding boxes from the `bbox` input.

`[selectedBbox,selectedScore,index] = selectStrongestBbox(bbox,score)` additionally returns the `index` vector associated with `selectedBbox`. This vector contains the indices of the selected boxes in the `bbox` input.

`[___] = selectStrongestBbox(___,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

Examples

Run Nonmaximal Suppression on Bounding Boxes Using People Detector

Load the pretrained aggregate channel features (ACF) people detector.

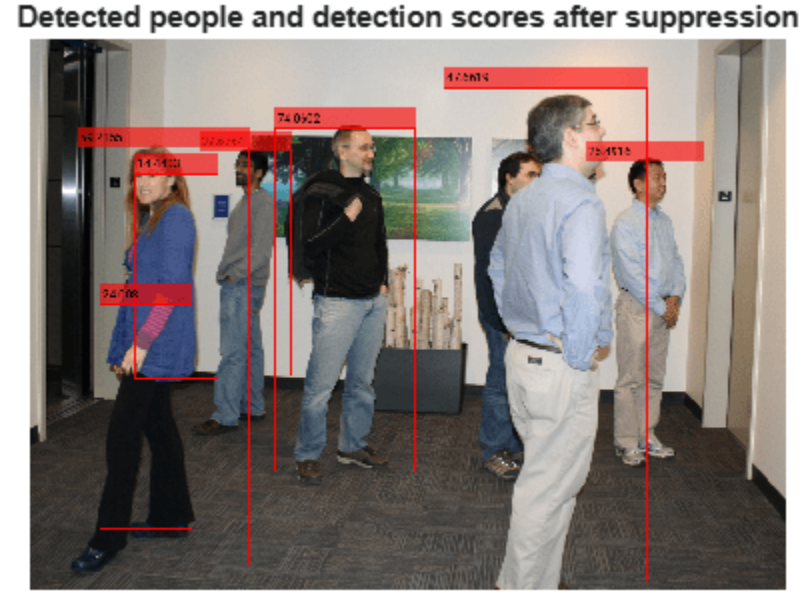
```
peopleDetector = peopleDetectorACF();
```

Detect people in an image. Disable the default nonmaximal suppression used by the detector.

```
I = imread('visionteam1.jpg');
[bbox,score] = detect(peopleDetector,I,'SelectStrongest',false);
```

Run nonmaximal suppression with custom threshold.

```
[selectedBbox,selectedScore] = selectStrongestBbox(bbox,score,'OverlapThreshold',0.3);
```

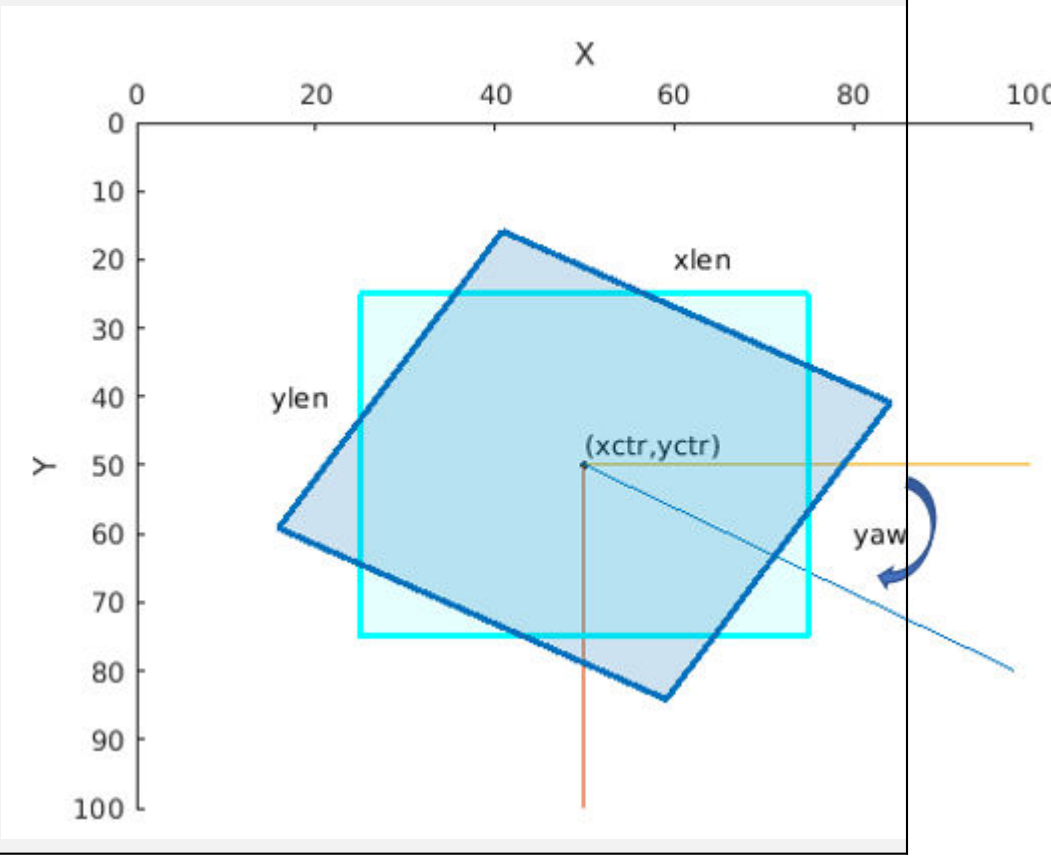


Display the results.

```
I1 = insertObjectAnnotation(I,'rectangle',bbox,score,'AnnotationColor','r');
I2 = insertObjectAnnotation(I,'rectangle',selectedBbox,selectedScore,'AnnotationColor','r');

figure, imshow(I1);
title('Detected people and detection scores before suppression');
```

```
figure, imshow(I2);
title('Detected people and detection scores after suppression');
```



Input Arguments

bbox — Bounding boxes

M-by-4 matrix | *M*-by-5 matrix

Bounding boxes, specified as an *M*-by-4 or *M*-by-5 nonsparse numeric matrix. *M* is the number of bounding boxes. Each row of the matrix defines a bounding box as either an axis-aligned rectangle or a rotated rectangle. This table describes the format for each bounding box.

Bounding Box	Description
Axis-aligned rectangle	Defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and y specify the upper-left corner of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis. • *h* specifies the height of the rectangle, which is its length along the *y*-axis.

Bounding Box	Description
Rotated rectangle	Defined in spatial coordinates as an *M*-by-5 numeric matrix with rows of the form [*xctr yctr xlen ylen yaw*], where: • *M* is the number of rotated rectangles. • *xctr* and *yctr* specify the center of the rectangle. • *xlen* specifies the width of the rectangle, which is its length along the *x*-axis before rotation. • *ylen* specifies the height of the rectangle, which is its length along the *y*-axis before rotation. • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the bounding box. 

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

`score` — Confidence score

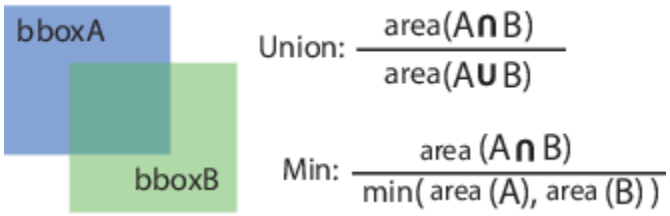
M-by-1 vector

Confidence score, specified as an *M*-by-1 vector. The *M*th score corresponds to the *M*th bounding box in the `bbox` input. The `selectStrongestBbox` function uses nonmaximal suppression to eliminate overlapping bounding boxes and associate the confidence score with the boxes. A higher score represents a higher confidence in keeping the bounding box. The `score` input must be real, finite, and nonsparse.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.



Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'RatioType','Union'` sets the `'RatioType'` property to `'Union'`.

`RatioType` — Bounding box overlap ratio denominator
`'Union'` (default) | `'Min'`

Ratio type, specified as the character vector `'Union'` or `'Min'`.

- Set the ratio type to `'Union'` to compute the ratio as the area of intersection between `bboxA` and `bboxB`, divided by the area of the union of the two.
- Set the ratio type to `'Min'` to compute the ratio as the area of intersection between `bboxA` and `bboxB`, divided by the minimum area of the two bounding boxes.

Data Types: `char`

`OverlapThreshold` — Overlap ratio threshold
`0.5` (default) | scalar in the range [0 1]

Overlap ratio threshold, specified as the comma-separated pair consisting of '`OverlapThreshold`' and a scalar in the range [0 1]. When the overlap ratio is above the threshold you set, the function removes bounding boxes around the reference box. Decrease this value to reduce the number of selected bounding boxes. However, if you decrease the overlap ratio too much, you might eliminate boxes that represent objects close to each other in the image.

Data Types: `single` | `double`

`NumStrongest` — Maximum number of strongest boxes
`inf` (default) | positive scalar

Maximum number of strongest boxes, specified as the comma-separated pair consisting of `'NumStrongest'` and `inf` or a positive scalar. Use this argument to reduce processing time when you have a priori knowledge about the maximum number of boxes. Set the value to `inf` to select all the strongest, non-overlapping, bounding boxes.

Output Arguments

`selectedBbox` — Selected bounding boxes

M-by-4 matrix | *M*-by-5 matrix

Selected bounding boxes, returned as an *M*-by-4 or an *M*-by-5 matrix. The 4-element vectors represent axis-aligned rectangles and the 5-element vectors represent rotated rectangles.

The `selectedBbox` output returns the selected bounding boxes from the `bbox` input that have the highest confidence score. The function uses nonmaximal suppression to eliminate overlapping bounding boxes.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

`selectedScore` — Scores of selected bounding boxes

M-by-1 vector

Scores of selected bounding boxes, returned as an *M*-by-1 vector. The *M*th score in the `selectedScore` output corresponds to the *M*th bounding box in the `selectedBbox` output.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

`index` — Index of selected bounding boxes

M-by-1 vector

Index of selected bounding boxes, returned as an *M*-by-1 vector. The `index` vector contains the indices to the selected boxes in the `bbox` input.

Data Types: `double`

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- GPU Arrays is not supported for rotated rectangle bounding box inputs.

See Also

`bboxOverlapRatio` | `selectStrongestBboxMulticlass`

selectStrongestBboxMulticlass

Select strongest multiclass bounding boxes from overlapping clusters using nonmaximal suppression (NMS)

Syntax

```
selectedBboxes = selectStrongestBboxMulticlass(bboxes,scores,labels)
[selectedBboxes,selectedScores,selectedLabels,index] =
selectStrongestBboxMulticlass(bboxes,scores,labels)
[ ___ ] = selectStrongestBboxMulticlass( ___ ,Name,Value)
```

Description

`selectedBboxes = selectStrongestBboxMulticlass(bboxes,scores,labels)` returns selected bounding boxes that have high confidence scores. The function uses greedy nonmaximal suppression (NMS) to eliminate overlapping bounding boxes from the `bboxes` input, only if they have the same class label.

`[selectedBboxes,selectedScores,selectedLabels,index] = selectStrongestBboxMulticlass(bboxes,scores,labels)` additionally returns the scores, labels, and index associated with the selected bounding boxes.

`[ ___ ] = selectStrongestBboxMulticlass( ___ ,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

Examples

Run Multiclass Nonmaximal Suppression on Bounding Boxes Using People Detector

Create detectors using two different models. These will be used to generate multiclass detection results.

```
detectorInria = peopleDetectorACF('inria-100x41');
detectorCaltech = peopleDetectorACF('caltech-50x21');
```

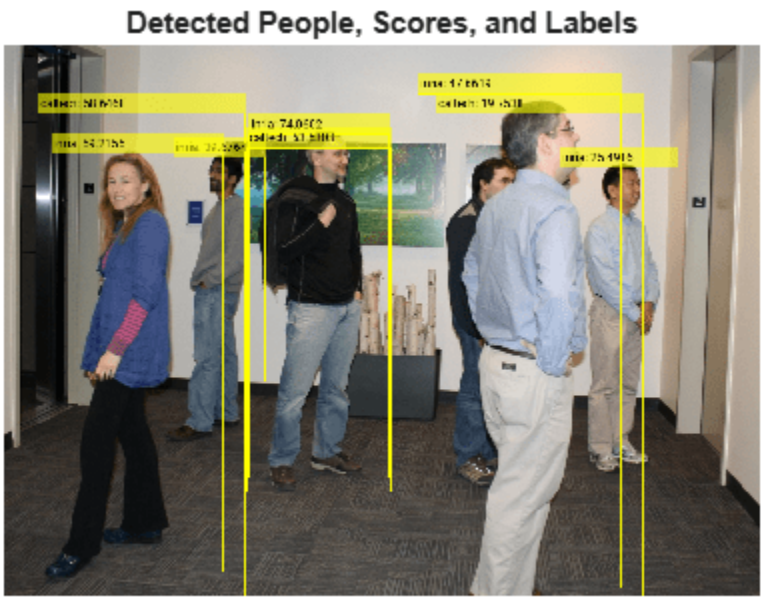
Apply the detectors.

```
I = imread('visionteam1.jpg');
[bboxesInria,scoresInria] = detect(detectorInria,I,'SelectStrongest',false);
[bboxesCaltech,scoresCaltech] = detect(detectorCaltech,I,'SelectStrongest',false);
```

Create categorical labels for each the result of each detector.

```
labelsInria = repelem("inria",numel(scoresInria),1);
labelsInria = categorical(labelsInria,{'inria','caltech'});
labelsCaltech = repelem("caltech",numel(scoresCaltech),1);
labelsCaltech = categorical(labelsCaltech,{'inria','caltech'});
```

Combine results from all detectors to for multiclass detection results.



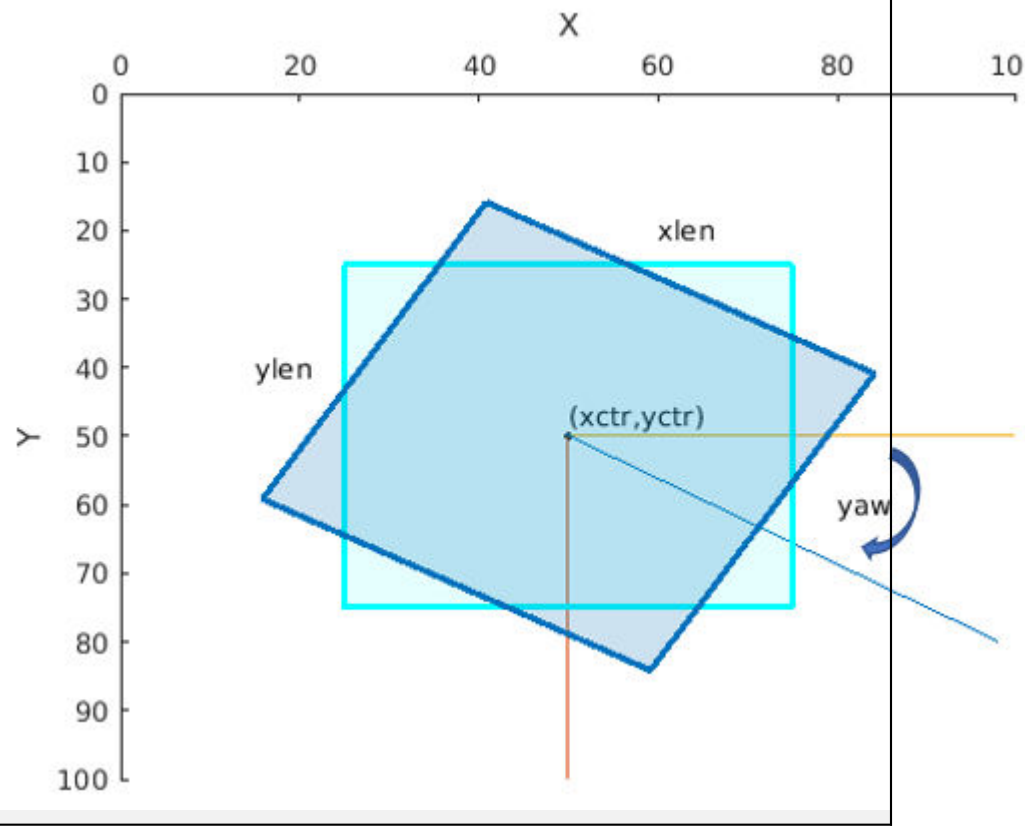
```
allBBoxes = [bboxesInria;bboxesCaltech];
allScores = [scoresInria;scoresCaltech];
allLabels = [labelsInria;labelsCaltech];
```

Run multiclass non-maximal suppression.

```
[bboxes,scores,labels] = selectStrongestBboxMulticlass(allBBoxes,allScores,allLabels,...
    'RatioType','Min','OverlapThreshold',0.65);
```

Annotate detected people.

```
annotations = string(labels) + ": " + string(scores);
I = insertObjectAnnotation(I,'rectangle',bboxes,cellstr(annotations));
imshow(I)
title('Detected People, Scores, and Labels')
```



Input Arguments

bboxes — Bounding boxes

M-by-4 matrix | *M*-by-5 matrix

Bounding boxes, specified as an *M*-by-4 or *M*-by-5 nonsparse numeric matrix. *M* is the number of bounding boxes. Each row of the matrix defines a bounding box as either an axis-aligned rectangle or a rotated rectangle. This table describes the format for each bounding box.

Bounding Box	Description
Axis-aligned rectangle	Defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and y specify the upper-left corner of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis. • *h* specifies the height of the rectangle, which is its length along the *y*-axis.
Rotated rectangle	Defined in spatial coordinates as an *M*-by-5 numeric matrix with rows of the form [*xctr yctr xlen ylen yaw*], where: • *M* is the number of rotated rectangles. • *xctr* and *yctr* specify the center of the rectangle. • *xlen* specifies the width of the rectangle, which is its length along the *x*-axis before rotation. • *ylen* specifies the height of the rectangle, which is its length along the *y*-axis before rotation. • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the bounding box. 

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

`scores` — Confidence scores
M-by-1 vector

Confidence scores corresponding to the input bounding boxes, specified as an *M*-by-1 vector. The `selectStrongestBboxMulticlass` function uses greedy NMS to eliminate overlapping bounding boxes and associate the confidence score with the boxes. A higher score represents a higher confidence in keeping the bounding box. The `scores` input must be real, finite, and nonsparse.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

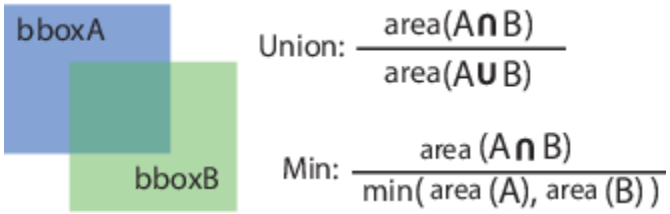
`labels` — Labels
M-by-1 categorical vector | *M*-by-1 numeric vector

Labels corresponding to the input bounding boxes, specified as an *M*-by-1 categorical or numeric vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `categorical`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.



Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'RatioType','Union'` sets the `'RatioType'` property to `'Union'`.

`RatioType` — Bounding box overlap ratio denominator
`'Union'` (default) | `'Min'`

Ratio type, specified as the character vector `'Union'` or `'Min'`.

- Set the ratio type to `'Union'` to compute the ratio as the area of intersection between `bboxA` and `bboxB`, divided by the area of the union of the two.
- Set the ratio type to `'Min'` to compute the ratio as the area of intersection between `bboxA` and `bboxB`, divided by the minimum area of the two bounding boxes.

Data Types: `char`

`OverlapThreshold` — Overlap ratio threshold
`0.5` (default) | scalar in the range [0 1]

Overlap ratio threshold, specified as the comma-separated pair consisting of '`OverlapThreshold`' and a scalar in the range [0 1]. When the overlap ratio is above the threshold, the function removes

bounding boxes around the reference box. Decrease the threshold to reduce the number of selected bounding boxes. However, if you decrease the threshold too much, you might eliminate boxes that represent objects close to each other in the image.

Data Types: `single` | `double`

`NumStrongest` — Maximum number of strongest boxes
`inf` (default) | positive scalar

Maximum number of strongest boxes, specified as the comma-separated pair consisting of `'NumStrongest'` and `inf` or a positive scalar. Use this argument to reduce processing time when you have a priori knowledge about the maximum number of boxes. Set the value to `inf` to select all the strongest, non-overlapping, bounding boxes.

When the `labels` input contains categorical labels, you can also specify a vector that contains the maximum number of strongest boxes for each category in the labels input. The length of the specified vector must equal the number of categories in the label.

Output Arguments

`selectedBboxes` — Selected bounding boxes
M-by-4 matrix | *M*-by-5 matrix

Selected bounding boxes, returned as an *M*-by-4 or an *M*-by-5 matrix. The 4-element vectors represent axis-aligned rectangles and the 5-element vectors represent rotated rectangles.

The `selectedBbox` output returns the selected bounding boxes from the `bbox` input that have the highest confidence score. The function uses nonmaximal suppression to eliminate overlapping bounding boxes.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

`selectedScores` — Scores of selected bounding boxes
M-by-1 vector

Scores of selected bounding boxes, returned as an *M*-by-1 vector. The *M*th score in the `selectedScores` output corresponds to the *M*th bounding box in the `selectedBboxes` output. The data type of `selectedScores` matches the data type of `scores`.

`selectedLabels` — Labels of selected bounding boxes
M-by-1 categorical vector | *M*-by-1 numeric vector

Labels of selected bounding boxes, returned as an *M*-by-1 categorical or numeric vector. The *M*th label in the `selectedLabels` output corresponds to the *M*th bounding box in the `selectedBboxes` output. The data type of `selectedLabels` matches the data type of `labels`.

`index` — Index of selected bounding boxes
M-by-1 vector

Index of selected bounding boxes, returned as an *M*-by-1 vector. The `index` vector contains the indices to the selected boxes in the `bboxes` input.

Data Types: `double`

showExtrinsics

Visualize extrinsic camera parameters

Syntax

```
showExtrinsics(cameraParams)
showExtrinsics(cameraParams,viewStyle)
showExtrinsics( ___ ,Name=Value)

ax = showExtrinsics( ___ )
```

Description

`showExtrinsics(cameraParams)` renders a 3-D visualization of extrinsic parameters of a single calibrated camera, a calibrated stereo pair, or multiple calibrated cameras. The function plots a 3-D view of the calibration patterns with respect to the camera. The `cameraParams` input contains one of:

- `cameraParameters` or `stereoParameters` object which the `estimateCameraParameters` function returns.
- `fisheyeParameters` or object which the `estimateFisheyeParameters` function returns.
- `multiCameraParameters` object which the `estimateMultiCameraParameters` function returns.

The showExtrinsics function shows the 3-D view of the calibration pattern as a convex polygon containing all the detected keypoints of the pattern in the original calibration image.

`showExtrinsics(cameraParams,viewStyle)` displays visualization of the camera extrinsic parameters using the style specified by the `viewStyle` input.

`showExtrinsics( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `HighlightIndex = [1,4]` sets the highlight patterns to 1 and 4.

`ax = showExtrinsics( ___ )` returns the plot axis, using any of the preceding syntaxes.

Examples

Visualize Single Camera Extrinsic Parameters

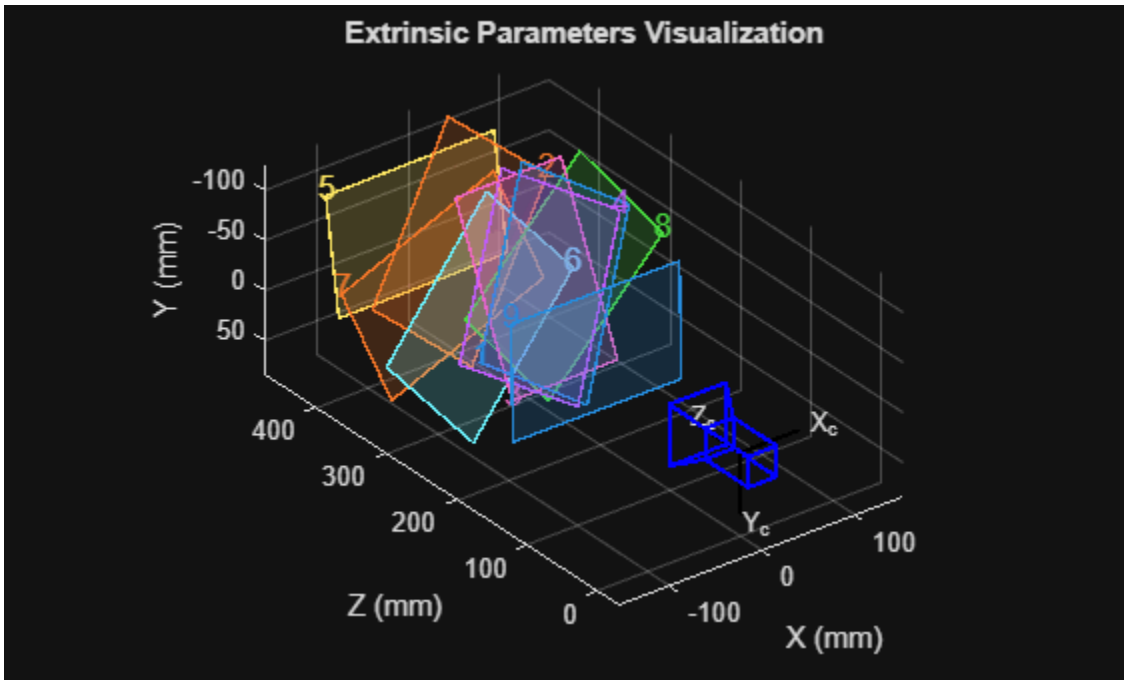
Create a set of calibration images.

```
images = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
  "calibration","dslr"));
imageFileNames = images.Files;
```

Detect calibration pattern.

```
[imagePoints,patternDims] = detectCheckerboardPoints(imageFileNames);
```

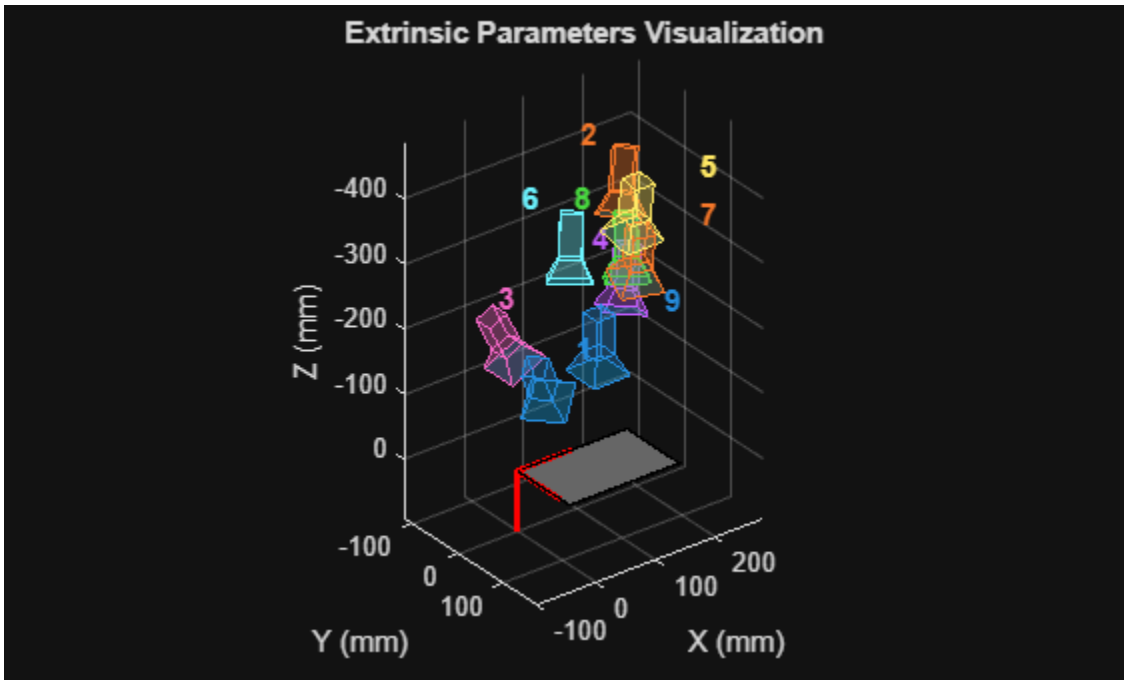
Generate world coordinates of the corners of the squares. The square size is in millimeters.



```
squareSide = 23; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSide);
```

Calibrate the camera.

```
I = readimage(images,1);
imageSize = size(I,1:2);
cameraParams = estimateCameraParameters(imagePoints,worldPoints,ImageSize=imageSize);
```



Visualize pattern locations.

```
figure
showExtrinsics(cameraParams);
```

Visualize camera locations.

```
figure
showExtrinsics(cameraParams,"patternCentric");
```

Visualize Stereo Pair of Camera Extrinsic Parameters

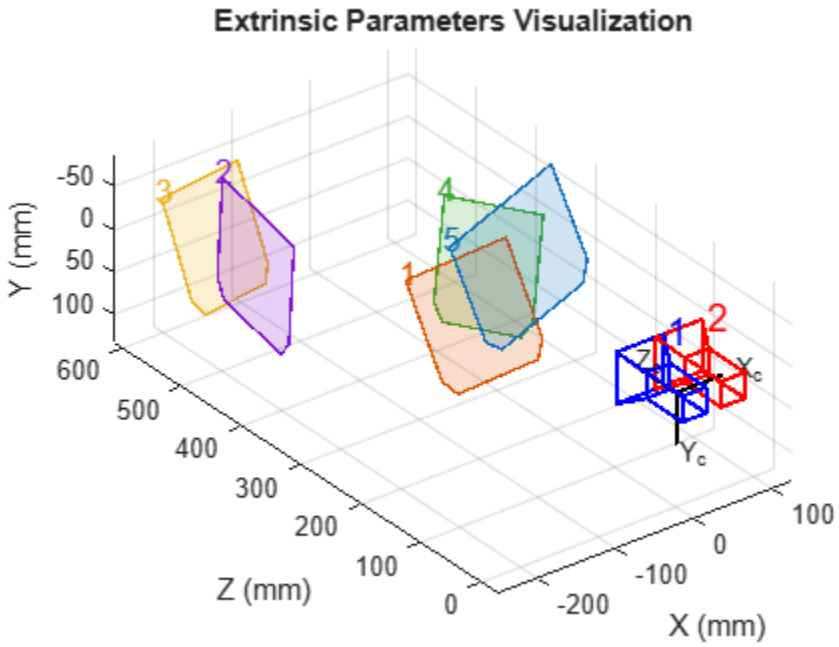
Specify calibration images.

```
imageDir = fullfile(toolboxdir("vision"),"visiondata",...
        "calibration","circleGrid","stereo");
leftImages = imageDatastore(fullfile(imageDir,"left"));
rightImages = imageDatastore(fullfile(imageDir,"right"));
leftImageFileNames = leftImages.Files(2:2:10);
rightImageFileNames = rightImages.Files(2:2:10);
```

Define the circle grid pattern dimensions, and detect the pattern in the images.

```
patternDims = [4 11];
imagePoints = detectCircleGridPoints(leftImageFileNames,rightImageFileNames,patternDims);
```

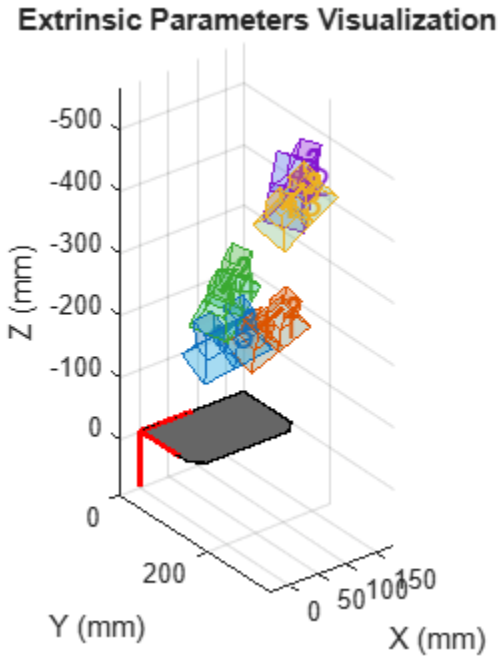
Specify the world coordinates for the circle grid keypoints. Center distance is in millimeters.



```
centerDistance = 36.5; % millimeters
worldPoints = patternWorldPoints("circle-grid-asymmetric",patternDims,centerDistance);
```

Calibrate the stereo camera system. Both cameras have the same resolution.

```
I = readimage(leftImages,1);
imageSize = [size(I,1),size(I,2)];
cameraParams = estimateCameraParameters(imagePoints,worldPoints,ImageSize=imageSize);
```



Visualize pattern locations.

```
figure
showExtrinsics(cameraParams)
```

Visualize camera locations.

```
figure
showExtrinsics(cameraParams,"patternCentric")
```

Calibrate a Multi-Camera System using a ChArUco board

Estimate the relative position and orientation of six cameras with overlapping fields of view by using calibration images that contain a single ChArUco board.

Download the calibration images.

```
calibImagesURL = "https://www.mathworks.com/supportfiles/vision/data/overlapping-cameras-charuco
calibImagesDir = fullfile(pwd,"overlapping-cameras-charuco");
calibImagesZip = fullfile(pwd,"overlapping-cameras-charuco.zip");
if ~exist(calibImagesZip,"file")
    disp("Downloading calibration images (52 MB)...")
    websave(calibImagesZip,calibImagesURL);
end
```

```
Downloading calibration images (52 MB)...
```

```
if ~exist(calibImagesDir,"dir")
    unzip(calibImagesZip,pwd)
end
```

Specify calibration image filenames for each camera.

```
numCameras = 6;
camDirPrefix = "Cam00";
imageFiles = cell(1,numCameras);
for i = 1:numCameras
    camDir = fullfile(calibImagesDir,camDirPrefix+i);
    imds = imageDatastore(camDir);
    imageFiles{i} = imds.Files;
end
imageFiles = [imageFiles{:}];
```

Define the ChArUco board properties. Specify checker size and marker size in centimeters.

```
markerFamily = "DICT_6X6_1000";
patternDims = [5 5];
markerSize = 6.8;   % in cm
checkerSize = 9.15; % in cm
numKeyPoints = prod(patternDims - 1);
minMarkerId = 144;
```

Detect the key points of the ChArUco board in the calibration images.

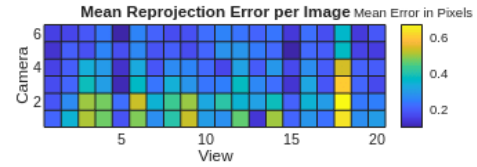
```
imagePoints = detectPatternPoints(imageFiles,"charuco-board",patternDims, ...
    markerFamily,checkerSize,markerSize,MinMarkerID=minMarkerId);
```

```
[==================================================] 100%
Elapsed time: 00:00:09
Estimated time remaining: 00:00:00
```

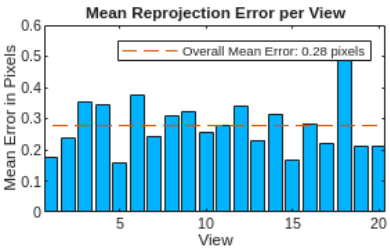
Generate the world points for the pattern.

```
worldPoints = patternWorldPoints("charuco-board",patternDims,checkerSize);
```

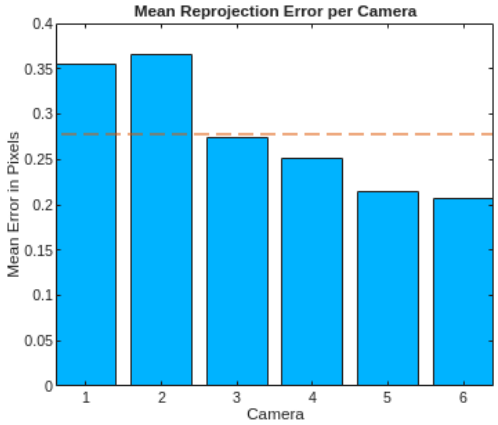
Load the intrinsic parameters of the six cameras. These parameters have been estimated using the “Using the Single Camera Calibrator App”.



```
ld = load("sixCameraIntrinsics.mat");
```



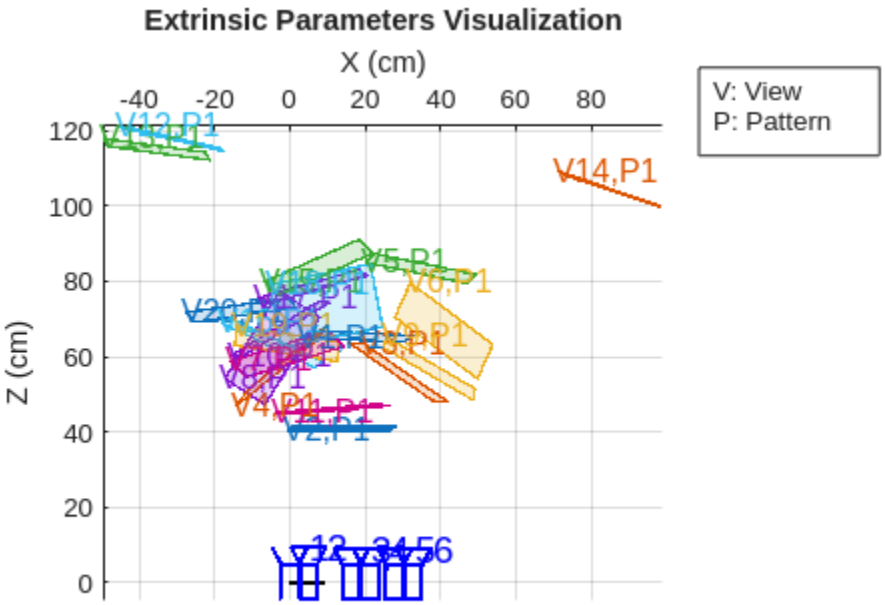
Perform multi-camera calibration.



```
params = estimateMultiCameraParameters(imagePoints,worldPoints,ld.intrinsics,WorldUnits="cm");
```

Visualize the calibration accuracy.

```
figure(Position=[100,100,1000,400])
showReprojectionErrors(params)
```



Visualize the camera extrinsic parameters.

```
figure
showExtrinsics(params)
view(2)
```

Input Arguments

`cameraParams` — Object containing parameters of single camera or stereo pair

`cameraParameters` object | `fisheyeParameters` object | `stereoParameters` object | `multiCameraParameters` object

Object containing parameters for a single, fisheye, stereo pair, or multi-camera system, specified as either a `cameraParameters`, `fisheyeParameters`, `stereoParameters`, `multiCameraParameters` object. You can create these objects using the:

- `estimateCameraParameters` function to return a `cameraParameters` or `stereoParameters` object.
- `estimateFisheyeParameters` function to return a `fisheyeParameters` object.
- `estimateMultiCameraParameters` function to return a `multiCameraParameters` object.

You can also use the Camera Calibrator app to create the `cameraParameters` input object, or use Stereo Camera Calibrator app to create the `stereoParameters` input object. See “Using the Single Camera Calibrator App” and “Using the Stereo Camera Calibrator App”.

`viewStyle` — Camera- or pattern-centric view

`"CameraCentric"` | `"PatternCentric"`

Camera or pattern-centric view, specified as `"CameraCentric"` or `"PatternCentric"`. The `viewStyle` input sets the visualization for the camera extrinsic parameters. If you keep your camera stationary while moving the calibration pattern, set `viewStyle` to `"CameraCentric"`. If the pattern is stationary while you move your camera, set it to `"PatternCentric"`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `showExtrinsics(cameraParams,HighlightIndex = [1,4])`, sets the highlight selection index to patterns 1 and 4.

`HighlightIndex` — Highlight selection index

`[]` (default) | vector | scalar

Highlight selection index, specified as a scalar or a vector of integers. When you specify this index, the opacity of one or more specified patterns is increased, making the selection stand out in contrast to the other patterns.

`CameraIndex` — Camera selection index

`[]` (default) | vector | scalar

Camera selection index, specified as a scalar or a vector of integers. This argument applies only when you set `cameraParams` to a `multiCameraParameters` object. When `CameraIndex` is empty, all cameras are displayed.

`ViewIndex` — View selection index

`[]` (default) | vector | scalar

View selection index, specified as a scalar or a vector of integers. Specify the index of camera views to display. When this value is empty, all views will be displayed.

`PatternIndex` — Pattern selection index
`[ ]` (default) | vector | scalar

Pattern selection index, specified as a scalar or a vector of integers. Specify the index of calibration patterns to display. This argument applies only when you set `cameraParams` to a `multiCameraParameters` object and `viewStyle` to `"CameraCentric"`. When this value is empty, all patterns will be displayed.

`Parent` — Output axes
current axes (default)

Output axes, specified as an axes. You can obtain the current axes handle by returning the function to an output variable:
`ax = showExtrinsics(cameraParams)`
You can also use the `gca` function to get the current axes handle.

Output Arguments

`ax` — Current axes handle
scalar value

Current axes handle, returned as a scalar value. The function returns the handle to the current axes for the current figure.

Example: `ax = showExtrinsics(cameraParams)`

Tips

- When displaying multiple patterns in the `"CameraCentric"` view, patterns corresponding to the same view are displayed with the same color and are labeled as "*V*`viewIndex`, *P*`patternIndex`". For example, patterns 1 and 2 of view 3 are labeled as "`V3,P1`" and "`V3,P2`", respectively.

  In the `"CameraCentric"` view, the cameras with the same color have overlapped fields of view.
- In the `"PatternCentric"` view, the first pattern is chosen as the reference pattern. All cameras are displayed relative to this reference and are labeled as "*V*`viewIndex`, *C*`cameraIndex`". For example, cameras 1 and 2 of view 3 are labeled as "`V3,C1`" and "`V3,C2`, respectively.

Version History

Introduced in R2014a

R2026a: New `ViewIndex` and `PatternIndex` name-value arguments

Added the `ViewIndex` and `PatternIndex` name-value arguments to support multiple calibration patterns.

showMatchedFeatures

Display corresponding feature points

Syntax

```
showMatchedFeatures(I1,I2,matchedPoints1,matchedPoints2)
showMatchedFeatures(I1,I2,matchedPoints1,matchedPoints2,method)

showMatchedFeatures(___,PlotOptions, {MarkerStyle1, MarkerStyle2, LineStyle})
showMatchedFeatures(___,Name=Value)

H = showMatchedFeatures(___)
```

Description

`showMatchedFeatures(I1,I2,matchedPoints1,matchedPoints2)` displays an overlay of images `I1` and `I2` with a color-coded plot of corresponding points connected by a line. `matchedPoints1` and `matchedPoints2` contain the coordinates of corresponding points in `I1` and `I2`.

`showMatchedFeatures(I1,I2,matchedPoints1,matchedPoints2,method)` displays images `I1` and `I2` using the visualization style specified by the `method` parameter.

`showMatchedFeatures(___,PlotOptions, {MarkerStyle1, MarkerStyle2, LineStyle})` lets you specify custom plot options in a cell array containing three values. The `MarkerStyle1`, `MarkerStyle2`, and `LineStyle` values correspond to the marker symbol in `I1`, marker symbol in `I2`, and the line style and color. The `LineSpec` syntax of the `plot` function defines each of the specifiers.

`showMatchedFeatures(___,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `showMatchedFeatures(__,PlotOptions={"d","+","g"})` sets the marker style to a diamond for `I1`, a plus sign for `I2`, and the color to green.

`H = showMatchedFeatures(___)` returns the handle to the image object returned by `showMatchedFeatures`.

Examples

Find Corresponding Points Between Two Images Using Harris Features

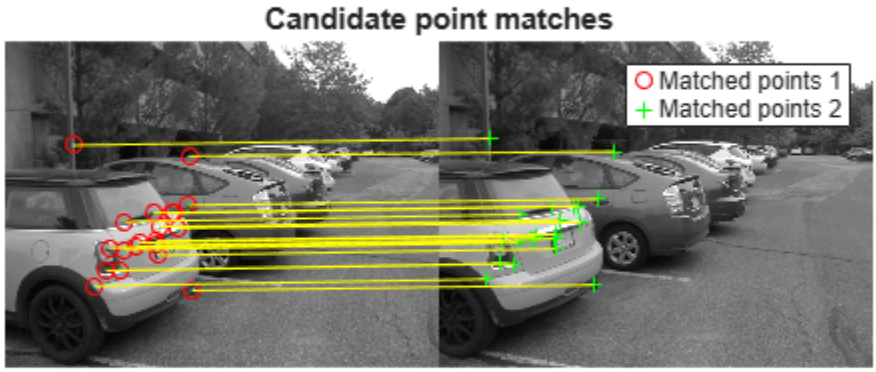
Read images.

```
I1 = im2gray(imread("parkinglot_left.png"));
I2 = im2gray(imread("parkinglot_right.png"));
```

Detect Harris features.

```
points1 = detectHarrisFeatures(I1);
points2 = detectHarrisFeatures(I2);
```

Extract features.



```
[f1,vpts1] = extractFeatures(I1,points1);
[f2,vpts2] = extractFeatures(I2,points2);
```

Match features.

```
indexPairs = matchFeatures(f1,f2);
matchedPoints1 = vpts1(indexPairs(1:20,1));
matchedPoints2 = vpts2(indexPairs(1:20,2));
```

Visualize candidate matches.

```
figure;
showMatchedFeatures(I1,I2,matchedPoints1,matchedPoints2,"montage");
title("Candidate point matches");
legend("Matched points 1","Matched points 2");
```

Display Corresponding Points Between Two Rotated and Scaled Images

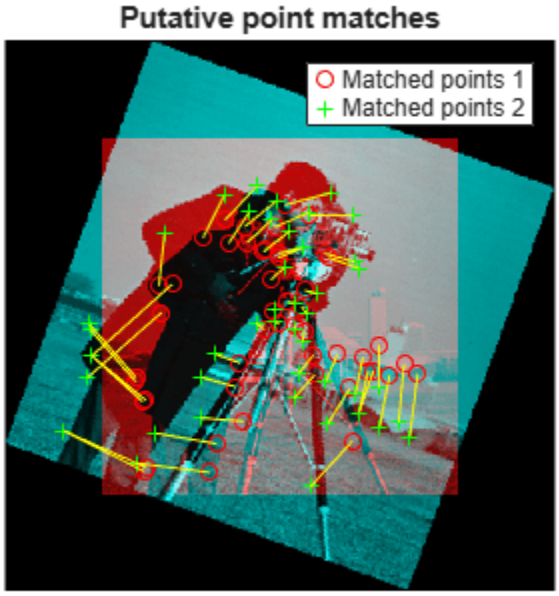
Read images.

```
I1 = imread("cameraman.tif");
I2 = imresize(imrotate(I1,-20), 1.2);
```

Detect SURF features.

```
points1 = detectSURFFeatures(I1);
points2 = detectSURFFeatures(I2);
```

Extract features.



```
[f1,vpts1] = extractFeatures(I1,points1);
[f2,vpts2] = extractFeatures(I2,points2);
```

Match features.

```
indexPairs = matchFeatures(f1,f2);
matchedPoints1 = vpts1(indexPairs(:,1));
matchedPoints2 = vpts2(indexPairs(:,2));
```

Visualize candidate matches.

```
figure;
showMatchedFeatures(I1,I2,matchedPoints1,matchedPoints2);
title("Putative point matches");
legend("Matched points 1","Matched points 2");
```

Input Arguments

`I1` — Input image

numeric array

Input image one, specified as a numeric array.

`I2` — Input image

numeric array

Input image two, specified as a numeric array.

`matchedPoints1` — Coordinates of points

M-by-2 matrix | point feature object

Coordinates of points in image one, specified as an *M*-by-2 matrix of *M* number of [*x* *y*] coordinates, or as one of the point feature objects described in “Point Feature Types”.

`matchedPoints2` — Coordinates of points
M-by-2 matrix | point feature object

Coordinates of points in image two, specified as an *M*-by-2 matrix of *M* number of [*x* *y*] coordinates, or as one of the point feature objects described in “Point Feature Types”.

`method` — Display method
`falsecolor` (default) | `blend` | `montage`

Display style method, specified as one of the following:

`falsecolor`	Overlay the images by creating a composite red-cyan image showing `I1` as red and `I2` as cyan.
`blend`	Overlay `I1` and `I2` using alpha blending.
`montage`	Place `I1` and `I2` next to each other in the same image.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `showMatchedFeatures(__,PlotOptions={"d","+","g"})` sets the marker style to a diamond for `I1`, a plus sign for `I2`, and the color to green.

`PlotOptions` — Marker, line style, and color
`{"ro","g+","y-"}` (default) | cell array of character vectors | string array

Marker, line style, and color options, specified as a cell array of character vectors or a string array. The three values {*MarkerStyle1*, *MarkerStyle2*, *LineStyle*}, correspond to the marker symbol in `I1`, the marker symbol in `I2`, and the line style and color. The `LineSpec` syntax of the `plot` function defines each of the specifiers.

`Parent` — Output axes
`axes` graphics object

Output axes for displaying visualization, specified as an `axes` graphics object.

Output Arguments

`H` — Handle to image object
handle

Handle to image object, displayed by `showMatchedFeatures`.

showPointCloud

Plot 3-D point cloud

Syntax

```
showPointCloud
```

Description

`showPointCloud` was renamed to `pcshow`. Please use `pcshow` in place of `showPointCloud`.

Version History

Introduced in R2014b

R2020a: `showPointCloud` renamed to `pcshow`
Behavior changed in R2020a

`showPointCloud` was renamed to `pcshow`. Please use `pcshow` in place of `showPointCloud`.

pcshow

Plot 3-D point cloud

Syntax

```
pcshow(ptCloud)

pcshow(xyzPoints)
pcshow(xyzPoints,color)
pcshow(xyzPoints,colorMap)
pcshow(filename)

pcshow( ___ ,Name=Value)

ax = pcshow( ___ )
```

Description

`pcshow(ptCloud)` displays points using the locations and colors stored in the point cloud object.

To visualize a large point cloud (greater than one million points), use the `pcviewer` object.

`pcshow(xyzPoints)` displays points specified by the `xyzPoints` matrix.

`pcshow(xyzPoints,color)` displays points contained in the `xyzPoints` matrix, with colors specified by `color`.

`pcshow(xyzPoints,colorMap)` displays points contained in the `xyzPoints` matrix, with colors specified by `colorMap`.

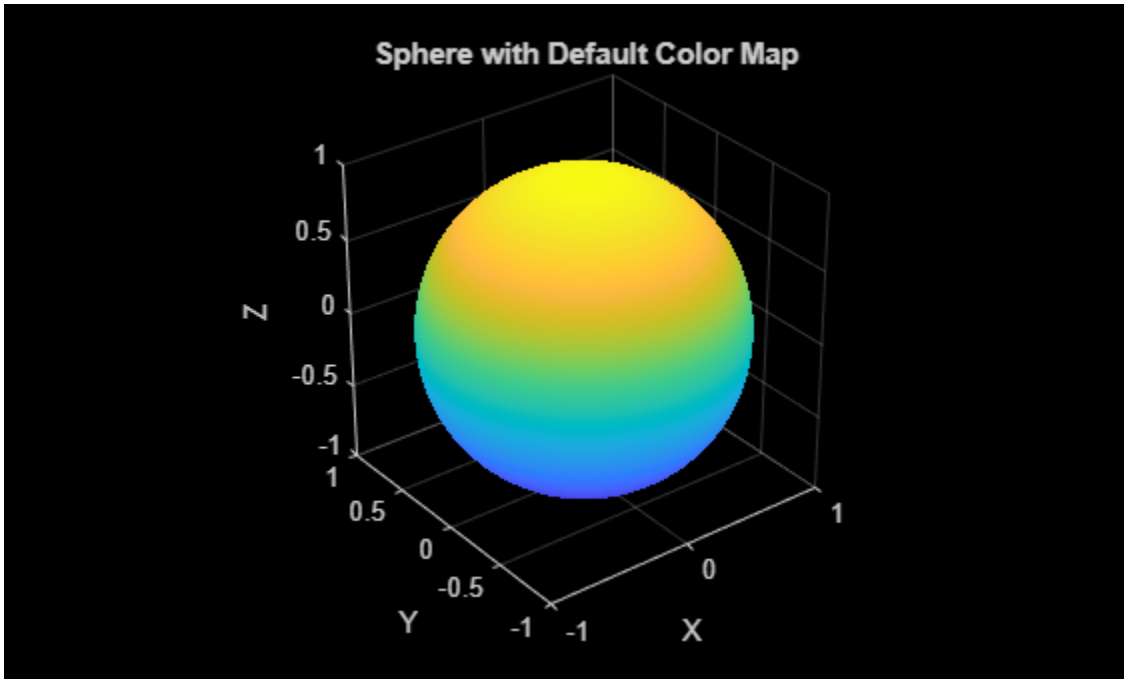
`pcshow(filename)` displays the point cloud stored in the file specified by `filename`.

`pcshow( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination input of arguments from previous syntaxes. For example, `ViewPlane="XY"` sets the plane from which to visualize the point cloud as the *xy*-plane.

`ax = pcshow( ___ )` returns the plot axes.

Examples

Plot Spherical Point Cloud with Texture Mapping



Generate a sphere consisting of 600-by-600 faces.

```
numFaces = 600;
[x,y,z] = sphere(numFaces);
```

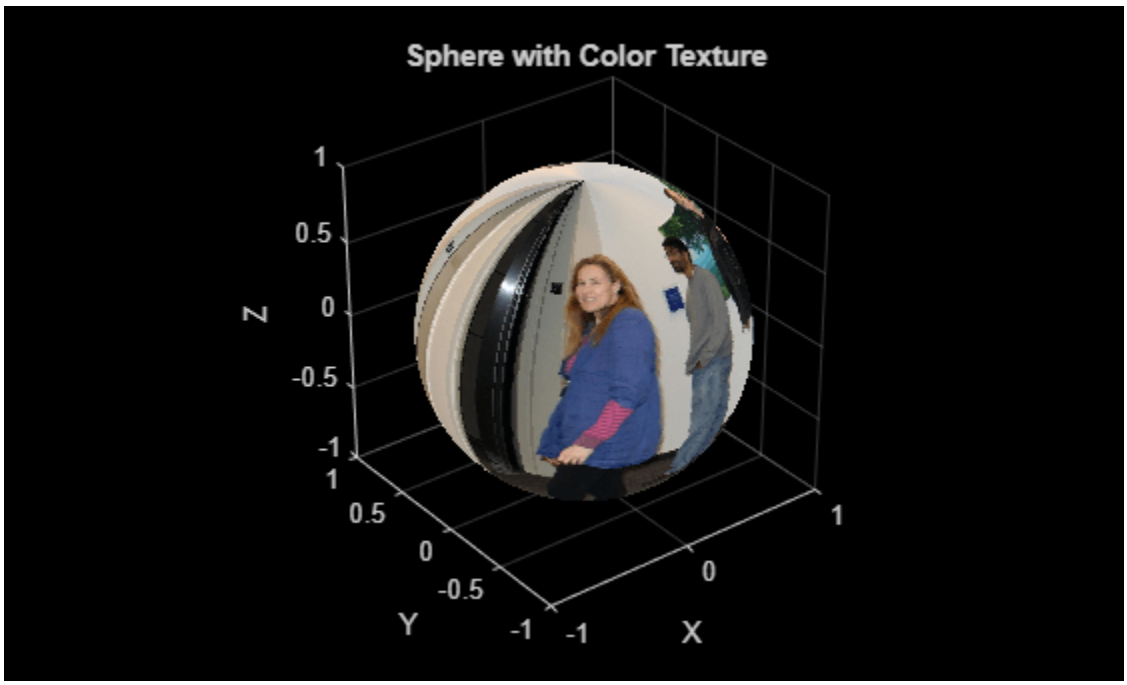
Plot the sphere using the default color map.

```
figure;
pcshow([x(:) y(:) z(:)])
```

```
title("Sphere with Default Color Map")
xlabel("X")
ylabel("Y")
zlabel("Z")
```

Load and display an image for texture mapping.

```
I = im2double(imread("visionteam1.jpg"));
imshow(I)
```

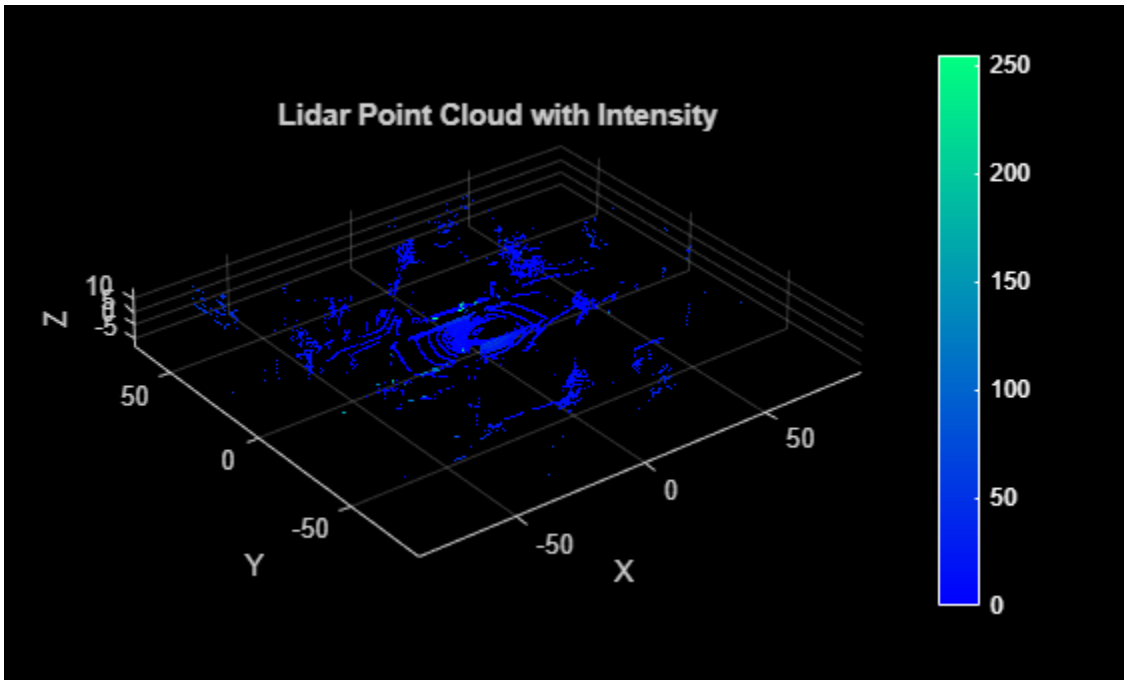


Resize and flip the image in preparation for mapping the coordinates.

```
J = flipud(imresize(I,size(x)));
```

Plot the sphere with the image as a color texture.

```
pcshow([x(:) y(:) z(:)],reshape(J,[],3))
title("Sphere with Color Texture")
xlabel("X")
ylabel("Y")
zlabel("Z")
```



Plot Lidar Point Cloud Based On Intensity

Load an organized lidar point cloud that includes intensity data.

```
ld = load("drivingLidarPoints.mat");
```

Plot the point cloud and label the figure. By default, the intensity is mapped to the `jet` colormap.

```
figure
pcshow(ld.ptCloud, ColorSource="Intensity")
title("Lidar Point Cloud with Intensity")
xlabel("X")
ylabel("Y")
zlabel("Z")
colorbar(Color=[1 1 1])
colormap("winter")
```

Input Arguments

`ptCloud` — Point cloud

`pointCloud` object

Point cloud, specified as a `pointCloud` object. The object contains the locations, intensities, and RGB colors to render the point cloud.

`filename` — Point cloud filename

character vector | string scalar

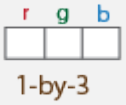
Point cloud filename, specified as a character vector or a string scalar. The file must be of a type supported by `pcread`. The `pcshow` function calls `pcread` to read the point cloud from the file, but does not store the data in the MATLAB workspace.

`xyzPoints` — Point cloud *x*-, *y*-, and *z*- locations

M-by-3 numeric matrix | *M*-by-*N*-by-3 numeric array

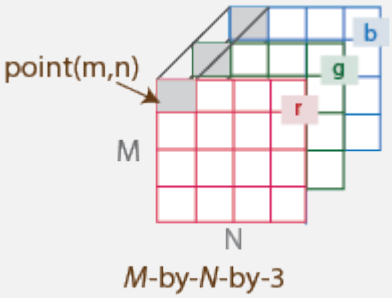
Point cloud *x*-, *y*-, and *z*- locations, specified as either an *M*-by-3 numeric matrix or an *M*-by-*N*-by-3 numeric array. The `xyzPoints` argument contains *M* or *M*-by-*N* points in the form [*x*,*y*,*z*]. The *z* values, which generally correspond to depth or elevation, determine the color of each point. When you do not specify the input color, the function maps each *z* value to a color in the current colormap.

`color` — Color for points in point cloud



RGB triplet | short name of color | long name of color | array of color names | cell array of color names | *M*-by-3 array | *M*-by-*N*-by-3 matrix

Color for points in the point cloud, specified as an RGB triplet, an *M*-by-3 matrix, an *M*-by-*N*-by-3 array, a short color name, a long color name, array of color names, or a cell array of color names. For details on color values, see the Color Value on page 3-1212 table.



- For the `single` or `double` data type, each `color` RGB value must be in the range [0, 1].
- For the `uint8` data type, each `color` RGB value must be in the range [0, 255].
- The function stores the `color` value as either an *M*-by-3 matrix or *M*-by-*N*-by-3 array. If you specify the color as a string or a 1-by-3 vector, the function converts it to one of these dimensions.

Color	Format	Example

Specify one color for all points	short or long color name	`"r"`
		
		`"red"`

	1-by-3 vector (RGB triplet)	 `[255 0 0]`
Specify a color for each point	string array of character vectors	`["red","yellow","blue"]`

	M-by-3 matrix, in which each row is an RGB triplet	`255 0 0`
		`255 0 0`
		`0 255 255`
		

	M-by-*N*-by-3 array for an organized point cloud, containing RGB values for each point, where *M*-by-*N* is the size of the point cloud.	

`colorMap` — Point cloud color map

M-by-1 vector | *M*-by-*N* matrix

Point cloud color map, specified as an *M*-by-1 vector or an *M*-by-*N* matrix.

Points Input	Color Selection	Valid Values of color	
`xyzPoints`	Different color for each point	Vector or *M*-by-*N* matrix. The matrix must contain values that are linearly mapped to a color in the current `colormap`.	

Points Input	Color Selection	Valid Values of color	
			

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `ViewPlane="XY"` sets the plane to the x-y axes from which to visualize the point cloud.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

`MarkerSize` — Diameter of marker

`6` (default) | positive scalar

Diameter of the marker, specified as a positive scalar. The value specifies the approximate diameter of the point marker. MATLAB graphics defines the unit as points. A marker size larger than 6 can reduce rendering performance.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`BackgroundColor` — Background color

`[0 0 0]` (black) (default) | RGB triplet | hexadecimal color code | character vector

Background color, specified as an RGB triplet, hexadecimal color code, or a character vector that specifies a long or short color name.

Data Types: `cell` | `char` | `uint8` | `uint16` | `int16` | `double` | `single`

`VerticalAxis` — Vertical axis
`"Z"` (default) | `"X"` | `"Y"`

Vertical axis, specified as `"X"`, `"Y"`, or `"Z"`. This value sets the selected axis of the point cloud in the vertical direction.

`VerticalAxisDir` — Vertical axis direction
`"Up"` (default) | `"Down"`

Vertical axis direction, specified as `"Up"` or `"Down"`.

`Projection` — Camera projection for 3-D views
`"perspective"` (default) | `"orthographic"`

Camera projection for 3-D views, specified as one of these values:

- `"perspective"` — Projects the viewing volume as the frustum of a pyramid (a pyramid whose apex has been cut off parallel to the base). Objects further from the camera appear smaller. Distance causes foreshortening, which enables you to perceive the depth of 3-D objects. This projection type is useful when you want to display realistic views of real objects. Perspective projection does not preserve the relative dimensions of objects. Instead, it displays a distant line segment smaller than a nearer line segment of the same length. Lines that are parallel in the data might not appear parallel in the scene.
- `"orthographic"` — This projection type maintains the correct relative dimensions of graphics objects regarding the distance of a given point from the viewer. Relative distance from the camera does not affect the size of objects. Lines that are parallel in the data parallel appear parallel on the screen. This projection type is useful when it is important to maintain the actual size of objects and the angles between objects.

`ViewPlane` — Plane to visualize point cloud
`"auto"` (default) | `"XY"` | `"YX"` | `"XZ"` | `"ZX"` | `"YZ"` | `"ZY"`

Plane to visualize point cloud, specified as `"auto"`, `"XY"`, `"YX"`, `"XZ"`, `"ZX"`, `"YZ"`, or `"ZY"`. The `ViewPlane` argument sets the line of sight from the camera, centered in the selected plane, to the center of the plot.

`ColorSource` — Point cloud property for colormap
`"auto"` (default) | `"X"` | `"Y"` | `"Z"` | `"Intensity"` | `"Color"` | `"Row"` | `"Column"`

Point cloud property for colormap, specified as `"auto"`,`"X"`, `"Y"`, `"Z"`, `"Intensity"`, `"Color"`, `"Row"`, `"Column"`. The `pcshow` function uses the value of `ColorSource` to assign a colormap when rendering the point cloud. The values use these properties:

- `"X"` — *x*-coordinates in the `Location` property of the input point cloud.
- `"Y"` — *y*-coordinates in the `Location` property of the input point cloud.
- `"Z"` — *z*-coordinates in the `Location` property of the input point cloud.
- `"Intensity"` — `Intensity` property of the input point cloud.
- `"Color"` — `Color` property of the input point cloud.
- `"Row"` — Row values of an organized point cloud.
- `"Column"` — Column values of an organized point cloud.

When you set `ColorSource` to `"auto"`, the function sets the colormap depending on which property values are available in the input point cloud object:

Available Point Cloud Property	Color Source
`Location` only	Maps the *z*-value to a color value in the current colormap.
`Location` and `Intensity`	Maps the *z*-value to a color value in the current colormap.
`Location` and `Color`	Maps the color values to the current colormap.
`Location`, `Intensity`, and `Color`	Maps the color values to the current colormap.

`AxesVisibility` — State of axes visibility
`"on"` or `1` (`true`) (default) | `"off"` or `0` (`false`)

State of axes visibility, specified as `"on"` or `"off"`, or as numeric or logical `0` (`false`) or `1` (`true`). A value of `"on"` is equivalent to `true`, and `"off"` is equivalent to `false`. Thus, you can use the value of this property as a logical value. The value is stored as an on/off logical value of type `matlab.lang.OnOffSwitchState`.

- `"on"` — Display the axes and its children.
- `"off"` — Hide the axes without deleting it. You still can access the properties of an invisible axes object. (Child objects such as lines remain visible.)

`Parent` — Axes on which to display visualization
`Axes` graphics object

Axes on which to display the visualization, specified as an `Axes` object. To create an `Axes` object, use the `axes` function. To display the visualization in a new figure, leave `Parent` unspecified.

Output Arguments

`ax` — Plot axes
`Axes` graphics object

Plot axes, returned as an `axes` graphics object. Points that are represented as `NaN` or `Inf` are not included.

You can set the default center of rotation for the point cloud viewer as the axes center or as a point. Set the default behavior from the “Computer Vision Toolbox Preferences”.

A rotation axes (represented with red, blue, and green lines) appears at the center of rotation when rotating the point cloud.

More About

Axes Toolbar Operations

Keyboard shortcuts are enabled only for the rotate (default) mode. To view the axes toolbar operations, point to the figure and select one of these options. Click the Restore View icon to reset the display.

Feature	Description
Vertical Axis	Select an *X*-, *Y*-, or *Z*-direction to set the direction of that axis of the point cloud as the positive vertical direction. Use the keyboard arrow keys to move the point cloud with respect to the direction selected.
View Plane	Select the viewing angle of the point cloud figure as the *XY*, *YX*, *XZ*, *ZX*, *YZ*, or *ZY* plane.
Background Color	Display a color chart from which you can select a background color.
Axes On/Off	Turn the display axes on or off.
Projection	Select perspective or orthogonal view.
Export	• — Save the content as a tightly cropped image or PDF. • — Copy the content as an image. • — Copy the content as a vector graphic.
Brush	Enable data brushing mode.
Data Tips	View the point data values of a point by selecting it in the point cloud figure. The Data Tips display shows the *x*, *y*, and *z* values of the points. Point clouds for depth images and lidar contain these additional data properties:

Point Cloud Data Source	Data Value Properties
Depth image (RGB-D sensor)	**Color**, **Row**, and **Column**
Lidar	**Intensity**, **Range**, **Azimuth** angle, **Elevation** angle, **Row**, and **Column**

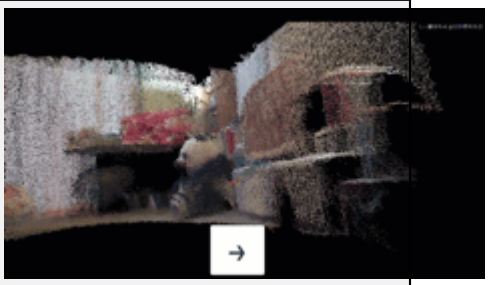
<table>
<tr><th>Feature</th><th>Description</th></tr>
<tr><td>Rotate 3D</td><td>Drag to rotate the point cloud figure. You can also right-click any point on the point cloud figure and select Rotate Around a Point to specify that point as the center of rotation for the figure. To return to axes rotation, right-click again and select Rotate Around Axes Center.

While in Rotate 3D mode, you can also select the color source for the point cloud by right-clicking anywhere in the point cloud figure and selecting Color Source, and then selecting an option from the list. The figure applies the active colormap to the point cloud based on the values in the selected source. For a point cloud of only position data, the Color Source options are X, Y, Z, and User Specified. Point clouds for depth image and lidar data include these additional color source options:

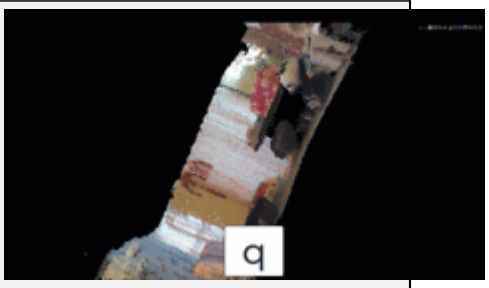
<table>
<tr><th>Point Cloud Data Source</th><th>Color Source Options</th></tr>
<tr><td>Depth image (RGB-D sensor)</td><td>Color, Row, and Column</td></tr>
<tr><td>Lidar</td><td>Intensity, Range, Azimuth angle, Elevation angle, Row, and Column</td></tr>
</table>
</td></tr>
<tr><td>Pan, Zoom in, and Zoom out</td><td>Maneuver the point cloud in the figure, or zoom the point cloud figure in or out.</td></tr>
<tr><td>Restore View</td><td>Restore the original view of the axes.</td></tr>
</table>

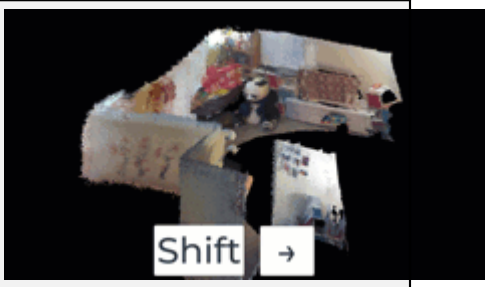
Move Camera Through Scene

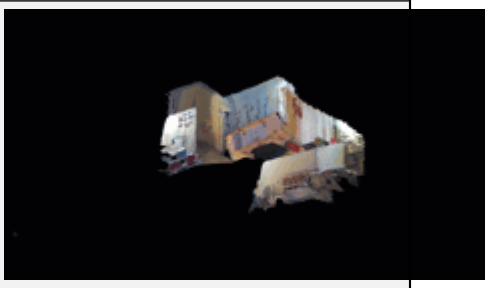
To navigate into a point cloud and observe the scene, use these keyboard shortcuts:



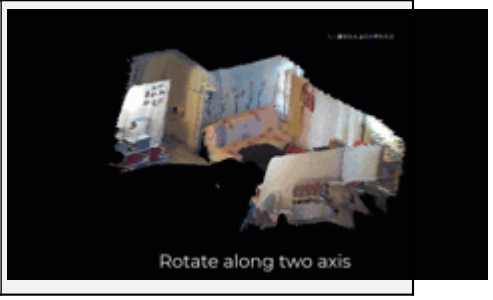
<table>
<tr><th>Action</th><th>Keyboard Shortcut</th><th>Example</th></tr>
<tr><td>Move forward or backward through the scene. The camera and the target can move.</td><td>w — Forward







s — Backward</td><td rowspan="2">
</td></tr>
<tr><td>Move left or right through the scene. The camera and the target can move.</td><td>a — Left



d — Right</td></tr>
<tr><td>Look around the scene (pitch/yaw rotation of the camera). Camera position is fixed, target moves.</td><td>Up arrow — Camera pitches up

Down arrow — Camera pitches down

Left arrow — Camera turns left in yaw

Right arrow — Camera turns right in yaw</td><td></td></tr>
</table>

Action	Keyboard Shortcut	Example
Roll the scene (roll rotation of the camera).	**q** — Camera moves clockwise. (Scene appears to move counterclockwise.) **e** — Camera moves counterclockwise. (Scene appears to move clockwise.)	
Rotate the scene (rotate the camera around the point cloud). Camera position changes, target is fixed.	**Shift** + **Left** or **Right** — Camera orbits horizontally around the point cloud. (Scene appears to stand still as camera moves externally around it horizontally.) **Shift** + **Up** or **Down** — Camera orbits vertically around the point cloud. (Scene appears to stand still as camera moves externally around it vertically.)	
Zoom in or out.	**z** — Zoom in **x** — Zoom out	
Look at a view plane.	1 — **XY** 2 — **YX** 3 — **XZ** 4 — **ZX** 5 — **YZ** 6 — **ZY** Camera positioned in the selected plane with a line of sight to the center of the plot.	

Action	Keyboard Shortcut	Example
Switch between rotate and pan.	**Space bar** — Press and hold the space bar to switch the interaction to pan. Release the space bar to switch back to rotate.	
Rotate in X-, Y-, and Z-dimensions.	**T** — Adds rotate interaction in the third dimension.	

Color Values

Color Name	Short Name	RGB Triplet	Appearance
`"red"`	`"r"`	`[1 0 0]`	
`"green"`	`"g"`	`[0 1 0]`	
`"blue"`	`"b"`	`[0 0 1]`	
`"cyan"`	`"c"`	`[0 1 1]`	
`"magenta"`	`"m"`	`[1 0 1]`	
`"yellow"`	`"y"`	`[1 1 0]`	
`"black"`	`"k"`	`[0 0 0]`	
`"white"`	`"w"`	`[1 1 1]`	

Performance and Tips

- To improve performance, the function automatically downsamples the rendered point cloud when you rotate, pan, or zoom in or out by clicking the mouse. Downsampling is not applied for zoom in or out by using the mouse scroll mechanism. When using data tips, the figure does not apply downsampling. The downsampling occurs only for rendering the point cloud and does not affect the saved points.
- The keyboard shortcuts described in “Move Camera Through Scene” on page 3-1210 are not supported when loading a saved figure or for popped-out windows using Live Editor.
- When you reload a saved figure, any action on the figure resets the vertical axis to the *z*-axis and in the up direction.

- To visualize a large point cloud (greater than one million points), use the `pcviewer` object.

Version History

Introduced in R2015b

R2022b: Default projection changed to perspective

The default projection for the camera 3-D view display has changed from orthographic to perspective. You can use the new `Projection` name-value argument to specify the projection as `"perspective"` or `"orthographic"`. Prior to R2022b, the display rendered the point cloud in an orthographic view only.

pcshowpair

Visualize difference between two point clouds

Syntax

```
pcshowpair(ptCloudA,ptCloudB)

pcshowpair(ptCloudA,ptCloudB,Name=Value)

ax = pcshowpair( ___ )
```

Description

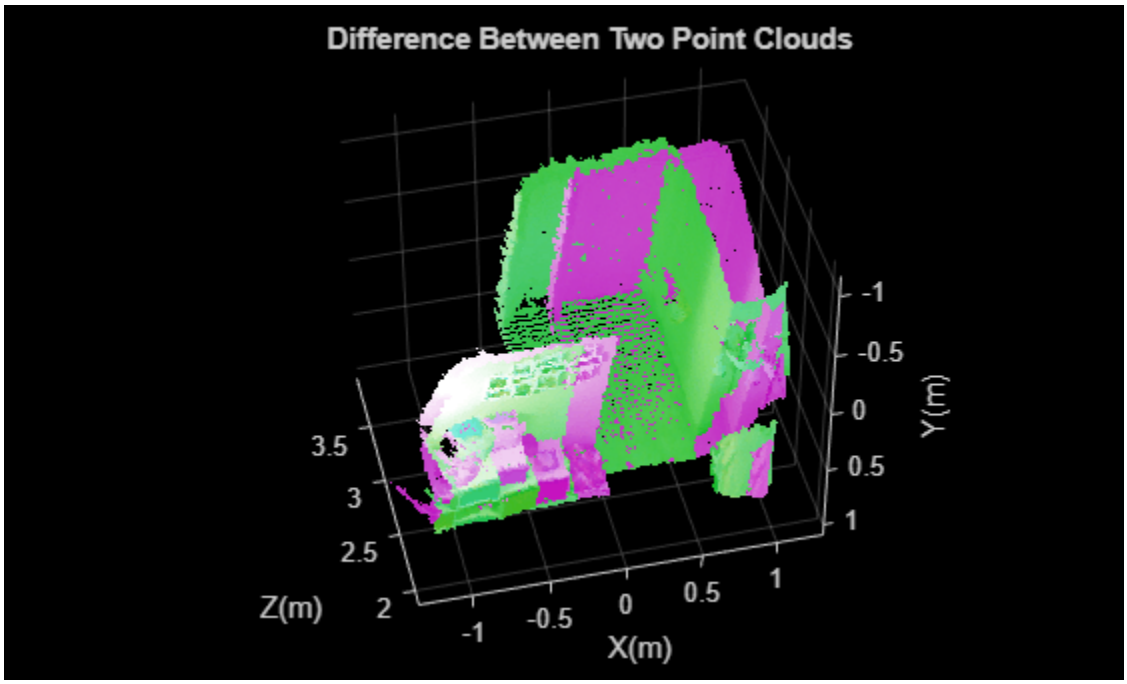
`pcshowpair(ptCloudA,ptCloudB)` creates a visualization depicting the differences between the two input point clouds. The differences are displayed using a blending of magenta for point cloud A and green for point cloud B.

`pcshowpair(ptCloudA,ptCloudB,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `pchowpair(ptCloudA,ptCloudB,BackgroundColor="yellow")`, sets the figure background color to yellow.

`ax = pcshowpair( ___ )` returns the plot axes to the visualization of the differences, using any of the preceding syntaxes.

Examples

Visualize the Difference Between Two Point Clouds



Load two point clouds that were captured using a Kinect device in a home setting.

```
load("livingRoom");

pc1 = livingRoomData{1};
pc2 = livingRoomData{2};
```

Plot and set the viewpoint of point clouds.

```
figure
pcshowpair(pc1,pc2,VerticalAxis="Y",VerticalAxisDir="Down")
title("Difference Between Two Point Clouds")
xlabel("X(m)")
ylabel("Y(m)")
zlabel("Z(m)")
```

Input Arguments

`ptCloudA` — Point cloud
`pointCloud` object

Point cloud A, specified as a `pointCloud` object. The function uses levels of magenta to represent `ptCloudA` and a pure magenta when the point cloud contains no color information.

`ptCloudB` — Point cloud
`pointCloud` object

Point cloud B, specified as a `pointCloud` object. The function uses levels of green to represent `ptCloudB` and a pure green when the point cloud contains no color information.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `pchowpair(ptCloudA,ptCloudB,BackgroundColor="yellow")`, sets the figure background color to yellow.

`MarkerSize` — Diameter of marker
`6` (default) | positive scalar

Approximate diameter of the point marker, specified as a positive scalar. The units are in points. A marker size larger than six can reduce the rendering performance.

`BackgroundColor` — Background color
`[0 0 0]` (black) (default) | RGB triplet | hexadecimal color code | character vector

Background color, specified as an RGB triplet, hexadecimal color code, or a character vector that specifies a long or short color name.

`VerticalAxis` — Vertical axis
`"Z"` (default) | `"X"` | `"Y"`

Vertical axis, specified as `"X"`, `"Y"`, or `"Z"`. When you reload a saved figure, any action on the figure resets the vertical axis to the *z*-axis.

`VerticalAxisDir` — Vertical axis direction
`"Up"` (default) | `"Down"`

Vertical axis direction, specified as `"Up"` or `"Down"`. When you reload a saved figure, any action on the figure resets the direction to the up direction.

`Projection` — Camera projection for 3-D views
`"perspective"` (default) | `"orthographic"`

Camera projection for 3-D views, specified as one of these values:

- `"perspective"` — Projects the viewing volume as the frustum of a pyramid (a pyramid whose apex has been cut off parallel to the base). Objects further from the camera appear smaller. Distance causes foreshortening, which enables you to perceive the depth of 3-D objects. This projection type is useful when you want to display realistic views of real objects. Perspective projection does not preserve the relative dimensions of objects. Instead, it displays a distant line segment smaller than a nearer line segment of the same length. Lines that are parallel in the data might not appear parallel in the scene.
- `"orthographic"` — This projection type maintains the correct relative dimensions of graphics objects regarding the distance of a given point from the viewer. Relative distance from the camera does not affect the size of objects. Lines that are parallel in the data parallel appear parallel on the screen. This projection type is useful when it is important to maintain the actual size of objects and the angles between objects.

`ViewPlane` — Plane to visualize point cloud
`"XY"` (default) | `"YX"` | `"XZ"` | `"ZX"` | `"YZ"` | `"ZY"`

Plane to visualize point cloud, specified as `"XY"`, `"YX"`, `"XZ"`, `"ZX"`, `"YZ"`, `"ZY"`. The `ViewPlane` sets the line of site from the camera, centered in the selected plane, to the center of the plot.

`ColorSource` — Point cloud property for color map
`"auto"` (default) | `"X"` | `"Y"` | `"Z"` | `"Intensity"` | `"Color"` | `"Row"` | `"Column"`

Point cloud property for color map, specified as `"auto"`,`"X"`, `"Y"`, `"Z"`, `"Intensity"`, `"Color"`, `"Row"`, `"Column"`. The `pcshow` function uses the value of `ColorSource` to assign a color map for rendering the point cloud. The values use these properties:

- `"X"` — *x* coordinates in the `Location` property of the input point cloud.
- `"Y"` — *y* coordinates in the `Location` property of the input point cloud.
- `"Z"` — *z* coordinates in the `Location` property of the input point cloud.
- `"Intensity"` — `Intensity` property of the input point cloud.

- `"Color"` — `Color` property of the input point cloud.
- `"Row"` — Using the row values of an organized point cloud.
- `"Column"` — Using the column values of an organized point cloud.

When you set `ColorSource` to `"auto"`, the function sets the color map depending on which property values are available in the input point cloud object:

Available Point Cloud Property	Color Source
`Location` only	Maps the Z-value to a color value in the current color map.
`Location` and `Intensity`	Maps the z-value to a color value in the current color map.
`Location` and `Color`	Maps the color values to the current color map.
`Location`, `Intensity`, and `Color`	Maps the color values to the current color map.

`AxesVisibility` — State of axes visibility
`"on"` or `1` (`true`) (default) | `"off"` or `0` (`false`)

State of axes visibility, specified as `"on"` or `"off"`, or as numeric or logical `0` (`false`) or `1` (`true`). A value of `"on"` is equivalent to `true`, and `"off"` is equivalent to `false`. Thus, you can use the value of this property as a logical value. The value is stored as an on/off logical value of type `matlab.lang.OnOffSwitchState`.

- `"on"` — Display the axes and its children.
- `"off"` — Hide the axes without deleting it. You still can access the properties of an invisible axes object. (Child objects such as lines remain visible.)

`Parent` — Axes on which to display the visualization
`axes` graphics object

Axes on which to display the visualization, specified as an `Axes` object. To create an `Axes` object, use the `axes` function. To display the visualization in a new figure, leave `"Parent"` unspecified.

Output Arguments

ax — Plot axes
`axes` graphics object

Plot axes, returned as an `axes` graphics object. Points with `NaN` or `Inf` coordinates are not displayed.

You can set the default center of rotation for the point cloud viewer to rotate around the axes center or around a point. Set the default behavior from the “Computer Vision Toolbox Preferences”.

More About

Axes Toolbar Operations

Keyboard shortcuts are enabled only for the rotate (default) mode. To view the axes toolbar operations, point to the figure and select one of these options. Click the Restore View icon to reset the display.

Feature	Description
Vertical Axis	Select an *X*-, *Y*-, or *Z*-direction to set the direction of that axis of the point cloud as the positive vertical direction. Use the keyboard arrow keys to move the point cloud with respect to the direction selected.
View Plane	Select the viewing angle of the point cloud figure as the *XY*, *YX*, *XZ*, *ZX*, *YZ*, or *ZY* plane.
Background Color	Display a color chart from which you can select a background color.
Axes On/Off	Turn the display axes on or off.
Projection	Select perspective or orthogonal view.
Export	• — Save the content as a tightly cropped image or PDF. • — Copy the content as an image. • — Copy the content as a vector graphic.
Brush	Enable data brushing mode.
Data Tips	View the point data values of a point by selecting it in the point cloud figure. The Data Tips display shows the *x*, *y*, and *z* values of the points. Point clouds for depth images and lidar contain these additional data properties:

Point Cloud Data Source	Data Value Properties
Depth image (RGB-D sensor)	**Color**, **Row**, and **Column**
Lidar	**Intensity**, **Range**, **Azimuth** angle, **Elevation** angle, **Row**, and **Column**

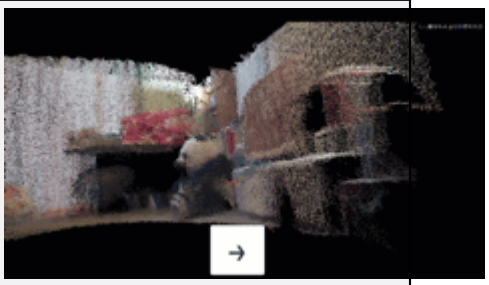
<table>
<tr><th>Feature</th><th>Description</th></tr>
<tr><td>Rotate 3D</td><td>Drag to rotate the point cloud figure. You can also right-click any point on the point cloud figure and select Rotate Around a Point to specify that point as the center of rotation for the figure. To return to axes rotation, right-click again and select Rotate Around Axes Center.

While in Rotate 3D mode, you can also select the color source for the point cloud by right-clicking anywhere in the point cloud figure and selecting Color Source, and then selecting an option from the list. The figure applies the active colormap to the point cloud based on the values in the selected source. For a point cloud of only position data, the Color Source options are X, Y, Z, and User Specified. Point clouds for depth image and lidar data include these additional color source options:

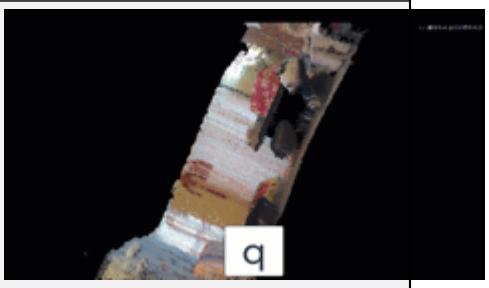
<table>
<tr><th>Point Cloud Data Source</th><th>Color Source Options</th></tr>
<tr><td>Depth image (RGB-D sensor)</td><td>Color, Row, and Column</td></tr>
<tr><td>Lidar</td><td>Intensity, Range, Azimuth angle, Elevation angle, Row, and Column</td></tr>
</table>
</td></tr>
<tr><td>Pan, Zoom in, and Zoom out</td><td>Maneuver the point cloud in the figure, or zoom the point cloud figure in or out.</td></tr>
<tr><td>Restore View</td><td>Restore the original view of the axes.</td></tr>
</table>

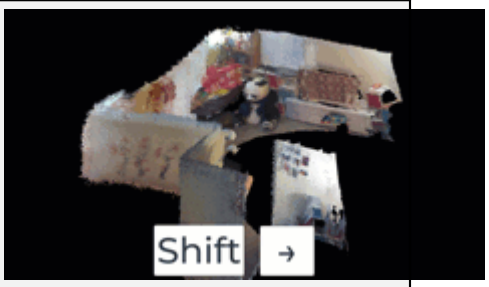
Move Camera Through Scene

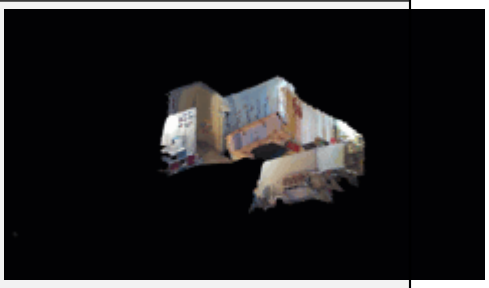
To navigate into a point cloud and observe the scene, use these keyboard shortcuts:



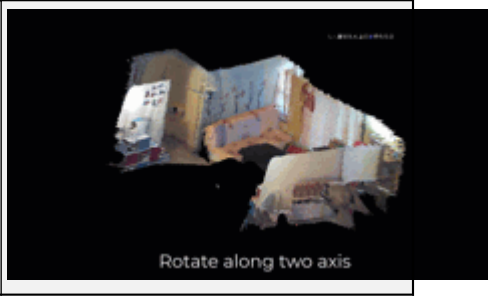
<table>
<tr><th>Action</th><th>Keyboard Shortcut</th><th>Example</th></tr>
<tr><td>Move forward or backward through the scene. The camera and the target can move.</td><td>w — Forward







s — Backward</td><td rowspan="2">
</td></tr>
<tr><td>Move left or right through the scene. The camera and the target can move.</td><td>a — Left



d — Right</td></tr>
<tr><td>Look around the scene (pitch/yaw rotation of the camera). Camera position is fixed, target moves.</td><td>Up arrow — Camera pitches up

Down arrow — Camera pitches down

Left arrow — Camera turns left in yaw

Right arrow — Camera turns right in yaw</td><td></td></tr>
</table>

Action	Keyboard Shortcut	Example
Roll the scene (roll rotation of the camera).	**q** — Camera moves clockwise. (Scene appears to move counterclockwise.) **e** — Camera moves counterclockwise. (Scene appears to move clockwise.)	
Rotate the scene (rotate the camera around the point cloud). Camera position changes, target is fixed.	**Shift** + **Left** or **Right** — Camera orbits horizontally around the point cloud. (Scene appears to stand still as camera moves externally around it horizontally.) **Shift** + **Up** or **Down** — Camera orbits vertically around the point cloud. (Scene appears to stand still as camera moves externally around it vertically.)	
Zoom in or out.	**z** — Zoom in **x** — Zoom out	
Look at a view plane.	1 — **XY** 2 — **YX** 3 — **XZ** 4 — **ZX** 5 — **YZ** 6 — **ZY** Camera positioned in the selected plane with a line of sight to the center of the plot.	

Action	Keyboard Shortcut	Example
Switch between rotate and pan.	**Space bar** — Press and hold the space bar to switch the interaction to pan. Release the space bar to switch back to rotate.	
Rotate in X-, Y-, and Z-dimensions.	**T** — Adds rotate interaction in the third dimension.	

Color Formats

Color Name	Short Name	RGB Triplet	Appearance
`"red"`	`"r"`	`[1 0 0]`	
`"green"`	`"g"`	`[0 1 0]`	
`"blue"`	`"b"`	`[0 0 1]`	
`"cyan"`	`"c"`	`[0 1 1]`	
`"magenta"`	`"m"`	`[1 0 1]`	
`"yellow"`	`"y"`	`[1 1 0]`	
`"black"`	`"k"`	`[0 0 0]`	
`"white"`	`"w"`	`[1 1 1]`	

Performance and Tips

- To improve performance, the function automatically downsamples the rendered point cloud when you rotate, pan, or zoom in or out by clicking the mouse. Downsampling is not applied for zoom in or out by using the mouse scroll mechanism. When using data tips, the figure does not apply downsampling. The downsampling occurs only for rendering the point cloud and does not affect the saved points.
- The keyboard shortcuts described in “Move Camera Through Scene” on page 3-1210 are not supported when loading a saved figure or for popped-out windows using Live Editor.
- When you reload a saved figure, any action on the figure resets the vertical axis to the *z*-axis and in the up direction.

- To visualize a large point cloud (greater than one million points), use the `pcviewer` object.

Version History

Introduced in R2015b

R2022b: Projection display default behavior changed to perspective

The default projection for the camera 3-D view display is changed from orthographic to perspective. You can use the new `Projection` name-value argument to specify the projection as `"perspective"` or `"orthographic"`. Prior to R2022b, the display rendered the point cloud in an orthographic view only.

showReprojectionErrors

Visualize calibration errors

Syntax

```
showReprojectionErrors(cameraParams)
showReprojectionErrors(cameraParams,viewStyle)
showReprojectionErrors( ___ ,Name=Value)

ax = showReprojectionErrors( ___ )
```

Description

`showReprojectionErrors(cameraParams)` displays a bar graph that represents the calibration accuracy for a single camera, a stereo pair, a fisheye camera, or a multi-camera system. For non-multi-camera systems, the bar graph shows the mean reprojection error for each image. For multi-camera systems, the graph is divided into three sub-plots, displaying the mean reprojection error per image, per view, and per camera. A view represents a specific position where the calibration pattern is observed by the cameras. The `cameraParams` object contains one of:

- `cameraParameters` or `stereoParameters` object which the `estimateCameraParameters` function returns.
- `fisheyeParameters` or object which the `estimateFisheyeParameters` function returns.
- `multiCameraParameters` object which the `estimateMultiCameraParameters` function returns.

`showReprojectionErrors(cameraParams,viewStyle)` displays the reprojection errors using the visualization style specified by the `viewStyle` input. The `viewStyle` argument is not supported for a multi-camera system.

`showReprojectionErrors( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `HighlightIndex = [1,4]` sets the highlight patterns to 1 and 4.

`ax = showReprojectionErrors( ___ )` returns the plot axis, using any of the preceding syntaxes.

Examples

Visualize Reprojection Errors for a Single Camera

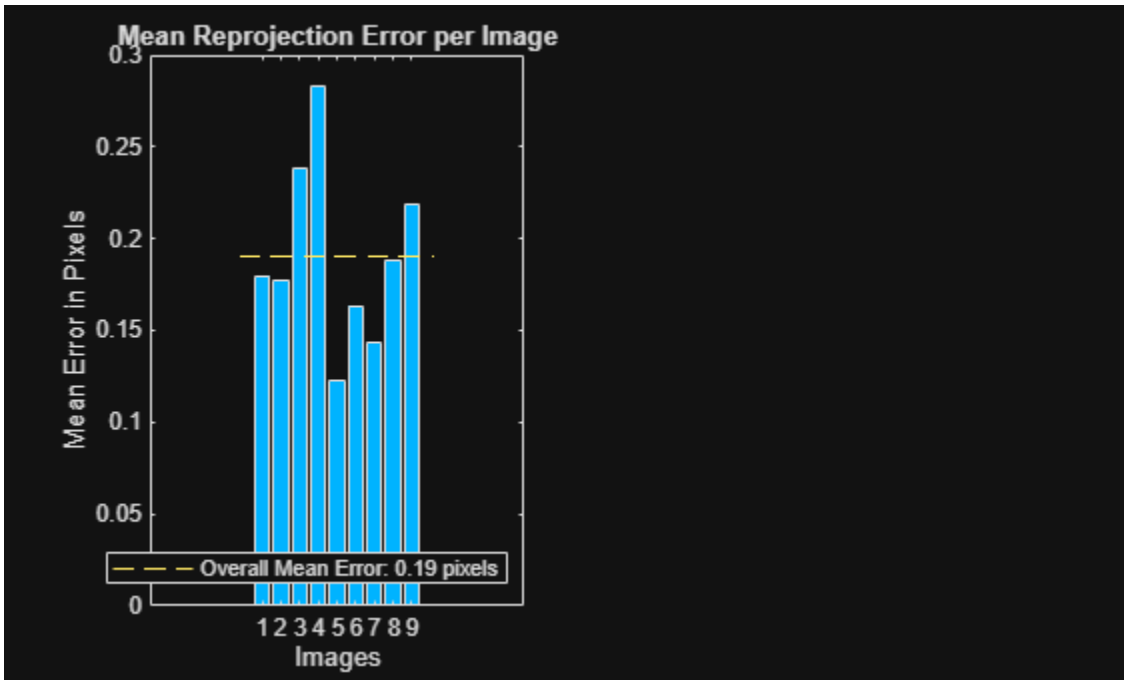
Create a set of calibration images.

```
images = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
  "calibration","dslr"));
imageFileNames = images.Files;
```

Detect calibration pattern.

```
[imagePoints,patternDims] = detectCheckerboardPoints(imageFileNames);
```

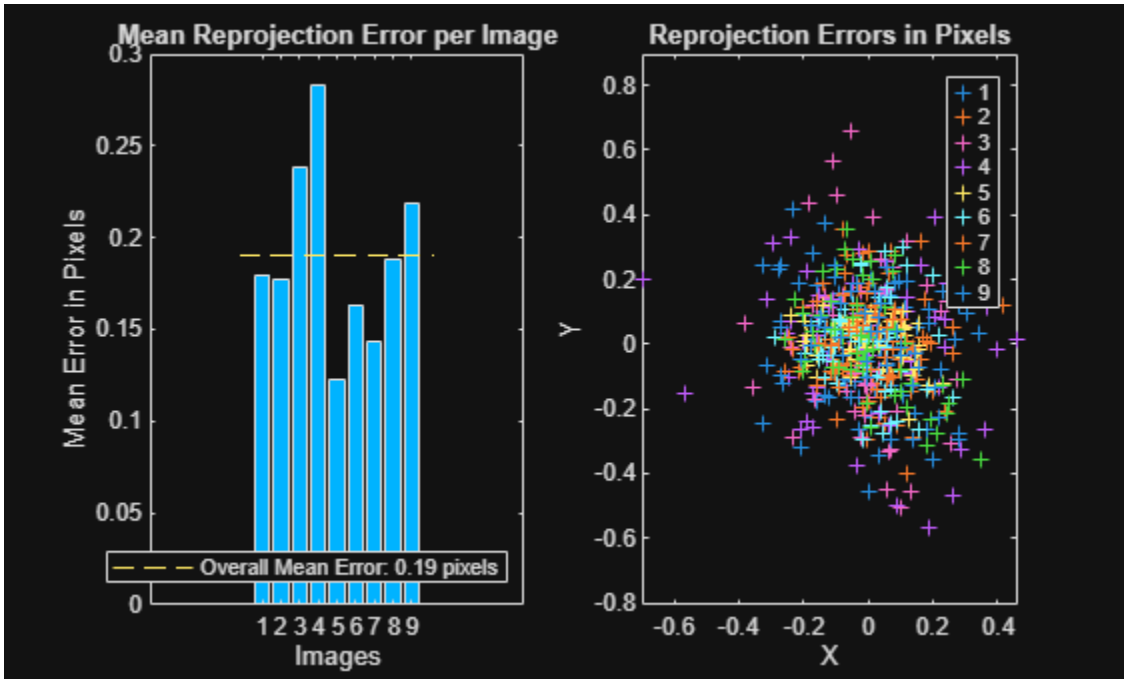
Generate world coordinates of the corners of the squares. The square size is in millimeters.



```
squareSize = 23; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Calibrate the camera.

```
I = readimage(images,1);
imageSize = [size(I, 1), size(I, 2)];
params = estimateCameraParameters(imagePoints,worldPoints,ImageSize=imageSize);
```



Visualize the errors as a bar graph.

```
subplot(1,2,1);
showReprojectionErrors(params);
```

Visualize the errors as a scatter plot.

```
subplot(1,2,2);
showReprojectionErrors(params,"ScatterPlot");
```

Visualize Reprojection Errors for a Stereo Pair of Cameras

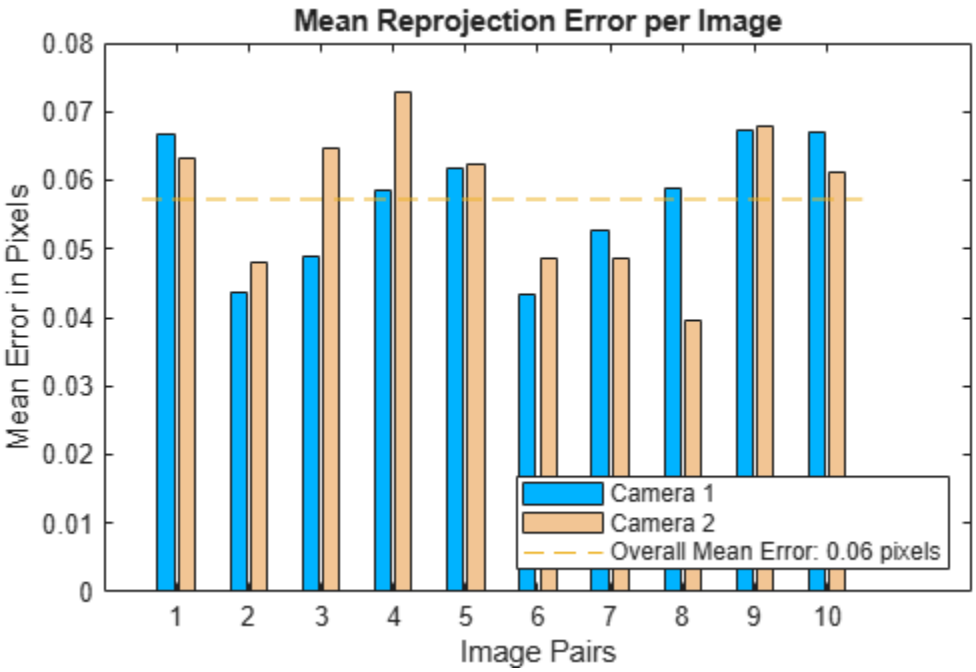
Specify calibration images

```
imageDir = fullfile(toolboxdir("vision"),"visiondata", ...
    "calibration","stereo");
leftImages = imageDatastore(fullfile(imageDir,"left"));
rightImages = imageDatastore(fullfile(imageDir,"right"));
```

Detect the checkerboards.

```
[imagePoints,patternDims] = detectCheckerboardPoints(...
     leftImages.Files,rightImages.Files);
```

Specify world coordinates of checkerboard keypoints. The square size is in millimeters.



```
squareSize = 108; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Calibrate the stereo camera system. Here both cameras have the same resolution.

```
I = readimage(leftImages,1);
imageSize = size(I,1:2);
params = estimateCameraParameters(imagePoints,worldPoints,ImageSize=imageSize);
```

Visualize calibration accuracy.

```
showReprojectionErrors(params);
```

Calibrate a Multi-Camera System using a ChArUco board

Estimate the relative position and orientation of six cameras with overlapping fields of view by using calibration images that contain a single ChArUco board.

Download the calibration images.

```
calibImagesURL = "https://www.mathworks.com/supportfiles/vision/data/overlapping-cameras-charuco
calibImagesDir = fullfile(pwd,"overlapping-cameras-charuco");
calibImagesZip = fullfile(pwd,"overlapping-cameras-charuco.zip");
if ~exist(calibImagesZip,"file")
    disp("Downloading calibration images (52 MB)...")
    websave(calibImagesZip,calibImagesURL);
end
```

```
Downloading calibration images (52 MB)...
```

```
if ~exist(calibImagesDir,"dir")
    unzip(calibImagesZip,pwd)
end
```

Specify calibration image filenames for each camera.

```
numCameras = 6;
camDirPrefix = "Cam00";
imageFiles = cell(1,numCameras);
for i = 1:numCameras
    camDir = fullfile(calibImagesDir,camDirPrefix+i);
    imds = imageDatastore(camDir);
    imageFiles{i} = imds.Files;
```

```
end
imageFiles = [imageFiles{:}];
```

Define the ChArUco board properties. Specify checker size and marker size in centimeters.

```
markerFamily = "DICT_6X6_1000";
patternDims = [5 5];
markerSize = 6.8;   % in cm
checkerSize = 9.15; % in cm
numKeyPoints = prod(patternDims - 1);
minMarkerId = 144;
```

Detect the key points of the ChArUco board in the calibration images.

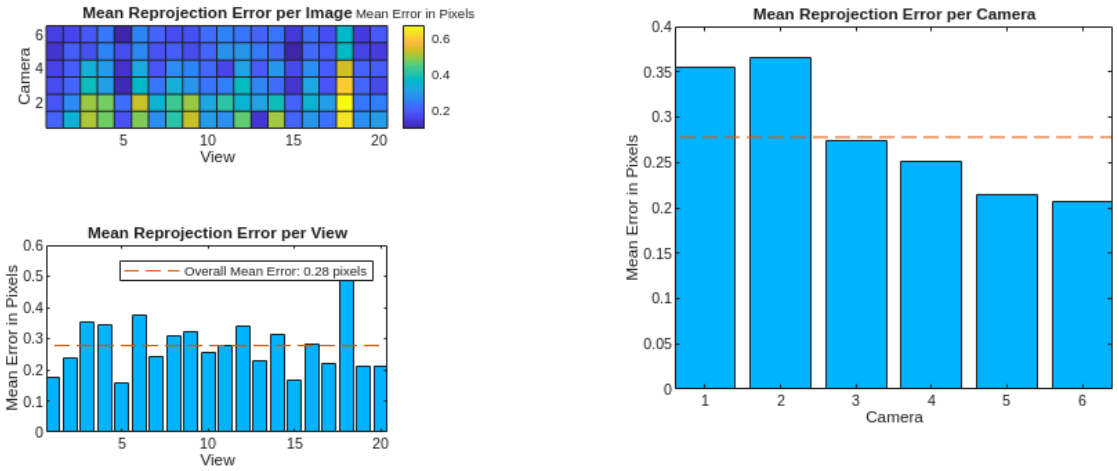
```
imagePoints = detectPatternPoints(imageFiles,"charuco-board",patternDims, ...
    markerFamily,checkerSize,markerSize,MinMarkerID=minMarkerId);
```

```
[==================================================] 100%
Elapsed time: 00:00:09
Estimated time remaining: 00:00:00
```

Generate the world points for the pattern.

```
worldPoints = patternWorldPoints("charuco-board",patternDims,checkerSize);
```

Load the intrinsic parameters of the six cameras. These parameters have been estimated using the “Using the Single Camera Calibrator App”.



```
ld = load("sixCameraIntrinsics.mat");
```

Perform multi-camera calibration.

```
params = estimateMultiCameraParameters(imagePoints,worldPoints,ld.intrinsics,WorldUnits="cm");
```

Visualize the calibration accuracy.

```
figure(Position=[100,100,1000,400])
showReprojectionErrors(params)
```

Visualize the camera extrinsic parameters.

```
figure
showExtrinsics(params)
view(2)
```

Input Arguments

`cameraParams` — Object containing parameters of single camera or stereo pair
`cameraParameters` object | `fisheyeParameters` object | `stereoParameters` object | `multiCameraParameters` object

Object containing parameters for a single, fisheye, stereo pair, or multi-camera system, specified as either a `cameraParameters`, `fisheyeParameters`, `stereoParameters`, `multiCameraParameters` object. You can create these objects using the:

- `estimateCameraParameters` function to return a `cameraParameters` or `stereoParameters` object.
- `estimateFisheyeParameters` function to return a `fisheyeParameters` object.
- `estimateMultiCameraParameters` function to return a `multiCameraParameters` object.

You can also use the Camera Calibrator app to create the `cameraParameters` input object, or use Stereo Camera Calibrator app to create the `stereoParameters` input object. See “Using the Single Camera Calibrator App” and “Using the Stereo Camera Calibrator App”.

`viewStyle` — Plot view
`"BarGraph"` | `"ScatterPlot"`

Plot view, specified as either `"BarGraph"` or `"ScatterPlot"`. The `viewStyle` input sets the visualization for the camera extrinsic parameters. Set `viewStyle` to `"BarGraph"` to display the

mean error per image as a bar graph. Set `viewStyle` to `"ScatterPlot"` to display the error for each point as a scatter plot. The `"ScatterPlot"` option applies only to the single camera case. This argument is not supported for a multi-camera system.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `showReprojectionErrors(cameraParams,HighlightIndex = [1,4])`, sets the highlight selection index to patterns 1 and 4.

`HighlightIndex` — Highlight selection index

`[]` (default) | vector of integers | scalar

Highlight selection index, specified as a scalar or a vector of integers. When you set the `viewStyle` to `"BarGraph"`, the function highlights the bars corresponding to the selected images. When you set the `viewStyle` to `"ScatterPlot"`, the function highlights the points corresponding to the selected images with circle markers. This argument is not supported for a multi-camera system.

`Parent` — Output axes

current axes (default) | scalar value

Output axes, specified as the comma-separated pair consisting of '`Parent`' and a scalar value. Specify output axes to display the visualization. You can obtain the current axes handle by returning the function to an output variable:
`ax = showReprojectionErrors(cameraParams)`
You can also use the `gca` function to get the current axes handle.

Example: `showReprojectionErrors(cameraParams,'Parent',ax)`

Output Arguments

`ax` — Current axes handle

scalar value

Current axes handle, returned as a scalar value. The function returns the handle to the current axes for the current figure.

Example: `ax = showReprojectionErrors(cameraParams)`

stereoAnaglyph

Create red-cyan anaglyph from stereo pair of images

Syntax

```
J = stereoAnaglyph(I1,I2)
```

Description

`J = stereoAnaglyph(I1,I2)` combines images `I1` and `I2` into a red-cyan anaglyph. When the inputs are rectified stereo images, you can view the output image with red-blue stereo glasses to see the stereo effect.

Examples

Create 3-D Stereo Display

Load parameters for a calibrated stereo pair of cameras.

```
load('webcamsSceneReconstruction.mat')
```

Load a stereo pair of images.

```
I1 = imread('sceneReconstructionLeft.jpg');
I2 = imread('sceneReconstructionRight.jpg');
```

Rectify the stereo images.

```
[J1, J2] = rectifyStereoImages(I1, I2, stereoParams);
```

Create the anaglyph.

```
A = stereoAnaglyph(J1, J2);
```

Display the anaglyph. Use red-blue stereo glasses to see the stereo effect.

```
figure; imshow(A);
```

Input Arguments

`I1` — Input image

M-by-*N*-by-3 truecolor image | *M*-by-*N* 2-*D* grayscale image

Input image `I1`, specified as an *M*-by-*N*-by-3 truecolor image or an *M*-by-*N* 2-*D* grayscale image. `I1` and `I2` must be real, finite, and nonsparse, and the images must be the same size. If the images are not the same size, use `imfuse` to pad the smaller image dimension with zeros before creating the anaglyph.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

`I2` — Input image

M-by-*N* 2-*D* grayscale image | *M*-by-*N*-by-3 truecolor image

Input image `I2`, specified as an *M*-by-*N*-by-3 truecolor image or an *M*-by-*N* 2-*D* grayscale image. `I1` and `I2` must be real, finite, and nonsparse, and the images must be the same size. If the images are not the same size, use `imfuse` to pad the smaller image dimension with zeros before creating the anaglyph.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

Output Arguments

`J` — Stereo anaglyph output image

M-by-*N*-by-3 truecolor image

Stereo anaglyph output image, returned as an *M*-by-*N*-by-3 truecolor image. Output image `J` is the same size as input images `I1` and `I2`.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

tform

Extract homogeneous transformation

Syntax

```
transformationMatrix = tform(transformation)
transformationMatrix = tform(rotation)
```

Description

`transformationMatrix = tform(transformation)` extracts the homogeneous transformation matrix `transformationMatrix` that corresponds to the SE(3) transformation `transformation`.

`transformationMatrix = tform(rotation)` creates a homogeneous transformation matrix `transformationMatrix`, with zero translation, that corresponds to the SO(3) rotation `rotation`.

Input Arguments

`transformation` — Transformation

`se3` object | *N*-element array of transformation objects

Transformation, specified as a scalar `se3` object or an *N*-element array of transformation objects. *N* is the total number of transformations.

If you specify `transformation` as an array, each element must be of the same type.

`rotation` — Rotation

`so3` object | *N*-element array of rotation objects

Rotation, specified as a scalar `so3` object or as an *N*-element array of rotation objects. *N* is the total number of rotations.

If you specify `rotation` as an array, each element must be of the same type.

Output Arguments

`transformationMatrix` — Homogeneous transformation matrix

3-by-3-by-*N* array | 4-by-4-by-*N* array

Homogeneous transformation matrix, returned as a 4-by-4-by-*N* array for `se3` and `so3` objects. *N* is the total number of transformations.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

trainCascadeObjectDetector

Train cascade object detector model

Syntax

```
trainCascadeObjectDetector(outputXMLFilename,positiveInstances,
negativeImages)
trainCascadeObjectDetector(outputXMLFilename,'resume')

trainCascadeObjectDetector( ___ ,Name=Value)
```

Description

`trainCascadeObjectDetector(outputXMLFilename,positiveInstances, negativeImages)` writes a trained cascade detector XML file named, `outputXMLFilename`. The file name must include an XML extension. For a more detailed explanation on how this function works, refer to “Get Started with Cascade Object Detector”.

`trainCascadeObjectDetector(outputXMLFilename,'resume')` resumes an interrupted training session. The `outputXMLFilename` input must match the output file name from the interrupted session. All arguments saved from the earlier session are reused automatically.

`trainCascadeObjectDetector( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `ObjectTrainingSize=[100,100]` sets the height and width of objects during training.

Examples

Train Stop Sign Detector

Load the positive samples data from a MAT file. The file contains the ground truth, specified as table of bounding boxes for several object categories. The ground truth was labeled and exported from the Image Labeler app.

```
load("stopSignsAndCars.mat");
```

Prefix the fullpath to the stop sign images.

```
stopSigns = fullfile(toolboxdir("vision"),"visiondata",stopSignsAndCars{:,1});
```

Create datastores to load the ground truth data for stop signs.

```
imds = imageDatastore(stopSigns);
blds = boxLabelDatastore(stopSignsAndCars(:,2));
```

Combine the image and box label datastores.

```
positiveInstances = combine(imds,blds);
```

Add the image folder path to the MATLAB® path.

```
imDir = fullfile(matlabroot,"toolbox","vision","visiondata","stopSignImages");
addpath(imDir);
```

Specify a folder for negative images.

```
negativeFolder = fullfile(matlabroot,"toolbox","vision","visiondata","nonStopSigns");
```

Create an imageDatastore object containing negative images.

```
negativeImages = imageDatastore(negativeFolder);
```

Train a cascade object detector called "`stopSignDetector.xml`" using HOG features. NOTE: The command can take a few minutes to run.

```
trainCascadeObjectDetector("stopSignDetector.xml",positiveInstances,negativeFolder,FalseAlarmRate
```

```
Automatically setting ObjectTrainingSize to [35, 32]
Using at most 42 of 42 positive samples per stage
Using at most 84 negative samples per stage

--cascadeParams--
Training stage 1 of 3
[..................................................................]
Used 42 positive and 84 negative samples
Time to train stage 1: 0 seconds

Training stage 2 of 3
[..................................................................]
Used 42 positive and 84 negative samples
Time to train stage 2: 1 seconds

Training stage 3 of 3
[..................................................................]
Used 42 positive and 84 negative samples
Time to train stage 3: 3 seconds

Training complete
```

Use the newly trained classifier to detect a stop sign in an image.

```
detector = vision.CascadeObjectDetector("stopSignDetector.xml");
```

Read the test image.

```
img = imread("stopSignTest.jpg");
```

Detect a stop sign in the test image.

```
bbox = step(detector,img);
```

Insert bounding box rectangles and return the marked image.

```
detectedImg = insertObjectAnnotation(img,"rectangle",bbox,"stop sign");
```

Display the detected stop sign.

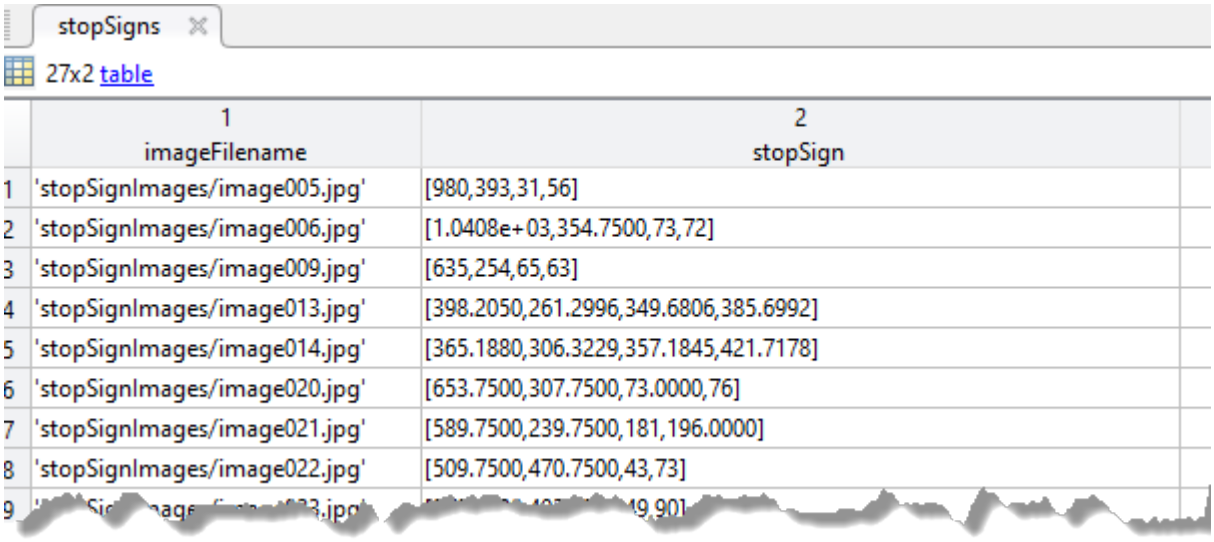
```
figure
imshow(detectedImg)
```

Remove the image folder from the path.

```
rmpath(imDir);
```

Input Arguments

`positiveInstances` — Positive samples



datastore | table

Positive samples, specified as a datastore or a two-column table.

- If you use a datastore, your data must be set up so that calling the datastore with the `read` and `readall` functions returns a cell array or table with at least two columns. The table describes the data contained in the columns:

Images	*boxes*	*labels (optional)*
Cell vector of grayscale or RGB images.	*M*-by-4 matrices of bounding boxes of the form [*x*, *y*, *width*, *height*], where [x,y] represent the top-left coordinates of the bounding box.	Cell array that contains an *M*-element categorical vector containing object class names. All categorical data returned by the datastore must contain the same categories. When you provide this data, the function uses the class label to fill the `ClassificationModel` property of the trained detector, specified as a `vision.CascadeObjectDetector` object. Otherwise, the class labels are not required for training because the cascade object detector is a single class detector.

- If you use a table, the table must have two or more columns. The first column of the table must contain image file names with paths. The images must be grayscale or truecolor (RGB) and they can be in any format supported by `imread`. Each of the remaining columns must be a cell vector that contains *M*-by-4 matrices that represent a single object class, such as *vehicle*, *flower*, or *stop sign*. The columns contain 4-element double arrays of *M* bounding boxes in the format [*x*,*y*,*width*,*height*]. The format specifies the upper-left corner location and size of the bounding box in the corresponding image. To create a ground truth table, you can use the Image Labeler app or Video Labeler app. To create a table of training data from the generated ground truth, use the `objectDetectorTrainingData` function.

stopSigns

27x2 table

	1 imageFilename	2 stopSign
1	'stopSignImages/image005.jpg'	[980,393,31,56]
2	'stopSignImages/image006.jpg'	[1.0408e+03,354.7500,73,72]
3	'stopSignImages/image009.jpg'	[635,254,65,63]
4	'stopSignImages/image013.jpg'	[398.2050,261.2996,349.6806,385.6992]
5	'stopSignImages/image014.jpg'	[365.1880,306.3229,357.1845,421.7178]
6	'stopSignImages/image020.jpg'	[653.7500,307.7500,73.0000,76]

9		

`negativeImages` — Negative images

`ImageDatastore` object | cell array | character vector | string scalar

Negative images, specified as an `ImageDatastore` object, a path to a folder containing images, or as a cell array of image file names. Because the images are used to generate negative samples, they must not contain any objects of interest. Instead, they should contain backgrounds associated with the object.

`outputXMLFilename` — Trained cascade detector file name
character vector | string scalar

Trained cascade detector file name, specified as a character vector or a string scalar with an XML extension. For example, '`stopSignDetector.xml`'.

Data Types: `char`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `FeatureType='Haar'` specifies Haar for the type of features to use.

`ObjectTrainingSize` — Object size for training
`'Auto'` (default) | two-element vector

Training object size, specified as either a two-element [*height*, *width*] vector or as `'Auto'`. Before training, the function resizes the positive and negative samples to `ObjectTrainingSize` in pixels. If you select `'Auto'`, the function determines the size automatically based on the median width-to-height ratio of the positive instances. For optimal detection accuracy, specify an object training size close to the expected size of the object in the image. However, for faster training and detection, set the object training size to be smaller than the expected size of the object in the image.

Data Types: `char` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`NegativeSamplesFactor` — Negative sample factor
`2` (default) | real-valued scalar

Negative sample factor, specified as a real-valued scalar. The number of negative samples to use at each stage is equal to

`NegativeSamplesFactor` × [*the number of positive samples used at each stage*].

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`NumCascadeStages` — Number of cascade stages
`20` (default) | positive integer

Number of cascade stages to train, specified as a positive integer. Increasing the number of stages may result in a more accurate detector but also increases training time. More stages can require more training images, because at each stage, some number of positive and negative samples are eliminated. This value depends on the values of `FalseAlarmRate` and `TruePositiveRate`. More stages can also enable you to increase the `FalseAlarmRate`. See the “Get Started with Cascade Object Detector” tutorial for more details.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`FalseAlarmRate` — Acceptable false alarm rate
`0.5` (default) | value in the range (0 1]

Acceptable false alarm rate at each stage, specified as a value in the range (0 1]. The false alarm rate is the fraction of negative training samples incorrectly classified as positive samples.

The overall false alarm rate is calculated using the `FalseAlarmRate` per stage and the number of cascade stages, `NumCascadeStages`:

$FalseAlarmRate^{NumCascadeStages}$

Lower values for `FalseAlarmRate` increase complexity of each stage. Increased complexity can achieve fewer false detections but can result in longer training and detection times. Higher values for `FalseAlarmRate` can require a greater number of cascade stages to achieve reasonable detection accuracy.

Data Types: `single` | `double`

`TruePositiveRate` — Minimum true positive rate
`0.995` (default) | value in the range (0,1]

Minimum true positive rate required at each stage, specified as a value in the range (0 1]. The true positive rate is the fraction of correctly classified positive training samples.

The overall resulting target positive rate is calculated using the `TruePositiveRate` per stage and the number of cascade stages, `NumCascadeStages`:

$TruePositiveRate^{NumCascadeStages}$

Higher values for `TruePositiveRate` increase complexity of each stage. Increased complexity can achieve a greater number of correct detections but can result in longer training and detection times.

Data Types: `single` | `double`

`FeatureType` — Feature type
`'HOG'` (default) | `'LBP'` | `'Haar'`

Feature type, specified as one of the following:
`'Haar'`[1] — Haar-like features
`'LBP'`[2] — Local binary patterns
`'HOG'`[3] — Histogram of oriented gradients

The function allocates a large amount of memory, especially the Haar features. To avoid running out of memory, use this function on a 64-bit operating system with a sufficient amount of RAM.

Data Types: `char`

Tips

- Training a good detector requires thousands of training samples. Processing time for a large amount of data varies, but it is likely to take hours or even days. During training, the function displays the time it took to train each stage in the MATLAB command window.
- The OpenCV HOG parameters used in this function are:

- Numbins: 9
- CellSize = `[8 8]`
- BlockSize = `[4 4]`
- BlockOverlap = `[2 2]`
- UseSignedOrientation = `false`

Version History

Introduced in R2013a

R2025a: MATLAB Compiler support will be removed
Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

trainImageCategoryClassifier

Train an image category classifier

Syntax

```
classifier = trainImageCategoryClassifier(imds,bag)
classifier = trainImageCategoryClassifier(imds,bag,Name,Value)
```

Description

`classifier = trainImageCategoryClassifier(imds,bag)` returns an image category classifier. The classifier contains the number of categories and the category labels for the input `imds` images. The function trains a support vector machine (SVM) multiclass classifier using the input `bag`, a `bagOfFeatures` object.

You must have a Statistics and Machine Learning Toolbox license to use this function.

This function supports parallel computing using multiple MATLAB workers. Enable parallel computing using the “Computer Vision Toolbox Preferences” dialog. To open Computer Vision Toolbox preferences, on the **Home** tab, in the **Environment** section, click **Preferences**. Select Computer Vision Toolbox.

`classifier = trainImageCategoryClassifier(imds,bag,Name,Value)` returns a `classifier` object with optional input properties specified by one or more `Name,Value` pair arguments.

Examples

Train, Evaluate, and Apply Image Category Classifier

Load two image categories.

```
setDir  = fullfile(toolboxdir('vision'),'visiondata','imageSets');
imds = imageDatastore(setDir,'IncludeSubfolders',true,'LabelSource',...
    'foldernames');
```

Split the data set into a training and test data. Pick 30% of images from each set for the training data and the remainder 70% for the test data.

```
[trainingSet,testSet] = splitEachLabel(imds,0.3,'randomize');
```

Create bag of visual words.

```
bag = bagOfFeatures(trainingSet);
```

```
Creating Bag-Of-Features.
-------------------------
* Image category 1: books
* Image category 2: cups
* Selecting feature point locations using the Grid method.
```

```
* Extracting SURF features from the selected feature point locations.
** The GridStep is [8 8] and the BlockWidth is [32 64 96 128].

* Extracting features from 4 images...done. Extracted 76800 features.

* Keeping 80 percent of the strongest features from each category.

* Creating a 500 word visual vocabulary.
* Number of levels: 1
* Branching factor: 500
* Number of clustering steps: 1

* [Step 1/1] Clustering vocabulary level 1.
* Number of features          : 61440
* Number of clusters          : 500
* Initializing cluster centers...100.00%.
* Clustering...completed 55/100 iterations (~0.92 seconds/iteration)...converged in 55 iterations

* Finished creating Bag-Of-Features
```

Train a classifier with the training sets.

```
categoryClassifier = trainImageCategoryClassifier(trainingSet,bag);
```

```
Training an image category classifier for 2 categories.
--------------------------------------------------------
* Category 1: books
* Category 2: cups

* Encoding features for 4 images...done.

* Finished training the category classifier. Use evaluate to test the classifier on a test set.
```

Evaluate the classifier using test images. Display the confusion matrix.

```
confMatrix = evaluate(categoryClassifier,testSet)
```

```
Evaluating image category classifier for 2 categories.
-------------------------------------------------------

* Category 1: books
* Category 2: cups

* Evaluating 8 images...done.

* Finished evaluating all the test sets.

* The confusion matrix for this test set is:

             PREDICTED
KNOWN    | books   cups
-------------------------
books    | 0.75    0.25
cups     | 0.25    0.75

* Average Accuracy is 0.75.
```

```
confMatrix = 2×2

    0.7500    0.2500
    0.2500    0.7500
```

Find the average accuracy of the classification.

```
mean(diag(confMatrix))
```

```
ans =
0.7500
```

Apply the newly trained classifier to categorize new images.

```
img = imread(fullfile(setDir,'cups','bigMug.jpg'));
[labelIdx, score] = predict(categoryClassifier,img);
```

```
Encoding images using Bag-Of-Features.
-------------------------------------
* Encoding an image...done.
```

Display the classification label.

```
categoryClassifier.Labels(labelIdx)
```

```
ans = 1×1 cell array
    {'cups'}
```

Input Arguments

`imds` — Images

`imageDatastore` object

Images specified as an `imageDatastore` object.

`bag` — Bag of features

`bagOfFeatures` object

Bag of features, specified as a `bagOfFeatures` object. The object contains a visual vocabulary of extracted feature descriptors from representative images of each image category.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'Verbose',true` sets `'Verbose'` to the logical `true`.

`Verbose` — Enable progress display to screen

`true` (default) | false

Enable progress display to screen, specified as the comma-separated pair consisting of 'Verbose' and the logical true or false.

LearnerOptions — Classifier options
default values of templateSVM function

Classifier options, specified as the comma-separated pair consisting of 'LearnerOptions' and the learner options output returned by the templateSVM function.

Example 3.2. Example

To adjust the regularization parameter of templateSVM and to set a custom kernel function, use the following syntax:

```
opts = templateSVM('BoxConstraint',1.1,'KernelFunction','gaussian');
classifier = trainImageCategoryClassifier(imds,bag,'LearnerOptions',opts);
```

Output Arguments

classifier — Image category classifier
imageCategoryClassifier object

Image category classifier, returned as an imageCategoryClassifier object. The function trains a support vector machine (SVM) multiclass classifier using the error correcting output codes (ECOC) framework.

Version History

Introduced in R2014b

R2025a: MATLAB Compiler support will be removed
Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

transform

Apply rigid body transformation to points

Syntax

```
tpoints = transform(transformation,points)
tpoints = transform(rotation,points)
tpoints = transform( ___ ,isCol=format)
```

Description

`tpoints = transform(transformation,points)` applies the rigid body transformation `transformation` to the input points `points`, and returns the transformed points `tpoints`.

`tpoints = transform(rotation,points)` applies the rotation `rotation` to the input points `points`, and returns the transformed points `tpoints`.

`tpoints = transform( ___ ,isCol=format)` sets the expected format of the input points `points` to be either column-wise or row-wise by using the logical flag `format` in addition to the input arguments from the previous syntax.

Input Arguments

`transformation` — Transformation

`se3` object | *N*-element array of transformation objects

Transformation, specified as a scalar `se3` object or an *N*-element array of transformation objects. *N* is the total number of transformations.

If you specify `transformation` as an array, each element must be of the same type.

`rotation` — Rotation

`so3` object | *N*-element array of rotation objects

Rotation, specified as a scalar `so3` object or as an *N*-element array of rotation objects. *N* is the total number of rotations.

If you specify `rotation` as an array, each element must be of the same type.

`points` — Points to transform

N-by-*D*-by-*M* array | *D*-by-*N*-by-*M* array

Points to transform, specified as an *N*-by-*D*-by-*M* array, where:

- *D* is the dimension of the transformation, defined as 2 for 2-D transformations and 3 for 3-D transformations.
- *N* is the total number of input points to transform.
- *M* is the total number of transforms to perform on each point.

For 2-D transformations and rotations, each row specifies a point in the form [*X Y*]. For 3-D transformations and rotations, each row specifies a point in the form [*X Y Z*].

If you specify `format` as `true`, then you must specify `points` as a *D*-by-*N*-by-*M* array, where each column specifies a point.

Data Types: `single` | `double`

`format` — Point format
`false` or `0` (default) | `true` or `1`

Point format, specified as a logical `0` (`false`) or `1` (`true`). If you specify this argument as true, you must specify the points in points as columns. Otherwise, specify points as rows.

Example: `isCol=true`

Data Types: `logical`

Output Arguments

`tpoints` — Transformed points
N-by-*D*-by-*M* array | *D*-by-*N*-by-*M* array

Transformed points, returned as an *N*-by-*D*-by-*M* array, where:

- *D* is the dimension of the transformation, defined as 2 for 2-D transformations and rotations and 3 for 3-D transformations or rotations.
- *N* is the total number of input points to transform.
- *M* is the total number of transforms to perform on each point.

For 2-D transformations and rotations, each row specifies a point in the form [*X Y*]. For 3-D transformations and rotations, each row specifies a point in the form [*X Y Z*].

If you specify `format` as `true`, `tpoints` is returned as a *D*-by-*N*-by-*M* array, where each column specifies a point.

Image Labeler

Label images for computer vision applications

Description

The Image Labeler app enables you to label ground truth data in a collection of images. Using the app, you can:

- Define axis-aligned or rotated rectangular regions of interest (ROI) labels, line ROI labels, pixel ROI labels, polygon ROI labels, point ROI labels, projected cuboid ROI labels, and scene labels. Use these labels to interactively label your ground truth data.
- Use built-in automation algorithms, such as Segment Anything Model or Grounding DINO, to label your ground truth data.
- Write, import, and use your own custom automation algorithm to automatically label ground truth. See “Create Custom Automation Algorithm for Labeling”.
- Evaluate the performance of your label automation algorithms using a visual summary. See “View Summary of Ground Truth Labels”.
- Export the labeled ground truth as a `groundTruth` object. You can use this object for system verification or for training an object detector or semantic segmentation network. See “Training Data for Object Detection and Semantic Segmentation”.

The Image Labeler app also enables you to create an individual- or a team labeling project. To launch the Image Labeler app, see “Open the Image Labeler App” on page 3-0 .

After launching the Image Labeler app, select one of these options to create a new labeling project.

- New Individual Project — Create a labeling project for yourself. To get started using an individual labeling project, see “Get Started with the Image Labeler”.
- New Team Project — Create a labeling project for a team with multiple users. To get started with a team-based project, see “Get Started with Team-Based Labeling”.

The Image Labeler app supports all image file formats supported by the `imread` function and additionally supports the Digital Imaging and Communication in Medicine (DICOM) format including the ability to load multiframe data such as an ultrasound video. To read additional file formats supported by the Image Labeler app, you can create an `imageDatastore` and use the `ReadFcn` property. To label 2-D or 3-D medical image data stored in the DICOM, Neuroimaging Informatics Technology Initiative (NIfTI), or nearly raw raster data (NRRD) file formats, use the Medical Image Labeler.

When loading images, if an image has a dimension larger than 8000 pixels or is a multiresolution image, the **Image Labeler** app offers you the option to convert the image into a blocked image. A *blocked image* consists of a large image that has been divided into smaller blocks that can fit in memory. Once the Image Labeler converts the large image into a blocked, you can process it in the app as you would any other image. While using blocked images enables you to process images in the app that you might not otherwise be able to, there are some limitations. For more information, see "Label Very Large High-Resolution Images Using Image Labeler".

Open the Image Labeler App

- MATLAB Toolstrip: On the **Apps** tab, under **Image Processing and Computer Vision**, click the app icon.
- MATLAB command prompt: Enter `imageLabeler`.

Programmatic Use

`imageLabeler` opens a new session of the app, enabling you to label ground truth data in images.

`imageLabeler(imageFolder)` opens the app and loads all the images from the folder named `imageFolder`.

The images in the folder can be unordered and can vary in size. To label a video, or a set of ordered images that resemble a video, use the Video Labeler app instead.

`imageLabeler(imageDatastore)` opens the app and reads all of the images from an `imageDatastore` object. The `ReadFcn` property of the `imageDatastore` object specifies how to read the data.

For example, to open the app with a collection of stop sign images:

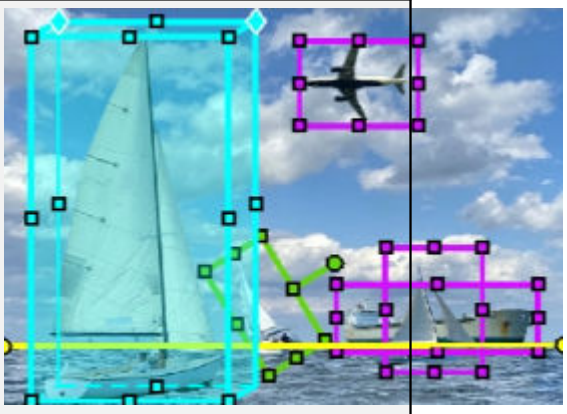
```
stopSignsFolder = fullfile(toolboxdir("vision"),"visiondata","stopSignImages");
imds = imageDatastore(stopSignsFolder)
imageLabeler(imds)
```

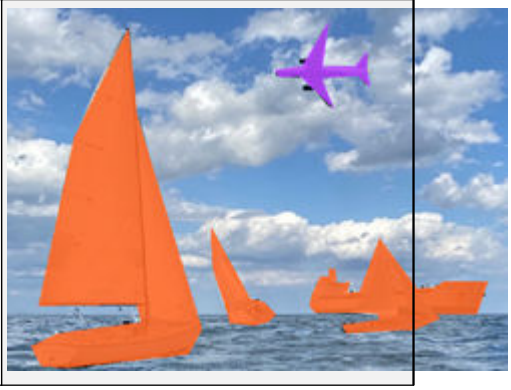
`imageLabeler(projectFile)` opens the app and loads a saved app session from the project file, `projectFile`. The `projectFile` input contains the path and name of the `.prj`-file corresponding to the saved project.

To load a labeling session from a MAT file exported by a legacy version of the app (as opposed to a project file), use this syntax, specifying the path and name of the MAT file.

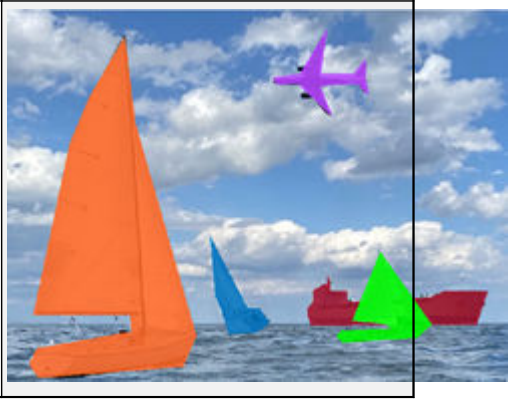
`imageLabeler(gTruth)` opens the app and loads a `groundTruth` object. The ground truth object data source must be an image collection or an `imageDatastore`.

More About





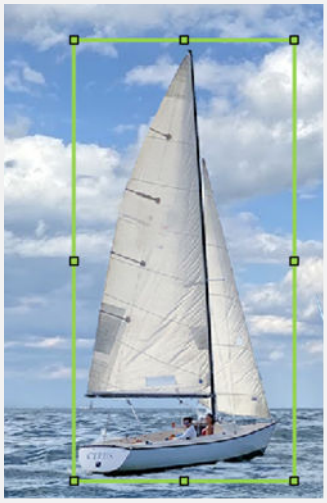
ROI Labels, Sublabels, and Attributes

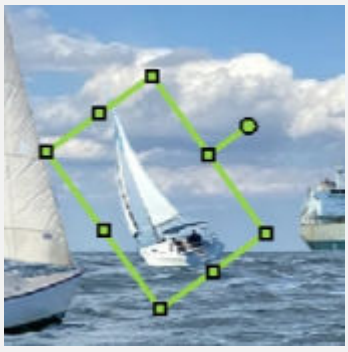


On the left side of the app, the **ROI Labels** pane contains the region of interest (ROI) label definitions that you can mark on the frames. You can create label definitions directly from this pane.

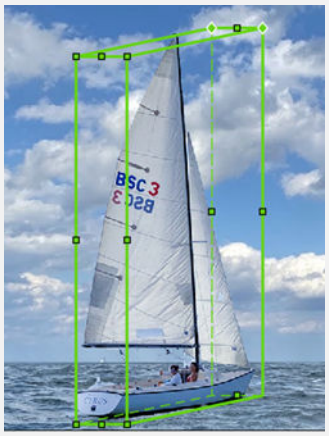
Alternatively, you can create label definitions programmatically by using a `labelDefinitionCreator` object and then import these label definitions into an app session.

Selecting ROI Label and Drawing Tool for Your Application





You can use labeled data to train or validate algorithms such as image classifiers, object detectors, and semantic and instance segmentation networks. Consider your application when choosing a labeling drawing tool to create ROI labels. The figure below shows labeling techniques for four different applications.



Application	Label Types	Example
Image Classification	N/A	 Boat, Plane
Object Detection	Line Rectangle Rotated Rectangle Projected Cuboid	
Semantic Segmentation	Pixel label Polygon	

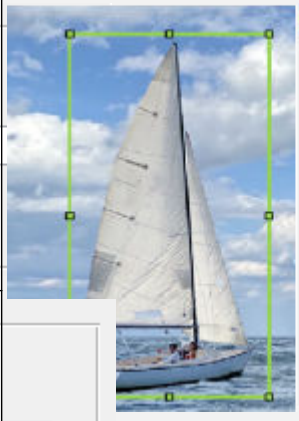
Application	Label Types	Example
Instance Segmentation	Polygon	

ROI Labels

An ROI label is a label that corresponds to a region of interest (ROI) in a signal frame. The table describes the supported label types.

ROI Label	Creation	Scene
`Rectangle`	• Automatically create rectangular ROI labels (bounding boxes) by specifying descriptive text to the Grounding DINO vision-language model. To learn more, see “Automatically Label Ground Truth Using Vision-Language Model”. • Automatically create rectangular ROI labels using the Segment Anything Model (SAM) tool. • Draw rectangular ROI labels around objects using manual selection.	
`Rotated Rectangle`	Draw rotated rectangle ROI labels (bounding boxes) around objects.	

ROI Label	Creation	Scene
`Projected cuboid`	Draw cuboidal ROI labels (3-D bounding boxes).	
`Line`	Draw linear ROI labels to represent lines. To draw a line ROI, use two or more points.	
`Pixel label`	Assign labels to pixels for semantic segmentation: • Label pixels automatically using the SAM. For an example, see “Automatically Label Ground Truth Using Segment Anything Model”. • Label pixels manually using polygons, brushes, or flood fill. For more information, see “Label Pixels for Semantic Segmentation”	



ROI Label	Creation	Scene
`Polygon`	Draw polygon ROI labels and label distinct instances of the same class using manual selection or the automatic SAM tool. For more information, see “Label Objects Using Polygons for Instance Segmentation”.	
`Point`	Draw point ROI labels for keypoint detection in objects.	 

ROI Sublabels

An ROI sublabel is an ROI label that belongs to a parent label. Use ROI sublabels to provide a greater level of detail about the ROIs in your labeled ground truth data. For example, a **vehicle** label might contain **headlight**, **licensePlate**, and **wheel** sublabels. You can create sublabels for rectangle, polygon, line, and projected cuboid labels. For more details about sublabels, see “Use Sublabels and Attributes to Label Ground Truth Data”.

ROI Attributes

An ROI attribute specifies additional information about an ROI label or sublabel. For example, in an ocean scene, attributes might include the type or color of a boat. The table describes the supported attribute types.

Attribute Type	Sample Attribute Definition	Sample Default Values
`Numeric Value`	Attributes numSails 2	
`String`	Attributes boatColor white	
`Logical`	Attributes underway True	
`List`	Attribute Name boatType List List Items (Each item must appear on a new line) Rowboat Sailboat Motorboat Cargo Tanker	

For more details on attributes, see “Use Sublabels and Attributes to Label Ground Truth Data”.

Algorithms

You can use label automation algorithms to speed up labeling within the app. To create your own label automation algorithm to use within the app, see “Create Custom Automation Algorithm for Labeling”. You can also use one of the built-in algorithms by following these steps:

1. Import the data you want to label, and create at least one label definition.
2. On the app toolstrip, click **Select Algorithm** and select one of the built-in automation algorithms.

3 Click **Automate**, and then follow the automation instructions in the right pane of the automation window.

ACF People Detector

Detect and label people using aggregate channel features (ACF). This algorithm is based on the `peopleDetectorACF` function. To use this algorithm, you must define at least one rectangle ROI label. You do not need to draw any ROI labels.

To help improve the algorithm results, first click **Settings**. You can change any of these settings.

- The pretrained people detector model that the algorithm uses — The `'inria-100x41'` model was trained using the INRIA person data set. The `'caltech-50x21'` model was trained using the Caltech Pedestrian data set.
- The overlap ratio threshold, from 0 to 1, for detecting people — When rectangle ROIs overlap by more than this threshold, the algorithm discards one of the ROIs.
- The classification score threshold for detecting people — Increase the score to increase the prediction confidence of the algorithm. Rectangles with scores below this threshold are discarded.

ACF Vehicle Detector

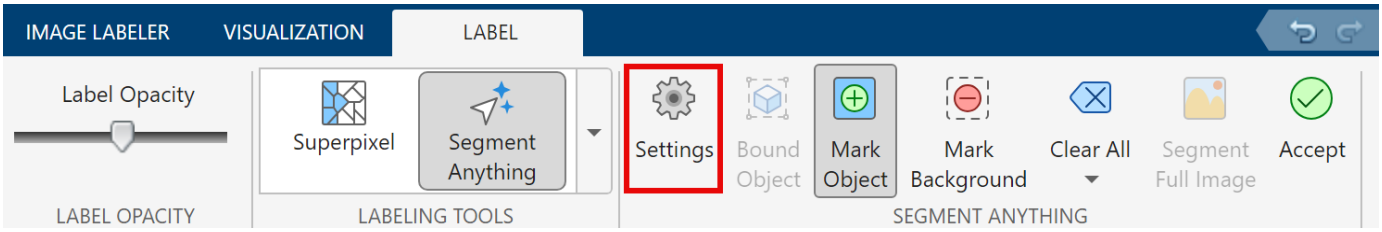
Detect and label vehicles using aggregate channel features (ACF). This algorithm is based on the `vehicleDetectorACF` function. To use this algorithm, you must define at least one rectangle ROI label. You do not need to draw any ROI labels.

To help improve the algorithm results, first click **Settings**. You can change any of these settings.

- The pretrained vehicle detector model that the algorithm uses — The `'full-view'` model was trained using unoccluded images of the front, rear, left, and right sides of vehicles. The `'front-rear-view'` model was trained using images of only the front and rear sides of the vehicle.
- The overlap ratio threshold, from 0 to 1, for detecting vehicles — When rectangle ROIs overlap by more than this threshold, the algorithm discards one of the ROIs.
- The classification score threshold for detecting vehicles — Increase the score to increase the prediction confidence of the algorithm. Rectangles with scores below this threshold are discarded.

You can also configure the detector with a calibrated monocular camera by importing a `monoCamera` object into the MATLAB workspace. Specify the length and width ranges of the vehicle in world units, such as meters.

Version History



Introduced in R2018a

R2026a: Label ground truth using Segment Anything Model 2 (SAM 2)

By default, the **Segment Anything** tool now uses the Segment Anything Model 2 (SAM 2). By selecting the Settings in the **Segment Anything** section of the app toolstrip, you can specify one of these SAM model types.

- Segment Anything Model 2 - Large *(default)*
- Segment Anything Model 2 - Base

- Segment Anything Model 2 - Small
- Segment Anything Model 2 - Tiny
- Segment Anything Model - Base

This functionality requires the Image Processing Toolbox Model for Segment Anything Model 2 add-on. You can install the add-on from Add-On Explorer. For more information about installing add-ons, see “Get and Manage Add-Ons”. The functionality also requires a Deep Learning Toolbox license.

R2026a: Automatically create rectangle ROI labels using Grounding DINO Vision-Language Model

Using the Grounding DINO vision-language model in the Image Labeler app, you can now automatically create rectangle ground truth ROI labels for object detection by specifying descriptive text. To use Grounding DINO for rectangle ROI labeling, select the **Grounding DINO** tool on the **Label** tab of the app toolstrip.

R2025a: Create rectangle and polygon ROI labels, and ROI-based pixel labels, using Segment Anything Model (SAM)

Using the Segment Anything Model (SAM) in the Image Labeler app, you can now interactively:

- Create rectangle ROI labels for object detection. To use the SAM for rectangle ROI labeling, select the **Segment Anything** tool on the **Label** tab of the app toolstrip.
- Create polygon ROI labels for instance segmentation. To use the SAM for polygon ROI labeling, select the **Segment Anything** tool on the **Label** tab of the app toolstrip. To learn more, see “Label Objects Using Polygons for Instance Segmentation”.
- Create pixel labels by drawing an ROI around an area to segment. To use the SAM for pixel labeling, select the **Segment Anything** tool on the **Label** tab of the Image Labeler app toolstrip. For an example, see “Label Pixels for Semantic Segmentation”.

This functionality requires the Image Processing Toolbox Model for Segment Anything Model add-on. You can install the add-on from Add-On Explorer. For more information about installing add-ons, see “Get and Manage Add-Ons”. The functionality also requires Deep Learning Toolbox.

R2024b: Segment and label ground truth for semantic segmentation using Segment Anything Model (SAM)

Use the **Segment Anything** pixel labeling tool within the Image Labeler app to automatically segment images using the Segment Anything Model (SAM) and create pixel labels. This functionality requires the Image Processing Toolbox Model for Segment Anything Model add-on. You can install the add-on from Add-On Explorer. For more information about installing add-ons, see “Get and Manage Add-Ons”. The functionality also requires Deep Learning Toolbox.

Assign pixel labels to objects by segmenting objects in an image with just a few clicks. Alternatively, using the **Segment Full Image** option of the **Segment Anything** tool, segment the entire image into regions and click on objects to easily create pixel labels for all the objects in a scene. For an example, see “Automatically Label Ground Truth Using Segment Anything Model”. To learn more about the SAM, see “Get Started with Segment Anything Model for Image Segmentation”.

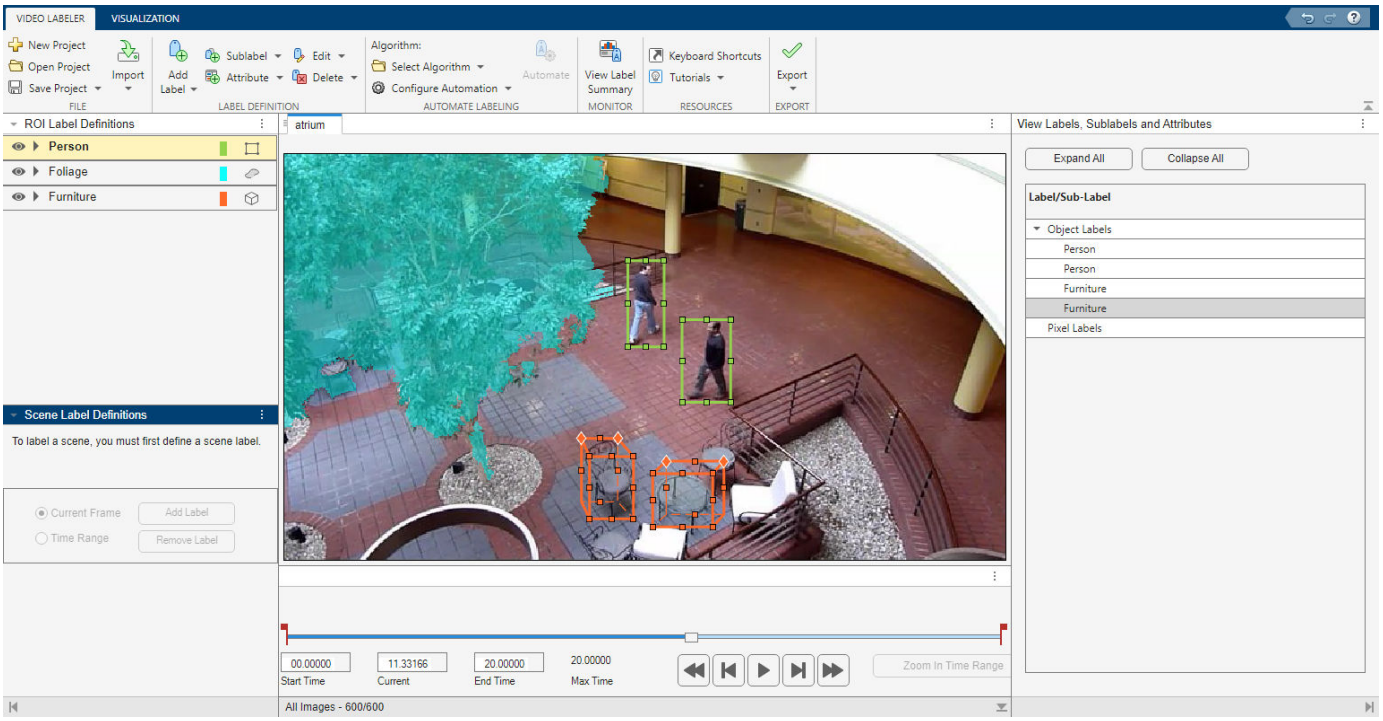
Video Labeler



Label video for computer vision applications

Description

The Video Labeler app enables you to label ground truth data in a video, in an image sequence, or from a custom data source reader. Using the app, you can:

- Define axis-aligned and rotated rectangular regions of interest (ROI) labels, projected cuboid ROI labels, line ROI labels, polygon ROI labels, point ROI labels, pixel ROI labels, and scene labels. Use these labels to interactively label your ground truth data.
- Use built-in detection or tracking algorithms to label your ground truth data. Use the built-in Segment Anything Model or Grounding DINO tools to automatically label ground truth.
- Write, import, and use your own custom automation algorithm to automatically label ground truth. See “Create Custom Automation Algorithm for Labeling”.
- Evaluate the performance of your label automation algorithms using a visual summary. See “View Summary of Ground Truth Labels”.
- Export the labeled ground truth as a `groundTruth` object. You can use this object for system verification or for training an object detector or semantic segmentation network. See “Training Data for Object Detection and Semantic Segmentation”.

To learn more about this app, see “Get Started with the Video Labeler”.

Open the Video Labeler App

- MATLAB Toolstrip: On the **Apps** tab, under **Image Processing and Computer Vision**, click the app icon.
- MATLAB command prompt: Enter `videoLabeler`.

Examples

- "Get Started with the Video Labeler"

Programmatic Use

`videoLabeler` opens a new session of the app, enabling you to label ground truth data in a video or image sequence.

`videoLabeler(videoFileName)` opens the app and loads the input video. The video file must have an extension supported by `VideoReader`.

Example: `videoLabeler('vipmen.avi')`

`videoLabeler(imageSeqFolder)` opens the app and loads the image sequence from the input folder. An image sequence is an ordered set of images that resemble a video.

`imageSeqFolder` must be a string scalar or character vector that specifies the folder containing the image files. The image files must have extensions supported by `imformats` and are loaded in the order returned by the `dir` function.

`videoLabeler(imageSeqFolder,timestamps)` opens the app and loads a sequence of images with their corresponding timestamps. `timestamps` must be a `duration` vector of the same length as the number of images in the sequence.

For example, load a sequence of images and their corresponding timestamps into the app.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata','NewTsukuba');
timeStamps = seconds(1:150);
videoLabeler(imageDir,timeStamps)
```

`videoLabeler(gtSource)` opens the app and loads the data source and corresponding timestamps from a `groundTruthDataSource` object, `gtSource`. To generate this object for a custom data source, you can specify a custom reader function. For details, see "Use Custom Image Source Reader for Labeling".

`groundTruthLabeler(projectFile)` opens the app and loads a saved app session from the project file, `projectFile`. The `projectFile` input contains the path and name of the `.prj`-file corresponding to the saved project.

To load a labeling session from a MAT file exported by a legacy version of the app (as opposed to a project file), use this syntax, specifying the path and name of the MAT file.

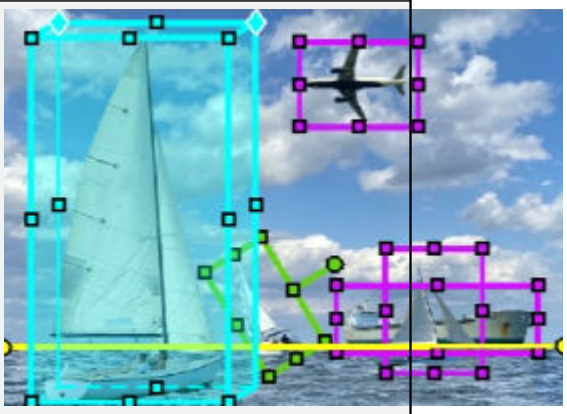
`videoLabeler(gTruth)` opens the app and loads a `groundTruth` object. You do not need to add a video before loading the object. The ground truth object data source must be an image sequence, video, or a custom data source.

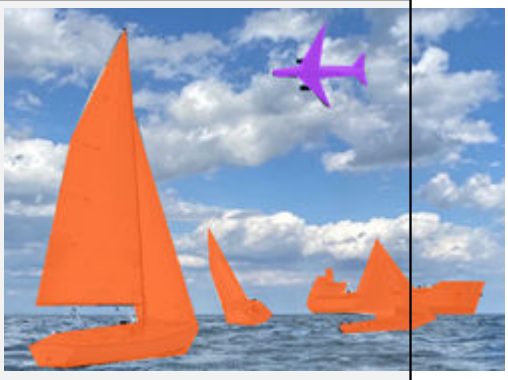
Limitations

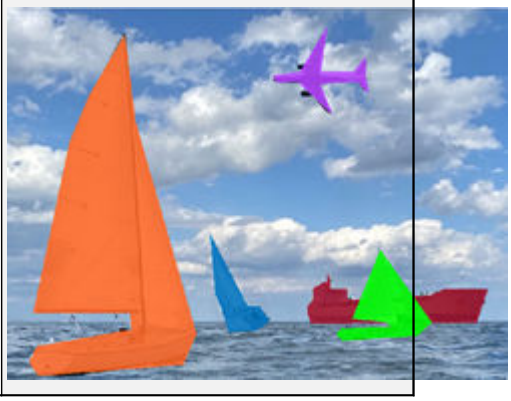
- The built-in automation algorithms support the automation of rectangular ROI labels and line ROI labels only. When you select a built-in algorithm and click **Automate**, scene labels, pixel ROI labels, polyline ROI labels, sublabels, and attributes are not imported into the automation session. To automate the labeling of these features, create a custom automation algorithm. See “Create Custom Automation Algorithm for Labeling”.
- Pixel ROI labels do not support sublabels or attributes.
- The Label Summary window does not support sublabels or attributes

More About

ROI Labels, Sublabels, and Attributes



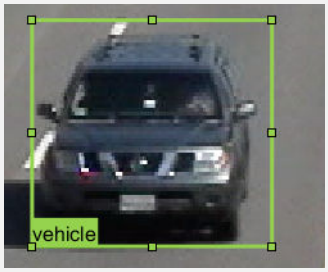


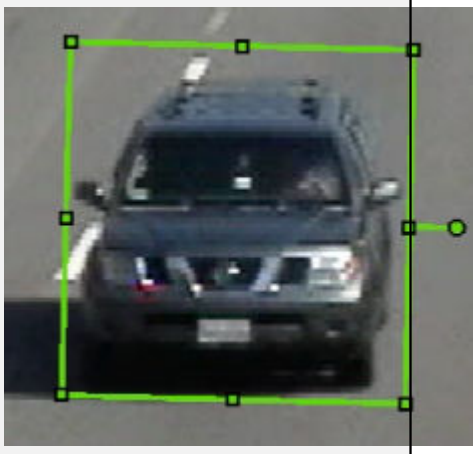


On the left side of the app, the **ROI Labels** pane contains the region of interest (ROI) label definitions that you can mark on the frames. You can create label definitions directly from this pane. Alternatively, you can create label definitions programmatically by using a `labelDefinitionCreator` object and then import these label definitions into an app session.

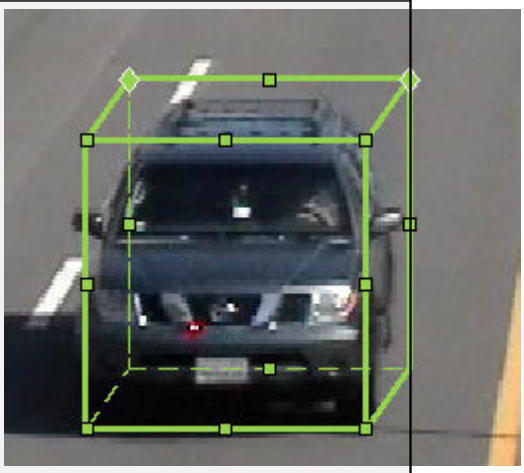
The app supports the definition of ROI labels, sublabels, and attributes.

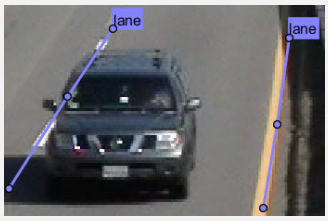
Selecting ROI Label and Drawing Tool for Your Application

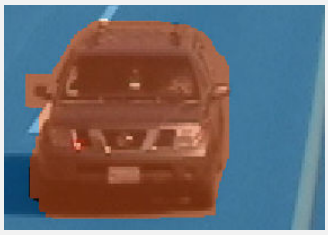




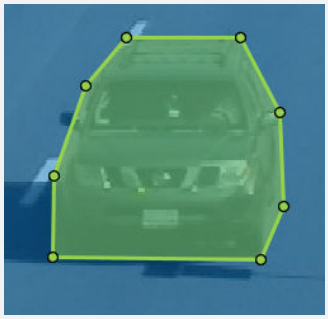
You can use labeled data to validate or train algorithms such as image classifiers, object detectors, and semantic and instance segmentation networks. Consider your application when choosing a labeling drawing tool to create ROI labels. The figure below shows labeling techniques for four different applications.







Application	Label Types	Example
Image Classification	N/A	 Boat, Plane



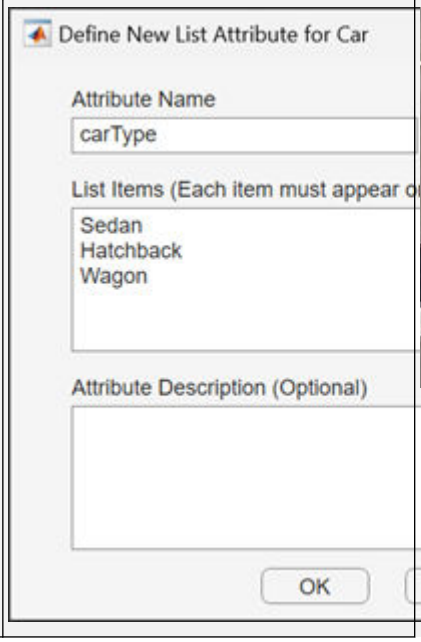
Application	Label Types	Example
Object Detection	Line Rectangle Rotated Rectangle Projected Cuboid	
Semantic Segmentation	Pixel label Polygon	
Instance Segmentation	Polygon	

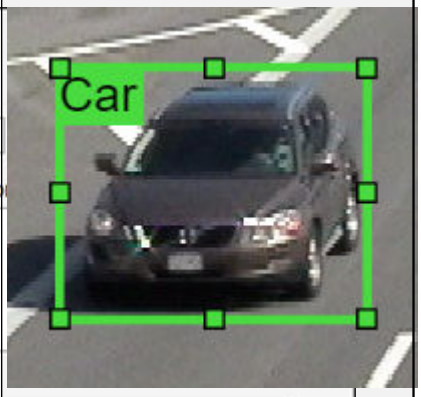
ROI Labels

An ROI label is a label that corresponds to a region of interest (ROI) in a signal frame. The table describes the supported label types.

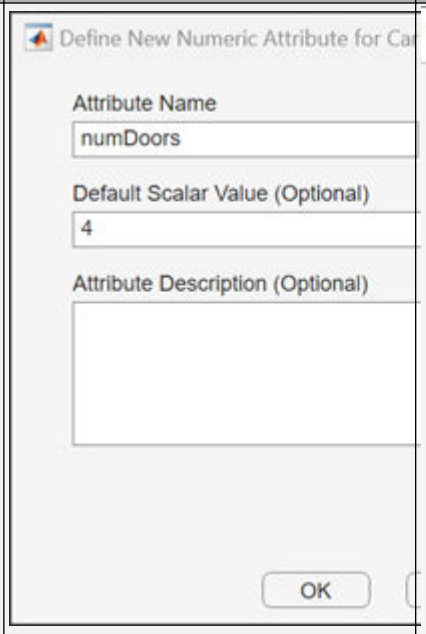
ROI Label	Description	Scene
`Rectangle`	Create axis-aligned or rotated rectangular ROI labels around objects using one of these options: • **Draw Rectangle** – Manual ROI selection • **Segment Anything** – Segment Anything Model (SAM) automatic ROI labeling tool. To learn more, see “Automatically Label Ground Truth Using Segment Anything Model”. • **Grounding DINO** – Grounding DINO automatic ROI labeling tool. To learn more, see “Automatically Label Ground Truth Using Vision-Language Model”.	Vehicles, pedestrians, road signs `Rectangle`: 
`Rotated Rectangle`	Draw rotated rectangular ROI labels around object.	`Rotated Rectangle`  :

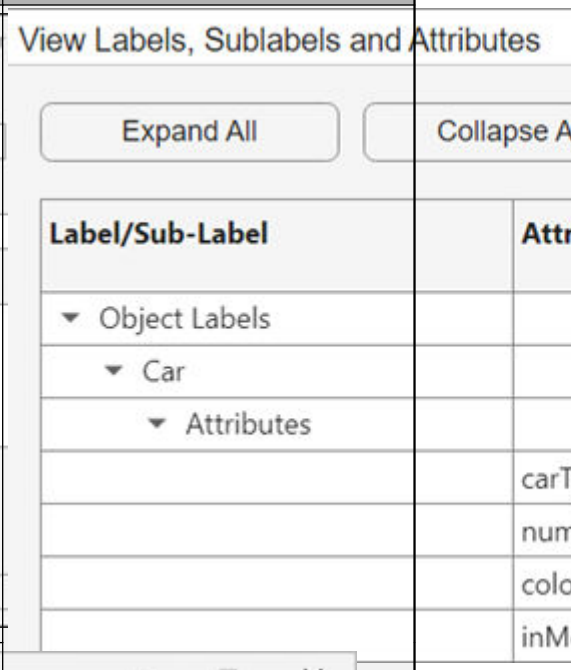
ROI Label	Description	Scene
`Projected cuboid`	Draw cuboidal ROI labels (3-D bounding boxes).	
`Line`	Draw linear ROI labels to represent lines. To draw a polyline ROI, use two or more points.	Lane boundaries, guard rails, road curbs 
`Pixel label`	Assign labels to pixels for semantic segmentation: • Label pixels automatically using the SAM. For an example, see “Automatically Label Ground Truth Using Segment Anything Model”. • Label pixels manually using polygons, brushes, or flood fill. For more information, see “Label Pixels for Semantic Segmentation”	Vehicles, road surface, trees, pavement 

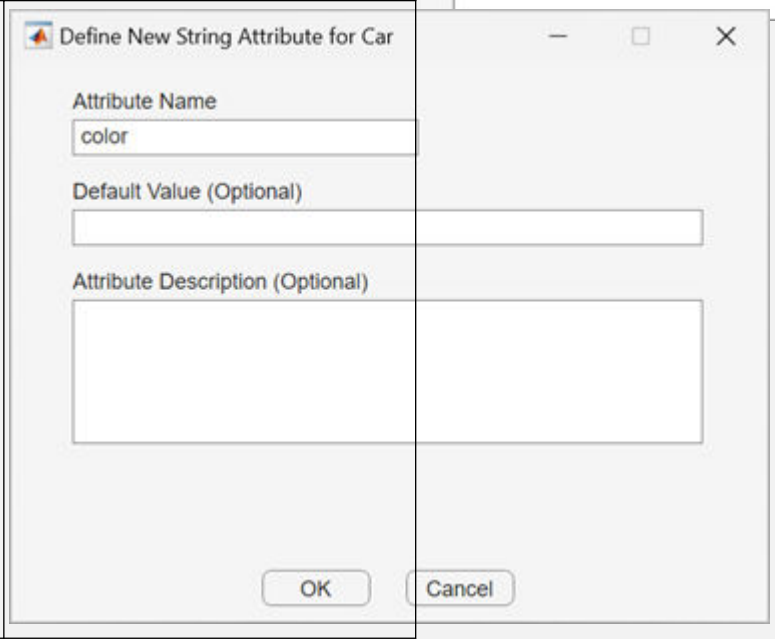




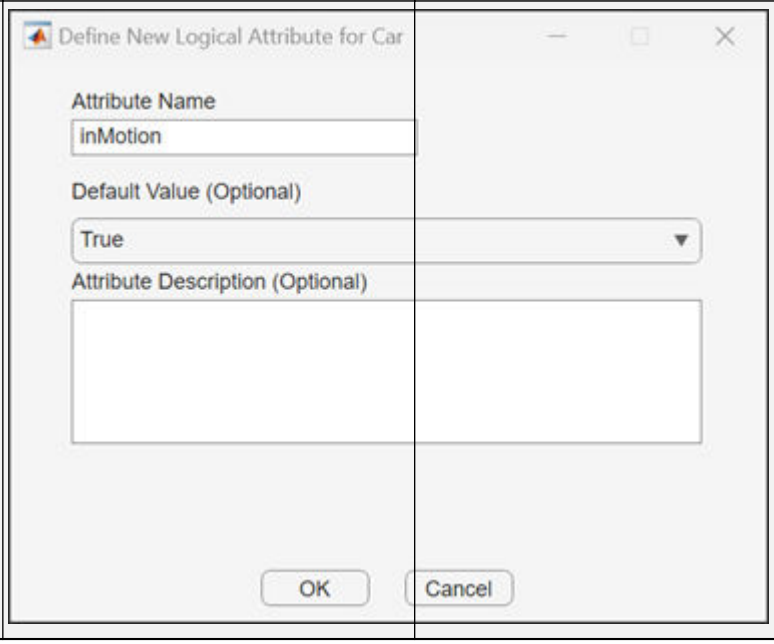
ROI Label	Description	Scene
`Polygon`	Draw polygon ROI labels and label distinct instances of the same class using manual selection or the automatic SAM tool. For more information on drawing polygon ROI labels for instance and semantic segmentation networks, see “Label Objects Using Polygons for Instance Segmentation”	Vehicles, road surface, trees, pavement 







ROI Sublabels



An ROI sublabel is an ROI label that belongs to a parent label. Use ROI sublabels to provide a greater level of detail about the ROIs in your labeled ground truth data. For example, a **vehicle** label might contain **headlight**, **licensePlate**, and **wheel** sublabels. You can create sublabels only for all ROI label types with the exception of pixel labels. For more details about sublabels, see “Use Sublabels and Attributes to Label Ground Truth Data”.

ROI Attributes

An ROI attribute specifies additional information about an ROI label or sublabel. For example, in a driving scene, attributes might include the type or color of a vehicle. The table describes the supported attribute types.

Attribute Type	Sample Attribute Definition	Sample Default Values
`List`		

Attribute Type	Sample Attribute Definition	Sample Default Values
`Numeric`		
`String`		

Attribute Type	Sample Attribute Definition	Sample Default Values
`Logical`		

For more details about attributes, see “Use Sublabels and Attributes to Label Ground Truth Data”.

Tips

- To avoid having to relabel ground truth with new labels, organize the labeling scheme you want to use before marking your ground truth.

Algorithms

You can use label automation algorithms to speed up labeling within the app. To create your own label automation algorithm to use within the app, see “Create Custom Automation Algorithm for Labeling”. You can also use one of the built-in algorithms by following these steps:

1. Import the data you want to label, and create at least one label definition.
2. On the app toolstrip, click **Select Algorithm** and select one of the built-in automation algorithms.
3. Click **Automate**, and then follow the automation instructions in the right pane of the automation window.

ACF People Detector

Detect and label people using aggregate channel features (ACF). This algorithm is based on the `peopleDetectorACF` function. To use this algorithm, you must define at least one rectangle ROI label. You do not need to draw any ROI labels.

To help improve the algorithm results, first click **Settings**. You can change any of these settings.

- The pretrained people detector model that the algorithm uses — The `'inria-100x41'` model was trained using the INRIA person data set. The `'caltech-50x21'` model was trained using the Caltech Pedestrian data set.

- The overlap ratio threshold, from 0 to 1, for detecting people — When rectangle ROIs overlap by more than this threshold, the algorithm discards one of the ROIs.
- The classification score threshold for detecting people — Increase the score to increase the prediction confidence of the algorithm. Rectangles with scores below this threshold are discarded.

Point Tracker

Track and label one or more axis-aligned or rotated rectangle ROI labels over short intervals by using the Kanade-Lucas-Tomasi (KLT) algorithm. This algorithm is based on the `vision.PointTracker` System object. To use this algorithm, you must define at least one rectangle ROI label, but you do not need to draw any ROI labels.

To change the feature detector used to obtain the initial points for tracking, click **Settings**. This table shows the feature detector options.

Feature Detector	Description	Equivalent Function
`Minimum Eigen Value`	Detect corners by using the minimum eigenvalue algorithm.	`detectMinEigenFeatures`
`Harris`	Detect corners by using the Harris–Stephens algorithm.	`detectHarrisFeatures`
`FAST`	Detect corners by using the features from accelerated segment test (FAST) algorithm.	`detectFASTFeatures`
`BRISK`	Detect features by using the binary robust invariant scalable keypoints (BRISK) algorithm.	`detectBRISKFeatures`
`KAZE`	Detect features by using nonlinear diffusion to construct a scale space of an image, and then detecting multiscale corner features (KAZE features) from that scale space.	`detectKAZEFeatures`
`SURF`	Detect blob features by using the speeded-up robust features (SURF) algorithm.	`detectSURFFeatures`
`MSER`	Detect regions by using the maximally stable extremal regions (MSER) algorithm.	`detectMSERFeatures`

Temporal Interpolator

Estimate axis-aligned or rotated rectangle ROIs or projected cuboid ROIs between frames by interpolating the ROI locations across the time range. To use this algorithm, you must draw a rectangle ROI or a projected cuboid ROI on a minimum of two frames: one at the beginning of the interval and one at the end of the interval. The interpolation algorithm estimates and draws ROIs in the intermediate frames.

Consider a video with 10 frames. The first frame has a rectangle ROI centered at [5, 5]. The 10th frame has a rectangle ROI centered at [25, 25]. At each frame, the algorithm moves the ROI 2 pixels in the *x*-direction and 2 pixels in the *y*-direction. Therefore, the algorithm centers the ROI at [7, 7] in the second frame, [9, 9] in the third frame, and so on, up to [23, 23] in the second-to-last frame.

ACF Vehicle Detector

Detect and label vehicles using aggregate channel features (ACF). This algorithm is based on the `vehicleDetectorACF` function. To use this algorithm, you must define at least one rectangle ROI label. You do not need to draw any ROI labels.

To help improve the algorithm results, first click **Settings**. You can change any of these settings.

- The pretrained vehicle detector model that the algorithm uses — The `'full-view'` model was trained using unoccluded images of the front, rear, left, and right sides of vehicles. The `'front-rear-view'` model was trained using images of only the front and rear sides of the vehicle.
- The overlap ratio threshold, from 0 to 1, for detecting vehicles — When rectangle ROIs overlap by more than this threshold, the algorithm discards one of the ROIs.
- The classification score threshold for detecting vehicles — Increase the score to increase the prediction confidence of the algorithm. Rectangles with scores below this threshold are discarded.

You can also configure the detector with a calibrated monocular camera by importing a `monoCamera` object into the MATLAB workspace. Specify the length and width ranges of the vehicle in world units, such as meters.

Lane Boundary Detector (requires Automated Driving Toolbox)

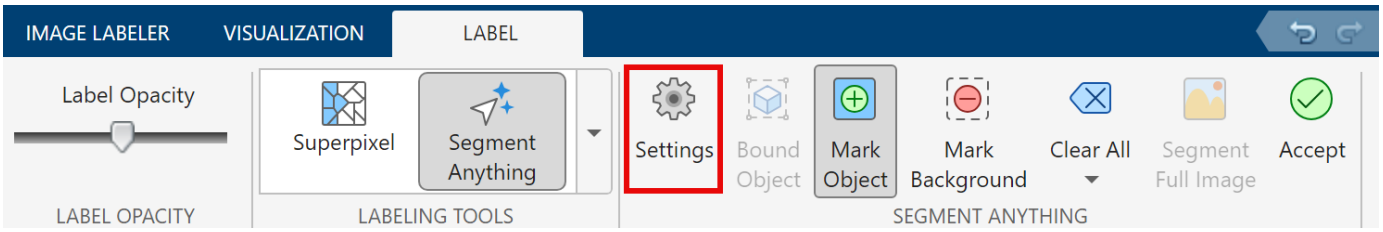
Detect and label lane boundaries using an estimated bird’s-eye-view projected image. To use this algorithm, you must define at least one line ROI label. You do not need to draw any ROI labels. To detect lane boundaries, the algorithm follows these steps:

1. It makes an initial guess at the placement of the lane boundaries in the image.
2. It transforms the ROI around the lanes into a bird's-eye view image to make the lanes parallel and remove distortion.
3. It uses this image to segment the lane boundaries.

To help improve the algorithm results, first click **Settings**. You can change any of these settings.

- The placement of the lane lines for generating the bird's-eye view image
- The ROI around the lanes, which you can expand to include more than just the ego lane boundaries in the image
- The pixel width of detected lane boundaries in the image

You can also change the number of lane boundaries that you want to detect. The default number of lane boundaries is 2.



Version History

Introduced in R2018b

R2026a: Label ground truth using Segment Anything Model 2 (SAM 2)

By default, the **Segment Anything** tool now uses the Segment Anything Model 2 (SAM 2). By selecting the Settings in the **Segment Anything** section of the app toolstrip, you can specify one of these SAM model types.

- Segment Anything Model 2 - Large *(default)*
- Segment Anything Model 2 - Base
- Segment Anything Model 2 - Small
- Segment Anything Model 2 - Tiny
- Segment Anything Model - Base

This functionality requires the Image Processing Toolbox Model for Segment Anything Model 2 add-on. You can install the add-on from Add-On Explorer. For more information about installing add-ons, see “Get and Manage Add-Ons”. The functionality also requires a Deep Learning Toolbox license.

R2025a: Create pixel, rectangle, and polygon ROI labels using Segment Anything Model (SAM)

Using the Segment Anything Model (SAM) in the Video Labeler, you can now interactively:

- Create pixel labels for semantic segmentation
- Create rectangle ROI labels for object detection
- Create polygon ROI labels for instance segmentation

To use the SAM for labeling, select the **Segment Anything** tool on the **Label** tab of the Video Labeler toolstrip.

This functionality requires the Image Processing Toolbox Model for Segment Anything Model support package. You can install the support package from the Add-On Explorer. For more information about installing add-ons, see “Get and Manage Add-Ons”.

Training Image Labeler

Label images for training a classifier

Description

The Image Labeler app replaces the Training Image Labeler app. Use the Image Labeler instead.

Open the Training Image Labeler App

- MATLAB command prompt: Enter `trainingImageLabeler`.

Note The `trainingImageLabeler` function opens the Image Labeler app.

Examples

Open Training Image Labeler App

Type `trainingImageLabeler` on the MATLAB command line or select it from the MATLAB desktop **Apps** tab.

Note The `trainingImageLabeler` function opens the Image Labeler app.

Programmatic Use

`trainingImageLabeler` invokes an app for labeling ground truth data in images. This app allows you to interactively specify rectangular Regions of Interest (ROIs). The ROIs define locations of objects, which are used to train a classifier. It outputs training data in a format supported by the `trainCascadeObjectDetector` function. The function trains a model to use with the `vision.CascadeObjectDetector` detector.

Note The `trainingImageLabeler` function opens the Image Labeler app.

Version History

Introduced in R2014a

triangulate

3-D locations of undistorted matching points in stereo images

Syntax

```
worldPoints = triangulate(matchedPoints1,matchedPoints2,stereoParams)
worldPoints = triangulate(matchedPoints1,matchedPoints2,camProjection1,
camProjection2)
[worldPoints,reprojectionErrors] = triangulate( ___ )
[worldPoints,reprojectionErrors,validIndex] = triangulate( ___ )
```

Description

`worldPoints = triangulate(matchedPoints1,matchedPoints2,stereoParams)` returns the 3-D locations of matching pairs of undistorted image points from two stereo images.

`worldPoints = triangulate(matchedPoints1,matchedPoints2,camProjection1, camProjection2)` returns the 3-D locations of the matching pairs in a world coordinate system. These locations are defined by camera projection matrices.

`[worldPoints,reprojectionErrors] = triangulate( ___ )` additionally returns reprojection errors for the world points using any of the input arguments from previous syntaxes.

`[worldPoints,reprojectionErrors,validIndex] = triangulate( ___ )` additionally returns the indices of valid and invalid world points. Valid points are located in front of the cameras.

Examples

Measure Real-World Distances to Objects Using a Stereo-Camera

Estimate the real-world distance to a face in an image by applying triangulation techniques to stereo-camera data.

Load stereo parameters.

```
load('webcamsSceneReconstruction.mat');
```

Read in the stereo pair of images.

```
I1 = imread('sceneReconstructionLeft.jpg');
I2 = imread('sceneReconstructionRight.jpg');
```

Undistort the images.

```
I1 = undistortImage(I1,stereoParams.CameraParameters1);
I2 = undistortImage(I2,stereoParams.CameraParameters2);
```

Detect a face in both images.

```
faceDetector = vision.CascadeObjectDetector;
face1 = faceDetector(I1);
face2 = faceDetector(I2);
```

Find the center of the face.

```
center1 = face1(1:2) + face1(3:4)/2;
center2 = face2(1:2) + face2(3:4)/2;
```

Compute the distance from camera 1 to the face.

```
point3d = triangulate(center1, center2, stereoParams);
distanceInMeters = norm(point3d)/1000;
```

Display the detected face and distance.

```
distanceAsString = sprintf('%0.2f meters', distanceInMeters);
I1 = insertObjectAnnotation(I1,'rectangle',face1,distanceAsString,'FontSize',18);
I2 = insertObjectAnnotation(I2,'rectangle',face2, distanceAsString,'FontSize',18);
I1 = insertShape(I1,'filled-rectangle',face1);
I2 = insertShape(I2,'filled-rectangle',face2);

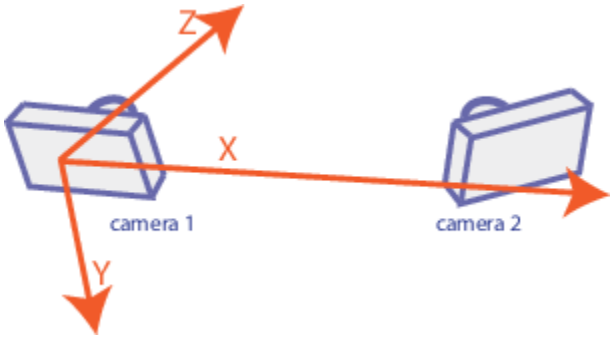
imshowpair(I1, I2, 'montage');
```

Input Arguments

`matchedPoints1` — Coordinates of corresponding points

M-by-2 matrix | point feature object

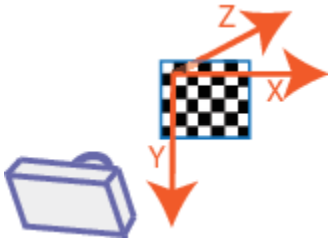
Coordinates of corresponding points in image one, specified as an *M*-by-2 matrix of *M* number of [*x* *y*] coordinates, or as one of the point feature objects described in “Point Feature Types”.



matchedPoints2 — Coordinates of corresponding points
M-by-2 matrix | point feature object

Coordinates of corresponding points in image one, specified as an *M*-by-2 matrix of *M* number of [*x* *y*] coordinates, or as one of the point feature objects described in “Point Feature Types”.

stereoParams — Camera parameters for stereo system
`stereoParameters` object

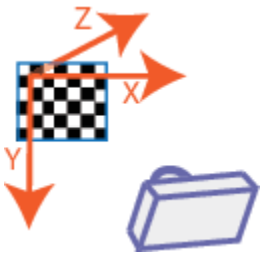


Camera parameters for stereo system, specified as a `stereoParameters` object. The object contains the intrinsic, extrinsic, and lens distortion parameters of the stereo camera system. You can use the `estimateCameraParameters` function to estimate camera parameters and return a `stereoParameters` object.

When you pass a `stereoParameters` object to the function, the origin of the world coordinate system is located at the optical center of camera 1. The *x*-axis points to the right, the *y*-axis points down, and the *z*-axis points away from the camera.

camProjection1 — Projection matrix for camera 1
3-by-4 matrix

Projection matrix for camera 1, specified as a 3-by-4 matrix. The matrix maps a 3-D point in homogeneous coordinates onto the corresponding point in the image from the camera. This input describes the location and orientation of camera 1 in the world coordinate system. `camProjection1` must be a real and nonsparse numeric matrix. You can obtain the camera matrix using the `cameraProjection` function.



Camera projection matrices, passed to the function, define the world coordinate system.

camProjection2 — Projection matrix for camera 2
3-by-4 matrix

Projection matrix for camera 2, specified as a 3-by-4 matrix. The matrix maps a 3-D point in homogeneous coordinates onto the corresponding point in the image from the camera. This input

describes the location and orientation of camera 2 in the world coordinate system. `camProjection2` must be a real and nonsparse numeric matrix. You can obtain the camera matrix using the `cameraProjection` function.

Camera projection matrices, passed to the function, define the world coordinate system.

Output Arguments

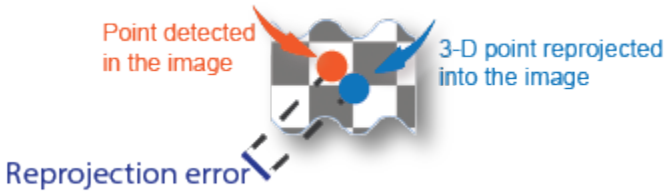
`worldPoints` — 3-D locations of matching pairs of undistorted image points

M-by-3 matrix

3-D locations of matching pairs of undistorted image points, returned as an *M*-by-3 matrix. The matrix contains *M* number of [*x y z*] locations of matching pairs of undistorted image points from two stereo images.

When you specify the camera geometry using `stereoParams`, the world point coordinates are relative to the optical center of camera 1.

When you specify the camera geometry using `camProjection1` and `camProjection2`, the world point coordinates are defined by the camera matrices.



The function returns `worldPoints` as data type `double` when `matchedPoints1` and `matchedPoints2` are of data type `double`. Otherwise, the function returns `worldPoints` as data type `single`.

Data Types: `single` | `double`

`reprojectionErrors` — Reprojection errors

M-by-1 vector

Reprojection errors, returned as an *M*-by-1 vector. The function projects each world point back into both images. Then, in each image, the function calculates the reprojection error as the distance between the detected and the reprojected point. The `reprojectionErrors` vector contains the average reprojection error for each world point.

`validIndex` — Validity of world points

M-by-1 logical vector

Validity of world points, returned as an *M*-by-1 logical vector. Valid points, denoted as a logical `1` (`true`), are located in front of the cameras. Invalid points, denoted as a logical `0` (`false`), are located behind the cameras.

The validity of a world point with respect to the position of a camera is determined by projecting the world point onto the image using the camera matrix and homogeneous coordinates. The world point is valid if the resulting scale factor is positive.

Tips

The `triangulate` function does not account for lens distortion. You can undistort the images using the `undistortImage` function before detecting the points. Alternatively, you can undistort the points themselves using the `undistortPoints` function.

Version History

Introduced in R2014b

R2022b: Supports premultiply geometric transformation convention

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, you can now specify the `camProjection1` and `camProjection2` arguments as 3-by-4 matrices calculated by the `cameraProjection` function, which uses the premultiply convention.

Although you can still specify `camProjection1` and `camProjection2` as 4-by-3 matrices calculated by the `cameraMatrix` function, this function is not recommended because it uses the postmultiply convention. You can streamline your geometric transformation workflows by switching to the premultiply geometric transformation convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

triangulateMultiview

3-D locations of world points matched across multiple images

Syntax

```
worldPoints = triangulateMultiview(pointTracks,cameraPoses,intrinsics)
[worldPoints,reprojectionErrors] = triangulateMultiview( ___ )
[worldPoints,reprojectionErrors,validIndex] = triangulateMultiview( ___ )
```

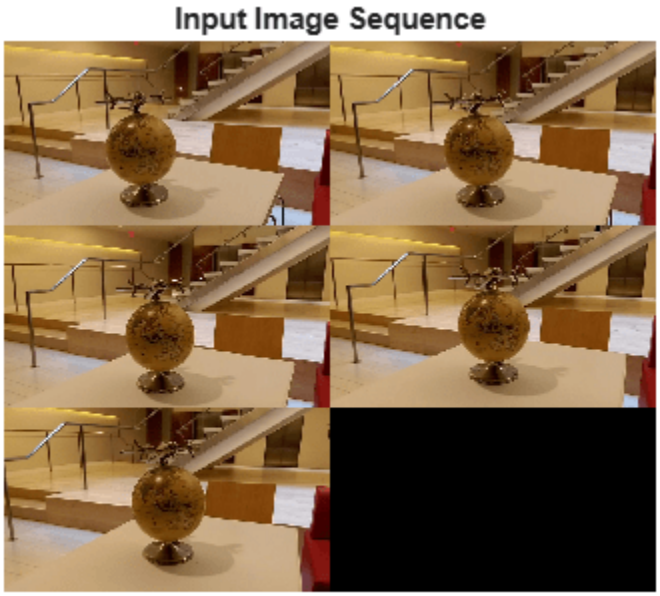
Description

`worldPoints = triangulateMultiview(pointTracks,cameraPoses,intrinsics)` returns the locations of 3-D world points that correspond to points matched across multiple images taken with calibrated cameras. `pointTracks` specifies an array of matched points. `cameraPoses` and `intrinsics` specify camera pose information and intrinsics, respectively. The function does not account for lens distortion.

`[worldPoints,reprojectionErrors] = triangulateMultiview( ___ )` additionally returns the mean reprojection error for each 3-D world point using all input arguments in the prior syntax.

`[worldPoints,reprojectionErrors,validIndex] = triangulateMultiview( ___ )` additionally returns the indices of valid and invalid world points. Valid points are located in front of the cameras.

Examples



Reconstruct Scene from Sequential Views

This example shows how to reconstruct 3-D structure from a sequence of images. To process non-sequential images, follow the steps in the “Structure from Motion from Multiple Views” example.

Read and display the image sequence.

```
% Use imageDatastore to get a list of all image file names in a directory
imageDir = fullfile(toolboxdir("vision"), "visiondata",  "structureFromMotion");
imds = imageDatastore(imageDir);

% Display the images
figure
montage(imds.Files);
title("Input Image Sequence");
```

```
% Load camera intrinsics
data = load(fullfile(imageDir, "cameraParams.mat"));
intrinsics = data.cameraParams.Intrinsics;

% Undistort the images.
images = cell(1, numel(imds.Files));
for viewId = 1:numel(imds.Files)
    images{viewId} = undistortImage(readimage(imds, viewId), intrinsics);
end

% Convert the image to grayscale.
I = im2gray(images{1});

% Detect SIFT features. Use an ROI to eliminate spurious
% features around the edges of the image.
border = 50;
roi = [border, border, size(I, 2)- 2*border, size(I, 1)- 2*border];
prevPoints   = detectSIFTFeatures(I, ROI=roi);

% Extract features. Using 'Upright' features improves matching, as long as
% the camera motion involves little or no in-plane rotation.
[prevFeatures, prevPoints] = extractFeatures(I, prevPoints);

% Create an empty imageviewset object to manage the data associated with each
% view.
vSet = imageviewset;

% Add the first view. Place the camera associated with the first view
% and the origin, oriented along the Z-axis.
viewId = 1;
pose1  = rigidtform3d;
vSet = addView(vSet, viewId, pose1, Points=prevPoints, Features=prevFeatures);
```

```
% Process the rest of the views
for viewId = 2:numel(images)
    % Convert the image to grayscale.
    I = im2gray(images{viewId});

    % Detect, extract and match features.
    currPoints   = detectSIFTFeatures(I, ROI=roi);
    [currFeatures, currPoints] = extractFeatures(I, currPoints);

    % Match features between the previous and current image.
    indexPairs = matchFeatures(prevFeatures, currFeatures, MatchThreshold=20, MaxRatio=0.2, Uniqu

    if viewId == 2
        % Select matched points
        matchedPoints1 = prevPoints(indexPairs(:, 1));
        matchedPoints2 = currPoints(indexPairs(:, 2));

        % Estimate the camera pose of current view relative to the previous view.
        % The pose is computed up to scale, meaning that the distance between
        % the cameras in the previous view and the current view is set to 1.
        [currPose, inlierIndex] = helperEstimateRelativePose(...
            matchedPoints1, matchedPoints2, intrinsics);

        indexPairs = indexPairs(inlierIndex, :);
    else
        % Triangulate points from the previous two views, and find the
        % corresponding points in the current view.
        [worldPoints, imagePoints] = helperFind3Dto2DCorrespondences(vSet, ...
            intrinsics, indexPairs, currPoints);

        % Estimate the world camera pose for the current view.
        currPose = estworldpose(imagePoints, worldPoints, intrinsics, MaxReprojectionError=3);
    end

    % Add the current view to the view set.
    vSet = addView(vSet, viewId, currPose, Points=currPoints, Features=currFeatures);

    % Store the point matches between the previous and the current views.
    vSet = addConnection(vSet, viewId-1, viewId, Matches=indexPairs);

    % Find point tracks across all views.
    tracks = findTracks(vSet);

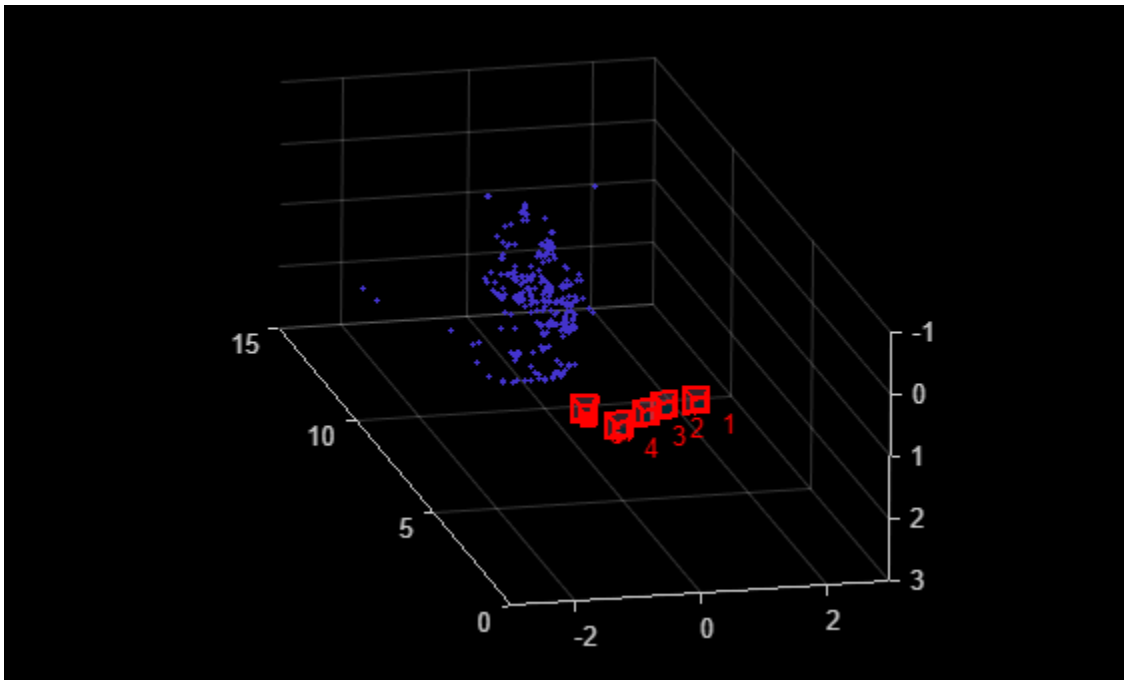
    % Get the table containing camera poses for all views.
    camPoses = poses(vSet);

    % Triangulate initial locations for the 3-D world points.
    xyzPoints = triangulateMultiview(tracks, camPoses, intrinsics);

    % Refine the 3-D world points and camera poses.
    [xyzPoints, camPoses, reprojectionErrors] = bundleAdjustment(xyzPoints, ...
        tracks, camPoses, intrinsics, FixedViewId=1, ...
        PointsUndistorted=true, AbsoluteTolerance=1e-6);

    % Store the refined camera poses.
    vSet = updateView(vSet, camPoses);
```

```
    prevFeatures = currFeatures;
end
```



Display the camera poses and 3-D world points.

```
% Display camera poses
figure;
plotCamera(camPoses, Size=0.2);
hold on

% Exclude noisy 3-D points
goodIdx = reprojectionErrors < 5;

% Display the dense 3-D world points
pcshow(xyzPoints(goodIdx, :), VerticalAxis="y", VerticalAxisDir="down", MarkerSize=40);
grid on
hold off

% Specify the viewing volume
loc1 = camPoses.AbsolutePose(1).Translation;
xlim([loc1(1)-3, loc1(1)+3]);
ylim([loc1(2)-1, loc1(2)+3]);
zlim([loc1(3), loc1(3)+15]);
camorbit(0, -30);
```

Input Arguments

`pointTracks` — Matched points across multiple images

N-element array of `pointTrack` objects

Matched points across multiple images, specified as an *N*-element array of `pointTrack` objects. Each element contains two or more points that match across multiple images.

`cameraPoses` — Camera pose information

two-column table

Camera pose information, specified as a two-column table. You can obtain `cameraPoses` from an `imageviewset` object by using the `poses` object function.

Column	Description
`ViewID`	View identifier in the `pointTrack` object, specified as an integer.
`AbsolutePose`	Absolute pose of the view, specified as a `rigidtform3d` object.

`intrinsics` — Camera intrinsics

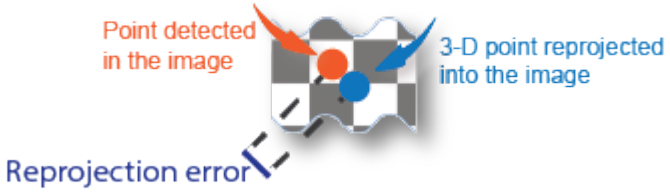
`cameraIntrinsics` object | *M*-element vector of `cameraIntrinsics` objects

Camera intrinsics, specified as a `cameraIntrinsics` object or an *M*-element vector of `cameraIntrinsics` objects. *M* is the number of camera poses. When all images are captured by the same camera, specify one `cameraIntrinsics` object. When images are captured by different cameras, specify a vector.

Output Arguments

`worldPoints` — 3-D world points

N-by-3 matrix



3-D world points, returned as an *N*-by-3 matrix. Each row represents one 3-D world point and is of the form [*x*, *y*, *z*]. *N* is the number of 3-D world points.

Data Types: `single` | `double`

`reprojectionErrors` — Reprojection errors

N-element vector

Reprojection errors, returned as an *N*-element vector. To calculate reprojection errors, first the function projects each world point back into each image. Then, in each image, the function calculates the distance between the detected and the reprojected point. Each element of the `reprojectionErrors` output is the average reprojection error for the corresponding world point in the `worldPoints` output.

`validIndex` — Validity of world points

M-by-1 logical vector

Validity of world points, returned as an *M*-by-1 logical vector. Valid points, denoted as a logical `1` (`true`), are located in front of the cameras. Invalid points, denoted as logical `0` (`false`), are located behind the cameras.

The validity of a world point with respect to the position of a camera is determined by projecting the world point onto the image using the camera matrix and homogeneous coordinates. The world point is valid if the resulting scale factor is positive.

Tips

Before detecting the points, correct the images for lens distortion by using by using the `undistortImage` function. Alternatively, you can directly undistort the points by using the `undistortPoints` function.

Version History

Introduced in R2016a

R2022b: Supports premultiply geometric transformation convention
Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, you can now specify the `AbsolutePose` field of the `cameraPoses` argument as a `rigidtform3d` object, which uses the premultiply convention. You can continue to estimate the camera poses using the `poses` object function of the `imageviewset` object, which has been updated to support the premultiply convention.

Although you can still specify `AbsolutePose` as a `rigid3d` object, this object is not recommended because it uses the postmultiply convention. You can streamline your geometric transformation workflows by switching to the premultiply geometric transformation convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

You can no longer specify `cameraPoses` as a three-column table with fields `ViewID`, `Orientation`, and `Location`. This table format is not supported because there is not enough information to determine whether the 3-by-3 rotation matrix in the `Orientation` field is intended for the premultiply or postmultiply convention.

trvec

Extract translation vector

Syntax

```
translationVector = trvec(transformation)
```

Description

`translationVector = trvec(transformation)` extracts the translation vector `translationVector` of the SE(3) transformation `transformation`.

Input Arguments

`transformation` — Transformation

`se3` object | *N*-element array of transformation objects

Transformation, specified as a scalar `se3` object or an *N*-element array of transformation objects. *N* is the total number of transformations.

If you specify `transformation` as an array, each element must be of the same type.

Output Arguments

`translationVector` — Translation vector

N-by-2 matrix | *N*-by-3 matrix

Translation vector, returned as an *N*-by-2 matrix for `se2` objects or an *N*-by-3 matrix for `se3` objects. *N* is the total number of transformations or rotations, and each row is a translation vector in the form [*X Y*] for 2-D transformations or [*X Y Z*] for 3-D transformations.

Extended Capabilities

undistortImage

Correct image for lens distortion

Syntax

```
[J,camIntrinsics] = undistortImage(I,intrinsics)
[J,camIntrinsics] = undistortImage(I,intrinsics,interp)
[J,camIntrinsics] = undistortImage( ___ ,Name=Value)
```

Description

`[J,camIntrinsics] = undistortImage(I,intrinsics)` removes the lens distortion in the input image `I` using the camera parameters defined in `intrinsics`. The function returns the corrected image `J` and the undistorted camera intrinsic parameters, `camIntrinsics`.

`[J,camIntrinsics] = undistortImage(I,intrinsics,interp)` specifies the interpolation method for the function to use on the input image.

`[J,camIntrinsics] = undistortImage( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `(FillValues=[0 0.4470 0.7410])` sets the output pixel values that are outside the input image boundaries to a blue color.

Examples

Correct Image for Lens Distortion

Create a set of calibration images.

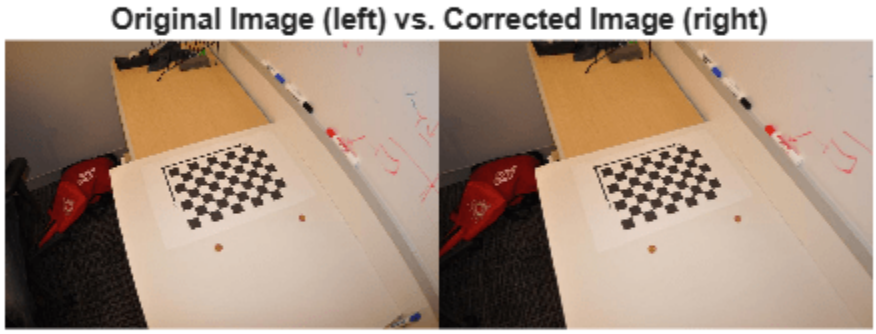
```
images = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
    "calibration","mono"));
```

Detect calibration pattern.

```
[imagePoints,patternDims] = detectCheckerboardPoints(images.Files);
```

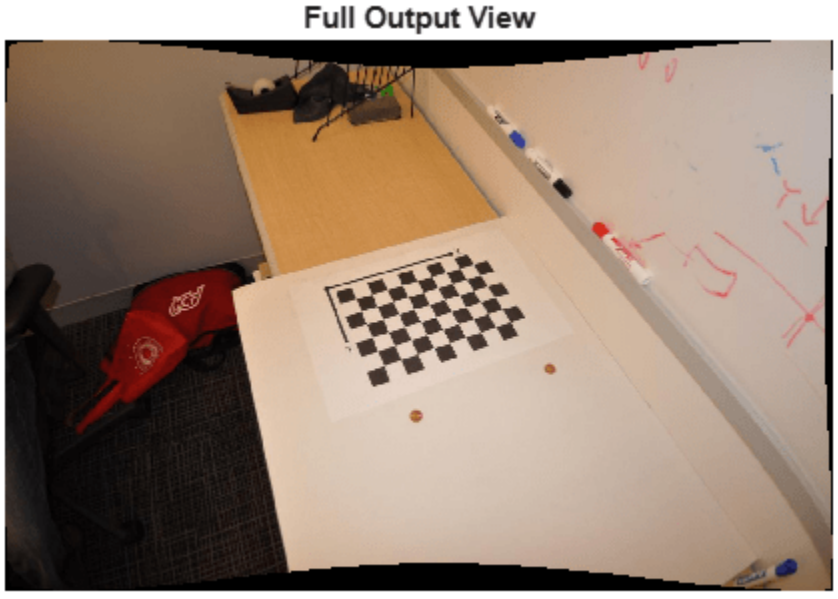
Generate world coordinates of the corners of the squares. The square size is in millimeters.

```
squareSize = 29; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```



Calibrate the camera.

```
I = readimage(images,1);
imageSize = size(I,1:2);
cameraParams = estimateCameraParameters(imagePoints,worldPoints,ImageSize=imageSize);
```



Remove lens distortion and display results.

```
I = images.readimage(1);
J1 = undistortImage(I,cameraParams);
```

```
figure;
imshowpair(I,J1,"montage");
title("Original Image (left) vs. Corrected Image (right)");
```

```
J2 = undistortImage(I,cameraParams,OutputView="full");
figure;
imshow(J2);
title("Full Output View");
```

Undistort Checkerboard Points

Create an imageDatastore object containing calibration images.

```
images = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
   "calibration","mono"));
imageFileNames = images.Files;
```

Detect the calibration pattern.

```
[imagePoints,patternDims] = detectCheckerboardPoints(imageFileNames);
```

Generate world coordinates of the corners of the squares. The square size is in millimeters.

```
squareSize = 29; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Calibrate the camera.

```
I = readimage(images,10);
imageSize = [size(I, 1), size(I, 2)];
params = estimateCameraParameters(imagePoints,worldPoints,ImageSize=imageSize);
intrinsics = params.Intrinsics;
```

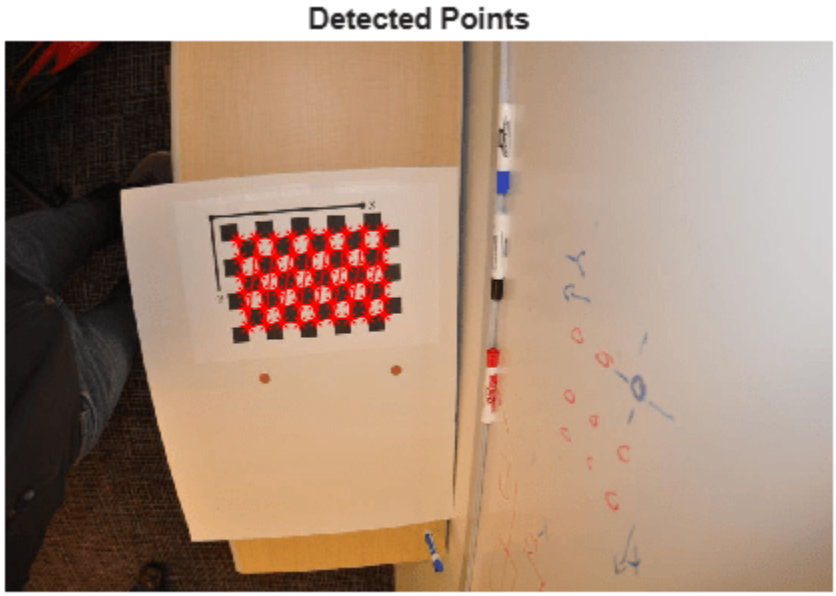
Load an image and detect the checkerboard points.

```
points = detectCheckerboardPoints(I);
```

Undistort the points

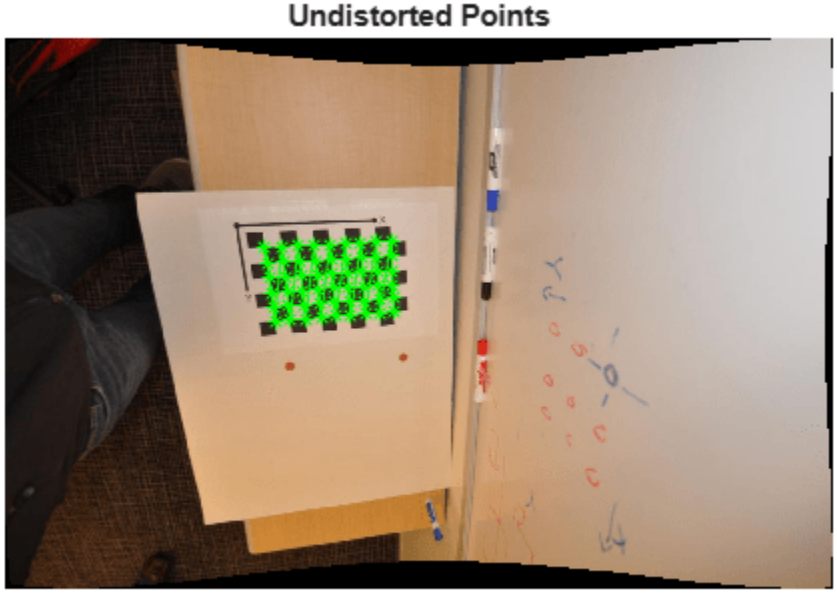
```
undistortedPoints = undistortPoints(points,intrinsics);
```

Undistort the image.



```
[J, newIntrinsics] = undistortImage(I,intrinsics,OutputView="full");
```

Translate undistorted points



```
newOrigin = intrinsics.PrincipalPoint - newIntrinsics.PrincipalPoint;
undistortedPoints = [undistortedPoints(:,1) - newOrigin(1), ...
                     undistortedPoints(:,2) - newOrigin(2)];
```

Display the results

```
figure;
imshow(I);
hold on;
plot(points(:,1),points(:,2),"r*-");
title("Detected Points");
hold off;
```

```
figure;
imshow(J);
hold on;
plot(undistortedPoints(:,1),undistortedPoints(:,2),"g*-");
title("Undistorted Points");
hold off;
```

Input Arguments

`I` — Input image

M-by-*N*-by-3 truecolor image | *M*-by-*N* 2-D grayscale image

Input image, specified in either *M*-by-*N*-by-3 truecolor or *M*-by-*N* 2-D grayscale. The input image must be real and nonsparse.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

`intrinsics` — Camera intrinsic parameters

`cameraParameters` object | `cameraIntrinsics` object | `cameraIntrinsicsKB` object

Camera intrinsic parameters, specified as a `cameraParameters`, `cameraIntrinsics`, `cameraIntrinsicsKB` object.

`interp` — Interpolation method

`"linear"` (default) | `"nearest"` | `"cubic"`

Interpolation method to use on the input image, specified as `"linear"`, `"nearest"` , or `"cubic"`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

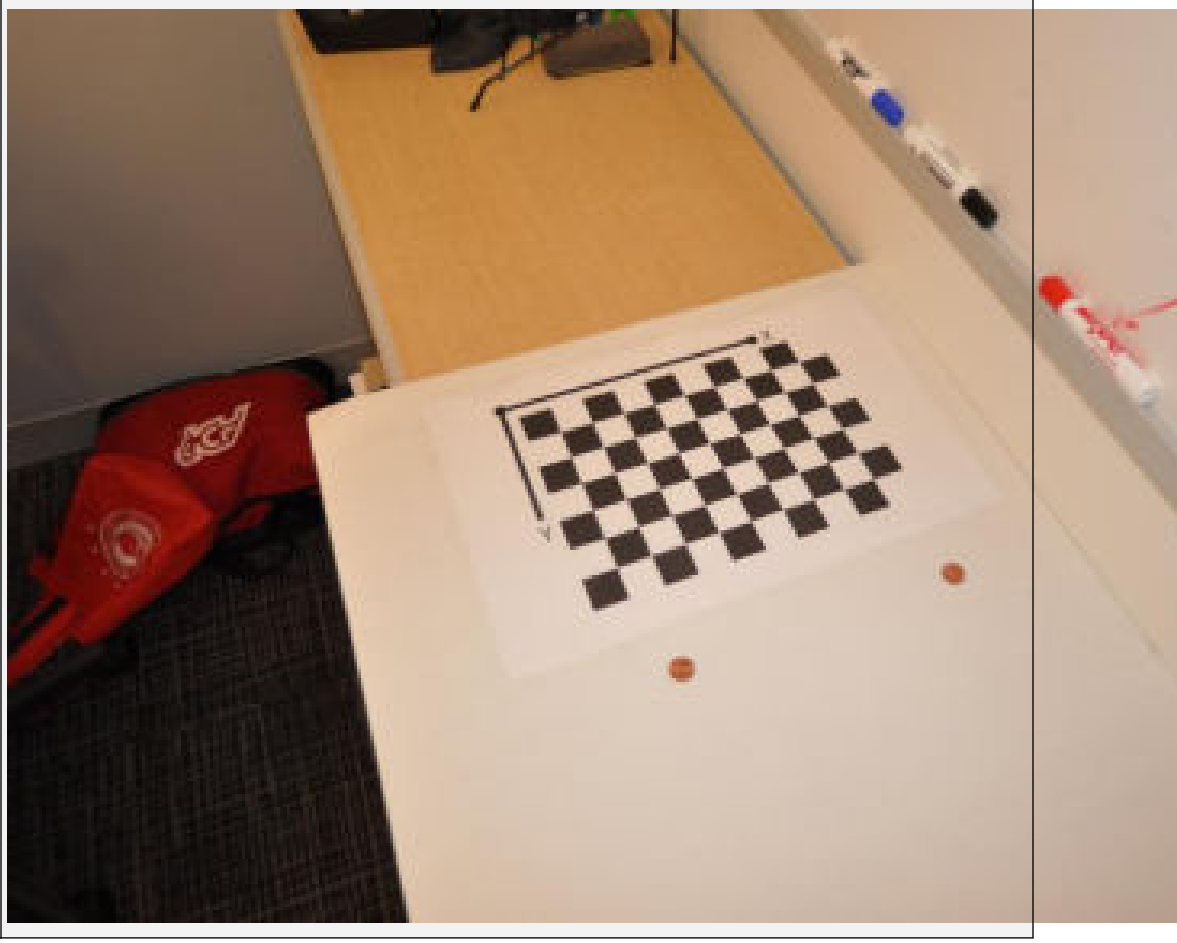
Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `(FillValues=[0 0.4470 0.7410])` sets the output pixel values that are outside the input image boundaries to a blue color.

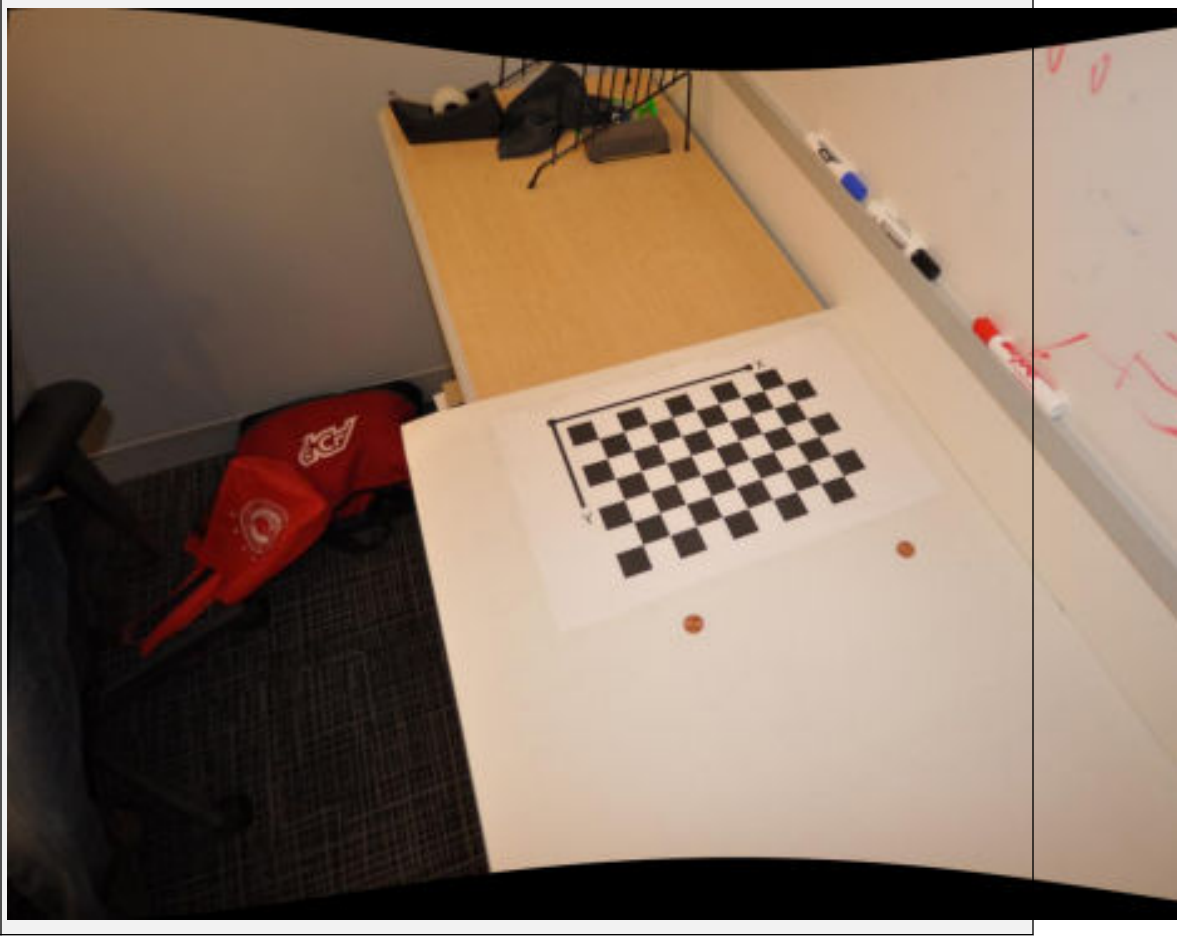
`FillValues` — Output pixel fill values

`0` (default) | scalar | 3-element vector

Output pixel fill values, specified as an array containing one or more fill values. When the corresponding inverse transformed location in the input image lies completely outside the input image boundaries, you use the fill values for output pixels. When you use a 2-D grayscale input image, you must set the `FillValues` to scalar. When you use a truecolor, `FillValues` can be a scalar or a 3-element vector of RGB values.



`OutputView` — Size of output image



`"same"` (default) | `"full"` | `"valid"`

Size of output image, specified as `"same"`, `"full"`, or `"valid"`. When you set the property to `"same"`, the function sets the output image to match the size of the input image. When you set the property to `"full"`, the output includes all pixels from the input image. When you set the property to `"valid"`, the function crops the output image to contain only valid pixels.

For the input image:

OutputView	Output Image
`"same"`	Match the size of the input image. 

OutputView	Output Image
`"full"`	All pixels from the input image. 

OutputView	Output Image
`"valid"`	Only valid pixels from the input image. 

Output Arguments

`J` — Undistorted image

M-by-*N*-by-3 truecolor image | *M*-by-*N* 2-D grayscale image

Undistorted image, returned in either *M*-by-*N*-by-3 truecolor or *M*-by-*N* 2-D grayscale.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

`camIntrinsics` — Camera intrinsic parameters

`cameraIntrinsics` object

Camera intrinsic parameters, returned as a `cameraIntrinsics` object. The object contains the intrinsic parameters and lens distortion coefficients for the camera, which are used to produce an output image with lens distortion removed.

It is recommended to use the `camIntrinsics` output in any photogrammetry application that uses the undistorted image `J`, such as stereo camera calibration, multi-camera calibration, lidar-camera calibration, triangulation, and similar tasks.

Version History

Introduced in R2014a

R2024a: Returns camera intrinsic parameters object
Behavior changed in R2024a

This release replaces the second optional output argument. The function now returns a `cameraIntrinsics` object in the second argument. Prior to this release, the function returned a 2-element vector `newOrigin`. You can still calculate the new origin by subtracting the output intrinsics principal point from the intrinsics input principal point using this code:

```
newOrigin = intrinsics.PrincipalPoint - newIntrinsics.PrincipalPoint
```

R2024a: Added support for the `cameraIntrinsicsKB` object

Support added for the `cameraIntrinsicsKB` object as the `intrinsics` input.

R2025a: Generate CUDA code using GPU Coder

The `undistortImage` function now supports the generation of CUDA code (requires GPU Coder).

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use in a MATLAB Function block is not supported.
- `'interp'` and `'OutputView'` must be compile-time constants.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

undistortPoints

Correct point coordinates for lens distortion

Syntax

```
undistortedPoints = undistortPoints(points,cameraParams)
[undistortedPoints,reprojectionErrors] = undistortPoints(points,cameraParams)
```

Description

`undistortedPoints = undistortPoints(points,cameraParams)` returns point coordinates corrected for lens distortion. This function uses numeric nonlinear least-squares optimization.

`[undistortedPoints,reprojectionErrors] = undistortPoints(points,cameraParams)` additionally returns the errors used to evaluate the accuracy of undistorted points.

Examples

Undistort Checkerboard Points

Create an imageDatastore object containing calibration images.

```
images = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
   "calibration","mono"));
imageFileNames = images.Files;
```

Detect the calibration pattern.

```
[imagePoints,patternDims] = detectCheckerboardPoints(imageFileNames);
```

Generate world coordinates of the corners of the squares. The square size is in millimeters.

```
squareSize = 29; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Calibrate the camera.

```
I = readimage(images,10);
imageSize = [size(I, 1), size(I, 2)];
params = estimateCameraParameters(imagePoints,worldPoints,ImageSize=imageSize);
intrinsics = params.Intrinsics;
```

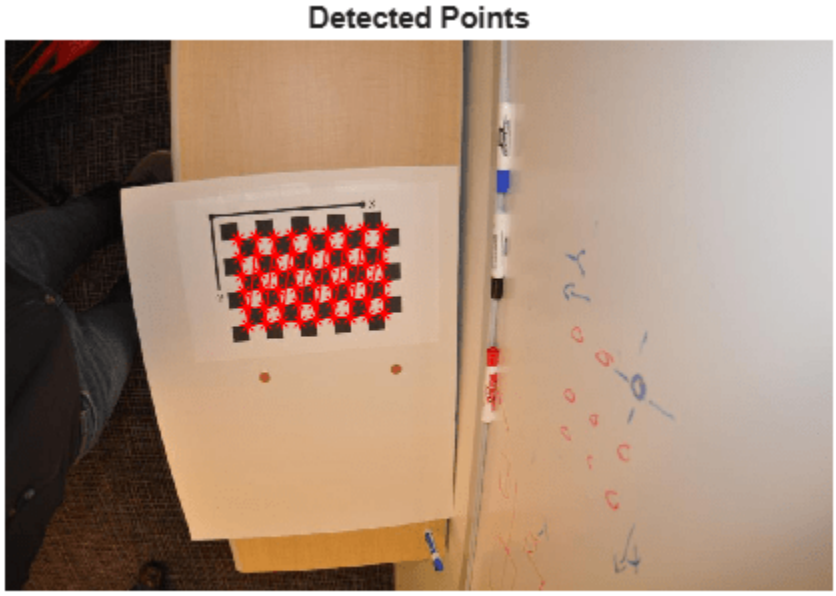
Load an image and detect the checkerboard points.

```
points = detectCheckerboardPoints(I);
```

Undistort the points

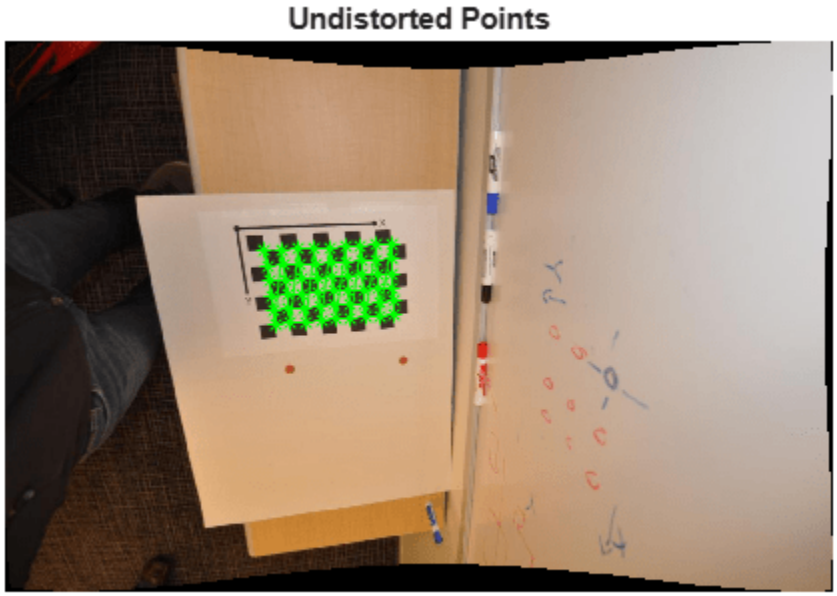
```
undistortedPoints = undistortPoints(points,intrinsics);
```

Undistort the image.



```
[J, newIntrinsics] = undistortImage(I,intrinsics,OutputView="full");
```

Translate undistorted points



```
newOrigin = intrinsics.PrincipalPoint - newIntrinsics.PrincipalPoint;
undistortedPoints = [undistortedPoints(:,1) - newOrigin(1), ...
                     undistortedPoints(:,2) - newOrigin(2)];
```

Display the results

```
figure;
imshow(I);
hold on;
plot(points(:,1),points(:,2),"r*-");
title("Detected Points");
hold off;
```

```
figure;
imshow(J);
hold on;
plot(undistortedPoints(:,1),undistortedPoints(:,2),"g*-");
title("Undistorted Points");
hold off;
```

Input Arguments

`points` — Input points

M-by-2 matrix

Input points, specified an *M*-by-2 matrix of *M* number of [x y] coordinates.

`cameraParams` — Object for storing camera parameters

`cameraParameters` object | `cameraIntrinsics` object | `cameraIntrinsicsKB` object

Camera parameters, specified as a `cameraParameters`, `cameraIntrinsics`, or a `cameraIntrinsicsKB` object. You can return the `cameraParameters` object using the `estimateCameraParameters` function. The `cameraParameters` object contains the intrinsic, extrinsic, and lens distortion parameters of a camera.

Output Arguments

`undistortedPoints` — Undistorted points

M-by-2 matrix

Undistorted points, returned as an *M*-by-2 matrix. The `undistortedPoints` output contains *M* [*x*,*y*] point coordinates corrected for lens distortion. When you input points as `double`, the function outputs `undistortedPoints` as `double`. Otherwise, it outputs `undistortedPoints` as single.

Data Types: `single` | `double`

`reprojectionErrors` — Reprojection errors

M-by-1 vector

Reprojection errors, returned as an *M*-by-1 vector. You can use the errors to evaluate the accuracy of undistorted points. The function computes the errors by applying distortion to the undistorted points,

and then taking the distances between the result and the corresponding input points. The `reprojectionErrors` output is in pixels.

Version History

Introduced in R2014b

R2024a: Added support for the `cameraIntrinsicsKB` object

Support added for the `cameraIntrinsicsKB` object as the `cameraParams` input.

R2026a: Code generation support for `cameraIntrinsicsKB` object input

Starting in R2026a, you can use a `cameraIntrinsicsKB` object as input when generating code for the `undistortPoints` function.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

visionlib

Open top-level Computer Vision Toolbox Simulink library

Syntax

```
visionlib
```

Description

`visionlib` opens the top-level Computer Vision Toolbox block library.

Examples

Open Computer Vision Toolbox Block Library

View and gain access to the Computer Vision Toolbox blocks.

```
visionlib
```

Alternatives

To view and gain access to the Computer Vision Toolbox blocks using the Simulink library browser:

- Type `simulink` at the MATLAB command line, and then expand the Computer Vision Toolbox node in the library browser.
- Click the Simulink icon  from the MATLAB desktop or from a model.

Version History

Introduced in R2011a

visionSupportPackages

Start Installer to download, install, or uninstall Computer Vision Toolbox data

Syntax

```
visionSupportPackages
```

Description

`visionSupportPackages` launches the Support Package Installer, which you can use to download, install, or uninstall support packages for Computer Vision Toolbox.

Computer Vision Toolbox Support Packages
“Install OCR Language Data Files”
“Install and Use Computer Vision Toolbox Interface for OpenCV in MATLAB”

Examples

Start Computer Vision Toolbox installer

```

ocvStructToKeyPoints

Convert MATLAB feature points struct to OpenCV `KeyPoint` vector

C++ Syntax

```
#include "opencvmex.hpp"
void ocvStructToKeyPoints(const mxArray * in,cv::vector<cv::KeyPoint>
&keypoints);
```

Arguments

`in`

Pointer to a MATLAB structure, `mxArray`, that represents a point feature. Format:

Field Name	Field Requirement	Field Data Type
`Location`	Required	Single
`Scale`	Required	Single
`Metric`	Required	Single
`Orientation`	Optional	Single
`Octave`	Optional	int32
`Misc`	Optional	int32

Description

The `ocvStructToKeyPoints` function converts a point feature data structure from a MATLAB struct to an OpenCV's KeyPoint vector.

See Also

`mxArray`, `ocvKeyPointsToStruct`, “C Matrix API”, “Write C Functions Callable from MATLAB (MEX Files)”

Version History

Introduced in R2015a

ocvMxGpuArrayToGpuMat_{DataType}

Create `cv::gpu::GpuMat` from `mxArray` containing GPU data.

C++ Syntax

Note This function will be removed in a future release.

```
#include "opencvgpumex.hpp"
cv::Ptr<cv::gpu::GpuMat> ocvMxGpuArrayToGpuMat_double(const mxArray * in);
cv::Ptr<cv::gpu::GpuMat> ocvMxGpuArrayToGpuMat_single(const mxArray * in);
cv::Ptr<cv::gpu::GpuMat> ocvMxGpuArrayToGpuMat_uint8(const mxArray * in);
cv::Ptr<cv::gpu::GpuMat> ocvMxGpuArrayToGpuMat_uint16(const mxArray * in);
cv::Ptr<cv::gpu::GpuMat> ocvMxGpuArrayToGpuMat_uint32(const mxArray * in);
cv::Ptr<cv::gpu::GpuMat> ocvMxGpuArrayToGpuMat_int8(const mxArray * in);
cv::Ptr<cv::gpu::GpuMat> ocvMxGpuArrayToGpuMat_int16(const mxArray * in);
cv::Ptr<cv::gpu::GpuMat> ocvMxGpuArrayToGpuMat_int32(const mxArray * in);
cv::Ptr<cv::gpu::GpuMat> ocvMxGpuArrayToGpuMat_bool(const mxArray * in);
```

Arguments

`in`

Pointer to a MATLAB struct, `mxArray`, containing GPU data. Supported data types:

`real_T` (`double`)	`real32_T` (`single`)	`uint8_T` (`uint8`)
`uint16_T` (`uint16`)	`uint32_T` (`uint32`)	`int8_T` (`int8`)
`int16_T` (`int16`)	`int32_T` (`int32`)	`boolean_T` (`bool`)

Returns

OpenCV smart pointer (`cv::Ptr`) to a `cv::gpu::GpuMat` object.

Description

The `ocvMxGpuArrayToGpuMat_{DataType}` function creates a `cv::gpu::GpuMat` object from an `mxArray` containing GPU data. This function requires the Parallel Computing Toolbox software.

See Also

`mxArray`, `ocvMxGpuArrayFromGpuMat_{DataType}`, “C Matrix API”, “Write C Functions Callable from MATLAB (MEX Files)”

Version History

Introduced in R2015a

ocvMxGpuArrayFromGpuMat_{DataType}

Create an `mxArray` from `cv::gpu::GpuMat` object

C++ Syntax

Note This function will be removed in a future release.

```
#include "opencvgpumex.hpp"
mxArray * ocvMxGpuArrayFromGpuMat_double(const cv::gpu::GpuMat & in);
mxArray * ocvMxGpuArrayFromGpuMat_single(const cv::gpu::GpuMat & in);
mxArray * ocvMxGpuArrayFromGpuMat_uint8(const cv::gpu::GpuMat & in);
mxArray * ocvMxGpuArrayFromGpuMat_uint16(const cv::gpu::GpuMat & in);
mxArray * ocvMxGpuArrayFromGpuMat_uint32(const cv::gpu::GpuMat & in);
mxArray * ocvMxGpuArrayFromGpuMat_int8(const cv::gpu::GpuMat & in);
mxArray * ocvMxGpuArrayFromGpuMat_int16(const cv::gpu::GpuMat & in);
mxArray * ocvMxGpuArrayFromGpuMat_int32(const cv::gpu::GpuMat & in);
mxArray * ocvMxGpuArrayFromGpuMat_bool(const cv::gpu::GpuMat & in)
```

Arguments

`in`

Reference to OpenCV `cv::gpu::GpuMat` object.

Returns

Pointer to a MATLAB struct, `mxArray`, containing GPU data. Supported data types:

`real_T` (`double`)	`real32_T` (`single`)	`uint8_T` (`uint8`)
`uint16_T` (`uint16`)	`uint32_T` (`uint32`)	`int8_T` (`int8`)
`int16_T` (`int16`)	`int32_T` (`int32`)	`boolean_T` (`bool`)

Description

The `ocvMxGpuArrayFromGpuMat` function creates an `mxArray` from a `cv::gpu::GpuMat` object. `GpuMat` supports 2-D arrays only. This function requires the Parallel Computing Toolbox software.

See Also

`mxArray`, `ocvMxGpuArrayToGpuMat_{DataType}`, “C Matrix API”, “Write C Functions Callable from MATLAB (MEX Files)”

Version History

Introduced in R2015a

ocvMxArrayToSize_{DataType}

Convert 2-element `mxArray` to `cv::Size`.

C++ Syntax

```
#include "opencvmex.hpp"
cv::Size ocvMxArrayToSize_single(const mxArray * in, bool rcInput = true);
cv::Size ocvMxArrayToSize_int32(const mxArray * in, bool rcInput = true);
```

Arguments

`in`

Pointer to a MATLAB `mxArray` having 2 elements. Supported data types:

`single`
`int32`

`rcInput`

Boolean flag that indicates if input `mxArray` is of the format [*r c*] or [*x y*].

rcInput	**in**
`true` (default)	[*r c*] (*height, width*)
`false`	[*x y*] (*width, height*)

Returns

OpenCV `cv::Size`

Description

The `ocvMxArrayToSize_{DataType}` function converts a 2-element `mxArray` to `cv::Size`. Empty input (`[]`) returns `cv::Size(0,0)`;

See Also

`mxArray`, “C Matrix API”, “Write C Functions Callable from MATLAB (MEX Files)”

Version History

Introduced in R2015a

ocvMxArrayToMat_{DataType}

Convert column major `mxArray` to row major `cv::Mat` for generic matrix

C++ Syntax

```
#include "opencvmex.hpp"
void ocvMxArrayToMat_double(const mxArray *in, cv::Mat &out);
void ocvMxArrayToMat_single(const mxArray *in, cv::Mat &out);
void ocvMxArrayToMat_uint8(const mxArray *in, cv::Mat &out);
void ocvMxArrayToMat_uint16(const mxArray *in, cv::Mat &out);
void ocvMxArrayToMat_uint32(const mxArray *in, cv::Mat &out);
void ocvMxArrayToMat_int8(const mxArray *in, cv::Mat &out);
void ocvMxArrayToMat_int16(const mxArray *in, cv::Mat &out);
void ocvMxArrayToMat_int32(const mxArray *in, cv::Mat &out);
void ocvMxArrayToMat_bool(const mxArray *in, cv::Mat &out);
cv::Ptr<cv::Mat> ocvMxArrayToMat_double(const mxArray *in, const bool
copyData = true);
cv::Ptr<cv::Mat> ocvMxArrayToMat_single(const mxArray *in, const bool
copyData = true);
cv::Ptr<cv::Mat> ocvMxArrayToMat_uint8(const mxArray *in, const bool copyData
= true);
cv::Ptr<cv::Mat> ocvMxArrayToMat_uint16(const mxArray *in, const bool
copyData = true);
cv::Ptr<cv::Mat> ocvMxArrayToMat_uint32(const mxArray *in, const bool
copyData = true);
cv::Ptr<cv::Mat> ocvMxArrayToMat_int8(const mxArray *in, const bool copyData
= true);
cv::Ptr<cv::Mat> ocvMxArrayToMat_int16(const mxArray *in, const bool copyData
= true);
cv::Ptr<cv::Mat> ocvMxArrayToMat_int32(const mxArray *in, const bool copyData
= true);
cv::Ptr<cv::Mat> ocvMxArrayToMat_uint8(const mxArray *in, const bool copyData
= true);
```

Arguments

`in`

Pointer to a MATLAB struct, `mxArray`, having column major data. The data can be *n*-channel matrices. Supported data types:

`real_T` (`double`)	`uint8_T` (`uint8`)	`uint32_T` (`uint32`)	`int16_T` (`int16`)
`real32_T` (`single`)	`uint16_T` (`uint16`)	`int8_T` (`int8`)	`int32_T` (`int32`)

`copyData`

Boolean flag to copy data from `mxArray` to the `Mat` object.

- `true` (default) — The function transposes and interleaves (for RGB images) column major `mxArray` data into a row major `cv::Mat` object.

- `false` — No data copies from the `mxArray` to the `Mat` object. The function creates a new `Mat` wrapper and uses it to point to the `mxArray` data. Because OpenCV is row-based and MATLAB is column-based, the columns of the `mxArray` become the rows of the `Mat` object. If the image is 2-D, then `copyData` is `false`.

`out`

Reference to OpenCV `cv::Mat` with row major data.

Returns

The functions that set `copyData` return an OpenCV smart pointer (`cv::Ptr`) to a `cv::Mat` object.

Description

The `ocvMxArrayToMat_{DataType}` function applies to two C++ implementations. One set returns `void` and the other set returns an OpenCV smart pointer. The functions that return `void` reallocate memory for the `cv::Mat` if needed.

The `ocvMxArrayToMat_{DataType}` transposes and interleaves column major `mxArray` data into row major `cv::Mat`. This matrix conversion is a generic routine for any number of channels.

`mxArray`, `ocvMxArrayToImage_{DataType}`, `ocvMxArrayFromMat_{DataType}`, “C Matrix API”, “Write C Functions Callable from MATLAB (MEX Files)”

Version History

Introduced in R2015a

ocvMxArrayToImage_{DataType}

Convert column major `mxArray` to row major `cv::Mat` for image

C++ Syntax

```
#include "opencvmex.hpp"
void ocvMxArrayToImage_double(const mxArray *in, cv::Mat &out);
void ocvMxArrayToImage_single(const mxArray *in, cv::Mat &out);
void ocvMxArrayToImage_uint8(const mxArray *in, cv::Mat &out);
void ocvMxArrayToImage_uint16(const mxArray *in, cv::Mat &out);
void ocvMxArrayToImage_uint32(const mxArray *in, cv::Mat &out);
void ocvMxArrayToImage_int8(const mxArray *in, cv::Mat &out);
void ocvMxArrayToImage_int16(const mxArray *in, cv::Mat &out);
void ocvMxArrayToImage_int32(const mxArray *in, cv::Mat &out);
void ocvMxArrayToImage_bool(const mxArray *in, cv::Mat &out);
cv::Ptr<cv::Mat> ocvMxArrayToImage_double(const mxArray *in, const bool
copyData = true);
cv::Ptr<cv::Mat> ocvMxArrayToImage_single(const mxArray *in, const bool
copyData = true);
cv::Ptr<cv::Mat> ocvMxArrayToImage_uint8(const mxArray *in, const bool
copyData = true);
cv::Ptr<cv::Mat> ocvMxArrayToImage_uint16(const mxArray *in, const bool
copyData = true);
cv::Ptr<cv::Mat> ocvMxArrayToImage_uint32(const mxArray *in, const bool
copyData = true);
cv::Ptr<cv::Mat> ocvMxArrayToImage_int8(const mxArray *in, const bool
copyData = true);
cv::Ptr<cv::Mat> ocvMxArrayToImage_int16(const mxArray *in, const bool
copyData = true);
cv::Ptr<cv::Mat> ocvMxArrayToImage_int32(const mxArray *in, const bool
copyData = true);
cv::Ptr<cv::Mat> ocvMxArrayToImage_bool(const mxArray *in, const bool
copyData = true);
```

Arguments

`in`

Pointer to a MATLAB struct, `mxArray`, having column major data that represents a 2-D or 3-D image. Supported data types:

`real_T` (`double`)	`uint8_T` (`uint8`)	`uint32_T` (`uint32`)	`int16_T` (`int16`)
`real32_T` (`single`)	`uint16_T` (`uint16`)	`int8_T` (`int8`)	`int32_T` (`int32`)

`copyData`

Boolean flag to copy data from `mxArray` to the `Mat` object.

- `true` (default) — The function transposes and interleaves (for RGB images) column major `mxArray` data into a row major `cv::Mat` object.

- `false` — No data copies from the `mxArray` to the `Mat` object. The function creates a new `Mat` wrapper and uses it to point to the `mxArray` data. Because OpenCV is row-based and MATLAB is column-based, the columns of the `mxArray` become the rows of the `Mat` object. If the image is 2-D, then `copyData` is `false`.

`out`

Reference to OpenCV `cv::Mat` with row major data.

Returns

The functions that set `copyData` return an OpenCV smart pointer (`cv::Ptr`) to a `cv::Mat` object.

Description

The `ocvMxArrayToImage_{DataType}` function applies to two C++ implementations. One set returns `void` and the other set returns an OpenCV smart pointer. The functions that return `void` reallocate memory for the `cv::Mat` if needed.

The `ocvMxArrayToImage_{DataType}` transposes and interleaves column major `mxArray` data into row major `cv::Mat`. The `ocvMxArrayToImage_{DataType}` function supports 2-D and 3-D images.

These functions are not a generic matrix conversion routine. For 3-D images, they take into account that the OpenCV format uses BGR ordering and manipulate the data to comply with that formatting.

Version History

Introduced in R2015a

ocvMxArrayToCvRect

Convert a MATLAB struct representing a rectangle to an OpenCV `CvRect`

C++ Syntax

```
#include "opencvmex.hpp"
CvRect ocvMxArrayToCvRect(const mxArray *in);
```

Arguments

`in`

Pointer to a MATLAB structure, `mxArray`, that represents a rectangle. The structure must have four scalar-valued fields: `x`, `y`, `width`, and `height`. The (`x`, `y`) fields represent the upper-left corner of the rectangle.

Returns

OpenCV `CvRect`.

Description

The `ocvMxArrayToCvRect` function converts a rectangle data structure from a MATLAB struct to an OpenCV KeyPoint vector.

See Also

`mxArray`, `ocvCvRectToMxArray`, “C Matrix API”, “Write C Functions Callable from MATLAB (MEX Files)”

Version History

Introduced in R2015a

ocvMxArrayFromVector_{DataType}

Convert numeric `vectorT` to `mxArray`

C++ Syntax

```
#include "opencvmex.hpp"
mxArray *ocvMxArrayFromVector_double(const std::vector<real_T> &v);
mxArray *ocvMxArrayFromVector_single(const std::vector<real32_T> &v);
mxArray *ocvMxArrayFromVector_uint8(const std::vector<uint8_T> &v);
mxArray *ocvMxArrayFromVector_uint16(const std::vector<uint16_T> &v);
mxArray *ocvMxArrayFromVector_uint32(const std::vector<uint32_T> &v);
mxArray *ocvMxArrayFromVector_int8(const std::vector<int8_T> &v);
mxArray *ocvMxArrayFromVector_int16(const std::vector<int16_T> &v);
mxArray *ocvMxArrayFromVector_int32(const std::vector<int32_T> &v);
mxArray *ocvMxArrayFromVector_bool(const std::vector<boolean_T> &v);
```

Arguments

v

Reference to `vector<DataType>`. Supported data types:

`real_T`	`real32_T`	`uint8_T`
`uint16_T`	`uint32_T`	`int8_T`
`int16_T`	`int32_T`	`boolean_T`

Returns

Pointer to a MATLAB struct `mxArray`.

Description

The `ocvMxArrayFromVector_{DataType}` function converts numeric `std::vector<DataType>` to an `mxArray`.

See Also

`mxArray`, “C Matrix API”, “Write C Functions Callable from MATLAB (MEX Files)”

Version History

Introduced in R2015a

ocvMxArrayFromPoints2f

Converts `vector<cv::Point2f>` to `mxArray`

C++ Syntax

```
#include "opencvmex.hpp"
mxArray *ocvMxArrayFromPoints2f(const std::vector<cv::Point2f> &points);
```

Arguments

`points`

Reference to OpenCV `vector<cv::Point2f>`.

Returns

Pointer to a MATLAB `mxArray`.

Description

The `ocvMxArrayFromPoints2f` function converts `std::vector<cv::Point2f>` to an `mxArray`.

See Also

“C Matrix API”, “Write C Functions Callable from MATLAB (MEX Files)”

Version History

Introduced in R2015a

ocvMxArrayFromMat_{DataType}

Convert row major `cv::Mat` to column major `mxArray` for generic matrix

C++ Syntax

```
#include "opencvmex.hpp"
mxArray *ocvMxArrayFromMat_double(const cv::Mat &in);
mxArray *ocvMxArrayFromMat_single(const cv::Mat &in);
mxArray *ocvMxArrayFromMat_uint8(const cv::Mat &in);
mxArray *ocvMxArrayFromMat_uint16(const cv::Mat &in);
mxArray *ocvMxArrayFromMat_uint32(const cv::Mat &in);
mxArray *ocvMxArrayFromMat_int8(const cv::Mat &in);
mxArray *ocvMxArrayFromMat_int16(const cv::Mat &in);
mxArray *ocvMxArrayFromMat_int32(const cv::Mat &in);
mxArray *ocvMxArrayFromMat_bool(const cv::Mat &in);
```

Arguments

`in`

Reference to OpenCV `cv::Mat` with row major data.

Returns

Pointer to a MATLAB struct, `mxArray`, having column major data. Supported data types:

`real_T` (`double`)	`uint8_T` (`uint8`)	`uint32_T` (`uint32`)	`int16_T` (`int16`)
`real32_T` (`single`)	`uint16_T` (`uint16`)	`int8_T` (`int8`)	`int32_T` (`int32`)

Description

The `ocvMxArrayFromMat_{DataType}` function creates an `mxArray` from a `cv::Mat` object. The `mxArray` contains column major data and `cv::Mat` contains row major data. This matrix conversion is a generic routine for any number of channels.

See Also

`mxArray`, `ocvMxArrayToImage_{DataType}`, `ocvMxArrayFromImage_{DataType}`, `ocvMxArrayToMat_{DataType}`, “C Matrix API”, “Write C Functions Callable from MATLAB (MEX Files)”

Version History

Introduced in R2015a

ocvMxArrayFromImage_{DataType}

Convert row major `cv::Mat` to column major `mxArray` for image

C++ Syntax

```
#include "opencvmex.hpp"
mxArray *ocvMxArrayFromImage_double(const cv::Mat &in);
mxArray *ocvMxArrayFromImage_single(const cv::Mat &in);
mxArray *ocvMxArrayFromImage_uint8(const cv::Mat &in);
mxArray *ocvMxArrayFromImage_uint16(const cv::Mat &in);
mxArray *ocvMxArrayFromImage_uint32(const cv::Mat &in);
mxArray *ocvMxArrayFromImage_int8(const cv::Mat &in);
mxArray *ocvMxArrayFromImage_int16(const cv::Mat &in);
mxArray *ocvMxArrayFromImage_int32(const cv::Mat &in);
mxArray *ocvMxArrayFromImage_bool(const cv::Mat &in);
```

Arguments

`in`

Reference to OpenCV `cv::Mat` with row major data.

Returns

Pointer to a MATLAB struct, `mxArray`, with column major data. Supported data types:

`real_T` (`double`)	`uint8_T` (`uint8`)	`uint32_T` (`uint32`)	`int16_T` (`int16`)
`real32_T` (`single`)	`uint16_T` (`uint16`)	`int8_T` (`int8`)	`int32_T` (`int32`)

Description

The `ocvMxArrayFromImage_{DataType}` function creates an `mxArray` from a `cv::Mat` object. The `mxArray` contains column major data and the `cv::Mat` contains row major data.

This function is not a generic matrix conversion routine. For 3-D images, it takes into account that the OpenCV format uses BGR ordering and manipulates the data to comply with that formatting.

`mxArray`, `ocvMxArrayToImage_{DataType}`, `ocvMxArrayFromMat_{DataType}`, “C Matrix API”, “Write C Functions Callable from MATLAB (MEX Files)”

Version History

Introduced in R2015a

ocvKeyPointsToStruct

Convert OpenCV `KeyPoint` vector to MATLAB struct

C++ Syntax

```
#include "opencvmex.hpp"
mxArray *ocvKeyPointsToStruct(cv::vector<cv::KeyPoint> &in);
```

Arguments

`in`

Reference to an OpenCV's KeyPoint vector.

Returns

Pointer to a MATLAB structure `mxArray` that represents a point feature.

Format:

Field Name	Field Requirement	Field Data Type
`Location`	Required	Single
`Scale`	Required	Single
`Metric`	Required	Single
`Orientation`	Optional	Single
`Octave`	Optional	int32
`Misc`	Optional	int32

Description

The `ocvKeyPointsToStruct` function converts a point feature data structure from an OpenCV KeyPoint vector to a MATLAB struct.

See Also

`mxArray`, `ocvStructToKeyPoints`, “C Matrix API”, “Write C Functions Callable from MATLAB (MEX Files)”

Version History

Introduced in R2015a

ocvCvRectToMxArray

Convert OpenCV `CvRect` to a MATLAB struct

C++ Syntax

```
#include "opencvmex.hpp"
mxArray *ocvCvRectToMxArray(const CvRect *in);
```

Arguments

`in`

Pointer to OpenCV `CvRect`.

Returns

Pointer to a MATLAB structure, `mxArray`, that represents a rectangle. The structure must have four scalar-valued fields, `x`, `y`, `width`, and `height`. The (`x`, `y`) fields represent the upper-left corner of the rectangle.

Description

The `ocvCvRectToMxArray` function converts a rectangle data structure from an OpenCV KeyPoint vector to a MATLAB struct.

`mxArray`, `ocvMxArrayToCvRect`, “C Matrix API”, “Write C Functions Callable from MATLAB (MEX Files)”

Version History

Introduced in R2015a

ocvCvRectToBoundingBox_{DataType}

Convert `vector<cv::Rect>` to *M*-by-4 `mxArray` of bounding boxes

C++ Syntax

```
#include "opencvmex.hpp"
mxArray * ocvCvRectToBoundingBox_double(const std::vector<cv::Rect> & rects);
mxArray * ocvCvRectToBoundingBox_single(const std::vector<cv::Rect> & rects);
mxArray * ocvCvRectToBoundingBox_uint8(const std::vector<cv::Rect> & rects);
mxArray * ocvCvRectToBoundingBox_uint16(const std::vector<cv::Rect> & rects);
mxArray * ocvCvRectToBoundingBox_uint32(const std::vector<cv::Rect> & rects);
mxArray * ocvCvRectToBoundingBox_int8(const std::vector<cv::Rect> & rects);
mxArray * ocvCvRectToBoundingBox_int16(const std::vector<cv::Rect> & rects);
mxArray * ocvCvRectToBoundingBox_int32(const std::vector<cv::Rect> & rects);
```

Arguments

`rects`

Reference to OpenCV `vector<cv::Rect>`.

Returns

Pointer to a MATLAB `mxArray` having *M*-by-4 elements. Supported data types:

`real_T` (`double`)	`uint8_T` (`uint8`)	`uint32_T` (`uint32`)	`int16_T` (`int16`)
`real32_T` (`single`)	`uint16_T` (`uint16`)	`int8_T` (`int8`)	`int32_T` (`int32`)

Description

The `ocvCvRectToBoundingBox_{DataType}` function converts `vector<cv::Rect>` to an *M*-by-4 `mxArray` of bounding boxes.

See Also

`mxArray`, `ocvCvBox2DToMxArray`, “C Matrix API”, “Write C Functions Callable from MATLAB (MEX Files)”

Version History

Introduced in R2015a

ocvCvBox2DToMxArray

Convert OpenCV `CvBox2D` to a MATLAB struct

C++ Syntax

```
#include "opencvmex.hpp"
mxArray *ocvCvBox2DToMxArray(const CvBox2D *in);
```

Arguments

`in`

Pointer to OpenCV `CvBox2D`.

Returns

Pointer to a MATLAB structure, `mxArray`, that represents a rectangle. The structure must have five scalar-valued fields: `x_center`, `y_center`, `width`, `height`, and `angle`. The (`x_center`, `y_center`) fields represent the center of the rectangle.

Description

The `ocvCvBox2DToMxArray` function converts a rectangle data structure from an OpenCV `CvBox2D` to a MATLAB struct.

See Also

`mxArray`, `ocvCvRectToBoundingBox_{DataType}`, “C Matrix API”, “Write C Functions Callable from MATLAB (MEX Files)”

Version History

Introduced in R2015a

ocvCheckFeaturePointsStruct

Check that MATLAB struct represents feature points

C++ Syntax

```
#include "opencvmex.hpp"
void ocvCheckFeaturePointsStruct(const mxArray *in);
```

Arguments

`in`

Pointer to a MATLAB structure, `mxArray`, that represents point feature. Format:

Field Name	Field Requirement	Field Data Type
`Location`	Required	Single
`Scale`	Required	Single
`Metric`	Required	Single
`Orientation`	Optional	Single
`Octave`	Optional	int32
`Misc`	Optional	int32

Description

The `ocvCheckFeaturePointsStruct` function performs the key point struct checker.

See Also

`mxArrayocvStructToKeyPoints`, `ocvKeyPointsToStruct`, “C Matrix API”, “Write C Functions Callable from MATLAB (MEX Files)”

Version History

Introduced in R2015a

createMat

Create MATLAB interface object for OpenCV `Mat` class

Syntax

```
[ocvMat,ocvInputArray] = createMat(img)
[ocvMat,ocvArray] = createMat(img,arrayType)
[ocvMat,ocvOutputArray] = createMat
[ocvMat,ocvArray] = createMat(arrayType)
```

Description

`[ocvMat,ocvInputArray] = createMat(img)` creates the MATLAB interface objects for the OpenCV `Mat` class and the associated `InputArray` class. Use these interface objects to pass an image as input to the OpenCV functions.

`[ocvMat,ocvArray] = createMat(img,arrayType)` creates the MATLAB interface objects for the OpenCV `Mat` class and the associated `InputArray`, `OutputArray`, or `InputOutputArray` class specified by `arrayType`.

`[ocvMat,ocvOutputArray] = createMat` creates an empty interface object for the OpenCV `Mat` class and the associated `OutputArray` class. Use this interface to write the output returned by an OpenCV function.

`[ocvMat,ocvArray] = createMat(arrayType)` creates an empty interface object for the OpenCV `Mat` class and the associated `InputArray`, `OutputArray`, or `InputOutputArray` class specified by `arrayType`.

Examples

Create MATLAB Interface Object for OpenCV `Mat` and Associated Array Classes

Add the prebuilt MATLAB interface to OpenCV package name to the import list.

```
import vision.opencv.util.*
```

Create MATLAB Interface Object for OpenCV `Mat` and `InputArray` Class

Read an image into the MATLAB workspace.

```
img = imread("cameraman.tif");
```

Create a MATLAB interface object for the OpenCV `Mat` class and store the image data. The function also creates an interface object for the OpenCV `InputArray` class that is constructed from the `Mat` class.

```
[ocvMat,ocvArray] = createMat(img);
```

Display and inspect the properties of the MATLAB interface object for the OpenCV `Mat` class.

```
ocvMat
```

```
ocvMat =
  MatND with properties:

        flags: 1124024320
         dims: 2
         rows: 256
         cols: 256
    allocator: [1×1 clib.opencv.cv.MatAllocator]
            u: [1×1 clib.opencv.cv.UMatData]
         size: [1×1 clib.opencv.cv.MatSize]
         step: [1×1 clib.opencv.cv.MatStep]
```

Inspect the type of array class returned by the function.

```
ocvArray
```

```
ocvArray =
  x_InputArray with no properties.
```

Use the `getImage` utility function to read the image stored in the `InputArray` class. Display the image.

```
outImg = getImage(ocvArray);
figure
imshow(outImg)
```

Create MATLAB Interface Object for OpenCV `Mat` and `OutputArray` Classes

Add the prebuilt MATLAB interface to OpenCV package name to the import list.

```
import vision.opencv.util.*
```

Create a MATLAB interface object for the OpenCV `Mat` class. The function also creates an interface object for the OpenCV `OutputArray` class that is constructed from the `Mat` class.

```
[ocvMat,ocvArray] = createMat;
```

Display and inspect the properties of the MATLAB interface object for the OpenCV `Mat` class.

```
ocvMat
```

```
ocvMat =
  MatND with properties:

        flags: 1124007936
         dims: 0
         rows: 0
         cols: 0
    allocator: [1×1 clib.opencv.cv.MatAllocator]
            u: [1×1 clib.opencv.cv.UMatData]
         size: [1×1 clib.opencv.cv.MatSize]
         step: [1×1 clib.opencv.cv.MatStep]
```

Inspect the type of array class returned by the function.

```
ocvArray
```

```
ocvArray =
  x_OutputArray with no properties.
```

Specify Array Class to Construct from OpenCV `Mat` Class

Add the prebuilt MATLAB interface to OpenCV package name to the import list.

```
import vision.opencv.util.*
```

Read an image into the MATLAB workspace.

```
img = imread("cameraman.tif");
```

Create a MATLAB interface object for the OpenCV `Mat` class. Specify the array type as `"InputOutput"` for the function to construct the OpenCV `InputOutputArray` class from the `Mat` class.

```
arrayType = "InputOutput";
[ocvMat,ocvArray] = createMat(img,arrayType);
```

Display and inspect the properties of the MATLAB interface object for the OpenCV `Mat` class.

```
ocvMat
```

```
ocvMat =
  MatND with properties:

        flags: 1124024320
         dims: 2
         rows: 256
```

```
        cols: 256
   allocator: [1×1 clib.opencv.cv.MatAllocator]
           u: [1×1 clib.opencv.cv.UMatData]
        size: [1×1 clib.opencv.cv.MatSize]
        step: [1×1 clib.opencv.cv.MatStep]
```

Inspect the type of array class returned by the function.

```
ocvArray
```

```
ocvArray =
  x_InputOutputArray with no properties.
```

Input Arguments

`img` — Input image

M-by-*N* matrix | *M*-by-*N*-by-3 array

Input image, specified as an *M*-by-*N* matrix representing an intensity image or *M*-by-*N*-by-3 array representing a color image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16`

`arrayType` — Type of array

`"Input"` | `"Output"` | `"InputOutput"`

Type of array to associate with the MATLAB interface object for the OpenCV `Mat` class, specified as: `"Input"`, `"Output"`, or `"InputOutput"`.

Data Types: `char` | `string`

Output Arguments

`ocvMat` — *n*-dimensional dense array class

`MatND` interface object

n-dimensional dense array class, returned as a `MatND` interface object. This interface object is a representation of the OpenCV class `cv::Mat`.

`ocvInputArray` — Proxy class for passing inputs

`InputArray` interface object

Proxy class for passing inputs to OpenCV functions, returned as an `InputArray` interface object. This interface object is a representation of the OpenCV class `cv::_InputArray`.

`ocvArray` — Proxy class for inputs or outputs

`InputArray` interface object | `InputOutputArray` interface object | `OutputArray` interface object

Proxy class for inputs or outputs, returned as one of these values:

- `InputArray` interface object — This MATLAB interface object is a representation of the OpenCV class `cv::_InputArray`. This value is returned if `arrayType` is specified as `"Input"`.

- `InputOutputArray` interface object — This MATLAB interface object is a representation of the OpenCV class `cv::_InputOutputArray`. This value is returned if `arrayType` is specified as `"InputOutput"`.
- `OutputArray` interface object — This MATLAB interface object is a representation of the OpenCV class `cv::_OutputArray`. This value is returned if `arrayType` is specified as `"Output"`.

`ocvOutputArray` — Proxy class for writing output
`OutputArray` interface object

Proxy class for writing outputs from OpenCV functions, returned as an `OutputArray` interface object. This MATLAB interface object is a representation of the OpenCV class `cv::_OutputArray`.

Version History

Introduced in R2021b

`createUMat` | `getImage` | `getBasePtr` | `keyPointsToStruct` | `rectToBbox`

Topics

“Use Prebuilt MATLAB Interface to OpenCV”

createUMat

Create MATLAB interface object for OpenCV `UMat` class

Syntax

```
[ocvUMat,ocvInputArray] = createUMat(img)
[ocvUMat,ocvArray] = createUMat(img,arrayType)
[ocvUMat,ocvOutputArray] = createUMat
[ocvUMat,ocvArray] = createUMat(arrayType)
```

Description

`[ocvUMat,ocvInputArray] = createUMat(img)` creates the MATLAB interface objects for the OpenCV `UMat` class and the associated `InputArray` class. Use these interface objects to pass an image as input to the OpenCV functions.

`[ocvUMat,ocvArray] = createUMat(img,arrayType)` creates the MATLAB interface objects for the OpenCV `UMat` class and the associated `InputArray`, `OutputArray`, or `InputOutputArray` class specified by `arrayType`.

`[ocvUMat,ocvOutputArray] = createUMat` creates an empty interface object for the OpenCV `UMat` class and the associated `OutputArray` class. Use this interface to write the output returned by an OpenCV function.

`[ocvUMat,ocvArray] = createUMat(arrayType)` creates an empty interface object for the OpenCV `UMat` class and the associated `InputArray`, `OutputArray`, or `InputOutputArray` class specified by `arrayType`.

Examples

Create MATLAB Interface Object for OpenCV `UMat` and Associated Array Classes

Add the prebuilt MATLAB interface to OpenCV package name to the import list.

```
import vision.opencv.util.*
```

Create MATLAB Interface Object for OpenCV `UMat` and `InputArray` Class

Read an image into the MATLAB workspace.

```
img = imread("cameraman.tif");
```

Create a MATLAB interface object for the OpenCV `UMat` class and store the image data. The function also creates an interface object for the OpenCV `InputArray` class that is constructed from the `UMat` class.

```
[ocvMat,ocvArray] = createUMat(img);
```

Display and inspect the properties of the MATLAB interface object for the OpenCV `UMat` class.

```
ocvMat
```

```
ocvMat =
  UMat with properties:

         flags: 1124024320
          dims: 2
          rows: 256
          cols: 256
     allocator: [1×1 clib.opencv.cv.MatAllocator]
    usageFlags: USAGE_DEFAULT
             u: [1×1 clib.opencv.cv.UMatData]
        offset: 0
          size: [1×1 clib.opencv.cv.MatSize]
          step: [1×1 clib.opencv.cv.MatStep]
```

Inspect the type of array class returned by the function.

```
ocvArray
```

```
ocvArray =
  x_InputArray with no properties.
```

Use the `getImage` utility function to read the image stored in the `InputArray` class. Display the image.

```
outImg = getImage(ocvArray);
figure
imshow(outImg)
```

Create MATLAB Interface Object for OpenCV `UMat` and `OutputArray` Classes

Add the prebuilt MATLAB interface to OpenCV package name to the import list.

```
import vision.opencv.util.*
```

Create a MATLAB interface object for the OpenCV `UMat` class. The function also creates an interface object for the OpenCV `OutputArray` class that is constructed from the `UMat` class.

```
[ocvMat,ocvArray] = createUMat;
```

Display and inspect the properties of the MATLAB interface object for the OpenCV `UMat` class.

```
ocvMat
```

```
ocvMat =
  UMat with properties:

         flags: 1124007936
          dims: 0
          rows: 0
          cols: 0
     allocator: [1×1 clib.opencv.cv.MatAllocator]
    usageFlags: USAGE_DEFAULT
             u: [1×1 clib.opencv.cv.UMatData]
        offset: 0
          size: [1×1 clib.opencv.cv.MatSize]
          step: [1×1 clib.opencv.cv.MatStep]
```

Inspect the type of array class returned by the function.

```
ocvArray
```

```
ocvArray =
  x_OutputArray with no properties.
```

Specify Array Class to Construct from OpenCV `UMat` Class

Add the prebuilt MATLAB interface to OpenCV package name to the import list.

```
import vision.opencv.util.*
```

Read an image into the MATLAB workspace.

```
img = imread("cameraman.tif");
```

Create a MATLAB interface object for the OpenCV `UMat` class. Specify the array type as `"InputOutput"` for the function to construct the OpenCV `InputOutputArray` class from the `UMat` class.

```
arrayType = "InputOutput";
[ocvMat,ocvArray] = createUMat(img,arrayType);
```

Display and inspect the properties of the MATLAB interface object for the OpenCV `UMat` class.

```
ocvMat
```

```
ocvMat =
  UMat with properties:

         flags: 1124024320
          dims: 2
          rows: 256
          cols: 256
     allocator: [1×1 clib.opencv.cv.MatAllocator]
    usageFlags: USAGE_DEFAULT
             u: [1×1 clib.opencv.cv.UMatData]
        offset: 0
          size: [1×1 clib.opencv.cv.MatSize]
          step: [1×1 clib.opencv.cv.MatStep]
```

Inspect the type of array class returned by the function.

```
ocvArray
```

```
ocvArray =
  x_InputOutputArray with no properties.
```

Input Arguments

`img` — Input image

M-by-*N* matrix | *M*-by-*N*-by-3 array

Input image, specified as an *M*-by-*N* matrix representing an intensity image or *M*-by-*N*-by-3 array representing a color image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16`

`arrayType` — Type of array

`"Input"` | `"Output"` | `"InputOutput"`

Type of array to associate with the MATLAB interface object for OpenCV `UMat` class, specified as : `"Input"`, `"Output"`, or `"InputOutput"`.

Data Types: `char` | `string`

Output Arguments

`ocvUMat` — Unified *n*-dimensional dense array class

`UMat` interface object

Unified *n*-dimensional dense array class, returned as a `UMat` interface object. This MATLAB interface object is a representation of the OpenCV class `cv::UMat`.

`ocvInputArray` — Proxy class for passing inputs

`InputArray` interface object

Proxy class for passing inputs to OpenCV functions, returned as an `InputArray` interface object. This MATLAB interface object is a representation of the OpenCV class `cv::_InputArray`.

ocvArray — Proxy class for inputs or outputs
`InputArray` interface object | `InputOutputArray` interface object | `OutputArray` interface object

Proxy class for inputs or outputs, returned as one of these values:

- `InputArray` interface object — This MATLAB interface object is a representation of the OpenCV class `cv::_InputArray`. This value is returned if `arrayType` is specified as `"Input"`.
- `InputOutputArray` interface object — This MATLAB interface object is a representation of the OpenCV class, `cv::_InputOutputArray`. This value is returned if `arrayType` is specified as `"InputOutput"`.
- `OutputArray` interface object — This MATLAB interface object is a representation of the OpenCV class `cv::_OutputArray`. This value is returned if `arrayType` is specified as `"Output"`.

ocvOutputArray — Proxy class for writing output
`OutputArray` interface object

Proxy class for writing outputs from OpenCV functions, returned as an `OutputArray` interface object. This MATLAB interface object is a representation of the OpenCV class `cv::_OutputArray`.

Topics
“Use Prebuilt MATLAB Interface to OpenCV”

getBasePtr

Namespace: `vision.opencv.util`

Create MATLAB interface object for OpenCV base class

Syntax

```
output = getBasePtr(ptr)
```

Description

`output = getBasePtr(ptr)` creates a MATLAB interface object for an OpenCV base class pointed by a smart pointer `ptr`. You can use the interface object to access the public member functions and public attributes of an OpenCV base class directly from MATLAB.

Examples

Perform Histogram Equalization by Using OpenCV in MATLAB

Perform histogram equalization of an image by using the prebuilt MATLAB interface to the OpenCV function `cv::CLAHE`. The `cv::CLAHE` function is a base class, and you must create a MATLAB interface object by using the `getBasePtr` utility function to access the public methods and attributes of the base class.

Add the MATLAB interface to OpenCV package names to the import list.

```
import clib.opencv.*;
import vision.opencv.util.*;
```

Read an image into the MATLAB workspace.

```
img = imread("cameraman.tif");
```

Create the MATLAB interface objects for the OpenCV `MatND` and `InputArray` classes to store the input image.

```
[inputMat,inputArray] = createMat(img);
```

Create the MATLAB interface objects for the OpenCV `MatND` and `OutputArray` classes to write the output image returned by the OpenCV function.

```
[outputMat,outputArray] = createMat;
```

Create a MATLAB interface object to represent the smart pointer of the OpenCV CLAHE class `cv::CLAHE`.

```
ocvPtr = cv.createCLAHE;
```

Create a MATLAB interface object for the base class `cv::CLAHE`.

```
basePtr = getBasePtr(ocvPtr);
```

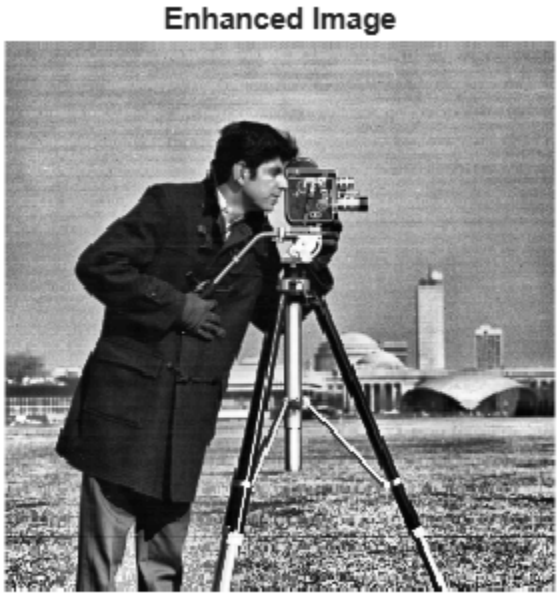
Set the value of clip limit to 4.

```
basePtr.setClipLimit(4);
```

Perform contrast-limited adaptive histogram equalization by using the `apply` method of the `cv::CLAHE` base class.

```
basePtr.apply(inputArray,outputArray);
```

Read the enhanced output image.



```
enhanced = getImage(outputArray);
```

Display the original input and the enhanced output image.

```
figure
imshow(img)
title("Input Image")
```

```
figure
imshow(enhanced)
title("Enhanced Image")
```

Input Arguments

`ptr` — OpenCV smart pointer

`Ptr_cv_<_T>` interface object

OpenCV smart pointer, specified as a `Ptr_cv_<_T>` interface object. This MATLAB interface object is a representation of an OpenCV smart pointer `cv::Ptr<_T>`.

Output Arguments

`output` — Representation of OpenCV base class

MATLAB interface object

Representation of OpenCV base class, returned as a MATLAB interface object. You can use the object to directly access the public member functions and public attributes of an OpenCV base class.

Topics

“Use Prebuilt MATLAB Interface to OpenCV”

getImage

Namespace: `vision.opencv.util`

Read images stored in MATLAB interface object for OpenCV class

Syntax

```
outputImg = getImage(ocvInput)
```

Description

`outputImg = getImage(ocvInput)` reads the image stored in a MATLAB interface object for an OpenCV class and writes it to the specified output variable `outputImg` in the MATLAB workspace.

Examples

Read Image Stored in OpenCV `Mat` Class

Add the MATLAB interface to OpenCV package names to the import list.

```
import clib.opencv.*
import vision.opencv.util.*
```

Read an image into the MATLAB workspace.

```
img = imread("cameraman.tif");
```

Create a MATLAB interface object for the OpenCV `InputOutput` array class.

```
[ocvMat,ocvArray] = createMat(img);
```

Read the image stored in the `InputOutput` interface object.

```
output = getImage(ocvArray);
```

Display the output image.

```
figure
imshow(output)
```

Input Arguments

`ocvInput` — MATLAB interface object for OpenCV class

`MatND` interface object | `UMat` interface object | `InputArray` interface object | `InputOutputArray` interface object | `OutputArray` interface object

MATLAB interface object for an OpenCV class, specified as one of these values:

- `MatND` interface object — Created by using the `createMat` function and represents the OpenCV `cv::Mat` class.
- `UMat` interface object — Created by using the `createUMat` function and represents the OpenCV `cv::UMat` class.
- `InputArray` interface object — Created by using the `createMat` or `createUMat` function and represents the OpenCV `cv::_InputArray` class. The `InputArray` interface object passes array inputs to the OpenCV functions.
- `InputOutputArray` interface object — Created by using the `createMat` or `createUMat` function and represents the OpenCV `cv::_InputOutputArray` class. The `InputOutputArray` interface object passes array inputs to the OpenCV functions and writes the array outputs returned by the OpenCV functions.
- `OutputArray` interface object — Created by using the `createMat` or `createUMat` function and represents the OpenCV `cv::_OutputArray` class. The `OutputArray` interface object contains the array outputs returned by the OpenCV functions.

Output Arguments

`outputImg` — Output image

M-by-*N* matrix | *M*-by-*N*-by-3 array

Output image read from a MATLAB interface object, returned as an *M*-by-*N* matrix for intensity images and *M*-by-*N*-by-3 array for color images.

“Use Prebuilt MATLAB Interface to OpenCV”

keyPointsToStruct

Namespace: `vision.opencv.util`

Convert OpenCV `KeyPoints` object to MATLAB structure

Syntax

```
mlstruct = keyPointsToStruct(keypoints)
```

Description

`mlstruct = keyPointsToStruct(keypoints)` converts an OpenCV `KeyPoints` object to a MATLAB structure.

Examples

Detect Keypoints in Image Using OpenCV in MATLAB

This example shows how to use the prebuilt MATLAB interface for the OpenCV function `cv::Fast` in MATLAB to detect keypoints in an image. Additionally, use the `keyPointsToStruct` utility function to write the keypoints returned by the OpenCV `cv::Fast` function to a MATLAB structure.

Add the MATLAB interface to OpenCV package names to the import list.

```
import clib.opencv.*;
import vision.opencv.util.*;
```

Read an image into the MATLAB workspace.

```
img = imread("elephant.jpg");
```

Create MATLAB interface objects for the OpenCV `MatND` and `InputArray` classes to store the input image.

```
[inputMat,inputArray] = createMat(img);
```

Create a MATLAB interface object for the OpenCV `KeyPoint` vector by using the `clibArray` function.

```
keyPointsVec = clibArray("clib.opencv.cv.KeyPoint",0);
```

Specify the parameters for computing keypoints using the FAST detector.

```
threshold = 100;
nonmaxSuppression = true;
```

Compute keypoints in the image by calling the OpenCV function `cv::FAST` in MATLAB.

```
cv.FAST(inputArray,keyPointsVec,threshold,nonmaxSuppression);
```

Convert the `KeyPoints` object returned by the OpenCV function into a MATLAB structure.

```
mlstruct = keyPointsToStruct(keyPointsVec);
```

Inspect the fields in the output MATLAB structure.

```
mlstruct
```

```
mlstruct = struct with fields:
       Location: [48×2 double]
          Scale: [48×1 double]
         Metric: [48×1 double]
           Misc: [48×1 double]
    Orientation: [48×1 double]
```

Display the input image and plot the detected keypoints.

```
figure
imshow(img)
hold on
plot(mlstruct.Location(:,1),mlstruct.Location(:,2),"*r")
hold off
```

Input Arguments

`keypoints` — OpenCV `KeyPoints` class

MATLAB interface object

OpenCV `KeyPoints` class, specified as a MATLAB interface object. This interface object is a representation of the `KeyPoints` class returned by any of the OpenCV functions for keypoint detection.

Output Arguments

`mlstruct` — Keypoints detected using OpenCV function

structure

Keypoints detected using the OpenCV function, returned as a MATLAB structure with fields `Location`, `Scale`, `Metric`, `Misc`, and `Orientation`.

Fields	Description
`Location`	*x* and *y*-coordinates of the keypoints.
`Scale`	Diameter of the neighborhood region around the keypoints.
`Metric`	Strength of the keypoints.
`Orientation`	Orientation of the keypoints.

rectToBbox

Namespace: `vision.opencv.util`

Compute bounding boxes from outputs returned by MATLAB interface object for OpenCV `Rect` class

Syntax

```
bbox = rectToBbox(input)
```

Description

`bbox = rectToBbox(input)` computes bounding box values from the outputs returned by a MATLAB interface object for OpenCV `Rect` class. The OpenCV `Rect` class creates rectangles on an input image. This function maps the zero-based indexing in OpenCV to one-based indexing in MATLAB.

Examples

Draw Rectangle on Image Using OpenCV in MATLAB

Draw a rectangle on an image by using the prebuilt MATLAB interface for the OpenCV function `cv::rectangle`. Compute the corresponding bounding box values in MATLAB to use to crop the image region.

Add the MATLAB interface to OpenCV package names to the import list.

```
import clib.opencv.*;
import vision.opencv.util.*;
```

Read an image into the MATLAB workspace.

```
img = imread("highway.png");
```

Create interface objects for the OpenCV `Mat` and `InputOutputArray` classes to store the input image.

```
[inputMat,ocvArray] = createMat(img,"InputOutput");
```

Define Rectangular Region

Call the OpenCV function `cv::Rect2i` using MATLAB, and specify the coordinates and dimensions for the rectangle. Display the values.

```
rec = cv.Rect2i(140,60,100,100)
```

```
rec =
  Rect2i with properties:

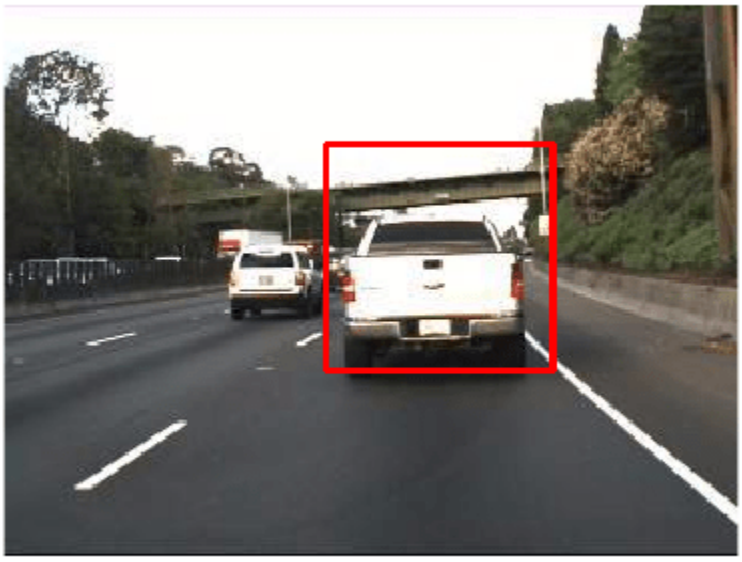
         x: 140
         y: 60
     width: 100
```

```
    height: 100
```

Draw Rectangle and Display Results

Specify the properties of the line to use for drawing the rectangle. Set these values:

- Color of the line to red. To set this value, use the OpenCV function `cv::Scalar`.
- Thickness of the line to `2`.
- Line type to `4`.
- Shift to `0`.



```
color = cv.Scalar(255,0,0);
thickness = 2;
lineType = 4;
shift = 0;
```

Draw the defined rectangle on the image by using the OpenCV function `cv::rectangle`.

```
cv.rectangle(ocvArray,rec,color,thickness,lineType,shift);
```

Read and display the output image.

```
outputImg = getImage(ocvArray);
figure
imshow(outputImg)
```

Compute Bounding Box

Use the utility function `rectToBbox` to compute the bounding box value from the values returned by OpenCV function `cv::Rect2i`.

```
bbox = rectToBbox(rec);
```

Display the bounding box values. Notice that the bounding box values in the MATLAB workspace have one-based indexing.

```
bbox
```

```
bbox = 1×4 int32 row vector

   141    61   100   100
```

Crop the region within the bounding box by using the `imcrop` function and display the cropped image.

```
croppedImg = imcrop(img,bbox);
figure
imshow(croppedImg)
```

Input Arguments

`input` — OpenCV class for rectangles

`Rect__unsignedChar_` interface object | `Rect2d` interface object | `Rect2f` interface object | `Rect2i` interface object

OpenCV class for rectangles, specified as one of these values:

- `Rect__unsignedChar_` interface object — This MATLAB interface object is a representation of the OpenCV class `cv::Rect_<unsigned char>`.
- `Rect2d` interface object — This MATLAB interface object is a representation of the OpenCV class `cv::Rect_<double>`.
- `Rect2f` interface object — This MATLAB interface object is a representation of the OpenCV class `cv::Rect_<float>`.

- `Rect2i` interface object — This MATLAB interface object is a representation of the OpenCV class `cv::Rect_<int>`.
- `Rect2i` interface object — This MATLAB interface object is a representation of the OpenCV class `cv::Rect_<int>`.

Output Arguments

bbox — Bounding box values
four-element row vector

Bounding box values, returned as a four-element row vector of the form [`x y width height`].

times, .*

Element-wise transformation or rotation multiplication

Syntax

```
transformationC = transformationA.*transformationB
rotationC = rotationA.*rotationB
```

Description

`transformationC = transformationA.*transformationB` multiplies transformations element-by-element by multiplying each element of transformation `transformationA` with the corresponding element of transformation `transformationB` and returns the product, transformation `transformationC`.

`rotationC = rotationA.*rotationB` multiplies rotations element-by-element by multiplying each element of rotation `rotationA` with the corresponding element of rotation `rotationB` and returns the product, rotation `rotationC`.

Input Arguments

`transformationA` — First transformation

`se3` object | *N*-element array of transformation objects

First transformation, a scalar `se3` object or as an *N*-element array of transformation objects. *N* is the total number of transformations.

If you specify `transformationA` as an array, each element must be of the same type.

Either `transformationA` or `transformationB` must be a scalar transformation object of the same type. For example, if `transformationA` is an array of `se3` objects, `transformationB` must be a scalar `se3` object.

`transformationB` — Last transformation

`se3` object | *N*-element array of transformation objects

Last transformation, specified as a scalar `se3` object or as an *N*-element array of transformation objects. *N* is the total number of transformations.

If you specify `transformationB` as an array, each element must be of the same type.

Either `transformationA` or `transformationB` must be a scalar transformation object of the same type. For example, if `transformationA` is an array of `se3` objects, `transformationB` must be a scalar `se3` object.

`rotationA` — First rotation

`so3` object | *N*-element array of rotation objects

First rotation, specified as a scalar `so3` object or as an *N*-element array of rotation objects. *N* is the total number of rotations.

If you specify `rotationA` as an array, each element must be of the same type.

Either `rotationA` or `rotationB` must be a scalar rotation object of the same type. For example, if `rotationA` is an array of `so3` objects, `rotationB` must be a scalar `so3` object.

`rotationB` — Last rotation
`so3` object | *N*-element array of rotation objects

Last rotation, specified as a scalar `so3` object or as an *N*-element array of rotation objects. *N* is the total number of rotations.

If you specify `rotationB` as an array, each element must be of the same type.

Either `rotationA` or `rotationB` must be a scalar rotation object of the same type. For example, if `rotationA` is an array of `se3` objects, `rotationB` must be a scalar `se3` object.

Output Arguments

`transformationC` — Transformation product
`se3` object | *N*-element array of transformation objects

Transformation product, returned as a scalar `se3` object or as an *N*-element array of the same transformation type as `transformationA` and `transformationB`. *N* is the length of the longer argument between `transformationA` and `transformationB` and each row represents the product between `transformationA` and `transformationB`.

`rotationC` — Rotation product
`so3` object | *N*-element array of rotation objects

Rotation product, returned as a scalar `so3` object or as an *N*-element array of the same rotation type as `rotationA` and `rotationB`. *N* is the length of the longer argument between `rotationA` and `rotationB` and each row represents the product between `rotationA` and `rotationB`.

trainSSDObjectDetector

Train SSD deep learning object detector

Syntax

```
trainedDetector = trainSSDObjectDetector(trainingData,detector,options)

trainedDetector = trainSSDObjectDetector(trainingData,checkpoint,options)

trainedDetector = trainSSDObjectDetector( ___ ,Name=Value)
[trainedDetector,info] = trainSSDObjectDetector( ___ )
```

Description

Train a Detector

`trainedDetector = trainSSDObjectDetector(trainingData,detector,options)` trains a single shot multibox detector (SSD) using deep learning. You can train an SSD detector to detect multiple object classes. Use this syntax to train either an untrained or pretrained SSD object detection network. You can also use this syntax to fine-tune a network with additional training data or to perform more training iterations to improve detector accuracy.

This function requires that you have Deep Learning Toolbox. It is recommended that you also have Parallel Computing Toolbox to use with a CUDA-enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

Resume Training a Detector

`trainedDetector = trainSSDObjectDetector(trainingData,checkpoint,options)` resumes training from a detector checkpoint.

Additional Properties

`trainedDetector = trainSSDObjectDetector( ___ ,Name=Value)` uses additional options specified by one or more name-value arguments and any of the previous inputs.

`[trainedDetector,info] = trainSSDObjectDetector( ___ )` also returns information on the training progress, such as training loss and accuracy, for each iteration.

Examples

Train SSD Object Detector

This example shows how to train an SSD object detector on a vehicle data set. The example then uses the trained detector for detecting vehicles in an image.

Load the training data into the workspace.

```
data = load("vehicleTrainingData.mat");
trainingData = data.vehicleTrainingData;
```

Specify the directory in which training samples are stored. Add full path to the filenames in training data.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata");
trainingData.imageFilename = fullfile(dataDir,trainingData.imageFilename);
```

Create an image datastore using the files from the table.

```
imds = imageDatastore(trainingData.imageFilename);
```

Create a box label datastore using the label columns from the table.

```
blds = boxLabelDatastore(trainingData(:,2:end));
```

Combine the datastores.

```
ds = combine(imds,blds);
```

Specify a base network.

```
baseNetwork = imagePretrainedNetwork("resnet50");
```

Specify the names of the classes to detect.

```
classNames = "vehicle";
```

Specify the anchor boxes to use for training the network.

```
anchorBoxes = { ...
    [30 60; 60 30; 50 50; 100 100], ...
    [40 70; 70 40; 60 60; 120 120]};
```

Specify the names of the feature extraction layers to connect to the detection subnetwork.

```
layersToConnect = ["activation_22_relu" "activation_40_relu"];
```

Create an SSD object detector by using the `ssdObjectDetector` function.

```
detector = ssdObjectDetector(baseNetwork,classNames,anchorBoxes, ...
    DetectionNetworkSource=layersToConnect);
```

Specify the training options.

```
options = trainingOptions("sgdm", ...
    InitialLearnRate=0.001, ...
    MiniBatchSize=16, ...
    Verbose=true, ...
    MaxEpochs=30, ...
    Shuffle="never", ...
    VerboseFrequency=10);
```

Train the SSD object detector.

```
[detector,info] = trainSSDObjectDetector(ds,detector,options);
```

```

    img = insertObjectAnnotation(img,"rectangle",bboxes,scores);
end
figure
imshow(img)
```

Input Arguments

`trainingData` — Labeled ground truth images

datastore

Labeled ground truth images, specified as a datastore or a table.

- If you use a datastore, your data must be set up so that calling the datastore with the `read` and `readall` functions returns a cell array or table with three columns. The second column must contain the bounding boxes, and the third column must contain the labels. The first column can contain image or point cloud data.

data	*boxes*	*labels*
The first column must be images.	*M*-by-4 matrices of bounding boxes of the form [*x*, *y*, *width*, *height*], where [x,y] represent the top-left coordinates of the bounding box.	The third column must be a cell array that contains *M*-by-1 categorical vectors containing object class names. All categorical data returned by the datastore must contain the same categories.

  For more information, see “Datastores for Deep Learning” (Deep Learning Toolbox).

`detector` — Untrained or pretrained SSD object detector

`ssdObjectDetector` object

Untrained or pretrained SSD object detector, specified as a `ssdObjectDetector` object.

`options` — Training options

`TrainingOptionsSGDM` object | `TrainingOptionsRMSProp` object | `TrainingOptionsADAM` object

Training options, specified as a `TrainingOptionsSGDM`, `TrainingOptionsRMSProp`, or `TrainingOptionsADAM` object returned by the `trainingOptions` function. To specify the solver name and other options for network training, use the `trainingOptions` function.

Note The trainSSDObjectDetector function does not support these training options:

- Datastore inputs are not supported when you set the `DispatchInBackground` training option to `true`.
- Datastore inputs are not supported if the `Shuffle` training option is set to `"never"` when the `ExecutionEnvironment` training option is `"multi-gpu"`. For more information about using datastore for parallel training, see “Preprocess Data in the Background or in Parallel” (Deep Learning Toolbox).

`checkpoint` — Saved detector checkpoint
`ssdObjectDetector` object

Saved detector checkpoint, specified as an `ssdObjectDetector` object. To periodically save a detector checkpoint during training, specify `CheckpointPath`. To control how frequently check points are saved see the `CheckPointFrequency` and `CheckPointFrequencyUnit` training options.

To load a checkpoint for a previously trained detector, load the MAT file from the checkpoint path. For example, if the `CheckpointPath` property of the object specified by `options` is `"/checkpath"`, you can load a checkpoint MAT file by using this code.

```
data = load("/checkpath/ssd_checkpoint__216__2018_11_16__13_34_30.mat");
checkpoint = data.detector;
```

The name of the MAT file includes the iteration number and timestamp of when the detector checkpoint was saved. The detector is saved in the `detector` variable of the file. Pass this file back into the trainSSDObjectDetector function:

```
ssdDetector = trainSSDObjectDetector(trainingData,checkpoint,options);
```

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `"PositiveOverlapRange",[0.5 1]` sets the vertical axis direction to up.

`PositiveOverlapRange` — Range of bounding box overlap ratios
`[0.5 1]` (default) | two-element vector

Range of bounding box overlap ratios between `0` and `1`, specified as a two-element vector. Anchor boxes that overlap with ground truth bounding boxes within the specified range are used as positive training samples. The function computes the overlap ratio using the intersection-over-union between two bounding boxes.

`NegativeOverlapRange` — Range of bounding box overlap ratios
`[0 0.5]` (default) | two-element vector

Range of bounding box overlap ratios between `0` and `1`, specified as a two-element vector. Anchor boxes that overlap with ground truth bounding boxes within the specified range are used as negative

training samples. The function computes the overlap ratio using the intersection-over-union between two bounding boxes.

`ExperimentManager` — Detector training experiment monitoring
`"none"` (default) | `experiments.Monitor` object

Detector training experiment monitoring, specified as an `experiments.Monitor` object for use with the Experiment Manager app. You can use this object to track the progress of training, update information fields in the training results table, record values of the metrics used by the training, and to produce training plots. For an example using this app, see “Train Object Detectors in Experiment Manager”.

Information monitored during training:

- Training loss at each iteration.
- Training accuracy at each iteration.
- Training root mean square error (RMSE) for the box regression layer.
- Learning rate at each iteration.

Validation information when the training `options` input contains validation data:

- Validation loss at each iteration.
- Validation accuracy at each iteration.
- Validation RMSE at each iteration.

Output Arguments

`trainedDetector` — Trained SSD multibox object detector
`ssdObjectDetector` object

Trained SSD object detector, returned as `ssdObjectDetector` object. You can train a SSD object detector to detect multiple object classes.

`info` — Training progress information
structure array

Training progress information, returned as a structure array with eight fields. Each field corresponds to a stage of training.

- `TrainingLoss` — Training loss at each iteration is calculated as the sum of regression loss and classification loss. To compute the regression loss, the `trainSSDObjectDetector` function uses smooth L1 loss function. To compute the classification loss the `trainSSDObjectDetector` function uses the softmax and binary cross-entropy loss function.
- `TrainingAccuracy` — Training set accuracy at each iteration.
- `TrainingRMSE` — Training root mean squared error (RMSE) is the RMSE calculated from the training loss at each iteration.
- `BaseLearnRate` — Learning rate at each iteration.
- `ValidationLoss` — Validation loss at each iteration.
- `ValidationAccuracy` — Validation accuracy at each iteration.
- `ValidationRMSE` — Validation RMSE at each iteration.

- `FinalValidationLoss` — Final validation loss at end of the training.
- `FinalValidationRMSE` — Final validation RMSE at end of the training.

Each field is a numeric vector with one element per training iteration. Values that have not been calculated at a specific iteration are assigned as `NaN`. The struct contains `ValidationLoss`, `ValidationAccuracy`, `ValidationRMSE`, `FinalValidationLoss`, and `FinalValidationRMSE` fields only when `options` specifies validation data.

Version History

Introduced in R2020a

R2025a: MATLAB Compiler support will be removed
Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

R2022a: `LayerGraph` input is not recommended
Not recommended starting in R2022a

Starting in R2022a, use of `LayerGraph` object to specify SSD object detection network as input to the `trainSSDObjectDetector` is not recommended.

The syntax `trainSSDObjectDetector(trainingData,net,options)`, specifying the input SSD detection network `net` as a `LayerGraph` object will be removed in a future release.

If your SSD object detection network is a `LayerGraph` object, configure the network as a `ssdObjectDetector` object by using the `ssdObjectDetector` function. Then, use the `ssdObjectDetector` object as input to the `trainSSDObjectDetector` function for training.

Extended Capabilities

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU acceleration.

By default, the `trainSSDObjectDetector` function uses a GPU if one is available. You can specify the hardware that the `trainSSDObjectDetector` function uses by setting the `ExecutionEnvironment` training option using the `trainingOptions` function.

For more information, see “Scale Up Deep Learning in Parallel, on GPUs, and in the Cloud” (Deep Learning Toolbox).

trainFasterRCNNObjectDetector

(Not recommended) Train Faster R-CNN deep learning object detector

Note `trainFasterRCNNObjectDetector` is not recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` detector. For more information, see “Version History”.

Syntax

```
trainedDetector = trainFasterRCNNObjectDetector(trainingData,network,options)
[trainedDetector,info] = trainFasterRCNNObjectDetector( ___ )

trainedDetector = trainFasterRCNNObjectDetector(trainingData,checkpoint,
options)

trainedDetector = trainFasterRCNNObjectDetector(trainingData,detector,
options)

trainedDetector = trainFasterRCNNObjectDetector( ___ ,Name,Value)
```

Description

Train a Detector

`trainedDetector = trainFasterRCNNObjectDetector(trainingData,network,options)` trains a Faster R-CNN (regions with convolution neural networks) object detector using deep learning. You can train a Faster R-CNN detector to detect multiple object classes.

This function requires that you have Deep Learning Toolbox. It is recommended that you also have Parallel Computing Toolbox to use with a CUDA-enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

`[trainedDetector,info] = trainFasterRCNNObjectDetector( ___ )` also returns information on the training progress, such as training loss and accuracy, for each iteration.

Resume Training a Detector

`trainedDetector = trainFasterRCNNObjectDetector(trainingData,checkpoint, options)` resumes training from a detector checkpoint.

Fine-Tune a Detector

`trainedDetector = trainFasterRCNNObjectDetector(trainingData,detector, options)` continues training a Faster R-CNN object detector with additional fine-tuning options. Use this syntax with additional training data or to perform more training iterations to improve detector accuracy.

Additional Properties

`trainedDetector = trainFasterRCNNObjectDetector( ___ ,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments and any of the previous inputs.

Examples

Train Faster R-CNN Vehicle Detector

Load training data.

```
data = load('fasterRCNNVehicleTrainingData.mat');

trainingData = data.vehicleTrainingData;

trainingData.imageFilename = fullfile(toolboxdir('vision'),'visiondata', ...
    trainingData.imageFilename);
```

Randomly shuffle data for training.

```
rng(0);
shuffledIdx = randperm(height(trainingData));
trainingData = trainingData(shuffledIdx,:);
```

Create an image datastore using the files from the table.

```
imds = imageDatastore(trainingData.imageFilename);
```

Create a box label datastore using the label columns from the table.

```
blds = boxLabelDatastore(trainingData(:,2:end));
```

Combine the datastores.

```
ds = combine(imds, blds);
```

Set up the network layers.

```
lgraph = layerGraph(data.detector.Network);
```

Configure training options.

```
 options = trainingOptions('sgdm', ...
      'MiniBatchSize', 1, ...
      'InitialLearnRate', 1e-3, ...
      'MaxEpochs', 7, ...
      'VerboseFrequency', 200, ...
      'CheckpointPath', tempdir);
```

Train detector. Training will take a few minutes. Adjust the NegativeOverlapRange and PositiveOverlapRange to ensure training samples tightly overlap with ground truth.

```
detector = trainFasterRCNNObjectDetector(ds, lgraph, options, ...
        'NegativeOverlapRange',[0 0.3], ...
        'PositiveOverlapRange',[0.6 1]);
```

```

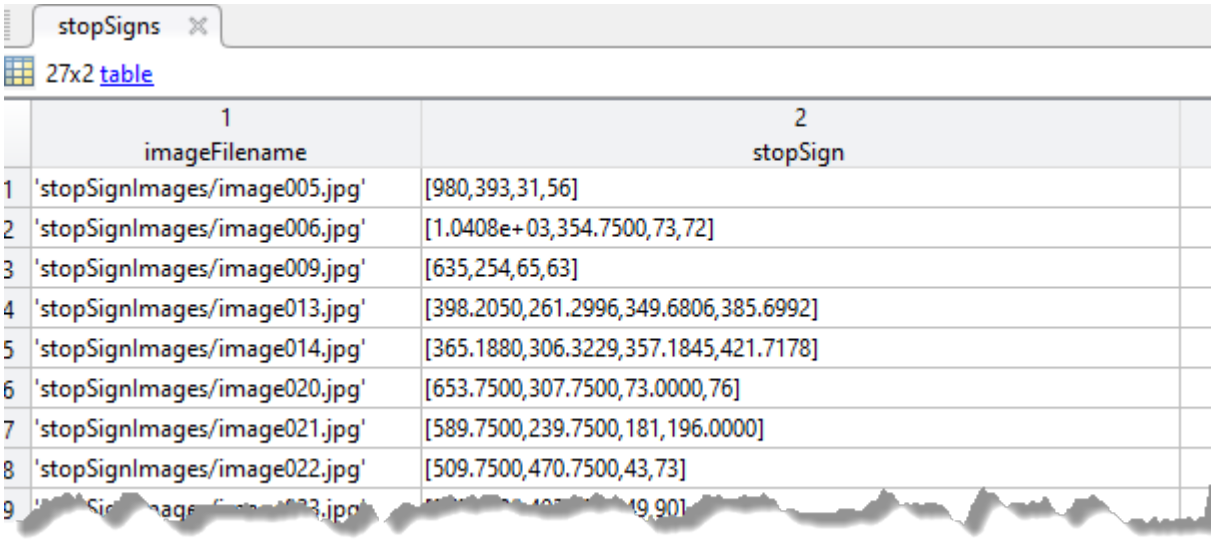
Input Arguments

`trainingData` — Labeled ground truth

datastore | table

Labeled ground truth, specified as a datastore or a table.



Each bounding box must be in the format [*x y width height*].

- If you use a datastore, your data must be set up so that calling the datastore with the `read` and `readall` functions returns a cell array or table with three columns. The second column must contain the bounding boxes, and the third column must contain the labels. The first column can contain image or point cloud data.

data	***boxes***	***labels***
The first column must be images.	*M*-by-4 matrices of bounding boxes of the form [*x*, *y*, *width*, *height*], where [x,y] represent the top-left coordinates of the bounding box.	The third column must be a cell array that contains *M*-by-1 categorical vectors containing object class names. All categorical data returned by the datastore must contain the same categories.

  For more information, see “Datastores for Deep Learning” (Deep Learning Toolbox).

- If you use a table, the table must have two or more columns. The first column of the table must contain image file names with paths. The images must be grayscale or truecolor (RGB) and they can be in any format supported by `imread`. Each of the remaining columns must be a cell vector that contains *M*-by-4 matrices that represent a single object class, such as *vehicle*, *flower*, or *stop sign*. The columns contain 4-element double arrays of *M* bounding boxes in the format [*x*,*y*,*width*,*height*]. The format specifies the upper-left corner location and size of the bounding box in the corresponding image. To create a ground truth table, you can use the Image Labeler app or Video Labeler app. To create a table of training data from the generated ground truth, use the `objectDetectorTrainingData` function.

`network` — Network

`SeriesNetwork` object | array of `Layer` objects | `LayerGraph` object | network name

Network, specified as a `SeriesNetwork`, an array of `Layer` objects, a `layerGraph` object, or by the network name. The network is trained to classify the object classes defined in the `trainingData` table. To use `SeriesNetwork`, `Layer`, and `layerGraph` objects, you must have Deep Learning Toolbox.

- When you specify the network as a `SeriesNetwork`, an array of `Layer` objects, or by the network name, the function transforms the network into a Faster R-CNN network by adding a region proposal network (RPN), an ROI max pooling layer, and new classification and regression layers to support object detection. Additionally, the `GridSize` property of the ROI max pooling layer is set to the output size of the last max pooling layer in the network.
- The array of `Layer` objects must contain a classification layer that supports the number of object classes, plus a background class. Use this input type to customize the learning rates of each layer. An example of an array of `Layer` objects follows:

```
layers = [imageInputLayer([28 28 3])
        convolution2dLayer([5 5],10)
        reluLayer()
        fullyConnectedLayer(10)
        softmaxLayer()
        classificationLayer()];
```

- When you specify the network as `SeriesNetwork` object, `Layer` array, or by the network name, the weights for additional convolution and fully connected layers are initialized to `'narrow-normal'`. The function adds these weights to create the network.
- The network name must be one of the following valid network names. You must also install the corresponding add-on.

Network Name	Feature Extraction Layer Name	ROI Pooling Layer OutputSize	Description
`alexnet`	`'relu5'`	[6 6]	Last max pooling layer is replaced by ROI max pooling layer
`vgg16`	`'relu5_3'`	[7 7]	
`vgg19`	`'relu5_4'`		
`squeezenet`	`'fire5-concat'`	[14 14]	ROI pooling layer is inserted after the feature extraction layer.
`resnet18`	`'res4b_relu'`		
`resnet50`	`'activation_40_relu'`		
`resnet101`	`'res4b22_relu'`		
`googlenet`	`'inception_4d-output'`		
`mobilenetv2`	`'block_13_expand_relu'`		
`inceptionv3`	`'mixed7'`	[17 17]	
`inceptionresnetv2`	`'block17_20_ac'`		

- The `LayerGraph` object must be a valid Faster R-CNN object detection network. You can use the `fasterRCNNLayers` function to create a `LayerGraph` object to train a custom Faster R-CNN network.

  Tip If your network is a `DAGNetwork`, use the `layerGraph` function to convert the network to a `LayerGraph` object. Then, create a custom Faster R-CNN network as described by the "Create Faster R-CNN Object Detection Network" example.

For more information on creating a Faster R-CNN network, see "Getting Started with R-CNN, Fast R-CNN, and Faster R-CNN".

`options` — Training options
`trainingOptions` output

Training options, returned by the `trainingOptions` function (requires Deep Learning Toolbox). To specify solver and other options for network training, use `trainingOptions`.

Note `trainFasterRCNNObjectDetector` does not support these training options:

- Datastore inputs are not supported when you set the `DispatchInBackground` training option to `true`.

Additionally, the function does not support the following training options if you use a combined datastore input:

- `'once'` and `'every-epoch'` values for `'Shuffle'` argument
- `'parallel'` and `'multi-gpu'` values for `'ExecutionEnvironment'` argument

`checkpoint` — Saved detector checkpoint
`fasterRCNNObjectDetector` object

Saved detector checkpoint, specified as a `fasterRCNNObjectDetector` object. To periodically save a detector checkpoint during training, specify `CheckpointPath`. To control how frequently check points are saved see the `CheckPointFrequency` and `CheckPointFrequencyUnit` training options.

To load a checkpoint for a previously trained detector, load the MAT file from the checkpoint path. For example, if the `'CheckpointPath'` property of `options` is `'/tmp'`, load a checkpoint MAT file using:

```
data = load('/tmp/faster_rcnn_checkpoint__105__2016_11_18__14_25_08.mat');
```

The name of the MAT file includes the iteration number and a timestamp indicating when the detector checkpoint was saved. The detector is saved in the `detector` variable of the file. Pass this file back into the `trainFasterRCNNObjectDetector` function:

```
frcnn = trainFasterRCNNObjectDetector(stopSigns,...
                            data.detector,options);
```

`detector` — Previously trained Faster R-CNN object detector
`fasterRCNNObjectDetector` object

Previously trained Faster R-CNN object detector, specified as a `fasterRCNNObjectDetector` object. Use this syntax to continue training a detector with additional training data or to perform more training iterations to improve detector accuracy.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `"PositiveOverlapRange",[0.75 1]`

`TrainingMethod` — Training method
`'end-to-end'` (default) | `'four-step'`

Training method, specified as `'end-to-end'` or `'four-step'`.

- `'end-to-end'` — Simultaneously train the region proposal and region classification subnetworks.
- `'four-step'` — Separately train the region proposal and region classification subnetworks in four steps.

`PositiveOverlapRange` — Bounding box overlap ratios for positive training samples
`[0.5 1]` (default) | 2-by-2 matrix | 4-by-2 matrix

Bounding box overlap ratios for positive training samples, specified as one of the following:

- A 2-element vector that specifies an identical overlap ratio for all four training stages.
- A 2-by-2 matrix, used only for the end-to-end training method. The first row of the matrix defines the overlap ratios for the region proposal subnetwork. The second row defines the overlap ratios for the region classification subnetwork.
- A 4-by-2 matrix, used only for the four-step training method. Each row of the matrix specifies the overlap ratio for each of the four training stages.

Values are in the range [0,1]. Region proposals that overlap with ground truth bounding boxes within the specified range are used as positive training samples.

The overlap ratio used for both the `PositiveOverlapRange` and `NegativeOverlapRange` is defined as:

$$\frac{area(A \cap B)}{area(A \cup B)}$$

A and B are bounding boxes.

`NegativeOverlapRange` — Bounding box overlap ratios for negative training samples
`[0.1 0.5]` (default) | 2-element vector | 4-by-2 matrix

Bounding box overlap ratios for negative training samples, specified as one of the following.

- A 2-element vector that specifies the overlap ratio.

- A 2-by-2 matrix, used only for the end-to-end training method. The first row of the matrix defines the overlap ratios for the region proposal subnetwork. The second row defines the overlap ratios for the region classification subnetwork.
- A 4-by-2 matrix, used only for the four-step training method. Each row of the matrix specifies the overlap ratio for each of the four training stages.

Values are in the range [0,1]. Region proposals that overlap with the ground truth bounding boxes within the specified range are used as negative training samples.

The overlap ratio used for both the `PositiveOverlapRange` and `NegativeOverlapRange` is defined as:

$$\frac{area(A \cap B)}{area(A \cup B)}$$

A and B are bounding boxes.

`NumStrongestRegions` — Maximum number of strongest region proposals
`2000` (default) | positive integer | two-element vector

Maximum number of strongest region proposals to use for generating training samples, specified as a positive integer. Reduce this value to speed up processing time at the cost of training accuracy. To use all region proposals, set this value to `Inf`.

`NumRegionsToSample` — Number of region proposals
128 (default) | integer | 1-by-2 vector | 1-by-4 vector

Number of region proposals to randomly sample from each training image, specified as an integer, 1-by-2 vector, or a 1-by-4 vector. Use the 1-by-2 vector for end-to-end training. Use the 1-by-4 vector for the four-step training. Reduce the number of regions to sample to reduce memory usage and speed up training. Reducing the value can also decrease training accuracy.

When you set '`TrainingMethod`' to `'end-to-end'`, the number of region proposals can be set to a 1-by-2 vector. The first element of the vector must be the number of regions sampled for the region proposal subnetwork. The second element must be the number of regions sampled for the region classification subnetwork.

When you set `TrainingMethod` to `'four-step'`, the number of region proposals can be set to a 1-by-4 vector. The i^{th} element specifies the number of regions to sample for the i^{th} training step.

`SmallestImageDimension` — Length of smallest image dimension
`[]` (default) | positive integer

Length of the smallest image dimension, either width or height, specified as a positive integer. Training images are resized such that the length of the shortest dimension is equal to the specified integer. By default, training images are not resized. Resizing training images helps reduce computational costs and memory used when training images are large. Typical values range from 400–600 pixels.

Dependencies

- The `SmallestImageDimension` property supports only table input training data. To resize the input data of a datastore input, use the `transform` function.

`MinBoxSizes` — Minimum anchor box sizes

`'auto'` (default) | *m*-by-2 matrix

Minimum anchor box sizes for building the anchor box pyramid of the region proposal network (RPN), specified as an *m*-by-2 matrix. Each row defines the [*height width*] of an anchor box.

The default `'auto'` setting uses the minimum size and the median aspect ratio from the bounding boxes for each class in the ground truth data. To remove redundant box sizes, the function keeps boxes that have an intersection-over-union value that is less than or equal to 0.5. This behavior ensures that the minimum number of anchor boxes is used to cover all the object sizes and aspect ratios.

When anchor boxes are computed based on `MinBoxSizes`, the i^{th} anchor box size is:

```
round(MinBoxSizes(i,:) .* BoxPyramidScale ,^ (0:NumBoxPyramidLevels-1)')
```

Dependencies

- You cannot use this property if you specify the network as a `LayerGraph` object or if you resume training from a detector checkpoint.
- The `MinBoxSizes` property supports only input training in table format. To estimate anchor boxes for a datastore input, use the `estimateAnchorBoxes` function.

`BoxPyramidScale` — Anchor box pyramid scale

2 (default) | scalar

Anchor box pyramid scale factor used to successively upscale anchor box sizes, specified as a scalar. Recommended values are from 1 through 2. Increase this value for faster results. Decrease the number for greater accuracy.

Dependencies

- The `BoxPyramidScale` property supports only input training data in table format. To estimate anchor boxes for a datastore input, use the `estimateAnchorBoxes` function.

`NumBoxPyramidLevels` — Number of anchor box pyramid levels

`'auto'` (default) | scalar

Number of levels in an anchor box pyramid, specified as a scalar. Select a value that ensures that the multiscale anchor boxes are comparable in size to the size of objects in the ground truth data.

The default setting `'auto'` selects the number of levels based on the size of objects within the ground truth data. The number of levels is selected such that it covers the range of object sizes.

Dependencies

- The `NumBoxPyramidLevels` property supports only input training data in table format. To estimate anchor boxes for a datastore input, use the `estimateAnchorBoxes` function.

`FreezeBatchNormalization` — Frozen batch normalization

`true` (default) | `false`

Frozen batch normalization during training, specified as `true` or `false`. The value indicates whether to freeze the input layers to the network during training. Set this value to `true` if you are training with a small mini-batch size. Small batch sizes result in poor estimates of the batch mean and variance, which are required for effective batch normalization.

If you do not specify a value for `FreezeBatchNormalization`, the function sets the property to:

- `true` if the `MiniBatchSize` name-value argument for the `trainingOptions` function is less than 8.
- `false` if the `MiniBatchSize` name-value argument for the `trainingOptions` function is greater than or equal to 8.

You must specify a value for `FreezeBatchNormalization` to override this default behavior.

`ExperimentManager` — Detector training experiment monitoring
`'none'` (default) | `experiments.Monitor` object

Detector training experiment monitoring, specified as an `experiments.Monitor` object for use with the Experiment Manager app. You can use this object to track the progress of training, update information fields in the training results table, record values of the metrics used by the training, and to produce training plots. For an example using this app, see "Train Object Detectors in Experiment Manager".

Information monitored during training:

- Training loss at each iteration.
- Training accuracy at each iteration.
- Training root mean square error (RMSE) for the box regression layer.
- Learning rate at each iteration.

Validation information when the training `options` input contains validation data:

- Validation loss at each iteration.
- Validation accuracy at each iteration.
- Validation RMSE at each iteration.

Output Arguments

`trainedDetector` — Trained Faster R-CNN object detector
`fasterRCNNObjectDetector` object

Trained Faster R-CNN object detector, returned as a `fasterRCNNObjectDetector` object.

`info` — Training progress information
structure array

Training progress information, returned as a structure array with eight fields. Each field corresponds to a stage of training.

- `TrainingLoss` — Training loss at each iteration is the mean squared error (MSE) calculated as the sum of localization error, confidence loss, and classification loss. For more information about the training loss function, see "YOLO v2 Training Loss" on page 3-1402.
- `TrainingAccuracy` — Training set accuracy at each iteration.
- `TrainingRMSE` — Training root mean squared error (RMSE) is the RMSE calculated from the training loss at each iteration.
- `BaseLearnRate` — Learning rate at each iteration.

- `ValidationLoss` — Validation loss at each iteration.
- `ValidationAccuracy` — Validation accuracy at each iteration.
- `ValidationRMSE` — Validation RMSE at each iteration.
- `FinalValidationLoss` — Final validation loss at end of the training.
- `FinalValidationRMSE` — Final validation RMSE at end of the training.

Each field is a numeric vector with one element per training iteration. Values that have not been calculated at a specific iteration are assigned as `NaN`. The struct contains `ValidationLoss`, `ValidationAccuracy`, `ValidationRMSE`, `FinalValidationLoss`, and `FinalValidationRMSE` fields only when `options` specifies validation data.

Tips

- To accelerate data preprocessing for training, `trainFastRCNNObjectDetector` automatically creates and uses a parallel pool based on your parallel preference settings. For more details about setting these preferences, see parallel preference settings. Using parallel computing preferences requires Parallel Computing Toolbox.
- VGG-16, VGG-19, ResNet-101, and Inception-ResNet-v2 are large models. Training with large images can produce "out-of-memory" errors. To mitigate these errors, try one or more of these options:
  - Reduce the size of your images by using the '`SmallestImageDimension`' argument.
  - Decrease the value of the '`NumRegionsToSample`' name-value argument.
- This function supports transfer learning. When you input a `network` by name, such as `'resnet50'`, then the function automatically transforms the network into a valid Faster R-CNN network model based on the pretrained `resnet50` model. Alternatively, manually specify a custom Faster R-CNN network by using the `LayerGraph` extracted from a pretrained DAG network. For more details, see “Create Faster R-CNN Object Detection Network”.
- This table describes how to transform each named network into a Faster R-CNN network. The feature extraction layer name specifies the layer for processing by the ROI pooling layer. The ROI output size specifies the size of the feature maps output by the ROI pooling layer.

Network Name	Feature Extraction Layer Name	ROI Pooling Layer OutputSize	Description
`alexnet`	`'relu5'`	[6 6]	Last max pooling layer is replaced by ROI max pooling layer
`vgg16`	`'relu5_3'`	[7 7]	
`vgg19`	`'relu5_4'`		
`squeezenet`	`'fire5-concat'`	[14 14]	
`resnet18`	`'res4b_relu'`		ROI pooling layer is inserted after the feature extraction layer.
`resnet50`	`'activation_40_relu'`		
`resnet101`	`'res4b22_relu'`		
`googlenet`	`'inception_4d-output'`		

Network Name	Feature Extraction Layer Name	ROI Pooling Layer OutputSize	Description
`mobilenetv2`	`'block_13_expand_relu'`		
`inceptionv3`	`'mixed7'`	[17 17]	
`inceptionresnetv2`	`'block17_20_ac'`		

For information on modifying how a network is transformed into a Faster R-CNN network, see “Design an R-CNN, Fast R-CNN, and a Faster R-CNN Model”.

- During training, multiple image regions are processed from the training images The number of image regions per image is controlled by the `NumRegionsToSample` property. The `PositiveOverlapRange` and `NegativeOverlapRange` properties control which image regions are used for training. Positive training samples are those that overlap with the ground truth boxes by 0.6 to 1.0, as measured by the bounding box intersection-over-union metric (IoU). Negative training samples are those that overlap by 0 to 0.3. Choose values for these properties by testing the trained detector on a validation set.

Overlap Values	Description
`PositiveOverlapRange` set to `[0.6 1]`	Positive training samples are set equal to the samples that overlap with the ground truth boxes by 0.6 to 1.0, measured by the bounding box IoU metric.
`NegativeOverlapRange` set to `[0 0.3]`	Negative training samples are set equal to the samples that overlap with the ground truth boxes by 0 to 0.3.

  If you set `PositiveOverlapRange` to `[0.6 1]`, then the function sets the positive training samples equal to the samples that overlap with the ground truth boxes by 0.6 to 1.0, measured by the bounding box IoU metric. If you set `NegativeOverlapRange` to `[0 0.3]`, then the function sets the negative training samples equal to the samples that overlap with the ground truth boxes by 0 to 0.3.
- Use the `trainingOptions` function to enable or disable verbose printing.

Version History

Introduced in R2017a

R2025a: MATLAB Compiler support will be removed
Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

R2024b: Not Recommended
Not recommended starting in R2024b

Starting in R2024b, R-CNN object detectors are no longer recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` object. These

object detectors are faster than R-CNN object detectors. For more information, see “Choose an Object Detector”.

R2019b: Default Training Method
Behavior changed in R2019b

Starting in R2019b, by default, the `trainFasterRCNNObjectDetector` function uses the end-to-end method for training a detector.

In previous releases, the default training method used the "four-step" method. To preserve compatibility, set the `TrainingMethod` property to `'four-step'`.

Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set `'UseParallel'` to `true` or enable this by default using the Computer Vision Toolbox preferences.

For more information, see “Parallel Computing Toolbox Support”.

trainMaskRCNN

Train Mask R-CNN network to perform instance segmentation

Syntax

```
trainedDetector = trainMaskRCNN(trainingData,network,options)
trainedDetector = trainMaskRCNN(trainingData,network,options,Name=Value)
[trainedDetector,info] = trainMaskRCNN(trainingData,network,options)
```

Description

`trainedDetector = trainMaskRCNN(trainingData,network,options)` trains a Mask R-CNN network. A trained Mask R-CNN network object can perform instance segmentation to detect and segment multiple object classes. This syntax supports transfer learning on a pretrained Mask R-CNN network and training an uninitialized Mask R-CNN network.

This function requires that you have Deep Learning Toolbox. It is recommended that you also have Parallel Computing Toolbox to use with a CUDA-enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

`trainedDetector = trainMaskRCNN(trainingData,network,options,Name=Value)` uses additional options specified by one or more name-value arguments.

`[trainedDetector,info] = trainMaskRCNN(trainingData,network,options)` also returns information on the training progress, such as training loss and accuracy, for each iteration.

Input Arguments

`trainingData` — Labeled ground truth

datastore

Labeled ground truth training data, specified as a datastore. Your data must be set up so that calling the datastore with the `read` and `readall` functions returns a cell array with four columns. This table describes the format of each column.

data	*boxes*	*labels*	*masks*
RGB image that serves as a network input, specified as an *H*-by-*W*-by-3 numeric array.	Bounding boxes, specified as *M*-by-4 matrices, where *M* is the number of objects within the image. Each bounding box has the format [*x y width height*], where [*x*, *y*] represent the top-left coordinates of the bounding box.	Object class names, specified as an *M*-by-1 categorical vector. All categorical data returned by the datastore must contain the same categories.	Binary masks, specified as a logical array of size *H*-by-*W*-by-*M*. Each mask is the segmentation of one instance in the image.

You can create a datastore that returns data in the required format using these steps:

1. Create an `imageDatastore` that returns RGB image data
2. Create a `boxLabelDatastore` that returns bounding box data and instance labels as a two-element cell array
3. Create an `imageDatastore` and specify a custom read function that returns mask data as a binary matrix
4. Combine the three datastores using the `combine` function

For more information, see “Getting Started with Mask R-CNN for Instance Segmentation”.

`network` — Mask R-CNN network to train
`maskrcnn` object

Mask R-CNN network to train, specified as a `maskrcnn` object.

`options` — Training options
`TrainingOptionsSGDM` object | `TrainingOptionsRMSProp` object | `TrainingOptionsADAM` object

Training options, specified as a `TrainingOptionsSGDM`, `TrainingOptionsRMSProp`, or `TrainingOptionsADAM` object returned by the `trainingOptions` function. To specify the solver name and other options for network training, use the `trainingOptions` function. You must set the `ResetInputNormalization` property as `false`.

Note If you specify the `OutputFcn` function handle using the `OutputFcn` name-value argument, it must use a per-epoch `info` structure with these fields:

- `Epoch`
- `Iteration`
- `TimeElapsed`
- `LearnRate`
- `TrainingLoss`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `trainedDetector = trainMaskRCNN(trainingData,network,options,NumRegionsToSample=64)` samples 64 region proposals from each training image

`PositiveOverlapRange` — Bounding box overlap ratios for positive training samples
`[0.5 1]` (default) | two-element numeric vector

Bounding box overlap ratios for positive training samples, specified as a two-element numeric vector with values in the range [0, 1]. Region proposals that overlap with ground truth bounding boxes within the specified range are used as positive training samples.

The overlap ratio for bounding boxes A and B is:

$$\frac{area(A \cap B)}{area(A \cup B)}$$

`NegativeOverlapRange` — Bounding box overlap ratios for negative training samples
`[0.1 0.5]` (default) | two-element numeric vector

Bounding box overlap ratios for negative training samples, specified as a two-element numeric vector with values in the range [0, 1]. Region proposals that overlap with the ground truth bounding boxes within the specified range are used as negative training samples.

The overlap ratio for bounding boxes A and B is:

$$\frac{area(A \cap B)}{area(A \cup B)}$$

`NumStrongestRegions` — Maximum number of strongest region proposals
`1000` (default) | positive integer | `Inf`

Maximum number of strongest region proposals to use for generating training samples, specified as a positive integer. Reduce this value to speed up processing time at the cost of training accuracy. To use all region proposals, set this value to `Inf`.

`NumRegionsToSample` — Number of region proposals
`128` (default) | positive integer

Number of region proposals to randomly sample from each training image, specified as a positive integer. Reduce the number of regions to sample to reduce memory usage and speed up training. Reducing the value can also decrease training accuracy.

`FreezeSubNetwork` — Subnetworks to freeze
`"none"` (default) | `"backbone"` | `"rpn"` | `["backbone" "rpn"]`

Subnetworks to freeze during training, specified as one of these values:

- `"none"` — Do not freeze subnetworks
- `"backbone"` — Freeze the feature extraction subnetwork, including the layers following the ROI align layer
- `"rpn"` — Freeze the region proposal subnetwork
- `["backbone" "rpn"]` — Freeze both the feature extraction and the region proposal subnetworks

The weight of layers in frozen subnetworks does not change during training.

`ExperimentManager` — Training experiment monitor
`"none"` (default) | `experiments.Monitor` object

Training experiment monitor, specified as an `experiments.Monitor` object for use with the Experiment Manager app. You can use this object to track the progress of training, update information fields in the training results table, record values of the metrics used by the training, and to produce training plots.

Information monitored during training:

- Training loss at each iteration

- Training accuracy at each iteration
- Training root mean square error (RMSE) for the box regression layer
- Training loss for the mask segmentation branch
- Learning rate at each iteration

Validation information when the training `options` input contains validation data:

- Validation loss at each iteration
- Validation accuracy at each iteration
- Validation RMSE at each iteration
- Validation loss for the mask segmentation branch

Output Arguments

`trainedDetector` — Trained Mask R-CNN network
`maskrcnn` object

Trained Mask R-CNN network, returned as a `maskrcnn` object.

`info` — Training progress information
structure

Training progress information, returned as a structure. Each field corresponds to a stage of training.

- `TrainingLoss` — Training loss at each iteration. The loss is the combination of the region proposal network (RPN), classification, regression and mask loss used to train the Mask R-CNN network.
- `TrainingRPNLoss` — Total RPN loss at the end of each iteration.
- `TrainingRMSE` — Training root mean squared error (RMSE) for the box regression layer at the end of each iteration.
- `TrainingMaskLoss` — Training cross-entropy loss for the mask segmentation branch at the end of each iteration.
- `LearnRate` — Learning rate at each iteration.
- `ValidationLoss` — Validation loss at each iteration.
- `ValidationRPNLoss` — Validation RPN loss at each iteration.
- `ValidationRMSE` — Validation RMSE at each iteration.
- `ValidationMaskLoss` — Validation cross-entropy loss for the mask segmentation branch at each iteration.

Each field is a numeric vector with one element per training iteration. Values that are not calculated at a specific iteration are assigned as `NaN`. The structure contains the `ValidationLoss`, `ValidationRPNLoss`, `ValidationRMSE`, and `ValidationMaskLoss` fields only when `options` specifies validation data.

Tips

- The `trainMaskRCNN` function has a high GPU memory requirement. It is recommended to train a Mask R-CNN network with at least 12 GB of available GPU memory.

- To reduce the training memory consumption, try reducing the `InputSize` property of the `network` argument or the `NumRegionsToSample` name-value argument.
- When you want to perform transfer learning on a data set with similar content to the COCO data set, freezing the feature extraction and region proposal subnetworks can help the network training converge faster.

Version History

Introduced in R2022a

R2025a: MATLAB Compiler support will be removed
Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

R2022b: Supports training options with plots

When you specify `options`, the `Plots` property of the `trainingOptions` object can now have a value other than `"none"`. Before, `trainMaskRCNN` supported only the value of `"none"`.

Extended Capabilities

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU acceleration.

By default, the `trainMaskRCNN` function uses a GPU if one is available. You can specify the hardware that the `trainMaskRCNN` function uses by setting the `ExecutionEnvironment` training option using the `trainingOptions` function.

For more information, see “Scale Up Deep Learning in Parallel, on GPUs, and in the Cloud” (Deep Learning Toolbox).

trainPoseMaskRCNN

Train Pose Mask R-CNN network to perform pose estimation

Syntax

```
net = trainPoseMaskRCNN(trainingData,network,trainingStage,options)
[net,info] = trainPoseMaskRCNN(trainingData,network,trainingStage,options)
[___] = trainPoseMaskRCNN(___,Name=Value)
```

Description

`net = trainPoseMaskRCNN(trainingData,network,trainingStage,options)` trains a Pose Mask R-CNN network to perform six-degrees-of-freedom (6-DoF) pose estimation for multiple object classes.

Note This functionality requires Deep Learning Toolbox and the Computer Vision Toolbox Model for Pose Mask R-CNN 6-DoF Object Pose Estimation. To use this functionality in parallel, you must have a license for Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

`[net,info] = trainPoseMaskRCNN(trainingData,network,trainingStage,options)` also returns information on the training progress, such as training loss and accuracy, for each iteration.

`[___] = trainPoseMaskRCNN(___,Name=Value)` specifies options using name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `NumRegionsToSample=64` specifies for the `trainPoseMaskRCNN` function to sample 64 region proposals from each training image.

Input Arguments

`trainingData` — Labeled training data

datastore

Labeled training data, specified as a datastore. Your data must be set up so that reading the datastore using the `read` or `readall` function returns a cell array with seven columns. This table describes the format of each column.

Input Image Data	Depth Image Data	Bounding Boxes	Labels	Masks	6-DoF Object Poses	Camera Intrinsic Parameters
RGB image, stored as an *H*-by-*W*-by-3 numeric array, or grayscale image, stored as an *H*-by-*W* numeric matrix.	Depth image, stored as an *H*-by-*W* numeric matrix.	Bounding boxes, stored as an *M*-by-4 matrix. *M* is the number of objects detected in the image. Each row of the matrix specifies the bounding box of the corresponding object in the form [*x y width height*], where *x* and *y* are the position of the top-left corner of the bounding box.	Object class names, stored as an *M*-by-1 categorical vector. All categorical data returned by the datastore must contain the same categories.	Binary masks, stored as an *H*-by-*W*-by-*M*. Each page of the array specifies the binary mask of the corresponding detected object.	6-DoF object poses, stored as an *M*-by-1 vector of `rigidtform3d` objects.	Camera intrinsic parameters, stored as a scalar `cameraIntrinsics` object. All images in the training data set must have the same camera intrinsic parameters.

`network` — Pose Mask R-CNN pose estimation network to train
`posemaskrcnn` object

Pose Mask R-CNN pose estimation network to train, specified as a `posemaskrcnn` object.

`trainingStage` — Training stage
`"mask"` | `"pose-and-mask"` | `"pose-refinement"`

Training stage that specifies the losses to apply during training, specified as one of these options:

- `"mask"` — Applies classification, bounding box regression, and segmentation mask losses.
- `"pose-and-mask"` — Applies classification, bounding box regression, segmentation mask, rotation, and translation losses.
- `"pose-refinement"` — Applies classification, bounding box regression, segmentation mask, rotation, and translation losses. This option calculates rotation loss using a ShapeMatch loss which has been optimized for object symmetry [1]. When you specify `trainingStage` as `"pose-refinement"`, you must specify the `ReferencePointClouds` name-value argument. To improve performance during this stage, increase the value of the `RotationLossWeight` name-value argument.

You must train a Pose Mask R-CNN pose estimation network in two stages. First, train the network on only the instance segmentation task in the `"mask"` stage. Then, train the output network on the pose

estimation task in the `"pose-and-mask"` stage. Optionally, you can train the network in the third `"pose-refinement"` stage to refine 6-DoF rotation predictions.

`options` — Training options
`TrainingOptionsSGDM` object | `TrainingOptionsRMSProp` object | `TrainingOptionsADAM` object

Training options, specified as a `TrainingOptionsSGDM`, `TrainingOptionsRMSProp`, or `TrainingOptionsADAM` object returned by the `trainingOptions` function. To specify the solver name and other options for network training, use the `trainingOptions` function.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `trainPoseMaskRCNN(trainingData,network,options,trainingMode,NumRegionsToSample=64)` samples 64 region proposals from each training image.

`PositiveOverlapRange` — Bounding box overlap ratios for positive training samples
`[0.5 1]` (default) | two-element numeric vector

Bounding box overlap ratios for positive training samples, specified as a two-element numeric vector with values in the range [0, 1]. The function compares region proposals to ground truth bounding boxes, and uses the proposals with overlap ratios within the specified range as positive training samples.

Given two bounding boxes, A and B, the overlap ratio is:

$$\frac{area(A \cap B)}{area(A \cup B)}$$

`NegativeOverlapRange` — Bounding box overlap ratios for negative training samples
`[0.1 0.5]` (default) | two-element numeric vector

Bounding box overlap ratios for negative training samples, specified as a two-element numeric vector with values in the range [0, 1]. The function compares region proposals to ground truth bounding boxes, and uses the proposals with overlap ratios within the specified range as negative training samples.

Given two bounding boxes, A and B, the overlap ratio is:

$$\frac{area(A \cap B)}{area(A \cup B)}$$

`NumStrongestRegions` — Maximum number of strongest region proposals
`1000` (default) | positive integer | `Inf`

Maximum number of strongest region proposals to use for generating training samples, specified as a positive integer. Reduce this value to speed up processing time at the cost of training accuracy. To use all region proposals, set this value to `Inf`.

`NumRegionsToSample` — Number of region proposals
128 (default) | positive integer

Number of region proposals to randomly sample from each training image, specified as a positive integer. Specifying a smaller number of regions to sample can reduce memory usage and increase training speed, but can also decrease training accuracy.

`FreezeSubNetwork` — Subnetworks to freeze
`"none"` (default) | `"backbone"` | `"rpn"` | `["backbone" "rpn"]`

Subnetworks to freeze during training, specified as one of these values:

- `"none"` — Do not freeze subnetworks.
- `"backbone"` — Freeze the feature extraction subnetwork, including the layers following the ROI align layer.
- `"rpn"` — Freeze the region proposal subnetwork.
- `["backbone" "rpn"]` — Freeze both the feature extraction and the region proposal subnetworks.

The weight of layers in frozen subnetworks does not change during training.

`ExperimentMonitor` — Training experiment monitor
`"none"` (default) | `experiments.Monitor` object

Training experiment monitor, specified as an `experiments.Monitor` object for use with the Experiment Manager app. You can use this object to track the progress of training, update information fields in the training results table, record values of the metrics used by the training, and to produce training plots.

Information monitored during training:

- Training loss at each iteration
- Training accuracy at each iteration
- Training root mean square error (RMSE) for the box regression layer
- Training loss for the mask segmentation branch
- Training rotation loss at each iteration
- Training translation loss at each iteration
- Learning rate at each iteration

Validation information when the training `options` input argument contains validation data:

- Validation loss at each iteration
- Validation accuracy at each iteration
- Validation RMSE at each iteration
- Validation loss for the mask segmentation branch
- Validation rotation loss at each iteration
- Validation translation loss at each iteration

`TranslationLossWeight` — Translation loss weight
1 (default) | positive scalar

Translation loss weight, specified as a positive scalar. Adjust the `TranslationLossWeight` value so that the translation loss `TrainingTranslationLoss` after weighting is the same order of magnitude as the values of `TrainingRPNLoss`, `TrainingRMSE`, `TrainingClassLoss`, and `TrainingMaskLoss`.

`RotationLossWeight` — Rotation loss weight
1 (default) | positive scalar

Rotation loss weight, specified as a positive scalar. Adjust the `RotationLossWeight` value so that the rotation loss `TrainingRotationLoss` after weighting is the same order of magnitude as the values of `TrainingRPNLoss`, `TrainingRMSE`, `TrainingClassLoss`, and `TrainingMaskLoss`.

`BoxLossWeight` — Bounding box regression loss weight
1 (default) | positive scalar

Bounding box regression loss weight, specified as a positive scalar. In most cases, train the Pose Mask R-CNN network with the default value.

`ClassLossWeight` — Classification loss weight
1 (default) | positive scalar

Classification loss weight, specified as a positive scalar. In most cases, train the Pose Mask R-CNN network with the default value.

`MaskLossWeight` — Mask loss weight
1 (default) | positive scalar

Mask loss weight to use for instance segmentation, specified as a positive scalar. In most cases, train the Pose Mask R-CNN network with the default value.

`RPNLossWeight` — Region proposal network (RPN) training loss weight
1 (default) | positive scalar

Region proposal network (RPN) training loss weight, specified as a positive scalar. In most cases, train the Pose Mask R-CNN network with the default value.

`ReferencePointClouds` — Reference point clouds
`[]` (default) | *N*-by-1 array of `pointCloud` objects

Reference point clouds, specified as an *N*-by-1 array of `pointCloud` objects. *N* is the number of object classes. The order of the point clouds corresponds to the order of ground truth labels.

Output Arguments

`net` — Trained Pose Mask R-CNN pose estimation network
`posemaskrcnn` object

Trained Pose Mask R-CNN pose estimation network, returned as a `posemaskrcnn` object.

`info` — Training progress information
structure

Training progress information, returned as a structure. Each field corresponds to a stage of training.

- `TrainingLoss` — Training loss at each iteration. The loss is the combination of the RPN, classification, regression, and mask segmentation losses used to train the Pose Mask R-CNN pose estimation network.
- `TrainingRPNLoss` — Total RPN loss at the end of each iteration.
- `TrainingRMSE` — Training RMSE for the box regression layer at the end of each iteration.
- `TrainingClassLoss` — Training cross-entropy loss for the classification layer at the end of each iteration.
- `TrainingMaskLoss` — Training cross-entropy loss for the mask segmentation branch at the end of each iteration.
- `TrainingRotationLoss` — Training rotation prediction branch loss at the end of each iteration.
- `TrainingTranslationLoss` — Training regression loss for the translation prediction branch at the end of each iteration.
- `LearnRate` — Learning rate at each iteration.
- `ValidationLoss` — Validation loss at each iteration.
- `ValidationRPNLoss` — Validation RPN loss at each iteration.
- `ValidationRMSE` — Validation RMSE at each iteration.
- `ValidationClassLoss` — Validation classification loss at each iteration.
- `ValidationMaskLoss` — Validation cross-entropy loss for the mask segmentation branch at each iteration.
- `ValidationRotationLoss` — Validation rotation loss at each iteration.
- `ValidationTranslationLoss` — Validation translation loss at each iteration.

Each field contains a numeric vector with one element per training iteration. If the function does not calculate a metric for a specific iteration, it assigns a value of `NaN` for that iteration. The structure contains the `ValidationLoss`, `ValidationRPNLoss`, `ValidationRMSE`, and `ValidationMaskLoss` fields only when `options` specifies validation data.

Tips

- The `trainPoseMaskRCNN` function has a high GPU memory requirement. It is recommended to train a Pose Mask R-CNN network with at least 12 GB of available memory.
- To reduce memory consumption during training, you can decrease the value of the `NumRegionsToSample` name-value argument to limit the number of proposals from the region proposal stage. Note that this also reduces accuracy and increases convergence time.

Version History

Introduced in R2024a

R2025a: MATLAB Compiler support will be removed
Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

R2025a: Train Post Mask R-CNN network in three stages to refine 6-DoF rotation predictions

Specify the `trainingMode` input argument as `"pose-refinement"` to use the ShapeMatch loss during an optional third training stage to refine 6-DoF rotation predictions. When you specify `trainingStage` as `"pose-refinement"`, you must also specify the `ReferencePointClouds` name-value argument.

trainReidentificationNetwork

Train re-identification (ReID) deep learning network

Syntax

```
trainedReID = trainReidentificationNetwork(trainingData,reID,options)
[trainedReID,info] = trainReidentificationNetwork( ___ )
[ ___ ] = trainReidentificationNetwork( ___ ,Name=Value)
```

Description

`trainedReID = trainReidentificationNetwork(trainingData,reID,options)` trains the specified ReID network `reID` to output appearance feature vectors. The `options` input specifies the network training parameters.

Note This functionality requires Deep Learning Toolbox.

`[trainedReID,info] = trainReidentificationNetwork( ___ )` returns information on training progress, such as training loss, for each iteration using the input arguments from the previous syntax.

`[ ___ ] = trainReidentificationNetwork( ___ ,Name=Value)` specifies options using one or more name-value arguments, in addition to any combination of arguments from previous syntaxes. For example, `FreezeBackbone=false` specifies not to freeze the backbone of the network during training.

Input Arguments

`trainingData` — Training data

`imageDatastore` object | datastore

Training data of RGB or grayscale images, specified as an `imageDatastore` object with a populated `Labels` property, or a datastore whose `read` function returns a 2-by-*B* cell array, where *B* is the number of images in the datastore. Each row of the cell array is of the form {*Image Class*}.

Image	Class
RGB image, stored as an *H*-by-*W*-by-3 numeric array, or grayscale image, stored as an *H*-by-*W* matrix.	String or a categorical cell vector which contains the object class name for the corresponding input image in *Image*. All categorical data returned by the datastore must have the same categories.

`reID` — Re-identification network

`reidentificationNetwork` object

Re-identification network, specified as a `reidentificationNetwork` object.

options — Training options
`TrainingOptionsSGDM` object | `TrainingOptionsRMSProp` object | `TrainingOptionsADAM` object

Training options, specified as a `TrainingOptionsSGDM`, `TrainingOptionsRMSProp`, or `TrainingOptionsADAM` object returned by the `trainingOptions` function. To specify the solver name and other options for network training, use the `trainingOptions` function.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example:
`trainReidentificationNetwork(trainingData,reID,options,FreezeBackbone=false)` specifies not to freeze the backbone of the network during training.

LossFunction — Loss function
`"additive-margin-softmax"` (default) | `"cross-entropy"` | `"cosine-softmax"`

Loss function to use in the ReID network, specified as `"additive-margin-softmax"`, `"cross-entropy"`, or `"cosine-softmax"`. To train the ReID network using data that contains very distinct objects, with large variations in shape, color, or texture, use cross-entropy loss, `"cross-entropy"`. To train the ReID network using data that contains both subtle and distinct objects, use additive-margin-softmax loss, `"additive-margin-softmax"` or cosine-softmax loss, `"cosine-softmax"`.

FreezeBackbone — Freeze backbone of ReID network
`true` or `1` (default) | `false` or `0`

Freeze the backbone of the ReID network during training, specified as a numeric or logical `true` (`1`) or `false` (`0`). When `true`, the function freezes the ReID network up to the feature layer, as specified by the `FeatureLayer` property of the `reidentificationNetwork` object. When `false`, the classification layers of the ReID network remain unfrozen, and training speed is slower.

Tip If you adjust the input size of the backbone network, or use a backbone network that has not been pretrained, set `FreezeBackbone` to `false`.

ExperimentMonitor — ReID training experiment monitoring
`[]` (default) | `experiments.Monitor` object

ReID training experiment monitoring, specified as an `experiments.Monitor` object for use with the Experiment Manager app. You can use this object to track the progress of training, update information fields in the training results table, record values of the metrics used by the training, or produce training plots. For more information on using this app, see the “Train Object Detectors in Experiment Manager” example.

The app monitors this information during training:

- Training loss at each iteration
- Learning rate at each iteration

- Validation loss at each iteration, if the `options` input contains validation data

`Margin` — Margin in loss function
`0.35` (default) | nonnegative scalar

Margin in the loss function, specified as a non-negative scalar in the range `[0, 1]`. To specify this argument, you must specify `LossFunction` as `"additive-margin-softmax"`.

`Scale` — Scale in loss function
`30` (default) | positive scalar

Scale in the loss function, specified as a positive scalar. To specify this argument, you must specify `LossFunction` as `"additive-margin-softmax"`.

Output Arguments

`trainedReID` — Trained ReID network
`reidentificationNetwork` object

Trained ReID network, returned as a `reidentificationNetwork` object. The trained network outputs feature vectors of the size specified by its `FeatureLength` property.

`info` — Training progress information
structure array

Training progress information, returned as a structure array with these fields. Each field corresponds to a stage of training.

- `TrainingLoss` — Training loss at each iteration
- `BaseLearnRate` — Learning rate at each iteration
- `ValidationLoss` — Validation loss at each iteration.
- `FinalValidationLoss` — Final validation loss at the end of the training

Each field contains a numeric vector with one element per training iteration. If the function does not calculate a metric for a specific iteration, it assigns a value of `NaN` for that iteration. The structure contains the `ValidationLoss` and `FinalValidationLoss` fields only when `options` specifies validation data.

Tips

- To improve ReID accuracy, increase the number of images you use to train the network. You can expand the training data set using data augmentation. For information on how to apply data augmentation for preprocessing, see “Preprocess Images for Deep Learning” (Deep Learning Toolbox).

Version History

plot

Plot re-identification (ReID) metrics

Syntax

```
plot(metrics,type)
plot(metrics,type,Name=Value)
```

Description

`plot(metrics,type)` plots the ReID metrics `metrics`.

`plot(metrics,type,Name=Value)` specifies options using one or more name-value arguments. For example, `LineColor="r"` plots the specified metric type with a red line.

Input Arguments

`metrics` — ReID metrics

`reidentificationMetrics` object

ReID metrics, specified as a `reidentificationMetrics` object.

`type` — Type of metric to plot

`"cmc"` | `"cmc-per-object"` | `"precision-recall"`

Type of metric to plot, specified as one of these options:

- `"cmc"` — Cumulative matching characteristic (CMC) curve over the entire data set
- `"cmc-per-object"` — Cumulative matching characteristic (CMC) curve per object class
- `"precision-recall"` — Precision-recall curve

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `plot(metrics,"precision-recall",LineColor="r")` plots the precision-recall curve with a red line.

`ShowLegend` — Option to display legend

`true` or `1` | `false` or `0`

Option to display legend, specified as a numeric or logical `1` (`true`) or `0` (`false`). If you specify the plot type as `"cmc-per-object"` and there are 10 or fewer object classes, `ShowLegend` is `true` by default and the `plot` object function displays the legend.

`Parent` — Figure axes

`gca` (default) | `Axes` object

Figure axes, specified as an `Axes` object.

`LineColor` — Plot line color
`[0 0 0]` (default) | short or long color name | RGB triplet | three-column matrix of RGB triplets

Plot line color, specified as one or more 1-by-3 RGB triplets, or a long or short color name. If you specify the plot type as `"cmc-per-object"`, you can specify a different color for each line by using a matrix in which each row is an RGB triplet. To specify one color for all lines, specify `LineColor` as a color name or a single RGB triplet.

`LineWidth` — Plot line width
2 (default) | positive integer

Plot line width, in pixels, specified as a positive integer.

trainSOLOV2

Train SOLOv2 network to perform instance segmentation

Syntax

```
trainedDetector = trainSOLOV2(trainingData,network,options)
[trainedDetector,info] = trainSOLOV2(trainingData,network,options)
[___] = trainSOLOV2(___,Name=Value)
```

Description

`trainedDetector = trainSOLOV2(trainingData,network,options)` trains a SOLOv2 network to perform instance segmentation. A trained SOLOv2 network object can perform instance segmentation to detect and segment multiple object classes. This syntax supports transfer learning on a pretrained SOLOv2 network, as well as training an uninitialized SOLOv2 network.

Note This functionality requires Deep Learning Toolbox and the Computer Vision Toolbox Model for SOLOv2 Instance Segmentation. You can install the Computer Vision Toolbox Model for SOLOv2 Instance Segmentation from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

`[trainedDetector,info] = trainSOLOV2(trainingData,network,options)` also returns information on the training progress, such as the training loss for each iteration.

`[___] = trainSOLOV2(___,Name=Value)` specifies network training options using name-value arguments, in addition to any combination of output arguments from previous syntaxes. For example, `FreezeSubNetwork="none"` specifies not to freeze subnetworks during training.

Input Arguments

`trainingData` — Labeled ground truth training data

datastore

Labeled ground truth training data, specified as a datastore. You must set up your data so that calling the `read` and `readall` functions on the datastore returns a cell array with four columns. This table describes the format of each cell in each column.

Data	Boxes	Labels	Masks
RGB or grayscale image that serves as a network input, specified as an *H*-by-*W*-by-3 or *H*-by-*W*-by-1 numeric array, respectively.	Bounding boxes, defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and `y` specify the upper-left corner of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis. • *h* specifies the height of the rectangle, which is its length along the *y*-axis.	Object class names, specified as an *M*-by-1 categorical vector, where *M* is the number of object instances in the image. All categorical data read from the datastore must contain the same categories.	Binary masks, specified as a logical array of size *H*-by-*W*-by-*M*, where *M* is the number of boxes in the image. Each channel is a mask, and each mask is the segmentation of one object instance in the image.

You can create a datastore that returns data in the required format using these steps:

1. Create an `ImageDatastore` that returns RGB or grayscale image data.
2. Create a `boxLabelDatastore` that returns bounding box data and instance labels as a two-element cell array.
3. Create an `ImageDatastore` and specify a custom read function that returns mask data as a binary matrix.
4. Combine the three datastores using the `combine` function.

For more information, see “Get Started with SOLOv2 for Instance Segmentation”.

`network` — SOLOv2 instance segmentation network to train
`solov2` object

SOLOv2 instance segmentation network to train, specified as a `solov2` object.

`options` — Training options
`TrainingOptionsSGDM` object | `TrainingOptionsRMSProp` object | `TrainingOptionsADAM` object

Training options, specified as a `TrainingOptionsSGDM`, `TrainingOptionsRMSProp`, or `TrainingOptionsADAM` object returned by the `trainingOptions` function. To specify the solver name and other options for network training, use the `trainingOptions` function.

Note If you specify the `OutputFcn` function handle using the `OutputFcn` name-value argument, it must use a per-epoch `info` structure with these fields:

- `Epoch`
- `Iteration`
- `TimeElapsed`
- `LearnRate`
- `TrainingLoss`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `trainedDetector = trainSOLOV2(trainingData,network,options,FreezeSubNetwork="none")` specifies not to freeze subnetworks during training.

`FreezeSubNetwork` — Subnetworks to freeze
`"backbone"` (default) | `"none"` | `"backboneAndNeck"`

Subnetworks to freeze during training, specified as one of these values:

- `"none"` — Do not freeze subnetworks.
- `"backbone"` — Freeze the feature extraction subnetwork, including the layers following the region of interest (ROI) align layer.
- `"backboneAndNeck"` — Freeze the feature extraction subnetwork, as well as the path aggregation network used to mix backbone features at different scales.

The weight of layers in frozen subnetworks does not change during training.

`ExperimentMonitor` — Network training experiment monitoring
`"none"` (default) | `experiments.Monitor` object

Network training experiment monitoring, specified as an `experiments.Monitor` object for use with the Experiment Manager app. You can use this object to track the progress of training, update information fields in the training results table, record values of the metrics used for training, and produce training plots. For more information on using this app, see the “Train Object Detectors in Experiment Manager” example.

The app monitors this information during training:

- Training loss at each iteration
- Learning rate at each iteration

When the `options` input contains validation data, the app also monitors validation loss at each iteration.

Output Arguments

`trainedDetector` — Trained SOLOv2 instance segmentation model
`solov2` object

Trained SOLOv2 instance segmentation model, returned as a `solov2` object.

`info` — Training progress information
structure

Training progress information, returned as a structure with these fields. Each field corresponds to a stage of training.

- `Epoch` — Epoch number.
- `Iteration` — Iteration number.
- `TimeElapsed` — Time elapsed since the start of training.
- `LearnRate` — Learning rate at each iteration.
- `TrainingLoss` — Training loss at each iteration. The loss is the combination of the region proposal network (RPN), classification, regression and mask loss used to train the SOLOv2 network.
- `OutputNetworkIteration` — Iteration number that corresponds to the returned trained network.

Each field contains a numeric vector with one element per training iteration. For information that the function does not calculate at a specific iteration, the value is `NaN`. If `solov2` specifies validation data, the `info` structure also contains a `ValidationLoss` field.

Tips

- For cases in which the network training does not converge, try specifying the `GradientThreshold` argument when calling the `trainingOptions` function.
- When you want to perform transfer learning on a data set with similar content to the COCO data set, freeze the backbone and neck of the network to help the network training converge faster.

Version History

Introduced in R2023b

R2025a: MATLAB Compiler support will be removed
Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

Extended Capabilities

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU acceleration.

By default, the `trainSOLOV2` function uses a GPU if one is available. You can specify the hardware that the `trainSOLOV2` function uses by setting the `ExecutionEnvironment` training option using the `trainingOptions` function.

For more information, see “Scale Up Deep Learning in Parallel, on GPUs, and in the Cloud” (Deep Learning Toolbox).

trainYOLOv2ObjectDetector

Train YOLO v2 object detector

Syntax

```
trainedDetector = trainYOLOv2ObjectDetector(trainingData,detector,options)
trainedDetector = trainYOLOv2ObjectDetector(trainingData,checkpoint,options)
[trainedDetector,info] = trainYOLOv2ObjectDetector( ___ )
 ___  = trainYOLOv2ObjectDetector( ___ ,Name=Value)
```

Description

`trainedDetector = trainYOLOv2ObjectDetector(trainingData,detector,options)` returns an object detector trained using the you only look once version 2 (YOLO v2) network specified by `detector`. The `options` argument specifies training parameters for the detection network.

You can use this syntax for training an untrained detector or for fine-tuning a pretrained detector.

`trainedDetector = trainYOLOv2ObjectDetector(trainingData,checkpoint,options)` resumes training from the saved detector checkpoint.

You can use this syntax to:

- Add more training data and continue the training.
- Improve training accuracy by increasing the maximum number of iterations.

`[trainedDetector,info] = trainYOLOv2ObjectDetector( ___ )` also returns information on the training progress, such as the training accuracy and learning rate for each iteration.

`___ = trainYOLOv2ObjectDetector( ___ ,Name=Value)` uses additional options specified by one or more name-value arguments and any of the previous inputs. For example, `ExperimentMonitor=[]` specifies not to track metrics with the Experiment Manager app.

Examples

Train YOLO v2 Network for Vehicle Detection

Load the training data for vehicle detection into the workspace.

```
data = load("vehicleTrainingData.mat");
trainingData = data.vehicleTrainingData;
```

Specify the directory in which training samples are stored. Add full path to the file names in training data.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata");
trainingData.imageFilename = fullfile(dataDir,trainingData.imageFilename);
```

Randomly shuffle data for training.

```
rng(0)
shuffledIdx = randperm(height(trainingData));
trainingData = trainingData(shuffledIdx,:);
```

Create an `imageDatastore` using the files from the table.

```
imds = imageDatastore(trainingData.imageFilename);
```

Create a `boxLabelDatastore` using the label columns from the table.

```
blds = boxLabelDatastore(trainingData(:,2:end));
```

Combine the datastores.

```
ds = combine(imds,blds);
```

Specify the class names using the label columns from the table.

```
classes = trainingData.Properties.VariableNames(2:end);
```

Specify anchor boxes.

```
anchorBoxes = [8 8; 32 48; 40 24; 72 48];
```

Load a preinitialized YOLO v2 object detection network.

```
load("yolov2VehicleDetectorNet.mat","net");
```

Create the YOLO v2 object detection network.

```
detector = yolov2ObjectDetector(net,classes,anchorBoxes)
```

```
detector =
  yolov2ObjectDetector with properties:

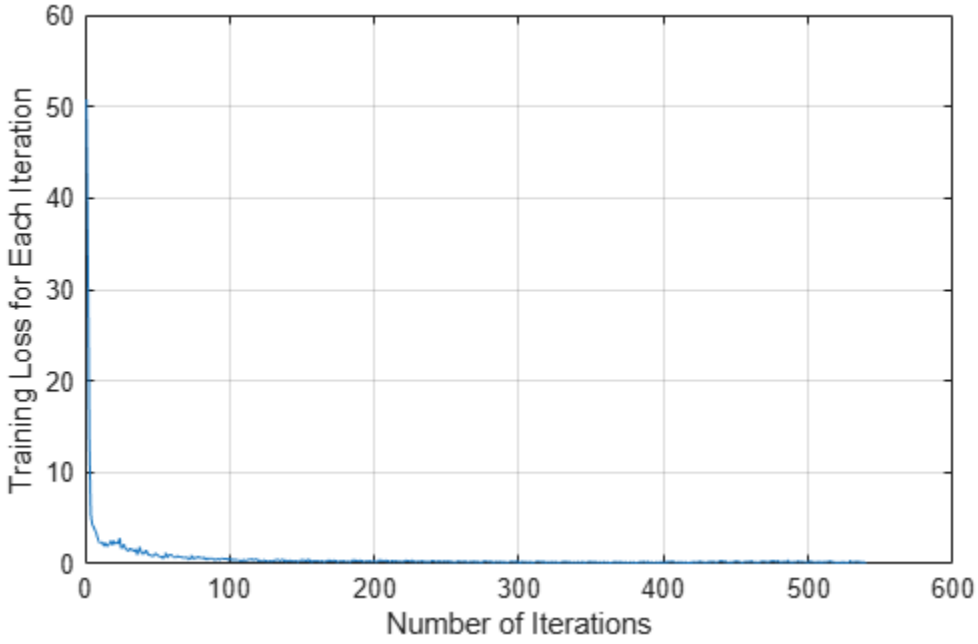
                 Network: [1×1 dlnetwork]
               InputSize: [128 128 3]
       TrainingImageSize: [128 128]
             AnchorBoxes: [4×2 double]
              ClassNames: vehicle
   ReorganizeLayerSource: ''
             LossFactors: [5 1 1 1]
               ModelName: ''
```

Configure the network training options.

```
options = trainingOptions("sgdm", ...
    InitialLearnRate=0.001, ...
    Verbose=true, ...
    MiniBatchSize=16, ...
    MaxEpochs=30, ...
    Shuffle="never", ...
    VerboseFrequency=30, ...
    CheckpointPath=tempdir);
```

Train the YOLO v2 network.

```
[trainedDetector,info] = trainYOLOv2ObjectDetector(ds,detector,options);
```



```

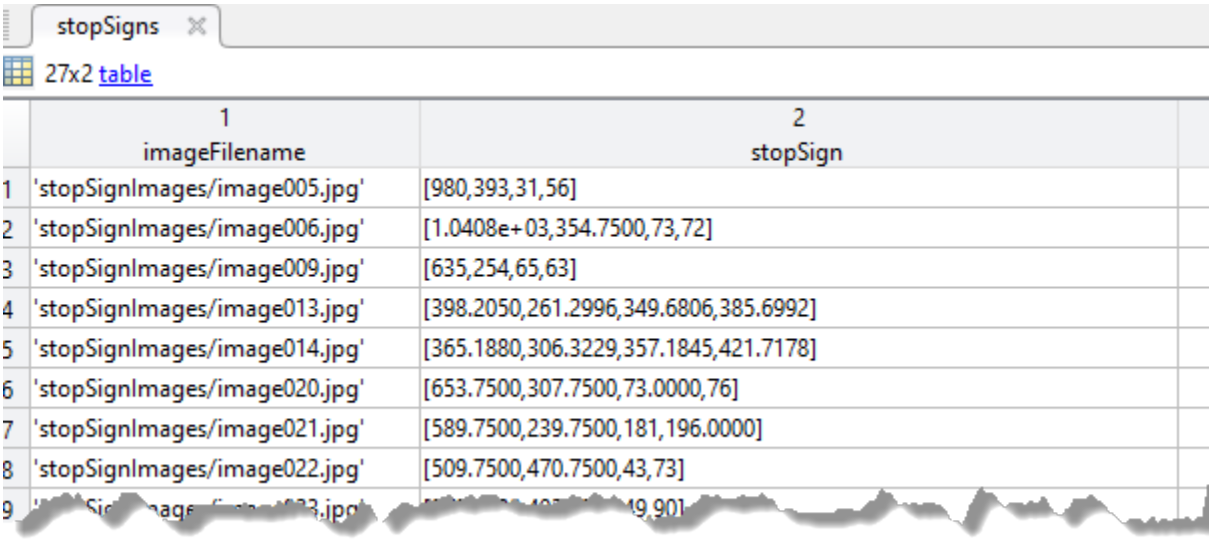
Input Arguments

`trainingData` — Labeled ground truth images

datastore | table

Labeled ground truth images, specified as a datastore or a table.



- If you use a datastore, your data must be set up so that calling the datastore with the `read` and `readall` functions returns a cell array or table with three columns. The second column must contain the bounding boxes, and the third column must contain the labels. The first column can contain image or point cloud data.

data	***boxes***	***labels***
The first column must be images.	*M*-by-4 matrices of bounding boxes of the form [*x*, *y*, *width*, *height*], where [x,y] represent the top-left coordinates of the bounding box.	The third column must be a cell array that contains *M*-by-1 categorical vectors containing object class names. All categorical data returned by the datastore must contain the same categories.

  For more information, see “Datastores for Deep Learning” (Deep Learning Toolbox).

- If you use a table, the table must have two or more columns. The first column of the table must contain image file names with paths. The images must be grayscale or truecolor (RGB) and they can be in any format supported by `imread`. Each of the remaining columns must be a cell vector that contains *M*-by-4 matrices that represent a single object class, such as *vehicle*, *flower*, or *stop sign*. The columns contain 4-element double arrays of *M* bounding boxes in the format [*x*,*y*,*width*,*height*]. The format specifies the upper-left corner location and size of the bounding box

in the corresponding image. To create a ground truth table, you can use the Image Labeler app or Video Labeler app. To create a table of training data from the generated ground truth, use the `objectDetectorTrainingData` function.

stopSigns

27x2 table

	1 imageFilename	2 stopSign

8	'stopSignImages/image022.jpg'	[509.7500,470.7500,43,73]
9		

Note When the training data is specified using a table, the `trainYOLOv2ObjectDetector` function checks these conditions

- The bounding box values must be integers. Otherwise, the function automatically rounds each noninteger values to its nearest integer.
- The bounding box must not be empty and must be within the image region. While training the network, the function ignores empty bounding boxes and bounding boxes that lie partially or fully outside the image region.

`detector` — Pretrained or untrained YOLO v2 object detector
`yolov2ObjectDetector` object

Pretrained or untrained YOLO v2 object detector, specified as a `yolov2ObjectDetector` object. If `detector` is a pretrained detector, then you can continue training the detector with additional training data or perform more training iterations to improve detector accuracy.

`options` — Training options
`TrainingOptionsSGDM` object | `TrainingOptionsRMSProp` object | `TrainingOptionsADAM` object

Training options, specified as a `TrainingOptionsSGDM`, `TrainingOptionsRMSProp`, or `TrainingOptionsADAM` object returned by the `trainingOptions` function. To specify the solver name and other options for network training, use the `trainingOptions` function.

Note The `trainYOLOv2ObjectDetector` function does not support these training options:

- The `trainingOptions` `Shuffle` values, `"once"` and `"every-epoch"` are not supported when you use a datastore input.

- Datastore inputs are not supported when you set the `DispatchInBackground` training option to `true`.

`checkpoint` — Saved detector checkpoint
`yolov2ObjectDetector` object

Saved detector checkpoint, specified as a `yolov2ObjectDetector` object. To periodically save a detector checkpoint during training, specify `CheckpointPath`. To control how frequently check points are saved see the `CheckPointFrequency` and `CheckPointFrequencyUnit` training options.

To load a checkpoint for a previously trained detector, load the MAT file from the checkpoint path. For example, if the `CheckpointPath` property of the object specified by `options` is `"/checkpath"`, you can load a checkpoint MAT file by using this code.

```
data = load("/checkpath/yolov2_checkpoint__216__2018_11_16__13_34_30.mat");
checkpoint = data.detector;
```

The name of the MAT file includes the iteration number and timestamp of when the detector checkpoint was saved. The detector is saved in the `detector` variable of the file. Pass this file back into the `trainYOLOv2ObjectDetector` function:

```
yoloDetector = trainYOLOv2ObjectDetector(trainingData,checkpoint,options);
```

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `ExperimentManager="none"` specifies not to monitor the detector training.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `"ExperimentManager","none"`

`ExperimentManager` — Detector training experiment monitoring
`"none"` (default) | `experiments.Monitor` object

Detector training experiment monitoring, specified as an `experiments.Monitor` object for use with the Experiment Manager app. You can use this object to track the progress of training, update information fields in the training results table, record values of the metrics used by the training, and to produce training plots. For an example using this app, see “Train Object Detectors in Experiment Manager”.

Information monitored during training:

- Training loss at each iteration.
- Training accuracy at each iteration.
- Training root mean square error (RMSE) for the box regression layer.
- Learning rate at each iteration.

Validation information when the training `options` input contains validation data:

- Validation loss at each iteration.
- Validation accuracy at each iteration.
- Validation RMSE at each iteration.

Output Arguments

`trainedDetector` — Trained YOLO v2 object detector

`yolov2ObjectDetector` object

Trained YOLO v2 object detector, returned as `yolov2ObjectDetector` object.

`info` — Training progress information

structure array

Training progress information, returned as a structure array with seven fields. Each field corresponds to a stage of training.

- `TrainingLoss` — Training loss at each iteration is the mean squared error (MSE) calculated as the sum of localization error, confidence loss, and classification loss. For more information about the training loss function, see YOLO v2 Training Loss on page 3-1402.
- `TrainingRMSE` — Training root mean squared error (RMSE) is the RMSE calculated from the training loss at each iteration.
- `BaseLearnRate` — Learning rate at each iteration.
- `ValidationLoss` — Validation loss at each iteration.
- `ValidationRMSE` — Validation RMSE at each iteration.
- `FinalValidationLoss` — Final validation loss at end of the training.
- `FinalValidationRMSE` — Final validation RMSE at end of the training.

Each field is a numeric vector with one element per training iteration. Values that have not been calculated at a specific iteration are assigned as `NaN`. The struct contains `ValidationLoss`, `ValidationAccuracy`, `ValidationRMSE`, `FinalValidationLoss`, and `FinalValidationRMSE` fields only when `options` specifies validation data.

More About

Data Preprocessing

By default, the `trainYOLOv2ObjectDetector` function preprocesses the training images by:

- Resizing the input images to match the input size of the network.
- Normalizing the pixel values of the input images to lie in the range [0, 1].

When you specify the training data by using a table, the `trainYOLOv2ObjectDetector` function also augments the input dataset by:

- Reflecting the training data horizontally. The probability for horizontally flipping each image in the training data is 0.5.
- Uniformly scaling (resizing) the training data by a scale factor that is randomly picked from a continuous uniform distribution in the range [1, 1.1].

- Random color jittering for brightness, hue, saturation, and contrast.

When you specify the training data by using a datastore, the `trainYOLOv2ObjectDetector` function does not perform data augmentation. Instead you can augment the training data in datastore by using the `transform` function and then, train the network with the augmented training data. For more information on how to apply augmentation while using datastores, see “Preprocess Images for Deep Learning” (Deep Learning Toolbox).

YOLO v2 Training Loss

During training, the `trainYOLOv2ObjectDetector` function predicts refined bounding box locations by optimizing the mean squared error (MSE) loss between predicted bounding boxes and the ground truth. The loss function is defined as

$$
\begin{aligned}
&K_1 \sum_{i=0}^{S^2} \sum_{j=0}^{B} 1_{ij}^{obj} \left[(x_i - \hat{x}_i)^2 + (y_i - \hat{y}_i)^2 \right] \\
&\quad + K_1 \sum_{i=0}^{S^2} \sum_{j=0}^{B} 1_{ij}^{obj} \left[(\sqrt{w_i} - \sqrt{\hat{w}_i})^2 + \left(\sqrt{h_i} - \sqrt{\hat{h}_i}\right)^2 \right] \\
&\qquad + K_2 \sum_{i=0}^{S^2} \sum_{j=0}^{B} 1_{ij}^{obj} \left(C_i - \hat{C}_i\right)^2 \\
&\qquad\quad + K_3 \sum_{i=0}^{S^2} \sum_{j=0}^{B} 1_{ij}^{noobj} \left(C_i - \hat{C}_i\right)^2 \\
&\qquad\qquad + K_4 \sum_{i=0}^{S^2} 1_i^{obj} \sum_{c \in classes} \left(p_i(c) - \hat{p}_i(c)\right)^2
\end{aligned}
$$

where:

- S is the number of grid cells.
- B is the number of bounding boxes in each grid cell.
- 1_{ij}^{obj} is 1 if the *jth* bounding box in grid cell i is responsible for detecting the object. Otherwise it is set to 0. A grid cell i is responsible for detecting the object, if the overlap between the ground truth and a bounding box in that grid cell is greater than or equal to 0.6.
- 1_{ij}^{noobj} is 1 if the *jth* bounding box in grid cell i does not contain any object. Otherwise it is set to 0.
- 1_i^{obj} is 1 if an object is detected in grid cell i. Otherwise it is set to 0.
- K_1, K_2, K_3, and K_4 are the weights. To adjust the weights, modify the `LossFactors on page 2-0` property of the `detector`.

The loss function can be split into three parts:

- **Localization loss**

  The first and second terms in the loss function comprise the localization loss. It measures error between the predicted bounding box and the ground truth. The parameters for computing the localization loss include the position, size of the predicted bounding box, and the ground truth. The parameters are defined as follows.

- (x_i, y_i), is the center of the *jth* bounding box relative to grid cell i.
- $(\widehat{x}_i, \widehat{y}_i)$, is the center of the ground truth relative to grid cell i.
- w_i and h_i is the width and the height of the *jth* bounding box in grid cell i, respectively. The size of the predicted bounding box is specified relative to the input image size.
- $\widehat{w}_i$ and $\widehat{h}_i$ is the width and the height of the ground truth in grid cell i, respectively.
- K_1 is the weight for localization loss. Increase this value to increase the weightage for bounding box prediction errors.

- **Confidence loss**

  The third and fourth terms in the loss function comprise the confidence loss. The third term measures the objectness (confidence score) error when an object is detected in the *jth* bounding box of grid cell i. The fourth term measures the objectness error when no object is detected in the *jth* bounding box of grid cell i. The parameters for computing the confidence loss are defined as follows.

  - C_i is the confidence score of the *jth* bounding box in grid cell i.
  - $\hat{C}_i$ is the confidence score of the ground truth in grid cell i.
  - K_2 is the weight for objectness error, when an object is detected in the predicted bounding box. You can adjust the value of K_2 to weigh confidence scores from grid cells that contain objects.
  - K_3 is the weight for objectness error, when an object is not detected in the predicted bounding box. You can adjust the value of K_3 to weigh confidence scores from grid cells that do not contain objects.

  The confidence loss can cause the training to diverge when the number of grid cells that do not contain objects is more than the number of grid cells that contain objects. To remedy this, increase the value for K_2 and decrease the value for K_3.

- **Classification loss**

  The fifth term in the loss function comprises the classification loss. For example, suppose that an object is detected in the predicted bounding box contained in grid cell i. Then, the classification loss measures the squared error between the class conditional probabilities for each class in grid cell i. The parameters for computing the classification loss are defined as follows.

  - $p_i(c)$ is the estimated conditional class probability for object class c in grid cell i.
  - $\widehat{p}_i(c)$ is the actual conditional class probability for object class c in grid cell i.
  - K_4 is the weight for classification error when an object is detected in the grid cell. Increase this value to increase the weightage for classification loss.

Tips

- To generate the ground truth, use the Image Labeler or Video Labeler app. To create a table of training data from the generated ground truth, use the `objectDetectorTrainingData` function.
- To improve prediction accuracy:
  - Increase the number of images you can use to train the network. You can expand the training dataset through data augmentation. For information on how to apply data augmentation for preprocessing, see “Preprocess Images for Deep Learning” (Deep Learning Toolbox).

- Perform multiscale training by specifying an input detector whose `TrainingImageSize on page 2-0` property is a matrix with two or more rows. For each training epoch, the `trainYOLOv2ObjectDetector` function randomly resizes the input training images to one of the specified training image sizes.
- Choose anchor boxes appropriate to the dataset for training the network. You can use the `estimateAnchorBoxes` function to compute anchor boxes directly from the training data.

Version History

Introduced in R2019a

R2025a: MATLAB Compiler support will be removed
Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

R2024b: Modified training process
Behavior change in future release

The `trainYOLOv2ObjectDetector` supports a new process to train a `yolov2ObjectDetector` object. The function now uses:

- Class names specified by the `ClassNames on page 2-0` property of the `yolov2ObjectDetector` object. The function no longer uses the class names from the `trainingData` table.
- Anchor boxes specified by the `AnchorBoxes on page 2-0` property of the `yolov2ObjectDetector` object.
- MSE loss weights specified by the `LossFactors on page 2-0` property of the `yolov2ObjectDetector` object.

The `TrainingImageSize` name-value argument is no longer recommended. Instead, specify training image sizes for multiscale training by using the `TrainingImageSize on page 2-0` name-value argument of the `yolov2ObjectDetector` object.

R2024b: `DAGNetwork` objects are not recommended
Not recommended starting in R2024b

Starting in R2024b, `DAGNetwork` objects are not recommended. Instead, specify the network architecture using a `yolov2ObjectDetector` object.

There are no plans to remove support for `DAGNetwork` objects.

trainYOLOv3ObjectDetector

Train YOLO v3 object detector

Syntax

```
detector = trainYOLOv3ObjectDetector(trainingData,detector,options)
detector = trainYOLOv3ObjectDetector(trainingData,checkpoint,options)
[detector,info] = trainYOLOv3ObjectDetector( ___ )
[ ___ ] = trainYOLOv3ObjectDetector( ___ ,Name=Value)
```

Description

`detector = trainYOLOv3ObjectDetector(trainingData,detector,options)` returns an object detector trained using the you only look once version 3 (YOLO v3) network specified by `detector`. The input `detector` can be an untrained or pretrained YOLO v3 object detector. The `options` input specifies training parameters for the detection network.

You can also use this syntax to fine-tune a pretrained YOLO v3 object detector.

`detector = trainYOLOv3ObjectDetector(trainingData,checkpoint,options)` resumes training from the saved detector checkpoint.

You can use this syntax to:

- Add more training data and continue training.
- Improve training accuracy by increasing the maximum number of iterations.

`[detector,info] = trainYOLOv3ObjectDetector( ___ )` also returns information on training progress, using any combination of input arguments from previous syntaxes, such as the training loss and learning rate for each iteration.

`[ ___ ] = trainYOLOv3ObjectDetector( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `ExperimentMonitor=[]` specifies not to track metrics with Experiment Manager.

Note This functionality requires Deep Learning Toolbox. To use the pretrained YOLO v3 deep learning networks trained on COCO dataset, you must install the Computer Vision Toolbox Model for YOLO v3 Object Detection from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Examples

Train YOLO v3 Network for Vehicle Detection

Train a pretrained YOLO v3 object detector to detect vehicles in an image. The object detector uses a tiny YOLO v3 network, trained on the COCO data set as the base network.

Load a `.mat` file containing training data, and extract the training data into the workspace. The training data is a table in which the first column contains the training images and the remaining columns contain the corresponding labeled bounding boxes.

```
data = load("vehicleTrainingData.mat");
trainingData = data.vehicleTrainingData;
```

Specify the directory that contains the training samples. Add the full paths to the filenames in the training data.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata");
trainingData.imageFilename = fullfile(dataDir,trainingData.imageFilename);
```

Create an image datastore using the files from the table.

```
imds = imageDatastore(trainingData.imageFilename);
```

Create a box label datastore using the label columns from the table.

```
blds = boxLabelDatastore(trainingData(:,2:end));
```

Combine the image and box label datastores.

```
ds = combine(imds,blds);
```

Specify the anchor boxes to use for training the network. You must assign at least one anchor box to each output layer of the network. Because the tiny YOLO v3 network contains two output layers, specify the anchor boxes as a two-element cell array.

```
anchorBoxes = {[91 115; 82 106; 58 83];[41 58; 24 32;19 23]};
```

Specify the names of the classes to detect.

```
classes = {'vehicle'};
```

Create a pretrained YOLO v3 deep learning network configured to retrain on the new dataset by using the `yolov3ObjectDetector` function.

```
detector = yolov3ObjectDetector("tiny-yolov3-coco",classes,anchorBoxes);
detector.Network
```

```
ans =
  dlnetwork with properties:

         Layers: [44×1 nnet.cnn.layer.Layer]
    Connections: [45×2 table]
     Learnables: [48×3 table]
          State: [22×3 table]
     InputNames: {'input'}
    OutputNames: {'convOut1'  'convOut2'}
    Initialized: 1

  View summary with summary.
```

Specify the training options.

```
options = trainingOptions("adam", ...
    InitialLearnRate=0.001, ...
```

```
    MiniBatchSize=8, ...
    MaxEpochs=30, ...
    BatchNormalizationStatistics="moving", ...
    ResetInputNormalization=false, ...
    VerboseFrequency=30);
```

Retrain the pretrained YOLO v3 network on the new data set by using the `trainYOLOv3ObjectDetector` function.

```
trainedDetector = trainYOLOv3ObjectDetector(ds,detector,options);
```

```

Fine-Tune YOLO v3 Network for Multiclass Object Detection

Perform transfer learning to fine-tune a pretrained YOLO v3 object detector by freezing its backbone. The detector has been trained for detecting stop signs and the front views and rear views of cars in an image. The detector uses a DarkNet-53 network, trained on the COCO data set, as the base network.

Load a `.mat` file containing training data, and extract the training data into the workspace. The training data is a table in which the first column contains the training images and the remaining columns contain the corresponding labeled bounding boxes.

```
data = load("stopSignsAndCars.mat");
trainingData = data.stopSignsAndCars;
```

Specify the directory that contains the training samples. Add the full paths to the filenames in the training data.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata");
trainingData.imageFilename = fullfile(dataDir,trainingData.imageFilename);
```

Create an image datastore using the files from the table.

```
imds = imageDatastore(trainingData.imageFilename);
```

Create a box label datastore using the label columns from the table.

```
blds = boxLabelDatastore(trainingData(:,2:end));
```

Combine the image and box label datastores.

```
ds = combine(imds,blds);
```

Specify the input size to use for resizing the training images. You must also resize the bounding boxes based on the specified input size.

```
inputSize = [224 224 3];
```

Resize and rescale the training images and bounding boxes by using the `preprocessData` helper function. Convert the preprocessed data to a `datastore` object by using the `transform` function.

```
trainingDataForEstimation = transform(ds,@(data)preprocessData(data,inputSize));
```

Specify the anchor boxes to use for training the network. You must assign at least one anchor box to each output layer of the network. Because the `darknet53-coco` YOLO v3 network contains three output layers, specify the anchor boxes as a three-element cell array.

```
numAnchors = 9;
[anchors,meanIoU] = estimateAnchorBoxes(trainingDataForEstimation,numAnchors);
```

Use larger anchor boxes at lower scale and smaller anchor boxes at higher scale output layers. To do so, sort `anchors` by area, in descending order, and assign the first three to the first output layer, the next three to the second output layer, and the last three to the third output layer of the network.

```
area = anchors(:,1).*anchors(:,2);
[~,idx] = sort(area,"descend");
anchors = anchors(idx,:);
anchorBoxes = {anchors(1:3,:); anchors(4:6,:); anchors(7:9,:)};
```

Specify the names of the classes to detect.

```
classes = {'stopSign','carRear','carFront'};
```

Create a pretrained YOLO v3 deep learning network configured to retrain on the new dataset by using the `yolov3ObjectDetector` function.

```
detector = yolov3ObjectDetector("darknet53-coco",classes,anchorBoxes,InputSize=inputSize);
detector.Network
```

```
ans =
  dlnetwork with properties:

         Layers: [247×1 nnet.cnn.layer.Layer]
    Connections: [273×2 table]
```

```
     Learnables: [294×3 table]
          State: [144×3 table]
     InputNames: {'input'}
    OutputNames: {'convOut1'  'convOut2'  'convOut3'}
    Initialized: 1

  View summary with summary.
```

Specify the training options.

```
options = trainingOptions("sgdm", ...
    InitialLearnRate=0.0001, ...
    MiniBatchSize=4, ...
    MaxEpochs=30, ...
    BatchNormalizationStatistics="moving", ...
    ResetInputNormalization=false, ...
    VerboseFrequency=30);
```

Retrain the pretrained YOLO v3 network on the new data set by using the `trainYOLOv3ObjectDetector` function. To freeze the backbone of the pretrained YOLO v3 network during training, specify the `FreezeSubNetwork` name-value argument to `"backbone"`. The weights of the frozen backbone layers do not change during training, which increases training speed and reduces GPU memory consumption.

```
trainedDetector = trainYOLOv3ObjectDetector(ds,detector,options,FreezeSubNetwork="backbone");
```

```

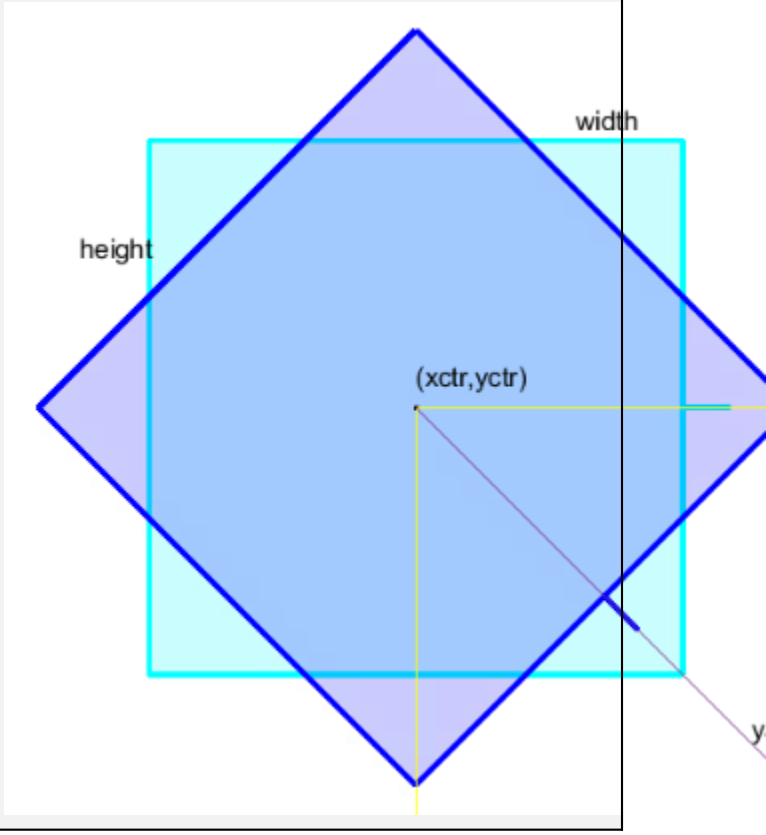
    data(num,1:2) = {I bboxes};
end
end
```

Input Arguments



`trainingData` — Labeled ground truth images
datastore

Labeled ground truth images, specified as a datastore. Data must be set up so that calling the datastore with the `read` and `readall` functions returns a cell array or table with three columns in the format {*data boxes labels*}.

The first column, *data*, must contain the image data, stored as a cell array. The second column, *boxes*, must contain the bounding boxes, stored as a matrix with dimensions determined by the type of bounding box. The third column, *labels*, must be a cell array in which each cell contains an *M*-by-1 categorical vector of object class names, where *M* is the number of bounding boxes. All the categorical data returned by the datastore must use the same categories.

This table describes the format of each element of the bounding boxes column.

Bounding Box	***Description***
Axis-aligned rectangle	Defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and y specify the upper-left corner of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis. • *h* specifies the height of the rectangle, which is its length along the *y*-axis.

Bounding Box	*Description*
Rotated rectangle	Defined in spatial coordinates as an *M*-by-5 numeric matrix with rows of the form [*xctr yctr w h yaw*], where: • *M* is the number of rotated rectangles. • *xctr* and *yctr* specify the center of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis before rotation. • *h* specifies the height of the rectangle, which is its length along the *y*-axis before rotation. • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the bounding box. 

For more information, see “Datastores for Deep Learning” (Deep Learning Toolbox).

Note You can convert a pretrained, axis-aligned network to a rotated rectangle network by providing rotated rectangle training data. When you provide the rotated rectangle training data, the `trainYOLOv3ObjectDetector` function fine-tunes the network, enabling the rotated rectangle detections.

`detector` — Pretrained or untrained YOLO v3 object detector
`yolov3ObjectDetector` object

Pretrained or untrained YOLO v3 object detector, specified as a `yolov3ObjectDetector` object.

`options` — Training options
`TrainingOptionsSGDM` object | `TrainingOptionsRMSProp` object | `TrainingOptionsADAM` object

Training options, specified as a `TrainingOptionsSGDM`, `TrainingOptionsRMSProp`, or `TrainingOptionsADAM` object returned by the `trainingOptions` function. To specify the solver name and other options for network training, use the `trainingOptions` function. You must set the `BatchNormalizationStatistics` property of the object to `"moving"`.

`checkpoint` — Saved detector checkpoint
`yolov3ObjectDetector` object

Saved detector checkpoint, specified as a `yolov3ObjectDetector` object. To periodically save a detector checkpoint during training as a MAT file, specify a location for the file using the `CheckpointPath` property of the training options object `options`. To control how frequently the detector saves checkpoints, use the `CheckPointFrequency` and `CheckPointFrequencyUnit` properties of the training options object.

To load a checkpoint for a previously trained detector, load the MAT file from the checkpoint path. For example, this code loads the checkpoint MAT file of a detector from the `"checkpath"` folder in the current working directory to which the detector saves checkpoints during training.

```
data = load("checkpath/net_checkpoint__6__2023_11_17__16_03_08.mat");
checkpoint = data.net;
```

The name of each MAT file includes the iteration number and timestamp at which the detector saves the checkpoint. The file stores the detector in the `net` variable. To continue training the network, specify the detector extracted from the file to the `trainYOLOv3ObjectDetector` function:

```
yoloDetector = trainYOLOv3ObjectDetector(trainingData,checkpoint,options);
```

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `ExperimentMonitor=[]` specifies not to track metrics with Experiment Manager.

`FreezeSubNetwork` — Subnetworks to freeze
`"none"` (default) | `"backbone"` | `"backboneAndNeck"`

Subnetworks to freeze during training, specified as one of these values:

- `"none"` — Do not freeze subnetworks.
- `"backbone"` — Freeze the feature extraction subnetwork.
- `"backboneAndNeck"` — Freeze both the feature extraction and the path aggregation subnetworks.

The weight of layers in frozen subnetworks does not change during training.

Note You cannot use the `FreezeSubNetwork` argument values `"backbone"` and `"backboneAndNeck"` with a custom YOLO v3 object detector created using the syntax `yolov3ObjectDetector(net,classes,aboxes)`.

`ExperimentMonitor` — Detector training experiment monitoring

`[]` (default) | `experiments.Monitor` object

Detector training experiment monitoring, specified as an `experiments.Monitor` object for use with the Experiment Manager app. You can use this object to track the progress of training, update information fields in the training results table, record values of the metrics used by the training, and to produce training plots. For an example using this app, see "Train Object Detectors in Experiment Manager".

The app monitors this Information during training:

- Training loss at each iteration
- Learning rate at each iteration
- Validation loss at each iteration, if the `options` input contains validation data

Output Arguments

`detector` — Trained YOLO v3 object detector

`yolov3ObjectDetector` object

Trained YOLO v3 object detector, returned as a `yolov3ObjectDetector` object. You can train a YOLO v3 object detector to detect multiple object classes.

`info` — Training progress information

structure array

Training progress information, returned as a structure array with these fields. Each field corresponds to a stage of training.

- `TrainingLoss` — Training loss at each iteration. The `trainYOLOv3ObjectDetector` function uses mean square error for computing bounding box regression loss and cross-entropy for computing classification loss.
- `BaseLearnRate` — Learning rate at each iteration.
- `OutputNetworkIteration` — Iteration number of the returned network.
- `ValidationLoss` — Validation loss at each iteration.
- `FinalValidationLoss` — Final validation loss at the end of the training.

Each field is a numeric vector with one element per training iteration. If the function does not calculate a metric at a specific iteration, the corresponding element of that vector has a value of `NaN`. The structure contains the `ValidationLoss` and `FinalValidationLoss` fields only when `options` specifies validation data.

Tips

- To generate the ground truth, use the Image Labeler or Video Labeler app. To create a table of training data from the generated ground truth, use the `objectDetectorTrainingData` function.

- Use these processes to improve prediction accuracy:
  - Increase the number of images you use to train the network. You can expand the training data set through data augmentation. For information on how to apply data augmentation for preprocessing, see “Preprocess Images for Deep Learning” (Deep Learning Toolbox).
  - Choose anchor boxes appropriate to the training dataset. You can use the `estimateAnchorBoxes` function to compute anchor boxes directly from the training data.
- When you train a rotated rectangle bounding box detector, use a learning rate approximately one order of magnitude below that of its axis-aligned counterpart.
- When you perform transfer learning using a YOLO v3 object detector, consider freezing the subnetworks using the `FreezeSubNetwork` name-value argument to increase training speed and reduce GPU memory consumption.

Version History

Introduced in R2024a

R2025a: MATLAB Compiler support will be removed
Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

R2024b: Monitor mean average precision metric during training

Starting in R2024b, you can use an `mAPObjectDetectionMetric` object to track the mean average precision (mAP) metric while training the YOLO v3 object detector. To use the metric, specify it to the `Metrics` name-value argument of the `trainingOptions` function.

Extended Capabilities

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU acceleration.

By default, the `trainYOLOv3ObjectDetector` function uses a GPU if one is available. You can specify the hardware that the `trainYOLOv3ObjectDetector` function uses by setting the `ExecutionEnvironment` training option using the `trainingOptions` function.

For more information, see “Scale Up Deep Learning in Parallel, on GPUs, and in the Cloud” (Deep Learning Toolbox).

trainYOLOv4ObjectDetector

Train YOLO v4 object detector

Syntax

```
detector = trainYOLOv4ObjectDetector(trainingData,detector,options)
detector = trainYOLOv4ObjectDetector(trainingData,checkpoint,options)
[detector,info] = trainYOLOv4ObjectDetector( ___ )
 ___  = trainYOLOv4ObjectDetector( ___ ,Name=Value)
```

Description

`detector = trainYOLOv4ObjectDetector(trainingData,detector,options)` returns an object detector trained using you only look once version 4 (YOLO v4) network specified by the input `detector`. The input `detector` can be an untrained or pretrained YOLO v4 object detector. The `options` input specifies training parameters for the detection network.

You can also use this syntax for fine-tuning a pretrained YOLO v4 object detector.

`detector = trainYOLOv4ObjectDetector(trainingData,checkpoint,options)` resumes training from the saved detector checkpoint.

You can use this syntax to:

- Add more training data and continue the training.
- Improve training accuracy by increasing the maximum number of iterations.

`[detector,info] = trainYOLOv4ObjectDetector( ___ )` also returns information on the training progress, such as the training accuracy and learning rate for each iteration.

` ___  = trainYOLOv4ObjectDetector( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `trainYOLOv4ObjectDetector(trainingData,ExperimentManager="none")` sets the metrics to track with Experiment Manager to `"none"`.

Note To run this function, you will require the Deep Learning Toolbox.

Examples

Train YOLO v4 Network for Vehicle Detection

This example shows how to fine-tune a pretrained YOLO v4 object detector for detecting vehicles in an image.

Load a tiny YOLO v4 object detector, pretrained on the COCO dataset, and inspect its properties.

```
detector = yolov4ObjectDetector("tiny-yolov4-coco")
```

```
detector =
  yolov4ObjectDetector with properties:

       Network: [1×1 dlnetwork]
    AnchorBoxes: {2×1 cell}
     ClassNames: {80×1 cell}
      InputSize: [416 416 3]
      ModelName: 'tiny-yolov4-coco'
```

The number of anchor boxes must be same the number of output layers in the YOLO v4 network. The tiny YOLO v4 network contains two output layers.

```
detector.Network
```

```
ans =
  dlnetwork with properties:

         Layers: [74×1 nnet.cnn.layer.Layer]
    Connections: [80×2 table]
     Learnables: [80×3 table]
          State: [38×3 table]
     InputNames: {'input_1'}
    OutputNames: {'conv_31'  'conv_38'}
    Initialized: 1
```

Prepare Training Data

Load a .mat file containing the vehicle data set to use for training, in which data is stored as a table. The first column contains the training images and the remaining columns contain the labeled bounding boxes.

```
data = load("vehicleTrainingData.mat");
trainingData = data.vehicleTrainingData;
```

Specify the directory in which to store the training samples. Add the full path to the file names in training data.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata");
trainingData.imageFilename = fullfile(dataDir,trainingData.imageFilename);
```

Create an `ImageDatastore` using the files from the table.

```
imds = imageDatastore(trainingData.imageFilename);
```

Create a `boxLabelDatastore` using the label columns from the table.

```
blds = boxLabelDatastore(trainingData(:,2:end));
```

Combine the datastores.

```
ds = combine(imds,blds);
```

Specify the input size to use for resizing the training images. The size of the training images must be a multiple of 32 for when you use the `tiny-yolov4-coco` and `csp-darknet53-coco` pretrained YOLO v4 deep learning networks. You must also resize the bounding boxes based on the specified input size.

```
inputSize = [224 224 3];
```

Resize and rescale the training images and the bounding boxes using the `preprocessData` helper function. Convert the preprocessed data to a `datastore` object using the `transform` function.

```
trainingDataForEstimation = transform(ds,@(data)preprocessData(data,inputSize));
```

Estimate Anchor Boxes

Estimate the anchor boxes from the training data. You must assign the same number of anchor boxes to each output layer in the YOLO v4 network.

```
numAnchors = 6;
[anchors,meanIoU] = estimateAnchorBoxes(trainingDataForEstimation,numAnchors);
area = anchors(:,1).*anchors(:,2);
[~,idx] = sort(area,"descend");
anchors = anchors(idx,:);
anchorBoxes = {anchors(1:3,:);anchors(4:6,:)};
```

Configure and Train YOLO v4 Network

Specify the class names and configure the pretrained YOLO v4 deep learning network to be retrained for the new data set using the `yolov4ObjectDetector` function.

```
classes = ["vehicle"];
detector = yolov4ObjectDetector("tiny-yolov4-coco",classes,anchorBoxes,InputSize=inputSize);
```

Specify the training options and retrain the pretrained YOLO v4 network on the new data set using the `trainYOLOv4ObjectDetector` function.

```
options = trainingOptions("sgdm", ...
    InitialLearnRate=0.001, ...
    MiniBatchSize=16, ...
    MaxEpochs=40, ...
    ResetInputNormalization=false, ...
    VerboseFrequency=30);
trainedDetector = trainYOLOv4ObjectDetector(ds,detector,options);
```

```

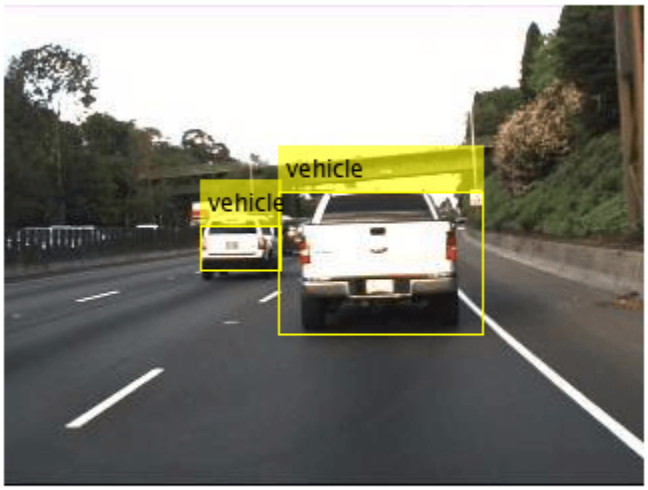
    40          750         00:15:40         0.001          0.1855

**************************************************************************
Detector training complete.
**************************************************************************
```



Detect Vehicles in Test Image

Load a test image from the workspace.

```
I = imread("highway.png");
```

Use the fine-tuned YOLO v4 object detector to detect vehicles in the test image and display the detection results.

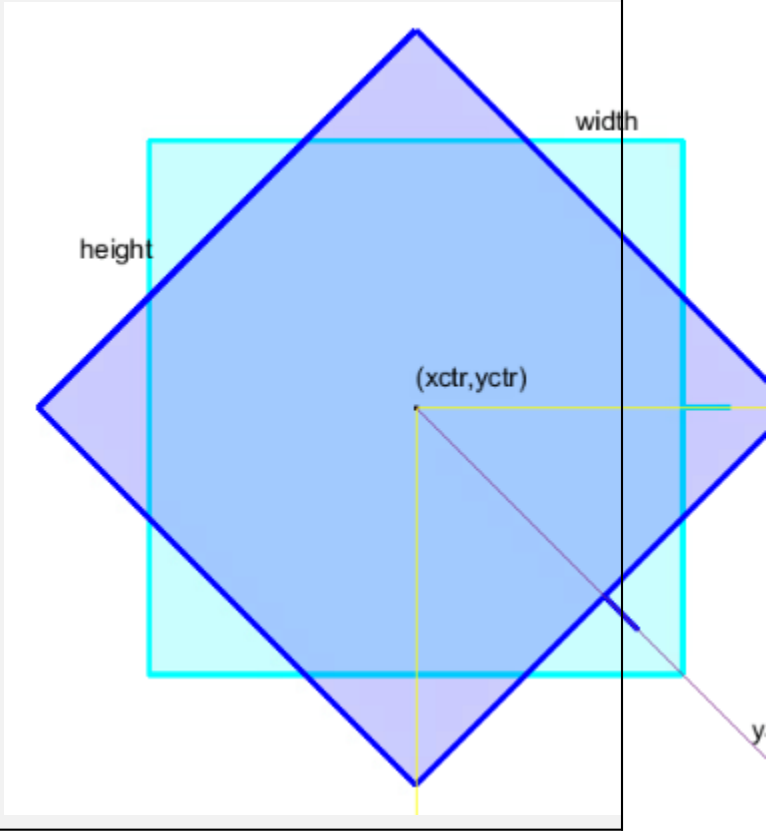
```
[bboxes,scores,labels] = detect(trainedDetector,I,Threshold=0.05);
detectedImg = insertObjectAnnotation(I,"Rectangle",bboxes,labels);
figure
imshow(detectedImg)
```

Supporting Functions

```
function data = preprocessData(data,targetSize)
for num = 1:size(data,1)
    I = data{num,1};
    imgSize = size(I);
    bboxes = data{num,2};
    I = im2single(imresize(I,targetSize(1:2)));
    scale = targetSize(1:2)./imgSize(1:2);
    bboxes = bboxresize(bboxes,scale);
    data(num,1:2) = {I,bboxes};
end
end
```

Input Arguments

`trainingData` — Labeled ground truth images



datastore

Labeled ground truth images, specified as a datastore. Data must be set up so that calling the datastore with the `read` and `readall` functions returns a cell array or table with three columns in the format {*data*,*boxes*,*labels*}.

The first column, *data*, must contain the image data, stored as a cell array. The second column, *boxes*, must contain the bounding boxes. The third column, *labels*, must be a cell array that contains *M*-by-1 categorical vectors containing object class names, where *M* is the number of bounding boxes. All the categorical data returned by the datastore must use the same categories.

The table describes the format of the bounding boxes column.

Bounding Box	***Description***
Axis-aligned rectangle	Defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and y specify the upper-left corner of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis. • *h* specifies the height of the rectangle, which is its length along the *y*-axis.

Bounding Box	*Description*
Rotated rectangle	Defined in spatial coordinates as an *M*-by-5 numeric matrix with rows of the form [*xctr yctr w h yaw*], where: • *M* is the number of rotated rectangles. • *xctr* and *yctr* specify the center of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis before rotation. • *h* specifies the height of the rectangle, which is its length along the *y*-axis before rotation. • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the bounding box. 

For more information, see “Datastores for Deep Learning” (Deep Learning Toolbox).

Note A pretrained axis-aligned network can be converted to a rotated rectangle network by providing rotated rectangle training data. When you provide the rotated rectangle training data, the `trainYOLOv4ObjectDetector` function fine tunes the network heads allowing the rotated rectangle detections to occur.

`detector` — Pretrained or untrained YOLO v4 object detector
`yolov4ObjectDetector` object

Pretrained or untrained YOLO v4 object detector, specified as a `yolov4ObjectDetector` object.

`options` — Training options
`TrainingOptionsSGDM` object | `TrainingOptionsRMSProp` object | `TrainingOptionsADAM` object

Training options, specified as a `TrainingOptionsSGDM`, `TrainingOptionsRMSProp`, or `TrainingOptionsADAM` object returned by the `trainingOptions` function. To specify the solver name and other options for network training, use the `trainingOptions` function.

Note If you specify the `OutputFcn` function handle using the `OutputFcn` name-value argument, it must use a per-epoch `info` structure with these fields:

- `Epoch`
- `Iteration`
- `TimeElapsed`
- `LearnRate`
- `TrainingLoss`

`checkpoint` — Saved detector checkpoint
`yolov4ObjectDetector` object

Saved detector checkpoint, specified as a `yolov4ObjectDetector` object. To periodically save a detector checkpoint during training, specify `CheckpointPath`. To control how frequently check points are saved see the `CheckPointFrequency` and `CheckPointFrequencyUnit` training options.

To load a checkpoint for a previously trained detector, load the MAT file from the checkpoint path. For example, if the `CheckpointPath` property of the object specified by `options` is `'checkpath'`, you can load a checkpoint MAT file by using this code. `'checkpath'` is the name of a folder in the current working directory to which the detector checkpoint has to be saved during training.

```
data = load('checkpath/net_checkpoint__19__2021_12_29__01_04_15.mat');
checkpoint = data.net;
```

The name of the MAT file includes the iteration number and timestamp of when the detector checkpoint was saved. The detector is saved in the `net` variable of the file. Pass this file back into the `trainYOLOv4ObjectDetector` function:

```
yoloDetector = trainYOLOv4ObjectDetector(trainingData,checkpoint,options);
```

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `ExperimentManager="none"` specifies the metrics to track with Experiment Manager to `"none"`.

`FreezeSubNetwork` — Subnetworks to freeze
`"none"` (default) | `"backbone"` | `"backboneAndNeck"`

Subnetworks to freeze during training, specified as one of these values:

- `"none"` — Do not freeze subnetworks
- `"backbone"` — Freeze the feature extraction subnetwork
- `"backboneAndNeck"` — Freeze both the feature extraction and the path aggregation subnetworks

The weight of layers in frozen subnetworks does not change during training.

Note You cannot use the `FreezeSubNetwork` argument values `"backbone"` and `"backboneAndNeck"` with a custom YOLO v4 object detector created using the syntax `yolov4ObjectDetector(net,classes,aboxes)`.

`ExperimentManager` — Detector training experiment monitoring
`"none"` (default) | `experiments.Monitor` object

Detector training experiment monitoring, specified as an `experiments.Monitor` object for use with the Experiment Manager app. You can use this object to track the progress of training, update information fields in the training results table, record values of the metrics used by the training, and to produce training plots. For an example using this app, see “Train Object Detectors in Experiment Manager”.

Information monitored during training:

- Training loss at each iteration.
- Learning rate at each iteration.

Validation information when the training `options` input contains validation data:

- Validation loss at each iteration.

Output Arguments

`detector` — Trained YOLO v4 object detector
`yolov4ObjectDetector` object

Trained YOLO v4 object detector, returned as `yolov4ObjectDetector` object. You can train a YOLO v4 object detector to detect multiple object classes.

`info` — Training progress information
structure array

Training progress information, returned as a structure array with seven fields. Each field corresponds to a stage of training.

- `TrainingLoss` — Training loss at each iteration. The `trainYOLOv4ObjectDetector` function uses mean square error for computing bounding box regression loss and cross-entropy for computing classification loss.
- `BaseLearnRate` — Learning rate at each iteration.
- `OutputNetworkIteration` — Iteration number of returned network.
- `ValidationLoss` — Validation loss at each iteration.
- `FinalValidationLoss` — Final validation loss at end of the training.

Each field is a numeric vector with one element per training iteration. Values that have not been calculated at a specific iteration are assigned as `NaN`. The struct contains `ValidationLoss` and `FinalValidationLoss` fields only when `options` specifies validation data.

Tips

- To generate the ground truth, use the Image Labeler or Video Labeler app. To create a table of training data from the generated ground truth, use the `objectDetectorTrainingData` function.
- To improve prediction accuracy,
  - Increase the number of images you can use to train the network. You can expand the training dataset through data augmentation. For information on how to apply data augmentation for preprocessing, see “Preprocess Images for Deep Learning” (Deep Learning Toolbox).
  - Choose anchor boxes appropriate to the dataset for training the network. You can use the `estimateAnchorBoxes` function to compute anchor boxes directly from the training data.
- A pretrained axis-aligned network can be converted to a rotated rectangle network by providing rotated rectangle training data. When you provide the rotated rectangle training data, the `trainYOLOv4ObjectDetector` function fine tunes the network heads allowing the rotated rectangle detections to occur.
- When you train a rotated rectangle bounding box detector, use a learning rate approximately one order of magnitude below that of its axis-aligned counterpart training rate.
- When you perform transfer learning using a YOLO v4 object detector, consider freezing the subnetworks using the name-value argument `FreezeSubNetwork` to increase training speed and reduce GPU memory consumption.

Version History

Introduced in R2022a

R2025a: MATLAB Compiler support will be removed

Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

R2024a: Subnetwork freezing support

The `trainYOLOv4ObjectDetector` function now supports freezing subnetworks during training using the new `FreezeSubNetwork` name-value argument.

R2024b: Monitor mean average precision metric during training

Starting in R2024b, you can use an `mAPObjectDetectionMetric` object to track the mean average precision (mAP) metric while training the YOLO v4 object detector. To use the metric, specify it to the `Metrics` name-value argument of the `trainingOptions` function.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU acceleration.

By default, the `trainYOLOv4ObjectDetector` function uses a GPU if one is available. You can specify the hardware that the `trainYOLOv4ObjectDetector` function uses by setting the `ExecutionEnvironment` training option using the `trainingOptions` function.

For more information, see “Scale Up Deep Learning in Parallel, on GPUs, and in the Cloud” (Deep Learning Toolbox).

trainYOLOXObjectDetector

Train YOLOX object detector

Syntax

```
detector = trainYOLOXObjectDetector(trainingData,detectorIn,options)
[detector,info] = trainYOLOXObjectDetector( ___ )
[ ___ ] = trainYOLOXObjectDetector( ___ ,Name=Value)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`detector = trainYOLOXObjectDetector(trainingData,detectorIn,options)` trains a YOLOX object detector using the untrained or pretrained YOLOX network, specified by `detectorIn`. The `options` input specifies the network training parameters.

You can also use this syntax for fine-tuning a pretrained YOLOX object detector.

Note This functionality requires Deep Learning Toolbox.

`[detector,info] = trainYOLOXObjectDetector( ___ )` returns information on training progress, such as training loss, for each iteration using the input arguments from the previous syntax.

`[ ___ ] = trainYOLOXObjectDetector( ___ ,Name=Value)` specifies options using one or more name-value arguments. For example, `trainYOLOXObjectDetector(trainingData,ExperimentMonitor=[])` specifies not to track metrics with Experiment Manager.

Examples

Train YOLOX Network for Vehicle Detection

Prepare Training Data

Load a MAT file containing information about a vehicle data set to use for training into the workspace. The MAT file stores the information stored as a table. The first column contains the training images and the remaining columns contain the labeled bounding boxes for those images.

```
data = load("vehicleTrainingData.mat");
trainingData = data.vehicleTrainingData;
```

Specify the directory that contains the training sample image data files and box labels. Add the full path to the filenames in the training data.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata");
trainingData.imageFilename = fullfile(dataDir,trainingData.imageFilename);
```

Create an `imageDatastore` object using the files from the table.

```
imds = imageDatastore(trainingData.imageFilename);
```

Create a `boxLabelDatastore` object using the label columns from the table.

```
blds = boxLabelDatastore(trainingData(:,2:end));
```

Combine the image datastore and box label datastore.

```
ds = combine(imds,blds);
```

Specify the input size to use for resizing the training images.

```
inputSize = [128 228 3];
```

Partition Data

Split the data set into training and validation sets. Allocate approximately 80% of the data for training, and the rest for validation.

```
numImages = numpartitions(ds);
shuffledIndices = randperm(numImages);
dsTrain = subset(ds,shuffledIndices(1:round(0.8*numImages)));
dsVal = subset(ds,shuffledIndices(numpartitions(dsTrain)+1:end));
```

Define YOLOX Object Detector Network Architecture

Create a YOLOX object detector by using the `yoloxObjectDetector` function. Specify `"tiny-coco"` as the pretrained network to use as the base network. Specify the class names and the network input size.

```
classes = {'vehicle'};
detector = yoloxObjectDetector("tiny-coco",classes,InputSize=inputSize);
```

Train YOLOX Object Detection Network

Specify network training options using the `trainingOptions` (Deep Learning Toolbox) function. Use the `mAPObjectDetectionMetric` object to track the mean average precision (mAP) metric when you train the detector.

```
options = trainingOptions("sgdm", ...
    InitialLearnRate=0.001, ...
    MiniBatchSize=16,...
    MaxEpochs=4, ...
    ResetInputNormalization=false, ...
    Metrics=mAPObjectDetectionMetric(Name="mAP50"), ...
    ObjectiveMetricName="mAP50", ...
    ValidationData=dsVal, ...
    ValidationFrequency=20, ...
    VerboseFrequency=2);
```

Train the pretrained YOLOX network on the new data set by using the `trainYOLOXObjectDetector` function.

```
trainedDetector = trainYOLOXObjectDetector(dsTrain,detector,options);
```

```
    Epoch    Iteration    TimeElapsed    LearnRate    TrainingYoloXLoss    ValidationYoloXLoss
```

```

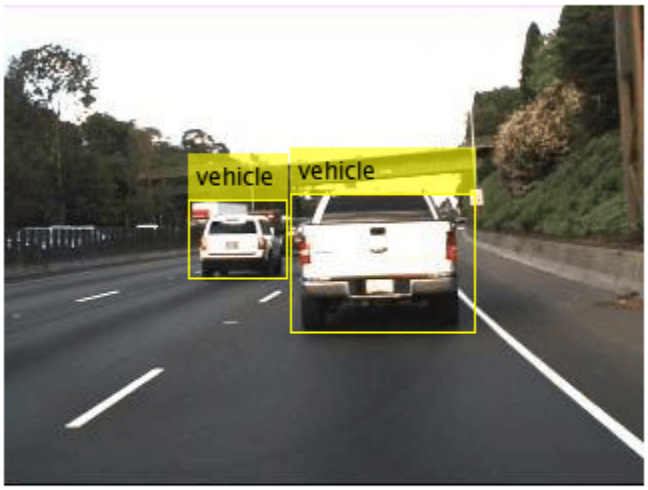
```



Detect Vehicles in Test Image

Read a test image.

```
img = imread("highway.png");
```

Use the fine-tuned YOLOX object detector to detect vehicles in the test image and display the detection results.

```
[boxes,scores,labels] = detect(trainedDetector,img,Threshold=0.5);
detectedImage = insertObjectAnnotation(img,"rectangle",boxes,labels);
figure
imshow(detectedImage)
```

Input Arguments

`trainingData` — Labeled ground truth images

datastore

Labeled ground truth images, specified as a datastore. You must configure the datastore so that calling it with the `read` and `readall` functions returns a cell array or table with these three columns:

Image Data	Bounding Boxes	Bounding Box Labels
Single-cell cell array, which contains the input image.	Single-cell array, which contains the bounding boxes, defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and `y` specify the upper-left corner of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis. • *h* specifies the height of the rectangle, which is its length along the *y*-axis.	Single-cell cell array, which contains an *M*-by-1 categorical vector of object class names. All the categorical data returned by the datastore must use the same categories.

Use the `combine` function on two datastores to create a datastore that returns these three data columns using `read`. The datastore that returns the first column of data should be an `ImageDatastore`, while the datastore that returns the second and third columns of data should be a `boxLabelDatastore`.

`detectorIn` — Pretrained or untrained YOLOX object detector
`yoloxObjectDetector` object

Pretrained or untrained YOLOX object detector, specified as a `yoloxObjectDetector` object.

`options` — Training options
`TrainingOptionsSGDM` object | `TrainingOptionsRMSProp` object | `TrainingOptionsADAM` object

Training options, specified as a `TrainingOptionsSGDM`, `TrainingOptionsRMSProp`, or `TrainingOptionsADAM` object returned by the `trainingOptions` function. To specify the solver name and other options for network training, use the `trainingOptions` function.

Note If you specify the `OutputFcn` function handle using the `OutputFcn` name-value argument, it must use a per-epoch `info` structure with these fields:

- `Epoch`
- `Iteration`
- `TimeElapsed`
- `LearnRate`
- `TrainingLoss`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `ExperimentMonitor=[]` specifies not to track metrics with Experiment Manager.

`ExperimentMonitor` — Detector training experiment monitoring
`[]` (default) | `experiments.Monitor` object

Detector training experiment monitoring, specified as an `experiments.Monitor` object for use with the Experiment Manager app. You can use this object to track the progress of training, update information fields in the training results table, record values of the metrics used by the training, or produce training plots. For more information on using this app, see the "Train Object Detectors in Experiment Manager" example.

The app monitors this information during training:

- Training loss at each iteration
- Learning rate at each iteration
- Validation loss at each iteration, if the `options` input contains validation data

`FreezeSubNetwork` — Subnetwork to freeze
`"none"` (default) | `"backbone"`

Subnetwork to freeze during training, specified as one of these values:

- `"none"` — Do not freeze a subnetwork.
- `"backbone"` — Freeze the feature extraction subnetwork, including the layers following the region of interest (ROI) align layer.

The weight of layers in frozen subnetworks does not change during training.

`ClassWeights` — Class weights for loss function
`1` (default) | positive scalar | *C*-element numeric vector

Class weights for the loss function, specified as a positive scalar or as a *C*-element numeric vector, where *C* is the number of classes in the `ClassNames` property of the `yoloxObjectDetector` object `detectorIn`, and all elements in the vector are positive.

By default, all classes have a weight of `1`, indicating equal weight for all classes. If you specify `ClassWeights` as any positive scalar, the function assigns equal weight to all classes. To assign different weights to each class, specify `ClassWeights` as a *C*-element numeric vector with positive values.

Class imbalance in the training data can affect the accuracy of the detector. You can reduce the effect of this class imbalance by assigning class weights inversely related to the class distribution in the training data. Assign higher weights to rare classes that have lower frequency in the training data and lower weights to common classes that have higher frequency in the training data. Ensure that the weights are approximately in inverse proportion to the class distribution in the training data. If you specify the weights of rare classes extremely higher than the required proportion, the model can become unstable or overfit to rare classes. If you specify the weights of rare classes extremely lower than the required proportion, the model may not reduce the effect of the class imbalance sufficiently.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`detector` — Trained YOLOX object detector

`yoloxObjectDetector` object

Trained YOLOX object detector, returned as a `yoloxObjectDetector` object. You can train a YOLOX object detector to detect multiple object classes.

`info` — Training progress information

structure array

Training progress information, returned as a structure array with these fields. Each field corresponds to a stage of training.

- `TrainingLoss` — Training loss at each iteration. The `trainYOLOXObjectDetector` function uses mean square error for computing bounding box regression loss and cross-entropy for computing classification loss.
- `BaseLearnRate` — Learning rate at each iteration.
- `OutputNetworkIteration` — Iteration number of the returned network.
- `ValidationLoss` — Validation loss at each iteration.
- `FinalValidationLoss` — Final validation loss at the end of the training.

Each field is a numeric vector with one element per training iteration. The function returns a value of `NaN` for iterations at which it does not calculate that value. The structure contains the `ValidationLoss` and `FinalValidationLoss` fields only when `options` specifies validation data.

Tips

- To generate the labeled ground truth image data, use the Image Labeler or Video Labeler app. To create a table of training data from the generated ground truth, use the `objectDetectorTrainingData` function.
- To help improve prediction accuracy, increase the number of images you use to train the network. You can expand the training data set using data augmentation. For information on how to apply data augmentation for preprocessing, see “Preprocess Images for Deep Learning” (Deep Learning Toolbox).

Version History

Introduced in R2023b

R2026a: Specify class weights for loss function

Specify class weights for the loss function by using the new `ClassWeights` name-value argument.

R2025a: MATLAB Compiler support will be removed

Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU acceleration.

By default, the `trainYOLOXObjectDetector` function uses a GPU if one is available. You can specify the hardware that the `trainYOLOXObjectDetector` function uses by setting the `ExecutionEnvironment` training option using the `trainingOptions` function.

For more information, see “Scale Up Deep Learning in Parallel, on GPUs, and in the Cloud” (Deep Learning Toolbox).

detect

Detect objects using ACF object detector

Syntax

```
bboxes = detect(detector,I)
[bboxes,scores] = detect(detector,I)
detectionResults = detect(detector,ds)
[___]= detect(detector,I,roi)
[___] = detect(___,Name=Value)
```

Description

`bboxes = detect(detector,I)` detects objects within image `I` using the input aggregate channel features (ACF) object detector. The locations of objects detected are returned as a set of bounding boxes.

`[bboxes,scores] = detect(detector,I)` also returns the detection scores for each bounding box.

`detectionResults = detect(detector,ds)` detects objects within all the images returned by the `read` function of the input datastore.

`[___]= detect(detector,I,roi)` detects objects within the rectangular search region specified by `roi`, using either of the preceding syntaxes.

`[___] = detect(___,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `WindowStride=2` sets the stride of the sliding window used to detects objects to `2`.

Examples

Train Stop Sign Detector Using ACF Object Detector

Use the `trainACFObjectDetector` with training images to create an ACF object detector that can detect stop signs. Test the detector with a separate image.

Load the training data.

```
load('stopSignsAndCars.mat')
```

Prefix the full path to the stop sign images.

```
stopSigns = fullfile(toolboxdir('vision'),'visiondata',stopSignsAndCars{:,1});
```

Create datastores to load the ground truth data for stop signs.

```
imds = imageDatastore(stopSigns);
blds = boxLabelDatastore(stopSignsAndCars(:,2));
```

Combine the image and box label datastores.

```
ds = combine(imds,blds);
```

Train the ACF detector. Set the number of negative samples to use at each stage to 2. You can turn off the training progress output by specifying `Verbose=false`, as a `Name-Value` argument.

```
acfDetector = trainACFObjectDetector(ds,NegativeSamplesFactor=2);
```

```
ACF Object Detector Training
The training will take 4 stages. The model size is 34x31.
Sample positive examples(~100% Completed)
Compute approximation coefficients...Completed.
Compute aggregated channel features...Completed.
--------------------------------------------
Stage 1:
Sample negative examples(~100% Completed)
Compute aggregated channel features...Completed.
Train classifier with 42 positive examples and 84 negative examples...Completed.
The trained classifier has 19 weak learners.
--------------------------------------------
Stage 2:
Sample negative examples(~100% Completed)
Found 84 new negative examples for training.
Compute aggregated channel features...Completed.
Train classifier with 42 positive examples and 84 negative examples...Completed.
The trained classifier has 20 weak learners.
--------------------------------------------
Stage 3:
Sample negative examples(~100% Completed)
Found 84 new negative examples for training.
Compute aggregated channel features...Completed.
Train classifier with 42 positive examples and 84 negative examples...Completed.
The trained classifier has 54 weak learners.
--------------------------------------------
Stage 4:
Sample negative examples(~100% Completed)
Found 84 new negative examples for training.
Compute aggregated channel features...Completed.
Train classifier with 42 positive examples and 84 negative examples...Completed.
The trained classifier has 61 weak learners.
--------------------------------------------
ACF object detector training is completed. Elapsed time is 17.9982 seconds.
```

Test the ACF detector on a test image.

```
img = imread('stopSignTest.jpg');
[bboxes,scores] = detect(acfDetector,img);
```

Display the detection results and insert the bounding boxes for objects into the image.

```
for i = 1:length(scores)
   annotation = sprintf('Confidence = %.1f',scores(i));
   img = insertObjectAnnotation(img,'rectangle',bboxes(i,:),annotation);
end

figure
imshow(img)
```

Input Arguments

`detector` — ACF object detector

`acfObjectDetector` object

ACF object detector, specified as an `acfObjectDetector` object. To create this object, call the `trainACFObjectDetector` function with training data as input.

`I` — Input image

grayscale image | RGB image

Input image, specified as a real, nonsparse, grayscale or RGB image.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single`

`ds` — Datastore

`datastore` object

Datastore, specified as a `datastore` object containing a collection of images. Each image must be a grayscale or RGB. The function processes only the first column of the datastore, which must contain images and must be cell arrays or tables with multiple columns. Therefore, datastore `read` function must return image data in the first column.

`roi` — Search region of interest

[*x y width height*] vector

Search region of interest, specified as an [*x y width height*] vector. The vector specifies the upper left corner and size of a region in pixels.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `WindowStride=2` sets the stride of the sliding window used to detects objects to 2.

`NumScaleLevels` — Number of scale levels per octave
8 (default) | positive integer

Number of scale levels per octave, specified a positive integer. Each octave is a power-of-two downscaling of the image. To detect people at finer scale increments, increase this number. Recommended values are in the range [4, 8].

`WindowStride` — Stride for sliding window
4 (default) | positive integer

Stride for the sliding window, specified as a positive integer. This value indicates the distance for the function to move the window in both the *x* and *y* directions. The sliding window scans the images for object detection.

`SelectStrongest` — Select strongest bounding box for each object
`true` (default) | `false`

Select the strongest bounding box for each detected object, specified as `true` or `false`.

- `true` — Return the strongest bounding box per object. To select these boxes, `detect` calls the `selectStrongestBbox` function, which uses nonmaximal suppression to eliminate overlapping bounding boxes based on their confidence scores.
- `false` — Return all detected bounding boxes. You can then create your own custom operation to eliminate overlapping bounding boxes.

`MinSize` — Minimum region size
[*height width*] vector

Minimum region size that contains a detected object, specified as a vector of the form [*height width*]. Units are in pixels.

By default, `MinSize` is the smallest object that the trained `detector` can detect.

`MaxSize` — Maximum region size
`size(I)` (default) | [*height width*] vector

Maximum region size that contains a detected object, specified as a vector of the form [*height width*]. Units are in pixels.

To reduce computation time, set this value to the known maximum region size for the objects being detected in the image. By default, `'MaxSize'` is set to the height and width of the input image, `I`.

`Threshold` — Classification accuracy threshold
–1 (default) | numeric scalar

Classification accuracy threshold, specified as a numeric scalar. Recommended values are in the range [–1, 1]. During multiscale object detection, the threshold value controls the accuracy and speed for classifying image subregions as either objects or nonobjects. To speed up the performance at the risk of missing true detections, increase this threshold.

Output Arguments

`bboxes` — Location of objects detected within image

M-by-4 matrix

Location of objects detected within the input image, returned as an *M*-by-4 matrix, where *M* is the number of bounding boxes. Each row of `bboxes` contains a four-element vector of the form [*x y width height*]. This vector specifies the upper left corner and size of that corresponding bounding box in pixels.

`scores` — Detection confidence scores

M-by-1 vector

Detection confidence scores, returned as an *M*-by-1 vector, where *M* is the number of bounding boxes. Scores are returned in the range [`-inf inf`]. A higher score indicates higher confidence in the detection.

`detectionResults` — Detection results

2-column table

Detection results, returned as a 2-column table with variable names, *Boxes*, and *Scores*.

The *Boxes* column contains *M*-by-4 matrices, representing *M* bounding boxes for the objects found in the image. Each row contains a bounding box as a 4-element vector in the format [*x*,*y*,*width*,*height*]. The format specifies the upper-left corner location and size in pixels of the bounding box in the corresponding image.

The *Scores* column contains *M*-by-1 vectors representing the detection confidence scores for each of the *M* bounding boxes.

Version History

Introduced in R2017a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- To generate code, use `toStruct` function to pass the `acfObjectDetector` object to the `detect` function. For more information, see “Generate Code for Detecting Objects in Images by Using ACF Object Detector”.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

Objects
`acfObjectDetector`

detect

(Not recommended) Detect objects using R-CNN deep learning detector

Note The `detect` function and R-CNN object detectors are not recommended. Use a different type of object detector instead. For more information, see “Version History”.

Syntax

```
bboxes = detect(detector,I)
[bboxes,scores] = detect(detector,I)
[___,labels] = detect(detector,I)
[___] = detect(___,roi)
[___] = detect(___,Name=Value)
```

Description

`bboxes = detect(detector,I)` detects objects within image `I` using an R-CNN (regions with convolutional neural networks) object detector. The locations of objects detected are returned as a set of bounding boxes.

When using this function, use of a CUDA enabled NVIDIA GPU is highly recommended. The GPU reduces computation time significantly. Usage of the GPU requires Parallel Computing Toolbox. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

`[bboxes,scores] = detect(detector,I)` also returns the detection scores for each bounding box.

`[___,labels] = detect(detector,I)` also returns a categorical array of labels assigned to the bounding boxes, using either of the preceding syntaxes. The labels used for object classes are defined during training using the `trainRCNNObjectDetector` function.

`[___] = detect(___,roi)` detects objects within the rectangular search region specified by `roi`.

`[___] = detect(___,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes.

Examples

Train R-CNN Stop Sign Detector

Load training data and network layers.

```
load('rcnnStopSigns.mat', 'stopSigns', 'layers')
```

Add the image directory to the MATLAB path.

```
imDir = fullfile(matlabroot, 'toolbox', 'vision', 'visiondata',...
  'stopSignImages');
addpath(imDir);
```

Set network training options to use mini-batch size of 32 to reduce GPU memory usage. Lower the InitialLearnRate to reduce the rate at which network parameters are changed. This is beneficial when fine-tuning a pre-trained network and prevents the network from changing too rapidly.

```
options = trainingOptions('sgdm', ...
  'MiniBatchSize', 32, ...
  'InitialLearnRate', 1e-6, ...
  'MaxEpochs', 10);
```

Train the R-CNN detector. Training can take a few minutes to complete.

```
rcnn = trainRCNNObjectDetector(stopSigns, layers, options, 'NegativeOverlapRange', [0 0.3]);
```

```
*********************************************************************
Training an R-CNN Object Detector for the following object classes:

Input Arguments

`detector` — R-CNN object detector

`rcnnObjectDetector` object

R-CNN object detector, specified as an `rcnnObjectDetector` object. To create this object, call the `trainRCNNObjectDetector` function with training data as input.

`I` — Input image

H-by-*W*-by-*C* numeric array of images

Input image, specified as an *H*-by-*W*-by-*C* numeric array of images. Images must be real, nonsparse, grayscale or RGB image.

- *H*: Height
- *W*: Width
- *C*: The channel size in each image must be equal to the network's input channel size. For example, for grayscale images, *C* must be equal to `1`. For RGB color images, it must be equal to `3`.

The detector is sensitive to the range of the input image. Therefore, ensure that the input image range is similar to the range of the images used to train the detector. For example, if the detector was trained on `uint8` images, rescale this input image to the range [0, 255] by using the `im2uint8` or `rescale` function. The size of this input image should be comparable to the sizes of the images used in training. If these sizes are very different, the detector has difficulty detecting objects because the scale of the objects in the input image differs from the scale of the objects the detector was trained to identify. Consider whether you used the `SmallestImageDimension` property during training to modify the size of training images.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single` | `logical`

`roi` — Search region of interest
[*x y width height*] vector

Search region of interest, specified as an [*x y width height*] vector. The vector specifies the upper left corner and size of a region in pixels.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `detect(detector,I,NumStrongestRegions=1000)` limits the number of strongest region proposals to 1000.

`NumStrongestRegions` — Maximum number of strongest region proposals
`2000` (default) | integer

Maximum number of strongest region proposals, specified as an integer. Reduce this value to speed up processing time at the cost of detection accuracy. To use all region proposals, specify this value as `Inf`.

`SelectStrongest` — Select strongest bounding box
`true` (default) | `false`

Select strongest bounding box for each detected object, specified as a logical `true` or `false`, where:

- `true` — Return the strongest bounding box per object. To select these boxes, `detect` calls the `selectStrongestBboxMulticlass` function, which uses nonmaximal suppression to eliminate overlapping bounding boxes based on their scores.

  For example:

```
selectStrongestBboxMulticlass(bbox,scores, ...
            'RatioType','Min', ...
            'OverlapThreshold',0.5);
```

- `false` — Return all detected bounding boxes. You can then use a custom operation to eliminate overlapping bounding boxes.

`MiniBatchSize` — Size of smaller batches for R-CNN data processing
128 (default) | integer

Size of smaller batches for R-CNN data processing, specified as an integer. Larger batch sizes lead to faster processing but take up more memory.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as `"auto"`, `"gpu"`, or `"cpu"`. The table shows the valid hardware resource values.

Resource	Action
`"auto"`	Use a GPU if it is available. Otherwise, use the CPU.
`"gpu"`	Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
`"cpu"`	Use the CPU.

Output Arguments

`bboxes` — Location of objects detected within image
M-by-4 matrix

Location of objects detected within the image, returned as an *M*-by-4 matrix defining *M* bounding boxes. Each row of `bboxes` contains a four-element vector of the form [*x y width height*]. This vector specifies the upper left corner and size of a bounding box in pixels.

`scores` — Detection scores
M-by-1 vector

Detection scores, returned as an *M*-by-1 vector. A higher score indicates higher confidence in the detection.

`labels` — Labels for bounding boxes
M-by-1 categorical array

Labels for bounding boxes, returned as an *M*-by-1 categorical array of *M* labels. You define the class names used to label the objects when you train the input `detector`.

Version History

Introduced in R2016b

R2024b: Not Recommended
Not recommended starting in R2024b

Starting in R2024b, R-CNN object detectors are no longer recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` object. These object detectors are faster than R-CNN object detectors. For more information, see “Choose an Object Detector”.

detect

(Not recommended) Detect objects using Fast R-CNN object detector

Note The `detect` function and Fast R-CNN object detectors are not recommended. Use a different type of object detector instead. For more information, see “Version History”.

Syntax

```
bboxes = detect(detector,I)
[bboxes,scores] = detect(detector,I)
[___,labels] = detect(detector,I)
[___] = detect(___,roi)

detectionResults = detect(detector,ds)

[___] = detect(___,Name=Value)
```

Description

`bboxes = detect(detector,I)` detects objects within a single image or an array of images, `I`, using a Fast R-CNN (regions with convolutional neural networks) object detector. The locations of objects detected are returned as a set of bounding boxes.

When using this function, use of a CUDA enabled NVIDIA GPU is highly recommended. The GPU reduces computation time significantly. Usage of the GPU requires Parallel Computing Toolbox. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

`[bboxes,scores] = detect(detector,I)` also returns the detection scores for each bounding box.

`[___,labels] = detect(detector,I)` also returns a categorical array of labels assigned to the bounding boxes, using either of the preceding syntaxes. The labels used for object classes are defined during training using the `trainFastRCNNObjectDetector` function.

`[___] = detect(___,roi)` detects objects within the rectangular search region specified by `roi`.

`detectionResults = detect(detector,ds)` detects objects within the series of images returned by the `read` function of the input datastore.

`[___] = detect(___,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes.

Examples

Detect Vehicles Using Faster R-CNN

Detect vehicles within an image by using a Faster R-CNN object detector.

Load a Faster R-CNN object detector pretrained to detect vehicles.

```
data = load('fasterRCNNVehicleTrainingData.mat', 'detector');
detector = data.detector;
```

Read in a test image.

```
I = imread('highway.png');
imshow(I)
```

Run the detector on the image and inspect the results. The labels come from the `ClassNames` property of the detector.

```
[bboxes,scores,labels] = detect(detector,I)
```

```
bboxes = 2×4

   150    86    80    72
    91    89    67    48

scores = 2×1 single column vector

    1.0000
    0.9001

labels = 2×1 categorical
     vehicle
```

```
vehicle
```

The detector has high confidence in the detections. Annotate the image with the bounding boxes for the detections and the corresponding detection scores.

```
detectedI = insertObjectAnnotation(I,'Rectangle',bboxes,cellstr(labels));
figure
imshow(detectedI)
```

Input Arguments

`detector` — Fast R-CNN object detector

`fastRCNNObjectDetector` object

Fast R-CNN object detector, specified as a `fastRCNNObjectDetector` object. To create this object, call the `trainFastRCNNObjectDetector` function with training data as input.

`I` — Input image

H-by-*W*-by-*C*-by-*B* numeric array of images

Input image, specified as an *H*-by-*W*-by-*C*-by-*B* numeric array of images. Images must be real, nonsparse, grayscale or RGB image.

- *H* — Height in pixels.
- *W* — Width in pixels
- *C* — The channel size in each image must be equal to the network's input channel size. For example, for grayscale images, *C* must be equal to 1. For RGB color images, it must be equal to 3.
- *B* — Number of images in the array.

The detector is sensitive to the range of the input image. Therefore, ensure that the input image range is similar to the range of the images used to train the detector. For example, if the detector was trained on `uint8` images, rescale this input image to the range [0, 255] by using the `im2uint8` or `rescale` function. The size of this input image should be comparable to the sizes of the images used in training. If these sizes are very different, the detector has difficulty detecting objects because the scale of the objects in the input image differs from the scale of the objects the detector was trained to identify. Consider whether you used the `SmallestImageDimension` property during training to modify the size of training images.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single` | `logical`

`ds` — Datastore
`datastore` object

Datastore, specified as a `datastore` object containing a collection of images. Each image must be a grayscale, RGB, or multichannel image. The function processes only the first column of the datastore, which must contain images and must be cell arrays or tables with multiple columns.

`roi` — Search region of interest
[*x y width height*] vector

Search region of interest, specified as a four-element vector of the form [*x y width height*]. The vector specifies the upper left corner and size of a region in pixels.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `detect(detector,I,NumStrongestRegions=1000)` limits the number of strongest region proposals to 1000.

`Threshold` — Detection threshold
`0.5` (default) | scalar in the range `[0, 1]`

Detection threshold, specified as a scalar in the range `[0, 1]`. Detections that have scores less than this threshold value are removed. To reduce false positives, increase this value.

`NumStrongestRegions` — Maximum number of strongest region proposals
`2000` (default) | positive integer | `Inf`

Maximum number of strongest region proposals, specified as a positive integer. Reduce this value to speed up processing time at the cost of detection accuracy. To use all region proposals, specify this value as `Inf`.

`SelectStrongest` — Select strongest bounding box
`true` (default) | `false`

Select the strongest bounding box for each detected object, specified as a logical `true` or `false`, where:

- `true` — Return the strongest bounding box per object. To select these boxes, `detect` calls the `selectStrongestBboxMulticlass` function, which uses non-maximum suppression to eliminate overlapping bounding boxes based on their confidence scores.

  For example:

  ```
  selectStrongestBboxMulticlass(bbox,scores, ...
              'RatioType','Min', ...
              'OverlapThreshold',0.5);
  ```

- `false` — Return all detected bounding boxes. You can then create your own custom operation to eliminate overlapping bounding boxes.

`MinSize` — Minimum region size
[*height width*] vector

Minimum region size that contains a detected object, specified as a [*height width*] vector. Units are in pixels.

By default, `MinSize` is the smallest object that the trained `detector` can detect.

`MaxSize` — Maximum region size
`size(I)` (default) | [*height width*] vector

Maximum region size that contains a detected object, specified as a [*height width*] vector. Units are in pixels.

To reduce computation time, set this value to the known maximum region size for the objects being detected in the image. By default, `'MaxSize'` is set to the height and width of the input image `I`.

`MiniBatchSize` — Minimum batch size
128 (default) | scalar

Minimum batch size, specified as a scalar value. Use the `MiniBatchSize` to process a large collection of images. Images are grouped into minibatches and processed as a batch to improve computation efficiency. Increase the minibatch size to decrease processing time. Decrease the size to use less memory.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as `"auto"`, `"gpu"`, or `"cpu"`.

- `"auto"` — Use a GPU if it is available. Otherwise, use the CPU.
- `"gpu"` — Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Use the CPU.

Output Arguments

`bboxes` — Location of objects detected
M-by-4 matrix | *B*-by-1 cell array

Location of objects detected within the input image or images, returned as an *M*-by-4 matrix or a *B*-by-1 cell array. *M* is the number of bounding boxes in an image, and *B* is the number of *M*-by-4 matrices when the input contains an array of images.

Each row of `bboxes` contains a four-element vector of the form [*x y width height*]. This vector specifies the upper left corner and size of that corresponding bounding box in pixels.

`scores` — Detection scores
M-by-1 vector | *B*-by-1 cell array

Detection confidence scores, returned as an *M*-by-1 vector or a *B*-by-1 cell array. *M* is the number of bounding boxes in an image, and *B* is the number of *M*-by-1 vectors when the input contains an array of images. A higher score indicates higher confidence in the detection.

`labels` — Labels for bounding boxes
M-by-1 categorical array | *B*-by-1 cell array

Labels for bounding boxes, returned as an *M*-by-1 categorical array or a *B*-by-1 cell array. *M* is the number of labels in an image, and *B* is the number of *M*-by-1 categorical arrays when the input contains an array of images. You define the class names used to label the objects when you train the input `detector`.

`detectionResults` — Detection results
3-column table

Detection results, returned as a 3-column table with variable names, *Boxes*, *Scores*, and *Labels*. The *Boxes* column contains *M*-by-4 matrices, of *M* bounding boxes for the objects found in the image. Each row contains a bounding box as a 4-element vector in the format [*x*,*y*,*width*,*height*]. The format specifies the upper-left corner location and size in pixels of the bounding box in the corresponding image.

Version History

Introduced in R2017a

R2024b: Not Recommended
Not recommended starting in R2024b

Starting in R2024b, R-CNN object detectors are no longer recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` object. These object detectors are faster than R-CNN object detectors. For more information, see “Choose an Object Detector”.

```
vehicle
```

The detector has high confidence in the detections. Annotate the image with the bounding boxes for the detections and the corresponding detection scores.

```
detectedI = insertObjectAnnotation(I,'Rectangle',bboxes,cellstr(labels));
figure
imshow(detectedI)
```

Input Arguments

`detector` — Faster R-CNN object detector

`fasterRCNNObjectDetector` object

Faster R-CNN object detector, specified as a `fasterRCNNObjectDetector` object. To create this object, call the `trainFasterRCNNObjectDetector` function with training data as input.

`I` — Input image

H-by-*W*-by-*C*-by-*B* numeric array of images

Input image, specified as an *H*-by-*W*-by-*C*-by-*B* numeric array of images. Images must be real, nonsparse, grayscale or RGB image.

- *H* — Height in pixels.
- *W* — Width in pixels
- *C* — The channel size in each image must be equal to the network's input channel size. For example, for grayscale images, *C* must be equal to 1. For RGB color images, it must be equal to 3.
- *B* — Number of images in the array.

The detector is sensitive to the range of the input image. Therefore, ensure that the input image range is similar to the range of the images used to train the detector. For example, if the detector was trained on `uint8` images, rescale this input image to the range [0, 255] by using the `im2uint8` or `rescale` function. The size of this input image should be comparable to the sizes of the images used in training. If these sizes are very different, the detector has difficulty detecting objects because the scale of the objects in the input image differs from the scale of the objects the detector was trained to identify. Consider whether you used the `SmallestImageDimension` property during training to modify the size of training images.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single` | `logical`

`ds` — Datastore
`datastore` object

Datastore, specified as a `datastore` object containing a collection of images. Each image must be a grayscale, RGB, or multichannel image. The function processes only the first column of the datastore, which must contain images and must be cell arrays or tables with multiple columns.

`roi` — Search region of interest
[*x y width height*] vector

Search region of interest, specified as a four-element vector of the form [*x y width height*]. The vector specifies the upper left corner and size of a region in pixels.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `detect(detector,I,NumStrongestRegions=1000)` limits the number of strongest region proposals to 1000.

`Threshold` — Detection threshold
`0.5` (default) | scalar in the range `[0, 1]`

Detection threshold, specified as a scalar in the range `[0, 1]`. Detections that have scores less than this threshold value are removed. To reduce false positives, increase this value.

`NumStrongestRegions` — Maximum number of strongest region proposals
`2000` (default) | positive integer | `Inf`

Maximum number of strongest region proposals, specified as a positive integer. Reduce this value to speed up processing time at the cost of detection accuracy. To use all region proposals, specify this value as `Inf`.

`SelectStrongest` — Select strongest bounding box
`true` (default) | `false`

Select the strongest bounding box for each detected object, specified as a logical `true` or `false`, where:

- `true` — Return the strongest bounding box per object. To select these boxes, `detect` calls the `selectStrongestBboxMulticlass` function, which uses non-maximum suppression to eliminate overlapping bounding boxes based on their confidence scores.

  For example:

  ```
  selectStrongestBboxMulticlass(bbox,scores, ...
              'RatioType','Min', ...
              'OverlapThreshold',0.5);
  ```

- `false` — Return all detected bounding boxes. You can then create your own custom operation to eliminate overlapping bounding boxes.

`MinSize` — Minimum region size
[*height width*] vector

Minimum region size that contains a detected object, specified as a [*height width*] vector. Units are in pixels.

By default, `MinSize` is the smallest object that the trained `detector` can detect.

`MaxSize` — Maximum region size
`size(I)` (default) | [*height width*] vector

Maximum region size that contains a detected object, specified as a [*height width*] vector. Units are in pixels.

To reduce computation time, set this value to the known maximum region size for the objects being detected in the image. By default, `'MaxSize'` is set to the height and width of the input image `I`.

`MiniBatchSize` — Minimum batch size
128 (default) | scalar

Minimum batch size, specified as a scalar value. Use the `MiniBatchSize` to process a large collection of images. Images are grouped into minibatches and processed as a batch to improve computation efficiency. Increase the minibatch size to decrease processing time. Decrease the size to use less memory.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as `"auto"`, `"gpu"`, or `"cpu"`.

- `"auto"` — Use a GPU if it is available. Otherwise, use the CPU.
- `"gpu"` — Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Use the CPU.

Output Arguments

`bboxes` — Location of objects detected
M-by-4 matrix | *B*-by-1 cell array

Location of objects detected within the input image or images, returned as an *M*-by-4 matrix or a *B*-by-1 cell array. *M* is the number of bounding boxes in an image, and *B* is the number of *M*-by-4 matrices when the input contains an array of images.

Each row of `bboxes` contains a four-element vector of the form [*x y width height*]. This vector specifies the upper left corner and size of that corresponding bounding box in pixels.

`scores` — Detection scores
M-by-1 vector | *B*-by-1 cell array

Detection confidence scores, returned as an *M*-by-1 vector or a *B*-by-1 cell array. *M* is the number of bounding boxes in an image, and *B* is the number of *M*-by-1 vectors when the input contains an array of images. A higher score indicates higher confidence in the detection.

`labels` — Labels for bounding boxes
M-by-1 categorical array | *B*-by-1 cell array

Labels for bounding boxes, returned as an *M*-by-1 categorical array or a *B*-by-1 cell array. *M* is the number of labels in an image, and *B* is the number of *M*-by-1 categorical arrays when the input contains an array of images. You define the class names used to label the objects when you train the input `detector`.

`detectionResults` — Detection results
3-column table

Detection results, returned as a 3-column table with variable names, *Boxes*, *Scores*, and *Labels*. The *Boxes* column contains *M*-by-4 matrices, of *M* bounding boxes for the objects found in the image. Each row contains a bounding box as a 4-element vector in the format [*x*,*y*,*width*,*height*]. The format specifies the upper-left corner location and size in pixels of the bounding box in the corresponding image.

Version History

Introduced in R2017a

R2024b: Not Recommended
Not recommended starting in R2024b

Starting in R2024b, R-CNN object detectors are no longer recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` object. detect

Detect objects using YOLO v2 object detector

Syntax

```
bboxes = detect(detector,I)
[bboxes,scores] = detect(detector,I)
[___,labels] = detect(detector,I)
[___,labels,info] = detect(detector,I)

detectionResults = detect(detector,ds)

[___] = detect(___,roi)
[___] = detect(___,Name=Value)
```

Description

`bboxes = detect(detector,I)` detects objects within a single image or an array of images, `I`, using you only look once version 2 (YOLO v2) object detector. The input size of the image must be greater than or equal to the network input size of the pretrained detector. The locations of objects detected are returned as a set of bounding boxes.

Note The use of a CUDA-enabled NVIDIA GPU is highly recommended. The GPU reduces computation time significantly. Usage of the GPU requires Parallel Computing Toolbox. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

`[bboxes,scores] = detect(detector,I)` also returns the class-specific confidence scores for each bounding box.

`[___,labels] = detect(detector,I)` returns a categorical array of labels assigned to the bounding boxes in addition to the output arguments from the previous syntax. The labels used for object classes are defined during training using the `trainYOLOv2ObjectDetector` function.

`[___,labels,info] = detect(detector,I)` also returns information about the class probabilities and objectness scores for each detection.

`detectionResults = detect(detector,ds)` detects objects within all the images returned by the `read` function of the input datastore.

`[___] = detect(___,roi)` detects objects within the rectangular search region specified by `roi`. Use output arguments from any of the previous syntaxes. Specify input arguments from any of the previous syntaxes.

`[___] = detect(___,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `Threshold=0.75` sets the threshold to remove detections to `0.75`.

Examples

Detect Vehicles Using YOLO v2 Object Detection Network

Load a YOLO v2 object detector pretrained to detect vehicles.

```
vehicleDetector = load('yolov2VehicleDetector.mat','detector');
detector = vehicleDetector.detector;
```

Read a test image into the workspace.

```
I = imread('highway.png');
```

Display the input test image.

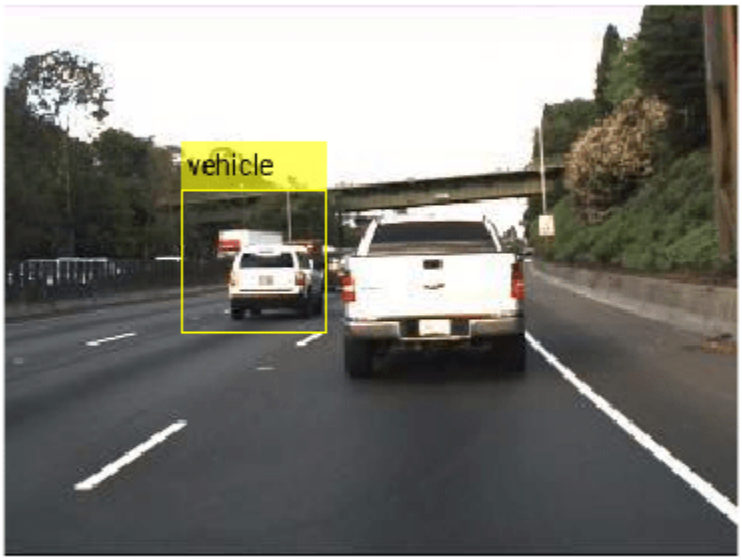
```
imshow(I);
```

Run the pretrained YOLO v2 object detector on the test image. Inspect the results for vehicle detection. The labels are derived from the `ClassNames` property of the detector.

```
[bboxes,scores,labels] = detect(detector,I)
```

```
bboxes = 1×4

    78    81    64    63



scores = single

0.6224
```

```
labels = categorical
     vehicle
```

Annotate the image with the bounding boxes for the detections.

```
if ~isempty(bboxes)
    detectedI = insertObjectAnnotation(I,'rectangle',bboxes,cellstr(labels));
end
figure
imshow(detectedI)
```

Input Arguments

`detector` — YOLO v2 object detector

`yolov2ObjectDetector` object

YOLO v2 object detector, specified as a `yolov2ObjectDetector` object. To create this object, call the `trainYOLOv2ObjectDetector` function with the training data as input.

`I` — Input image

H-by-*W*-by-*C*-by-*B* numeric array of images

Input image, specified as an *H*-by-*W*-by-*C*-by-*B* numeric array of images. Images must be real, nonsparse, grayscale or RGB image.

- *H* — Height in pixels.
- *W* — Width in pixels
- *C* — The channel size in each image must be equal to the network's input channel size. For example, for grayscale images, *C* must be equal to 1. For RGB color images, it must be equal to 3.

- *B* — Number of images in the array.

The detector is sensitive to the range of the input image. Therefore, ensure that the input image range is similar to the range of the images used to train the detector. For example, if the detector was trained on `uint8` images, rescale this input image to the range [0, 255] by using the `im2uint8` or `rescale` function. The size of this input image should be comparable to the sizes of the images used in training. If these sizes are very different, the detector has difficulty detecting objects because the scale of the objects in the input image differs from the scale of the objects the detector was trained to identify. Consider whether you used the `SmallestImageDimension` property during training to modify the size of training images.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single` | `logical`

`ds` — Datastore
`datastore` object

Datastore, specified as a `datastore` object containing a collection of images. Each image must be a grayscale, RGB, or multichannel image. The function processes only the first column of the datastore, which must contain images and must be cell arrays or tables with multiple columns.

`roi` — Search region of interest
[*x y width height*] vector

Search region of interest, specified as a four-element vector of the form [*x y width height*]. The vector specifies the upper left corner and size of a region in pixels.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Threshold=0.25` sets the threshold to remove detections to `0.25`.

`Threshold` — Detection threshold
`0.5` (default) | scalar in the range [0, 1]

Detection threshold, specified as a scalar in the range [0, 1]. Detections that have scores less than this threshold value are removed. To reduce false positives, increase this value.

`SelectStrongest` — Select strongest bounding box
`true` (default) | `false`

Select the strongest bounding box for each detected object, specified as `true` or `false`.

- `true` — Returns the strongest bounding box per object. The method calls the `selectStrongestBboxMulticlass` function, which uses nonmaximal suppression to eliminate overlapping bounding boxes based on their confidence scores.

  By default, the `selectStrongestBboxMulticlass` function is called as follows

```
selectStrongestBboxMulticlass(bboxes,scores,labels, ...
                              RatioType="Union", ...
                              OverlapThreshold=0.5);
```

- `false` — Return all the detected bounding boxes. You can then write your own custom method to eliminate overlapping bounding boxes.

`MinSize` — Minimum region size
`[1 1]` (default) | vector of the form [*height width*]

Minimum region size, specified as a vector of the form [*height width*]. Units are in pixels. The minimum region size defines the size of the smallest region containing the object.

By default, `MinSize` is 1-by-1.

`MaxSize` — Maximum region size
`size(I)` (default) | vector of the form [*height width*]

Maximum region size, specified as a vector of the form [*height width*]. Units are in pixels. The maximum region size defines the size of the largest region containing the object.

By default, `MaxSize` is set to the height and width of the input image, `I`. To reduce computation time, set this value to the known maximum region size for the objects that can be detected in the input test image.

`MiniBatchSize` — Minimum batch size
`128` (default) | scalar

Minimum batch size, specified as a scalar value. Use the `MiniBatchSize` to process a large collection of image. Images are grouped into minibatches and processed as a batch, which can improve computational efficiency at the cost of increased memory demand. Decrease the size to use less memory.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as `"auto"`, `"gpu"`, or `"cpu"`.

- `"auto"` — Use a GPU if it is available. Otherwise, use the CPU.
- `"gpu"` — Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA-enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Use the CPU.

`Acceleration` — Performance optimization
`"auto"` (default) | `"mex"` | `"none"`

Performance optimization, specified one of the following:

- `"auto"` — Automatically apply a number of optimizations suitable for the input network and hardware resource.
- `"mex"` — Compile and execute a MEX function. This option is available when using a GPU only. Using a GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If Parallel Computing Toolbox or a suitable GPU is not available, then the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

- `"none"` — Disable all acceleration.

The default option is `"auto"`. If `"auto"` is specified, MATLAB applies a number of compatible optimizations. If you use the `"auto"` option, MATLAB does not ever generate a MEX function.

Using the `Acceleration` options `"auto"` and `"mex"` can offer performance benefits, but at the expense of an increased initial run time. Subsequent calls with compatible parameters are faster. Use performance optimization when you plan to call the function multiple times using new input data.

The `"mex"` option generates and executes a MEX function based on the network and parameters used in the function call. You can have several MEX functions associated with a single network at one time. Clearing the network variable also clears any MEX functions associated with that network.

The `"mex"` option is only available for input data specified as a numeric array, cell array of numeric arrays, table, or image datastore. No other types of datastore support the `"mex"` option.

The `"mex"` option is only available when you are using a GPU. You must also have a C/C++ compiler installed. For setup instructions, see “Set Up Compiler” (GPU Coder).

`"mex"` acceleration does not support all layers. For a list of supported layers, see “Supported Layers” (GPU Coder).

Output Arguments

`bboxes` — Location of objects detected

M-by-4 matrix | *B*-by-1 cell array

Location of objects detected within the input image or images, returned as an *M*-by-4 matrix or a *B*-by-1 cell array. *M* is the number of bounding boxes in an image, and *B* is the number of *M*-by-4 matrices when the input contains an array of images.

Each row of `bboxes` contains a four-element vector of the form [*x y width height*]. This vector specifies the upper left corner and size of that corresponding bounding box in pixels.

`scores` — Detection scores

M-by-1 numeric vector | *T*-by-1 cell array

Detection confidence scores for each bounding box, returned as one of these options:

- *M*-by-1 numeric vector — The input is a single test image. *M* is the number of bounding boxes detected in the image.
- *B*-by-1 cell array — The input is a batch of test images, where *B* is the number of test images in the batch. Each cell in the array contains an *M*-element row vector, where each element indicates the detection score for a bounding box in the corresponding image.

A higher score indicates higher confidence in the detection. The confidence score for each detection is a product of the corresponding objectness score and maximum class probability. The objectness score is the probability that the object in the bounding box belongs to a class in the image. The maximum class probability is the largest probability that a detected object in the bounding box belongs to a particular class.

`labels` — Labels for bounding boxes

M-by-1 categorical vector | *T*-by-1 cell array

Labels for bounding boxes, returned as one of these options:

- *M*-by-1 categorical vector if the input is a single test image.
- *T*-by-1 cell array if the input is an array of test images. *T* is the number of test images in the array. Each cell in the array contains a *M*-by-1 categorical vector containing the names of the object classes.

M is the number of bounding boxes detected in an image.

`detectionResults` — Detection results
3-column table

Detection results, returned as a 3-column table with variable names, *Boxes*, *Scores*, and *Labels*. The *Boxes* column contains *M*-by-4 matrices, of *M* bounding boxes for the objects found in the image. Each row contains a bounding box as a 4-element vector in the format [*x*,*y*,*width*,*height*]. The format specifies the upper-left corner location and size in pixels of the bounding box in the corresponding image.

`info` — Class probabilities and objectness scores
structure array

Class probabilities and objectness scores of the detections, returned as a structure array with these fields.

- `ClassProbabilities` — Class probabilities for each of the detections, returned as a *B*-by-1 cell array. *B* is the number of images in the input batch of images, `I`. Each cell in the array contains the class probabilities as an *M*-by-*N* numeric matrix. *M* is the number of bounding boxes and *N* is the number of classes. Each class probability is a numeric scalar, indicating the probability that the detected object in the bounding box belongs to a class in the image.
- `ObjectnessScores` — Objectness scores for each of the detections, returned as a *B*-by-1 cell array. *B* is the number of images in the input batch of images, `I`. Each cell in the array contains the objectness score for each bounding box as an *M*-by-1 numeric vector. *M* is the number of bounding boxes. Each objectness score is a numeric scalar, indicating the probability that the bounding box contains an object belonging to one of the classes in the image.

More About

Data Preprocessing

By default, the `detect` function preprocesses the test image for object detection by:

- Resizing it to a nearest possible image size used for training the YOLO v2 network. The function determines the nearest possible image size from the `TrainingImageSize` property of the `yolov2ObjectDetector` object.
- Normalizing its pixel values to lie in same range as that of the images used to train the YOLO v2 object detector. For example, if the detector was trained on `uint8` images, the test image must also have pixel values in the range [0, 255]. Otherwise, use the `im2uint8` or `rescale` function to rescale the pixel values in the test image.

Version History

Introduced in R2019a

R2024a: Option to return class probabilities and objectness scores

Specify the `info` output argument to return information about the class probability and objectness score for each detection.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `roi` argument to the `detect` method must be a code generation constant (`coder.const()`) and a 1-by-4 vector.
- Only the `Threshold`, `SelectStrongest`, `MinSize`, `MiniBatchSize`, and `MaxSize` name-value arguments are supported.
- The `MiniBatchSize` name-value argument is not supported for code generation when the image input `I` is an *H*-by-*W*-by-*C*-by-*B* numeric array of images. All images will processed in one batch.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- The `roi` argument to the `detect` method must be a codegen constant (`coder.const()`) and a 1-by-4 vector.
- Only the `Threshold`, `SelectStrongest`, `MinSize`, `MaxSize`, and `MiniBatchSize` name-value arguments are supported.
- The height, width, channel, and batch size of the input image must be fixed size.
- The minimum batch size value passed to detect method must be fixed size.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

detect

Detect objects using YOLOX object detector

Syntax

```
bboxes = detect(detector,I)
[bboxes,scores] = detect(detector,I)
[bboxes,scores,labels] = detect(detector,I)
[bboxes,scores,labels,info] = detect(detector,I)

detectionResults = detect(detector,ds)

[___] = detect(___,roi)
[___] = detect(___,Name=Value)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`bboxes = detect(detector,I)` detects objects within a single image or a batch of images, `I`, using a YOLOX object detector, `detector`. The `detect` function returns the locations of objects detected in the input image as a set of bounding boxes.

Note This functionality requires Deep Learning Toolbox.

`[bboxes,scores] = detect(detector,I)` also returns the class-specific confidence scores for each bounding box.

`[bboxes,scores,labels] = detect(detector,I)` returns a categorical array of labels assigned to the bounding boxes. You must define the labels for object classes during training.

`[bboxes,scores,labels,info] = detect(detector,I)` also returns information about the class probabilities and objectness scores for each detection.

`detectionResults = detect(detector,ds)` returns object detection predictions within all the images returned by the `read` function of the input datastore `ds`, as a table.

`[___] = detect(___,roi)` detects objects within the rectangular search region `roi`, in addition to any combination of arguments from previous syntaxes.

`[___] = detect(___,Name=Value)` specifies options using one or more name-value arguments, in addition to any combination of arguments from previous syntaxes.. For example, `Threshold=0.25` specifies a detection threshold of 0.25.

Examples

Detect Objects Using Pretrained YOLOX Object Detector

Specify the name of a pretrained YOLOX deep learning network.

```
name = "tiny-coco";
```

Create YOLOX object detector by using the pretrained YOLOX network.

```
detector = yoloxObjectDetector(name);
```

Detect objects in a test image by using the pretrained YOLOX object detector.

```
img = imread("tima.png");
[bboxes,scores,labels] = detect(detector,img,Threshold=0.6)
```

```
bboxes = 1×4 single row vector

  185.1392  255.8597  119.6875  217.3186

scores = single

0.7775

labels = categorical
     cat
```

Display the detection results.

```
detectedImg = insertObjectAnnotation(img,"Rectangle",bboxes,labels);
figure
imshow(detectedImg)
```

Detect Objects in Image Datastore Using YOLOX Detector

Load a pretrained YOLOX object detector.

```
detector = yoloxObjectDetector("small-coco");
```

Specify the location of test data, then create an image datastore that reads the test data.

```
location = fullfile(matlabroot,"toolbox","vision","visiondata","vehicles");
imds = imageDatastore(location);
```

Detect objects in the datastore. Set the `Threshold` name-value argument to `0.4` and `MiniBatchSize` name-value argument to `32`.

```
detectionResults = detect(detector,imds,Threshold=0.4,MiniBatchSize=32);
```

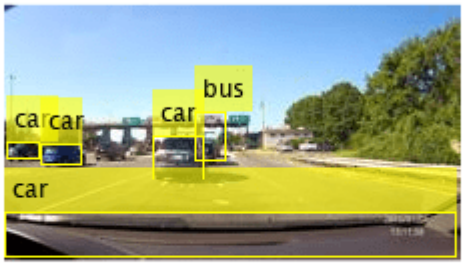
Read an image from the test data set and extract the corresponding detection results.

```
num = 20;
I = readimage(imds,num);
bboxes = detectionResults.Boxes{num};
labels = detectionResults.Labels{num};
scores = detectionResults.Scores{num}
```

```
scores = 5×1 single column vector

    0.6125
    0.7789
    0.7595
    0.6787
    0.4322
```

Perform non-maximal suppression to select strongest bounding boxes from the overlapping clusters. Set the `OverlapThreshold` name-value argument to `0.5`.



```
[bboxes,scores,labels] = selectStrongestBboxMulticlass(bboxes, ...
    scores,labels,OverlapThreshold=0.5);
```

Display the detection results.

```
results = table(bboxes,labels,scores)
```

```
results=5×3 table
     2.0755     69.2511     16.8517     9.0757    car    0.6125
    19.2191     70.2047     21.2572    10.8475    car    0.7789
    75.1651     65.7733     25.7689    23.2266    car    0.7595
    96.4793     54.2146     16.1751    24.6539    bus    0.6787
          1    104.9146    225.5654    22.6630    car    0.4322
```

```
detectedImg = insertObjectAnnotation(I,"Rectangle",bboxes,labels);
figure
imshow(detectedImg)
```

Detect Objects Within ROI by Using YOLOX Detector

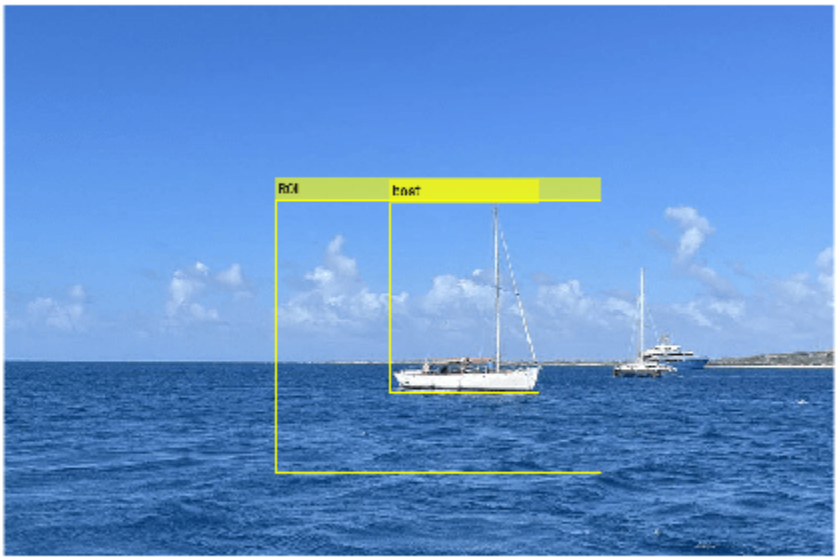
Load a pretrained YOLOX object detector.

```
detector = yoloxObjectDetector("small-coco");
```

Read a test image.

```
img = imread("aruba.png");
```

Specify a region of interest (ROI) within the test image.



```
roiBox = [250 180 300 250];
```

Detect objects within the specified ROI.

```
[bboxes,scores,labels] = detect(detector,img,roiBox,Threshold=0.55);
```

Display the ROI and the detection results.

```
img = insertObjectAnnotation(img,"Rectangle",roiBox,"ROI",AnnotationColor="yellow");
detectedImg = insertObjectAnnotation(img,"Rectangle",bboxes,labels);
figure
imshow(detectedImg)
```

Input Arguments

`detector` — YOLOX object detector

`yoloxObjectDetector` object

YOLOX object detector, specified as a `yoloxObjectDetector` object.

`I` — Test images

H-by-*W*-by-3 numeric array | *H*-by-*W*-by-3-by-*B* numeric array

Test images, specified as a numeric array of size *H*-by-*W*-by-3 or *H*-by-*W*-by-3-by-*B*. You must specify real and nonsparse RGB or grayscale images with 3 channels.

- *H* — Height of the input images.
- *W* — Width of the input images.
- *B* — Number of test images in the batch. The `detect` function computes the object detection results for each test image in the batch.

Note The channel size of each image must be equal to the input channel size of the network. If you have grayscale test images, `detector` must be a YOLOX network that was trained on 3-channel grayscale images. Convert grayscale images to 3-channel images before training.

When the test image size does not match the network input size, the detector resizes the input image to the value of the `InputSize` property of `detector`, unless you specify `AutoResize` as `false`.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single`

`ds` — Datastore of test images
`ImageDatastore` object | `CombinedDatastore` object | `TransformedDatastore` object

Datastore of test images, specified as an `imageDatastore` object, `CombinedDatastore` object, or `TransformedDatastore` object containing full filenames of the test images. The images in the datastore must be grayscale or RGB images.

`roi` — Region of interest to search
vector of form [*x y width height*]

Region of interest (ROI) to search, specified as a vector of form [*x y width height*]. The vector specifies the upper-left corner and size of a region, in pixels. If the input data is a datastore, the `detect` function applies the same ROI to every image.

Note You can specify the ROI to search only when the `detect` function automatically resizes the input test images to the network input size. To use `roi`, reset `AutoResize` to its default value.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `detect(detector,I,Threshold=0.25)` specifies a detection threshold of 0.25.

`Threshold` — Detection threshold
`0.25` (default) | scalar in the range `[0, 1]`

Detection threshold, specified as a scalar in the range `[0, 1]`. The function removes detections that have scores less than this threshold value. To reduce false positives, increase this value at the possible expense of missing some objects.

`SelectStrongest` — Strongest bounding box selection
`true` or `1` (default) | `false` or `0`

Strongest bounding box selection for each detected object, specified as a numeric or logical `1` (`true`) or `0` (`false`).

- `true` — Return the strongest bounding box for each object. The `detect` function calls the `selectStrongestBboxMulticlass` function, which uses nonmaximal suppression to eliminate overlapping bounding boxes based on their confidence scores.

  By default, the `detect` function uses this call to the `selectStrongestBboxMulticlass`.

  ```
  selectStrongestBboxMulticlass(bboxes,scores,labels, ...
                                RatioType="Union", ...
                                OverlapThreshold=0.45);
  ```

- `false` — Return all the detected bounding boxes. You can write a custom function to eliminate overlapping bounding boxes.

`MinSize` — Minimum region size
`[1 1]` (default) | vector of form [*height width*]

Minimum region size containing an object, specified as a vector of the form [*height width*]. Units are in pixels. The minimum region size defines the size of the smallest object that can be detected by the trained network. When the minimum size is known, you can reduce computation time by setting `MinSize` to that value.

`MaxSize` — Maximum region size
`size(I)` (default) | vector of form [*height width*]

Maximum region size, specified as a vector of the form [*height width*]. Units are in pixels. The maximum region size defines the size of the largest object that can be detected by the trained network.

By default, `MaxSize` is set to the height and width of the input image `I`. To reduce computation time, set this value to the known maximum region size for the objects that can be detected in the input test image.

`MiniBatchSize` — Minimum batch size
`128` (default) | positive integer

Minimum batch size, specified as a positive integer. Adjust the `MiniBatchSize` value to help process a large collection of images. The `detect` function groups images into minibatches of the specified size and processes them as a batch, which can improve computation efficiency at the cost of increased memory demand. Decrease the minibatch size to use less memory.

`AutoResize` — Automatic resizing of input images
`true` or `1` (default) | `false` or `0`

Automatic resizing of input images to preserve the aspect ratio, specified as a numeric or logical `1` (`true`) or `0` (`false`). When `AutoResize` is set to `1` (or `true`), the `detect` function resizes images to the nearest `InputSize` and the aspect ratio is preserved. Set `AutoResize` to logical `false` or `0` when performing image tiling-based training or inference at full test image size.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as one of these values:

- `"auto"` — Use a GPU if Parallel Computing Toolbox is installed and a supported GPU device is available. Otherwise, use the CPU.
- `"gpu"` — Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA-enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Use the CPU.

`Acceleration` — Performance optimization
`"auto"` (default) | `"mex"` | `"none"`

Performance optimization, specified as one of these options:

- `"auto"` — Automatically apply a number of compatible optimizations suitable for the input network and hardware resource.
- `"mex"` — Compile and execute a MEX function. This option is available only when using a GPU. Using a GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If Parallel

Computing Toolbox or a suitable GPU is not available, then the `detect` function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

- `"none"` — Disable all acceleration.

Using the `Acceleration` options `"auto"` and `"mex"` can offer performance benefits on subsequent calls with compatible parameters, at the expense of an increased initial run time. Use performance optimization when you plan to call the function multiple times using new input data.

The `"mex"` option generates and executes a MEX function based on the network and parameters used in the function call. You can have several MEX functions associated with a single network at one time. Clearing the network variable also clears any MEX functions associated with that network.

The `"mex"` option is available only for input data specified as a numeric array, cell array of numeric arrays, table, or image datastore. No other types of datastore support the `"mex"` option.

The `"mex"` option is available only when you are using a GPU. You must also have a C/C++ compiler installed. For setup instructions, see “Set Up Compiler” (GPU Coder).

`"mex"` acceleration does not support all layers. For a list of supported layers, see “Supported Layers” (GPU Coder).

Output Arguments

`bboxes` — Locations of objects detected

M-by-4 matrix | *B*-by-1 cell array

Locations of objects detected within the input image or images, returned as one of these options:

- *M*-by-4 matrix — The input is a single test image. *M* is the number of bounding boxes detected in an image.
- *B*-by-1 cell array — The input is a batch of images, where *B* is the number of test images in the batch. Each cell in the array contains an *M*-by-4 matrix specifying the detected bounding boxes.

`scores` — Detection confidence scores

M-by-1 numeric vector | *B*-by-1 cell array

Detection confidence scores for each bounding box, returned as one of these options:

- *M*-by-1 numeric vector — The input is a single test image. *M* is the number of bounding boxes detected in the image.
- *B*-by-1 cell array — The input is a batch of test images, where *B* is the number of test images in the batch. Each cell in the array contains an *M*-element row vector, where each element indicates the detection score for a bounding box in the corresponding image.

A higher score indicates higher confidence in the detection. The confidence score for each detection is a product of the corresponding objectness score and maximum class probability. The objectness score is the probability that the object in the bounding box belongs to a class in the image. The maximum class probability is the largest probability that a detected object in the bounding box belongs to a particular class.

`labels` — Labels for bounding boxes

M-by-1 categorical vector | *B*-by-1 cell array

Labels for bounding boxes, returned as one of these options:

- *M*-by-1 categorical vector — The input is a single test image. *M* is the number of bounding boxes detected in an image.
- *B*-by-1 cell array — The input is an array of test images. *B* is the number of test images in the batch. Each cell in the array contains an *M*-by-1 categorical vector containing the names of the object classes.

`detectionResults` — Detection results

three-column table

Detection results when the input is a datastore of test images, `ds`, returned as a table with these columns:

`bboxes`	`scores`	`labels`
Predicted bounding boxes, defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and `y` specify the upper-left corner of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis. • *h* specifies the height of the rectangle, which is its length along the *y*-axis.	Class-specific confidence scores in the range `[0, 1]` for each bounding box, returned as an *M*-by-1 numeric vector.	Predicted object labels assigned to bounding boxes, returned as an *M*-by-1 categorical vector. All categorical data returned by the datastore must contain the same categories.

`info` — Class probabilities and objectness scores

structure array

Class probabilities and objectness scores of the detections, returned as a structure array with these fields.

- `ClassProbabilities` — Class probabilities for each of the detections, returned as a *B*-by-1 cell array. *B* is the number of images in the input batch of images, `I`. Each cell in the array contains the class probabilities as an *M*-by-*N* numeric matrix. *M* is the number of bounding boxes and *N* is the number of classes. Each class probability is a numeric scalar, indicating the probability that the detected object in the bounding box belongs to a class in the image.
- `ObjectnessScores` — Objectness scores for each of the detections, returned as a *B*-by-1 cell array. *B* is the number of images in the input batch of images, `I`. Each cell in the array contains the objectness score for each bounding box as an *M*-by-1 numeric vector. *M* is the number of bounding boxes. Each objectness score is a numeric scalar, indicating the probability that the bounding box contains an object belonging to one of the classes in the image.

Version History

Introduced in R2023b

R2024a: Option to return class probabilities and objectness scores

Specify the `info` output argument to return information about the class probability and objectness score for each detection.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- To prepare a `yoloxObjectDetector` object for CPU code generation, use `vision.loadYOLOXObjectDetector`.
- The `roi` argument to the `detect` method must be a code generation constant (`coder.const()`) and a 1x4 vector.
- The `AutoResize` argument to the `detect` method must be a code generation constant (`coder.const()`).
- Only the `Threshold`, `SelectStrongest`, `MinSize`, `MaxSize`, `MiniBatchSize`, and `AutoResize` name-value pairs for `detect` are supported.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- To prepare a `yoloxObjectDetector` object for GPU code generation, use `vision.loadYOLOXObjectDetector`.
- The `roi` argument to the `detect` method must be a code generation constant (`coder.const()`) and a 1x4 vector.
- The `AutoResize` argument to the `detect` method must be a code generation constant (`coder.const()`).
- Only the `Threshold`, `SelectStrongest`, `MinSize`, `MaxSize`, and `MiniBatchSize`, and `AutoResize` name-value pairs for `detect` are supported.

classifyRegions

(Not recommended) Classify objects in image regions using R-CNN object detector

Note The `classifyRegions` function and R-CNN object detectors are not recommended. Use a different type of object detector instead. For more information, see “Version History”.

Syntax

```
[labels,scores] = classifyRegions(detector,I,rois)
[labels,scores,allScores] = classifyRegions(detector,I,rois)
[___] = classifyRegions(___,Name=Value)
```

Description

`[labels,scores] = classifyRegions(detector,I,rois)` classifies objects within the regions of interest of image `I`, using an R-CNN (regions with convolutional neural networks) object detector. For each region, `classifyRegions` returns the class label with the corresponding highest classification score.

When using this function, use of a CUDA enabled NVIDIA GPU is highly recommended. The GPU reduces computation time significantly. Usage of the GPU requires Parallel Computing Toolbox. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

`[labels,scores,allScores] = classifyRegions(detector,I,rois)` also returns all the classification scores of each region. The scores are returned in an *M*-by-*N* matrix of *M* regions and *N* class labels.

`[___] = classifyRegions(___,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `ExecutionEnvironment="cpu"` classifies objects within image regions using only the CPU hardware.

Examples

Classify Multiple Image Regions

Load a pretrained detector.

```
load('rcnnStopSigns.mat','rcnn')
```

Read the test image.

```
img = imread('stopSignTest.jpg');
```

Specify multiple regions to classify within the test image.

```
rois = [416   143    33    27
        347   168    36    54];
```

Classify regions.

```
[labels,scores] = classifyRegions(rcnn,img,rois);
detectedImg = insertObjectAnnotation(img,'rectangle',rois,cellstr(labels));
figure
imshow(detectedImg)
```

Input Arguments

`detector` — R-CNN object detector

`rcnnObjectDetector` object

R-CNN object detector, specified as an `rcnnObjectDetector` object. To create this object, call the `trainRCNNObjectDetector` function with training data as input.

`I` — Input image

grayscale image | RGB image

Input image, specified as a real, nonsparse, grayscale or RGB image.

The detector is sensitive to the range of the input image. Therefore, ensure that the input image range is similar to the range of the images used to train the detector. For example, if the detector was trained on `uint8` images, rescale this input image to the range [0, 255] by using the `im2uint8` or `rescale` function. The size of this input image should be comparable to the sizes of the images used in training. If these sizes are very different, the detector has difficulty detecting objects because the scale of the objects in the input image differs from the scale of the objects the detector was trained to identify. Consider whether you used the `SmallestImageDimension` property during training to modify the size of training images.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single` | `logical`

`rois` — Regions of interest
M-by-4 matrix

Regions of interest within the image, specified as an *M*-by-4 matrix defining *M* rectangular regions. Each row contains a four-element vector of the form [*x y width height*]. This vector specifies the upper left corner and size of a region in pixels.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `ExecutionEnvironment="cpu"` classifies objects within image regions using only the CPU hardware.

`MiniBatchSize` — Size of smaller batches for R-CNN data processing
`128` (default) | integer

Size of smaller batches for R-CNN data processing, specified as an integer. Larger batch sizes lead to faster processing but take up more memory.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource used to classify image regions, specified as `"auto"`, `"gpu"`, or `"cpu"`.

- `"auto"` — Use a GPU if it is available. Otherwise, use the CPU.
- `"gpu"` — Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Use the CPU.

Output Arguments

`labels` — Classification labels of regions
M-by-1 categorical array

Classification labels of regions, returned as an *M*-by-1 categorical array. *M* is the number of regions of interest in `rois`. Each class name in `labels` corresponds to a classification score in `scores` and a region of interest in `rois`. `classifyRegions` obtains the class names from the input `detector`.

`scores` — Highest classification score per region
M-by-1 vector of values in the range [0, 1]

Highest classification score per region, returned as an *M*-by-1 vector of values in the range [0, 1]. *M* is the number of regions of interest in `rois`. Each classification score in `scores` corresponds to a class name in `labels` and a region of interest in `rois`. A higher score indicates higher confidence in the classification.

`allScores` — All classification scores per region
M-by-*N* matrix of values in the range [0, 1]

All classification scores per region, returned as an *M*-by-*N* matrix of values in the range [0, 1]. *M* is the number of regions in `rois`. *N* is the number of class names stored in the input `detector`. Each row of classification scores in `allscores` corresponds to a region of interest in `rois`. A higher score indicates higher confidence in the classification.

Version History

Introduced in R2016b

R2024b: Not Recommended
Not recommended starting in R2024b

Starting in R2024b, R-CNN object detectors are no longer recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` object. These object detectors are faster than R-CNN object detectors. For more information, see “Choose an Object Detector”.

classifyRegions

(Not recommended) Classify objects in image regions using Fast R-CNN object detector

Note The `classifyRegions` function and Fast R-CNN object detectors are not recommended. Use a different type of object detector instead. For more information, see "Version History".

Syntax

```
[labels,scores] = classifyRegions(detector,I,rois)
[labels,scores,allScores] = classifyRegions(detector,I,rois)
[___] = classifyRegions(___,'ExecutionEnvironment',resource)
```

Description

`[labels,scores] = classifyRegions(detector,I,rois)` classifies objects within the regions of interest of image `I`, using a Fast R-CNN (regions with convolutional neural networks) object detector. For each region, `classifyRegions` returns the class label with the corresponding highest classification score.

When using this function, use of a CUDA enabled NVIDIA GPU is highly recommended. The GPU reduces computation time significantly. Usage of the GPU requires Parallel Computing Toolbox. For information about the supported compute capabilities, see "GPU Computing Requirements" (Parallel Computing Toolbox).

`[labels,scores,allScores] = classifyRegions(detector,I,rois)` also returns all the classification scores of each region. The scores are returned in an *M*-by-*N* matrix of *M* regions and *N* class labels.

`[___] = classifyRegions(___,'ExecutionEnvironment',resource)` specifies the hardware resource used to classify object within image regions: `"auto"`, `"cpu"`, or `"gpu"`. You can use this syntax with either of the preceding syntaxes.

Examples

Classify Image Regions Using Fast R-CNN

Configure a Fast R-CNN object detector and use it to classify objects within multiple regions of an image.

Load a `fastRCNNObjectDetector` object that is pretrained to detect stop signs.

```
data = load('rcnnStopSigns.mat','fastRCNN');
fastRCNN = data.fastRCNN;
```

Read in a test image containing a stop sign.

```
I = imread('stopSignTest.jpg');
figure
imshow(I)
```

Specify regions of interest to classify within the test image.

```
rois = [416   143    33    27
        347   168    36    54];
```

Classify the image regions and inspect the output labels and classification scores. The labels come from the `ClassNames` property of the detector.

```
[labels,scores] = classifyRegions(fastRCNN,I,rois)
```

```
labels = 2×1 categorical
     stopSign
     Background

scores = 2×1 single column vector

    0.9969
    1.0000
```

The detector has high confidence in the classifications. Display the classified regions on the test image.

```
detectedI = insertObjectAnnotation(I,'rectangle',rois,cellstr(labels));

figure
imshow(detectedI)
```

Input Arguments

`detector` — Fast R-CNN object detector

`fastRCNNObjectDetector` object

Fast R-CNN object detector, specified as a `fastRCNNObjectDetector` object. To create this object, call the `trainFastRCNNObjectDetector` function with training data as input.

`I` — Input image

grayscale image | RGB image

Input image, specified as a real, nonsparse, grayscale or RGB image.

The detector is sensitive to the range of the input image. Therefore, ensure that the input image range is similar to the range of the images used to train the detector. For example, if the detector was trained on `uint8` images, rescale this input image to the range [0, 255] by using the `im2uint8` or `rescale` function. The size of this input image should be comparable to the sizes of the images used in training. If these sizes are very different, the detector has difficulty detecting objects because the scale of the objects in the input image differs from the scale of the objects the detector was trained to identify. Consider whether you used the `SmallestImageDimension` property during training to modify the size of training images.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single` | `logical`

`rois` — Regions of interest

M-by-4 matrix

Regions of interest within the image, specified as an *M*-by-4 matrix defining *M* rectangular regions. Each row contains a four-element vector of the form [*x y width height*]. This vector specifies the upper left corner and size of a region in pixels.

`resource` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource used to classify image regions, specified as `"auto"`, `"gpu"`, or `"cpu"`.

- `"auto"` — Use a GPU if it is available. Otherwise, use the CPU.
- `"gpu"` — Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see "GPU Computing Requirements" (Parallel Computing Toolbox).
- `"cpu"` — Use the CPU.

Example: `classifyRegions(___,'ExecutionEnvironment',"cpu")`

Output Arguments

`labels` — Classification labels of regions
M-by-1 categorical array

Classification labels of regions, returned as an *M*-by-1 categorical array. *M* is the number of regions of interest in `rois`. Each class name in `labels` corresponds to a classification score in `scores` and a region of interest in `rois`. `classifyRegions` obtains the class names from the input `detector`.

`scores` — Highest classification score per region
M-by-1 vector of values in the range [0, 1]

Highest classification score per region, returned as an *M*-by-1 vector of values in the range [0, 1]. *M* is the number of regions of interest in `rois`. Each classification score in `scores` corresponds to a class name in `labels` and a region of interest in `rois`. A higher score indicates higher confidence in the classification.

`allScores` — All classification scores per region
M-by-*N* matrix of values in the range [0, 1]

All classification scores per region, returned as an *M*-by-*N* matrix of values in the range [0, 1]. *M* is the number of regions in `rois`. *N* is the number of class names stored in the input `detector`. Each row of classification scores in `allscores` corresponds to a region of interest in `rois`. A higher score indicates higher confidence in the classification.

Version History

Introduced in R2017a

R2024b: Not Recommended
Not recommended starting in R2024b

Starting in R2024b, R-CNN object detectors are no longer recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` object. These object detectors are faster than R-CNN object detectors. For more information, see "Choose an Object Detector".

Functions
`trainFastRCNNObjectDetector`

Objects
`fastRCNNObjectDetector`

trainFastRCNNObjectDetector

(Not recommended) Train Fast R-CNN deep learning object detector

Note `trainFastRCNNObjectDetector` is not recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` detector. For more information, see “Version History”.

Syntax

```
trainedDetector = trainFastRCNNObjectDetector(trainingData,network,options)
[trainedDetector,info] = trainFastRCNNObjectDetector( ___ )

trainedDetector = trainFastRCNNObjectDetector(trainingData,checkpoint,
options)

trainedDetector = trainFastRCNNObjectDetector(trainingData,detector,options)

trainedDetector = trainFastRCNNObjectDetector( ___ ,'RegionProposalFcn',
proposalFcn)

trainedDetector = trainFastRCNNObjectDetector( ___ ,Name,Value)
```

Description

Train a Detector

`trainedDetector = trainFastRCNNObjectDetector(trainingData,network,options)` trains a Fast R-CNN (regions with convolution neural networks) object detector using deep learning. You can train a Fast R-CNN detector to detect multiple object classes.

This function requires that you have Deep Learning Toolbox. It is recommended that you also have Parallel Computing Toolbox to use with a CUDA-enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

`[trainedDetector,info] = trainFastRCNNObjectDetector( ___ )` also returns information on the training progress, such as training loss and accuracy, for each iteration.

Resume Training a Detector

`trainedDetector = trainFastRCNNObjectDetector(trainingData,checkpoint, options)` resumes training from a detector checkpoint.

Fine Tune a Detector

`trainedDetector = trainFastRCNNObjectDetector(trainingData,detector,options)` continues training a detector with additional training data or performs more training iterations to improve detector accuracy.

Custom Region Proposal

`trainedDetector = trainFastRCNNObjectDetector( ___ ,'RegionProposalFcn', proposalFcn)` optionally trains a custom region proposal function, `proposalFcn`, using any of the

previous inputs. If you do not specify a proposal function, then the function uses a variation of the Edge Boxes [2] algorithm.

Additional Properties

`trainedDetector = trainFastRCNNObjectDetector( ___ ,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

Examples

Train Fast R-CNN Stop Sign Detector

Load training data.

```
data = load('rcnnStopSigns.mat', 'stopSigns', 'fastRCNNLayers');
stopSigns = data.stopSigns;
fastRCNNLayers = data.fastRCNNLayers;
```

Add fullpath to image files.

```
stopSigns.imageFilename = fullfile(toolboxdir('vision'),'visiondata', ...
    stopSigns.imageFilename);
```

Randomly shuffle data for training.

```
rng(0);
shuffledIdx = randperm(height(stopSigns));
stopSigns = stopSigns(shuffledIdx,:);
```

Create an imageDatastore using the files from the table.

```
imds = imageDatastore(stopSigns.imageFilename);
```

Create a boxLabelDatastore using the label columns from the table.

```
blds = boxLabelDatastore(stopSigns(:,2:end));
```

Combine the datastores.

```
ds = combine(imds, blds);
```

The stop sign training images have different sizes. Preprocess the data to resize the image and boxes to a predefined size.

```
ds = transform(ds,@(data)preprocessData(data,[920 968 3]));
```

Set the network training options.

```
options = trainingOptions('sgdm', ...
    'MiniBatchSize', 10, ...
    'InitialLearnRate', 1e-3, ...
    'MaxEpochs', 10, ...
    'CheckpointPath', tempdir);
```

Train the Fast R-CNN detector. Training can take a few minutes to complete.

```
frcnn = trainFastRCNNObjectDetector(ds, fastRCNNLayers , options, ...
    'NegativeOverlapRange', [0 0.1], ...
    'PositiveOverlapRange', [0.7 1]);

********************************************************************
Training a Fast R-CNN Object Detector for the following object classes:

```

Test the Fast R-CNN detector on a test image.

```
img = imread('stopSignTest.jpg');
```

Run the detector.

```
[bbox, score, label] = detect(frcnn, img);
```

Display detection results.

```
detectedImg = insertObjectAnnotation(img,'rectangle',bbox,score);
figure
imshow(detectedImg)
```

Supporting Functions

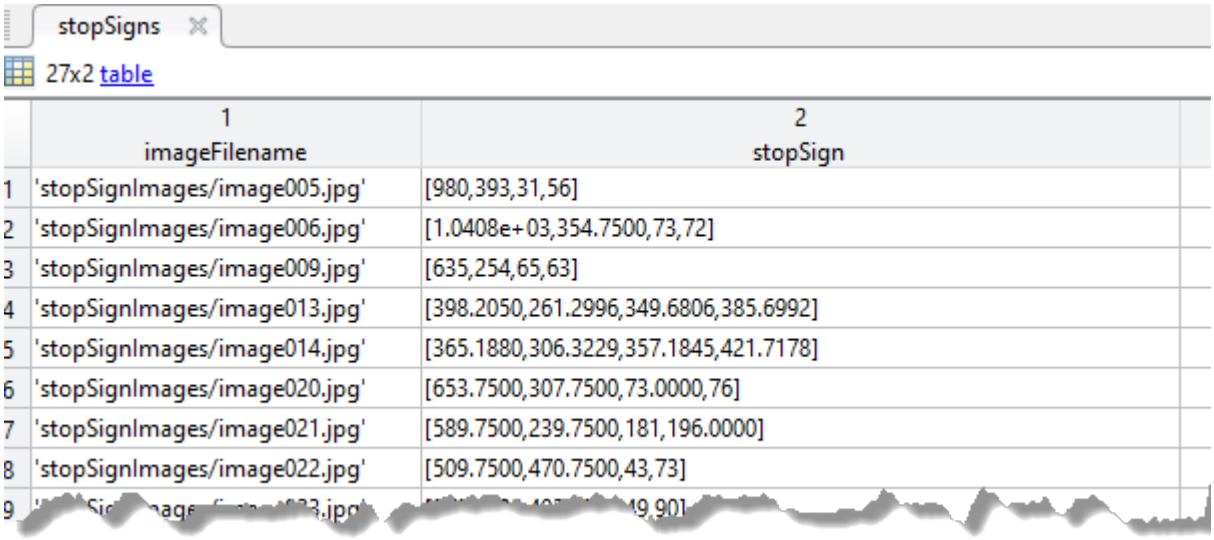
```
function data = preprocessData(data,targetSize)
% Resize image and bounding boxes to the targetSize.
scale = targetSize(1:2)./size(data{1},[1 2]);
data{1} = imresize(data{1},targetSize(1:2));
bboxes = round(data{2});
data{2} = bboxresize(bboxes,scale);
end
```

Input Arguments

`trainingData` — Labeled ground truth

datastore | table

Labeled ground truth, specified as a datastore or a table.



Each bounding box must be in the format [*x y width height*].

- If you use a datastore, your data must be set up so that calling the datastore with the `read` and `readall` functions returns a cell array or table with three columns. The second column must contain the bounding boxes, and the third column must contain the labels. The first column can contain image or point cloud data.

data	*boxes*	*labels*
The first column must be images.	*M*-by-4 matrices of bounding boxes of the form [*x*, *y*, *width*, *height*], where [x,y] represent the top-left coordinates of the bounding box.	The third column must be a cell array that contains *M*-by-1 categorical vectors containing object class names. All categorical data returned by the datastore must contain the same categories.

For more information, see “Datastores for Deep Learning” (Deep Learning Toolbox).

- If you use a table, the table must have two or more columns. The first column of the table must contain image file names with paths. The images must be grayscale or truecolor (RGB) and they can be in any format supported by `imread`. Each of the remaining columns must be a cell vector that contains *M*-by-4 matrices that represent a single object class, such as *vehicle*, *flower*, or *stop sign*. The columns contain 4-element double arrays of *M* bounding boxes in the format [*x*,*y*,*width*,*height*]. The format specifies the upper-left corner location and size of the bounding box in the corresponding image. To create a ground truth table, you can use the Image Labeler app or Video Labeler app. To create a table of training data from the generated ground truth, use the `objectDetectorTrainingData` function.

`network` — Network

`SeriesNetwork` object | array of `Layer` objects | `LayerGraph` object | network name

Network, specified as a `SeriesNetwork`, an array of `Layer` objects, a `layerGraph` object, or by the network name. The network is trained to classify the object classes defined in the `trainingData` table. The `SeriesNetwork`, `Layer`, and `layerGraph` objects are available in the Deep Learning Toolbox.

- When you specify the network as a `SeriesNetwork`, an array of `Layer` objects, or by the network name, the network is automatically transformed into a Fast R-CNN network by adding an ROI max pooling layer, and new classification and regression layers to support object detection. Additionally, the `GridSize` property of the ROI max pooling layer is set to the output size of the last max pooling layer in the network.

- The array of `Layer` objects must contain a classification layer that supports the number of object classes, plus a background class. Use this input type to customize the learning rates of each layer. An example of an array of `Layer` objects:

```
layers = [imageInputLayer([28 28 3])
        convolution2dLayer([5 5],10)
        reluLayer()
        fullyConnectedLayer(10)
        softmaxLayer()
        classificationLayer()];
```

- When you specify the network as `SeriesNetwork`, `Layer` array, or network by name, the weights for additional convolution and fully-connected layers that you add to create the network, are initialized to `'narrow-normal'`.
- The network name must be one of the following valid network names. You must also install the corresponding Add-on.

Network Name	Feature Extraction Layer Name	ROI Pooling Layer OutputSize	Description
`alexnet`	`'relu5'`	[6 6]	Last max pooling layer is replaced by ROI max pooling layer
`vgg16`	`'relu5_3'`	[7 7]	
`vgg19`	`'relu5_4'`		
`squeezenet`	`'fire5-concat'`	[14 14]	
`resnet18`	`'res4b_relu'`		ROI pooling layer is inserted after the feature extraction layer.
`resnet50`	`'activation_40_relu'`		
`resnet101`	`'res4b22_relu'`		
`googlenet`	`'inception_4d-output'`		
`mobilenetv2`	`'block_13_expand_relu'`		
`inceptionv3`	`'mixed7'`	[17 17]	
`inceptionresnetv2`	`'block17_20_ac'`		

- The `LayerGraph` object must be a valid Fast R-CNN object detection network. You can also use a `LayerGraph` object to train a custom Fast R-CNN network.

Tip If your network is a `DAGNetwork`, use the `layerGraph` function to convert the network to a `LayerGraph` object. Then, create a custom Fast R-CNN network as described by the “Create Fast R-CNN Object Detection Network” example.

See “Getting Started with R-CNN, Fast R-CNN, and Faster R-CNN” to learn more about how to create a Fast R-CNN network.

`options` — Training options
`trainingOptions` output

Training options, returned by the `trainingOptions` function from the Deep Learning Toolbox. To specify solver and other options for network training, use `trainingOptions`.

Note `trainFastRCNNObjectDetector` does not support these training options:

- The `trainingOptions` `'once'` and `'every-epoch'` `Shuffle` options are not supported for combined datastore inputs.
- The `trainingOptions` `'parallel'` and `'multi-gpu'` `ExecutionEnvironment` options are not supported when you use a combined datastore input.
- Datastore inputs are not supported when you set the `DispatchInBackground` training option to `true`.

`checkpoint` — Saved detector checkpoint

`fastRCNNObjectDetector` object

Saved detector checkpoint, specified as a `fastRCNNObjectDetector` object. To periodically save a detector checkpoint during training, specify `CheckpointPath`. To control how frequently check points are saved see the `CheckPointFrequency` and `CheckPointFrequencyUnit` training options.

To load a checkpoint for a previously trained detector, load the MAT file from the checkpoint path. For example, if the `'CheckpointPath'` property of `options` is `'/tmp'`, load a checkpoint MAT file using:

```
data = load('/tmp/faster_rcnn_checkpoint__105__2016_11_18__14_25_08.mat');
```

The name of the MAT file includes the iteration number and timestamp of when the detector checkpoint was saved. The detector is saved in the `detector` variable of the file. Pass this file back into the `trainFastRCNNObjectDetector` function:

```
frcnn = trainFastRCNNObjectDetector(stopSigns,...
                            data.detector,options);
```

`detector` — Previously trained Fast R-CNN object detector

`fastRCNNObjectDetector` object

Previously trained Fast R-CNN object detector, specified as a `fastRCNNObjectDetector` object.

`proposalFcn` — Region proposal method

function handle

Region proposal method, specified as a function handle. If you do not specify a region proposal function, the function implements a variant of the Edge Boxes [2] algorithm. The function must have the form:

```
[bboxes,scores] = proposalFcn(I)
```

The input, `I`, is an image defined in the `trainingData` table. The function must return rectangular bound boxes, `bboxes`, in an *m*-by-4 array. Each row of `bboxes` contains a four-element vector, `[x,y,width,height]`. This vector specifies the upper-left corner and size of a bounding box in pixels. The function must also return a score for each bounding box in an *m*-by-1 vector. Higher score values indicate that the bounding box is more likely to contain an object. The scores are used to select the strongest *n* regions, where *n* is defined by the value of `NumStrongestRegions`.

Dependencies

If you do not specify a custom proposal function and you use a table for the input training data, the function uses a variation of the Edge Boxes algorithm. If you use a datastore for input training data for multichannel images, you must specify a custom region proposal function.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'PositiveOverlapRange',[0.75 1]`

`PositiveOverlapRange` — Bounding box overlap ratios for positive training samples
`[0.5 1]` (default) | two-element vector

Bounding box overlap ratios for positive training samples, specified as a two-element vector. The vector contains values in the range [0,1]. Region proposals that overlap with ground truth bounding boxes within the specified range are used as positive training samples.

The overlap ratio used for both the `PositiveOverlapRange` and `NegativeOverlapRange` is defined as:

$$\frac{area(A \cap B)}{area(A \cup B)}$$

A and B are bounding boxes.

`NegativeOverlapRange` — Bounding box overlap ratios for negative training samples
`[0.1 0.5]` (default) | two-element vector

Bounding box overlap ratios for negative training samples, specified as a two-element vector. The vector contains values in the range [0,1]. Region proposals that overlap with the ground truth bounding boxes within the specified range are used as negative training samples.

The overlap ratio used for both the `PositiveOverlapRange` and `NegativeOverlapRange` is defined as:

$$\frac{area(A \cap B)}{area(A \cup B)}$$

A and B are bounding boxes.

`NumStrongestRegions` — Maximum number of strongest region proposals
`2000` (default) | positive integer

Maximum number of strongest region proposals to use for generating training samples, specified as a positive integer. Reduce this value to speed up processing time at the cost of training accuracy. To use all region proposals, set this value to `Inf`.

`NumRegionsToSample` — Number of region proposals
128 (default) | integer

Number of region proposals to randomly sample from each training image, specified as an integer. Reduce the number of regions to sample to reduce memory usage and speed-up training. Reducing the value can also decrease training accuracy.

`SmallestImageDimension` — Length of smallest image dimension
`[]` (default) | positive integer

Length of smallest image dimension, either width or height, specified as a positive integer. Training images are resized such that the length of the shortest dimension is equal to the specified integer. By default, training images are not resized. Resizing training images helps reduce computational costs and memory used when training images are large. Typical values range from 400–600 pixels.

Dependencies

- The `SmallestImageDimension` property only supports table input training data. To resize the input data of a datastore input, use the `transform` function.

`FreezeBatchNormalization` — Frozen batch normalization
`true` (default) | `false`

Frozen batch normalization during training, specified as `true` or `false`. The value indicates whether the input layers to the network are frozen during training. Set this value to `true` if you are training with a small mini-batch size. Small batch sizes result in poor estimates of the batch mean and variance that is required for effective batch normalization.

If you do not specify a value for `FreezeBatchNormalization`, the function sets the property to

- `true` if the `MiniBatchSize` name-value argument for the `trainingOptions` function is less than 8.
- `false` if the `MiniBatchSize` name-value argument for the `trainingOptions` function is greater than or equal to 8.

You must specify a value for `FreezeBatchNormalization` to override this default behavior.

`ExperimentManager` — Detector training experiment monitoring
`'none'` (default) | `experiments.Monitor` object

Detector training experiment monitoring, specified as an `experiments.Monitor` object for use with the Experiment Manager app. You can use this object to track the progress of training, update information fields in the training results table, record values of the metrics used by the training, and to produce training plots. For an example using this app, see “Train Object Detectors in Experiment Manager”.

Information monitored during training:

- Training loss at each iteration.
- Training accuracy at each iteration.
- Training root mean square error (RMSE) for the box regression layer.
- Learning rate at each iteration.

Output Arguments

`trainedDetector` — Trained Fast R-CNN object detector
`fastRCNNObjectDetector` object

Trained Fast R-CNN object detector, returned as a `fastRCNNObjectDetector` object.

`info` — Training progress information
structure array

Training progress information, returned as a structure array with eight fields. Each field corresponds to a stage of training.

- `TrainingLoss` — Training loss at each iteration is the mean squared error (MSE) calculated as the sum of localization error, confidence loss, and classification loss. For more information about the training loss function, see “YOLO v2 Training Loss” on page 3-1402.
- `TrainingAccuracy` — Training set accuracy at each iteration.
- `TrainingRMSE` — Training root mean squared error (RMSE) is the RMSE calculated from the training loss at each iteration.
- `BaseLearnRate` — Learning rate at each iteration.
- `ValidationLoss` — Validation loss at each iteration.
- `ValidationAccuracy` — Validation accuracy at each iteration.
- `ValidationRMSE` — Validation RMSE at each iteration.
- `FinalValidationLoss` — Final validation loss at end of the training.
- `FinalValidationRMSE` — Final validation RMSE at end of the training.

Each field is a numeric vector with one element per training iteration. Values that have not been calculated at a specific iteration are assigned as `NaN`. The struct contains `ValidationLoss`, `ValidationAccuracy`, `ValidationRMSE`, `FinalValidationLoss`, and `FinalValidationRMSE` fields only when `options` specifies validation data.

Tips

- To accelerate data preprocessing for training, `trainFastRCNNObjectDetector` automatically creates and uses a parallel pool based on your parallel preference settings. For more details about setting these preferences, see parallel preference settings. Using parallel computing preferences requires Parallel Computing Toolbox.
- VGG-16, VGG-19, ResNet-101, and Inception-ResNet-v2 are large models. Training with large images can produce "Out of Memory" errors. To mitigate these errors, try one or more of these options:
  - Reduce the size of your images by using the '`SmallestImageDimension`' argument.
  - Decrease the value of the '`NumRegionsToSample`' name-value argument value.
- This function supports transfer learning. When you input a `network` by name, such as `'resnet50'`, then the function automatically transforms the network into a valid Fast R-CNN network model based on the pretrained `resnet50` model. Alternatively, manually specify a custom Fast R-CNN network by using the `LayerGraph` extracted from a pretrained DAG network. For more details, see “Create Fast R-CNN Object Detection Network”.

- This table describes how to transform each named network into a Fast R-CNN network. The feature extraction layer name specifies which layer is processed by the ROI pooling layer. The ROI output size specifies the size of the feature maps output by the ROI pooling layer.

Network Name	Feature Extraction Layer Name	ROI Pooling Layer OutputSize	Description
`alexnet`	`'relu5'`	[6 6]	Last max pooling layer is replaced by ROI max pooling layer
`vgg16`	`'relu5_3'`	[7 7]	
`vgg19`	`'relu5_4'`		
`squeezenet`	`'fire5-concat'`	[14 14]	
`resnet18`	`'res4b_relu'`		ROI pooling layer is inserted after the feature extraction layer.
`resnet50`	`'activation_40_relu'`		
`resnet101`	`'res4b22_relu'`		
`googlenet`	`'inception_4d-output'`		
`mobilenetv2`	`'block_13_expand_relu'`		
`inceptionv3`	`'mixed7'`	[17 17]	
`inceptionresnetv2`	`'block17_20_ac'`		

  To modify and transform a network into a Fast R-CNN network, see “Design an R-CNN, Fast R-CNN, and a Faster R-CNN Model”.

- Use the `trainingOptions` function to enable or disable verbose printing.

Version History

Introduced in R2017a

R2025a: MATLAB Compiler support will be removed
Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

R2024b: Not Recommended
Not recommended starting in R2024b

Starting in R2024b, R-CNN object detectors are no longer recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` object. These object detectors are faster than R-CNN object detectors. For more information, see “Choose an Object Detector”.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set `'UseParallel'` to `true` or enable this by default using the Computer Vision Toolbox preferences.

For more information, see “Parallel Computing Toolbox Support”.

peopleDetectorACF

Detect people using aggregate channel features

Syntax

```
detector = peopleDetectorACF
detector = peopleDetectorACF(name)
```

Description

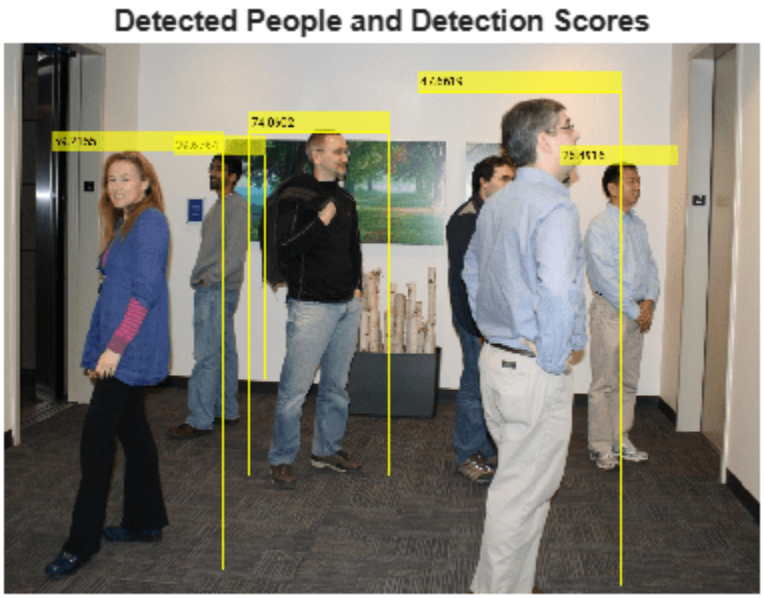
`detector = peopleDetectorACF` returns a pretrained upright people detector using aggregate channel features (ACF). The detector is an `acfObjectDetector` object, and is trained using the INRIA person data set.

`detector = peopleDetectorACF(name)` returns a pretrained upright people detector based on the specified model `name`.

Examples

Detect People Using Aggregated Channel Features

Load the upright people detector.



```
detector = peopleDetectorACF;
```

Read an image. Detect people in the image.

```
I = imread('visionteam1.jpg');
[bboxes,scores] = detect(detector,I);
```

Annotate detected people with bounding boxes and their detection scores.

```
I = insertObjectAnnotation(I,'rectangle',bboxes,scores);
figure
imshow(I)
title('Detected People and Detection Scores')
```

Input Arguments

`name` — ACF classification model

`'inria-100x41'` (default) | `'caltech-50x21'`

ACF classification model, specified as `'inria-100x41'` or `'caltech-50x21'`. The `'inria-100x41'` model was trained using the INRIA Person data set. The `'caltech-50x21'` model was trained using the Caltech Pedestrian data set.

Output Arguments

`detector` — Trained ACF-based object detector

`acfObjectDetector` object

Trained ACF-based object detector, returned as an `acfObjectDetector` object. The detector is trained to detect upright people in an image.

objectDetectorTrainingData

Create training data for an object detector

Syntax

```
[imds,blds] = objectDetectorTrainingData(gTruth)
[___,arrds] = objectDetectorTrainingData(gTruth)

trainingDataTable = objectDetectorTrainingData(gTruth)

[___] = objectDetectorTrainingData(gTruth,Name=Value)
```

Description

`[imds,blds] = objectDetectorTrainingData(gTruth)` creates an image datastore and a box label datastore training data from the specified ground truth. The function only selects images from the ground truth input that contain one or more annotated objects.

You can combine the image and box label datastores using `combine(imds,blds)` to create a datastore needed for training. Use the combined datastore with the training functions, such as `trainACFObjectDetector`, `trainYOLOv2ObjectDetector`, `trainYOLOv3ObjectDetector`, and `trainYOLOv4ObjectDetector`.

This function supports parallel computing using multiple MATLAB workers. Enable parallel computing using the “Computer Vision Toolbox Preferences” dialog.

`[___,arrds] = objectDetectorTrainingData(gTruth)` also returns a datastore `arrds`, that contains the attributes and sublabels associated with the labels.

`trainingDataTable = objectDetectorTrainingData(gTruth)` returns a table of training data from the specified ground truth. `gTruth` is an array of `groundTruth` objects. You can use the table to train an object detector using the Computer Vision Toolbox training functions.

`[___] = objectDetectorTrainingData(gTruth,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `Verbose=True` enables display to the workspace environment.

If you create the `groundTruth` objects in `gTruth` using a video file, a custom data source, or an `imageDatastore` object with different custom read functions, then you can specify any combination of name-value arguments. If you create the `groundTruth` objects from an image collection or image sequence data source, then you can specify only the `SamplingFactor` and the `LabelType` name-value arguments.

Examples

Train YOLO v2 Vehicle Detector

Train a vehicle detector based on a YOLO v2 network.

Add the folder containing training images to the workspace.

```
imageDir = fullfile(matlabroot,"toolbox","vision","visiondata","vehicles");
addpath(imageDir);
```

Load the vehicle ground truth data.

```
data = load("vehicleTrainingGroundTruth.mat");
gTruth = data.vehicleTrainingGroundTruth;
```

Create an image datastore and box label datastore using the ground truth object.

```
[imds,bxds] = objectDetectorTrainingData(gTruth);
```

Combine the datastores.

```
cds = combine(imds,bxds);
```

Load the detector containing the `dlnetwork` object for training.

```
load("yolov2VehicleDetectorNet.mat","net");
classes = "vehicle";
aboxes = [8 8; 32 48; 40 24; 72 48];
detector = yolov2ObjectDetector(net,classes,aboxes);
```

Configure training options.

```
options = trainingOptions("sgdm", ...
       InitialLearnRate=0.001, ...
       Verbose=true, ...
       MiniBatchSize=16, ...
       MaxEpochs=30, ...
       Shuffle="every-epoch", ...
       VerboseFrequency=10);
```

Train the detector.

```
[detector,info] = trainYOLOv2ObjectDetector(cds,detector,options);
```

```

```

Read all attributes.

```
readall(arrds)
```

```
ans=2×1 cell array
    {1×1 struct}
    {1×1 struct}
```

Input Arguments

`gTruth` — Ground truth data

scalar | array of `groundTruth` objects

Ground truth data, specified as a scalar or an array of `groundTruth` objects. You can create ground truth objects from existing ground truth data by using the `groundTruth` object.

If you use custom data sources in `groundTruth` with parallel computing enabled, then the reader function is expected to work with a pool of MATLAB workers to read images from the data source in parallel.

Note If you specify `gTruth` as an array of `groundTruth` objects, all label definitions must have the same label names.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: (`SamplingFactor=5`) sets the subsampling factor to `5`.

`SamplingFactor` — Factor for subsampling images

`"auto"` (default) | integer | vector of integers

Factor for subsampling images in the ground truth data source, specified as `"auto"`, an integer, or a vector of integers. For a sampling factor of *N*, the returned training data includes every *N*th image in the ground truth data source. The function ignores ground truth images with empty label data. To set the `SamplingFactor` with projected cuboid data, you must specify the `LabelType` name-value argument to `labelType.ProjectedCuboid`.

Use sampled data to reduce repeated data, such as a sequence of images with the same scene and labels. It can also help in reducing training time.

Value	Sampling Factor
`"auto"`	The function samples data sources with timestamps, such as a video, with a factor of `5`, and `1` for a collection of images.
Integer	Manually set the sampling factor to apply to all data.
Vector of integers	When you input an array of ground truth objects, the function uses the sampling factor specified by the corresponding vector element.

`LabelType` — Type of label to extract from ground truth data
`"labelType.Rectangle"` (default) | `"labelType.RotatedRectangle"` | `"labelType.ProjectedCuboid"` | character vector

Type of label to extract from ground truth data, specified as `"labelType.Rectangle"`, `"labelType.RotatedRectangle"`, or `"labelType.ProjectedCuboid"`. Use the type of label consistent with the type of object detector you want to train.

Note The `trainYOLOv2ObjectDetector` function does not support `"labelType.RotatedRectangle"`.

`WriteLocation` — Name of folder
`pwd` (current working folder) (default) | string scalar | character vector

Folder name to write extracted images to, specified as a string scalar or character vector. The specified folder must exist and have write permissions.

This argument applies only for:

- `groundTruth` objects created using a video file or a custom data source.
- An array of `groundTruth` objects created using `imageDatastore` , with different custom `read` functions.

The function ignores this argument when:

- The input `groundTruth` object was created from an image sequence data source.
- The array of input `groundTruth` objects all contain image datastores using the same custom `read` function.
- Any of the input `groundTruth` objects containing datastores, use the default `read` functions.

`ImageFormat` — Image file format
`"PNG"` (default) | string scalar | character vector

Image file format, specified as a string scalar or character vector. File formats must be supported by `imwrite`.

This argument applies only for:

- `groundTruth` objects created using a video file or a custom data source.
- An array of `groundTruth` objects created using `imageDatastore` with different custom `read` functions.

The function ignores this argument when:

- The input `groundTruth` object was created from an image sequence data source.
- The array of input `groundTruth` objects all contain image datastores using the same custom `read` function.
- Any of the input `groundTruth` objects containing datastores, use the default `read` functions.

`NamePrefix` — Prefix for output image file names
string scalar | character vector

Prefix for output image file names, specified as a string scalar or character vector. The image files are named as:

```
<name_prefix><source_number>_<image_number>.<image_format>
```

The default value uses the name of the data source that the images were extracted from, `strcat(sourceName,"_")`, for video and a custom data source, or `"datastore"`, for an image datastore.

This argument applies only for:

- `groundTruth` objects created using a video file or a custom data source.
- An array of `groundTruth` objects created using `imageDatastore` with different custom `read` functions.

The function ignores this argument when:

- The input `groundTruth` object was created from an image sequence data source.
- The array of input `groundTruth` objects all contain image datastores using the same custom `read` function.
- Any of the input `groundTruth` objects containing datastores, use the default `read` functions.

`Verbose` — Flag to display training progress
`true` (`1`) (default) | `false` (`0`)

Flag to display training progress at the MATLAB command line, specified as either `true` (`1`) or `false` (`0`). This property applies only for `groundTruth` objects created using a video file or a custom data source.

Output Arguments

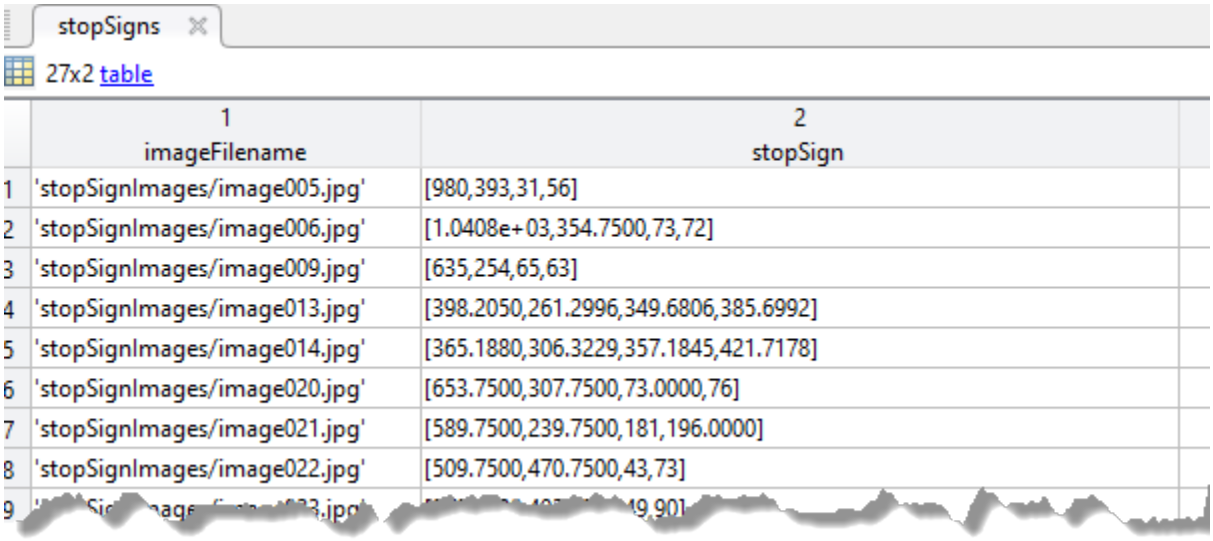
`imds` — Image datastore
`imageDatastore` object

Image datastore, returned as an `imageDatastore` object containing images extracted from the `gTruth` objects. The images in `imds` contain at least one class of annotated labels. The function ignores images that are not annotated.

`blds` — Box label datastore
`boxLabelDatastore` object

Box label datastore, returned as a `boxLabelDatastore` object. The datastore contains categorical vectors for ROI label names and *M*-by-4 matrices of *M* bounding boxes. The locations and sizes of the bounding boxes are represented as double *M*-by-4 element vectors in the format [*x*,*y*,*width*,*height*].

`arrds` — Array datastore



`struct` array

Array datastore, returned as a `struct` array. The fields of the `struct` contain the attributes and sublabel names for the corresponding labels in the box label datastore `blds`. The sublabel data is packaged into the `struct` with a `Position` field along with the fields that correspond to the sublabel attributes.

`trainingDataTable` — Training data table

table

Training data table, returned as a table with two or more columns. The first column of the table contains image file names with paths. The images can be grayscale or truecolor (RGB) and in any format supported by `imread`. Each of the remaining columns correspond to an ROI label and contains the locations of bounding boxes in the image (specified in the first column), for that label. The bounding boxes are specified as *M*-by-4 matrices of *M* bounding boxes in the format [*x*,*y*,*width*,*height*]. [*x*,*y*] specifies the upper-left corner location. To create a ground truth table, you can use the Image Labeler app or Video Labeler app.

stopSigns

27x2 table

	1 imageFilename	2 stopSign
1	'stopSignImages/image005.jpg'	[980,393,31,56]
2	'stopSignImages/image006.jpg'	[1.0408e+03,354.7500,73,72]
3	'stopSignImages/image009.jpg'	[635,254,65,63]
4	'stopSignImages/image013.jpg'	[398.2050,261.2996,349.6806,385.6992]
5	'stopSignImages/image014.jpg'	[365.1880,306.3229,357.1845,421.7178]
6	'stopSignImages/image020.jpg'	[653.7500,307.7500,73.0000,76]
7	'stopSignImages/image021.jpg'	[589.7500,239.7500,181,196.0000]
8	'stopSignImages/image022.jpg'	[509.7500,470.7500,43,73]
9		

The output table ignores any sublabel or attribute data present in the input `gTruth` object.

Version History

Introduced in R2017a

R2022b: Project cuboids from 3-D world coordinates to 2-D image coordinates

- Updated to support 3-D projected cuboid labels.
- Returns extracted attributes and sublabels as a third output. The attributes and sublabels are packaged as an array datastore.

estimateFisheyeParameters

Calibrate fisheye camera

Syntax

```
[fisheyeParams,imagesUsed,estimationErrors] = estimateFisheyeParameters(
imagePoints,worldPoints,imageSize)
[___] = estimateFisheyeParameters(___,Name=Value)
```

Description

`[fisheyeParams,imagesUsed,estimationErrors] = estimateFisheyeParameters(imagePoints,worldPoints,imageSize)` returns a `fisheyeParameters` object containing estimates for the intrinsic and extrinsic parameters of a fisheye camera. The function also returns the images you used to estimate the fisheye parameters and the standard estimation errors for the fisheye camera calibration.

`[___] = estimateFisheyeParameters(___,Name=Value)` specifies options using one or more name-value arguments in addition to the previous syntax. For example, `WorldUnits="cm"` set the world units to centimeters.

Examples

Fisheye Camera Calibration

Use calibration images to detect a checkerboard calibration pattern. Calibrate the camera using corners extracted from the pattern and visualize the results of the calibration.

Load calibration images using an image datastore.

```
calibrationImages = imageDatastore("calibImages");
imageFileNames = calibrationImages.Files;
```

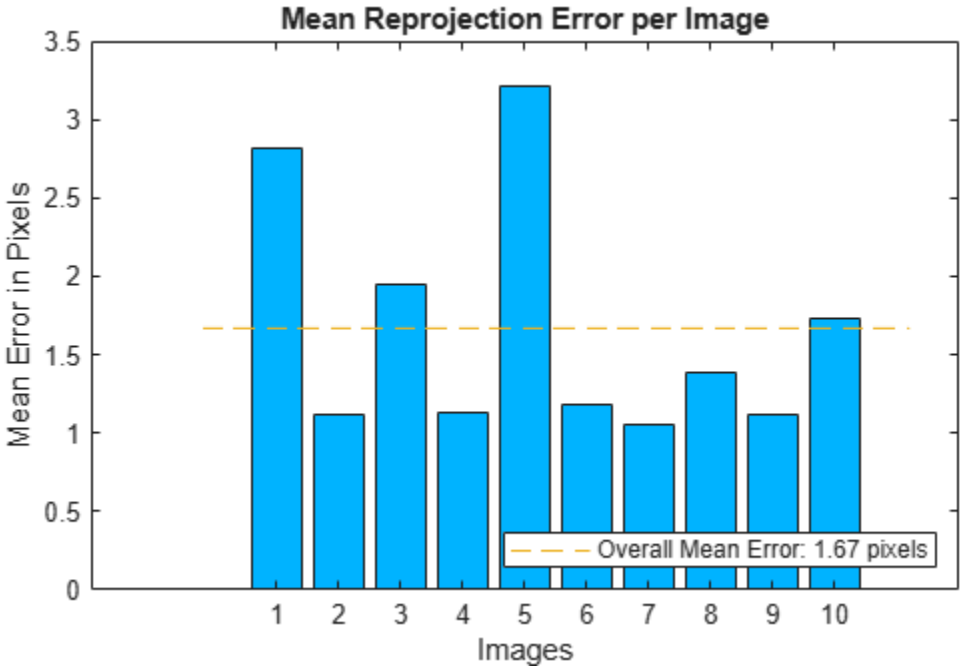
Detect the calibration pattern from the images. The `PartialDetections` name-value argument is set to true by default to allow detection of partial checkerboards.

```
[imagePoints,patternDims,imagesUsed] = detectCheckerboardPoints(imageFileNames,HighDistortion=tru
```

Collect the calibration images in which checkerboards were detected.

```
usedImageFileNames = imageFileNames(imagesUsed);
images = imageDatastore(usedImageFileNames);
```

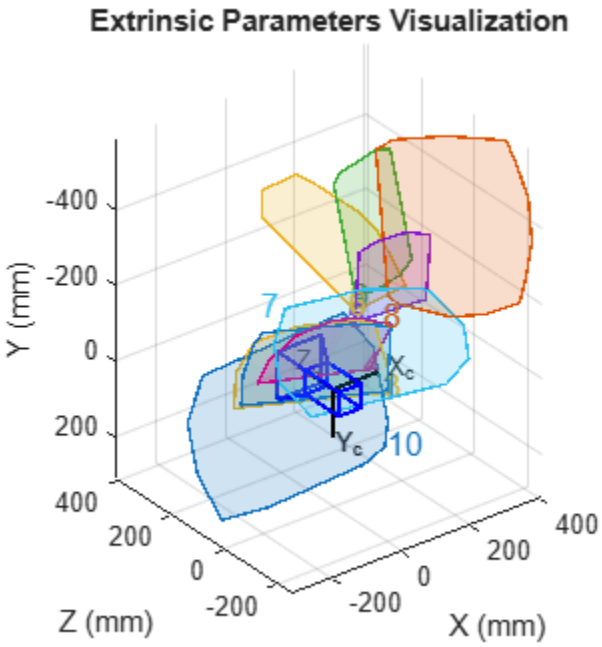
Generate world coordinates for the corners of the checkerboard squares.



```
squareSize = 20; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Estimate the fisheye camera calibration parameters based on the image and world points.

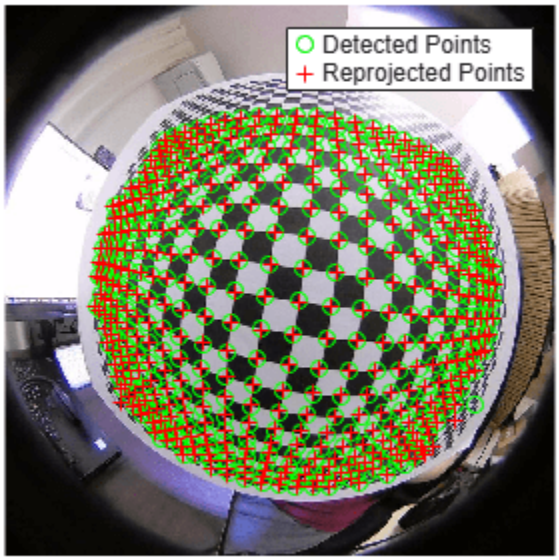
```
I = readimage(images,10);
imageSize = [size(I,1) size(I,2)];
params = estimateFisheyeParameters(imagePoints,worldPoints,imageSize);
```



Visualize the calibration accuracy.

```
figure
showReprojectionErrors(params);
```

Visualize the camera extrinsics.



```
figure
showExtrinsics(params);
```

```
drawnow
```

Plot the detected and reprojected points.

```
figure
imshow(I);
hold on
plot(imagePoints(:,1,10),imagePoints(:,2,10),"go");
plot(params.ReprojectedPoints(:,1,10),params.ReprojectedPoints(:,2,10),"r+");
legend("Detected Points","Reprojected Points");
hold off
```

Input Arguments

`imagePoints` — Key points of calibration pattern

M-by-2-by-*numImages* array

Key points of calibration pattern, specified as an *M*-by-2-by-*numImages* array of [*x*,*y*] intrinsic image coordinates. The number of images, *numImages*, must be greater than 2. The number of keypoint coordinates in each pattern, *M*, must be greater than 3. To include partially detected patterns in the estimate, use `[NaN,NaN]` as *x*-*y* coordinates for missing keypoints.

Data Types: `single` | `double`

`worldPoints` — Key points of calibration pattern in world coordinates

M-by-2 matrix

Key points of calibration pattern in world coordinates, specified as an *M*-by-2 matrix of *M* [*x*,*y*] world coordinates. Because the pattern must be planar, the *z*-coordinates are zero.

Data Types: `single` | `double`

`imageSize` — Image size

`[mrows ncols]` vector

Image size, specified as an `[mrows ncols]` vector.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `WorldUnits="mm"` sets the world point units to millimeters.

`EstimateAlignment` — Estimate axes alignment
`false` or `0` (default) | `true` or `1`

Estimate the axes alignment, specified as `false` (`0`) or `true` (`1`). Set the value to `true` if the optical axis of the fisheye lens is not perpendicular to the image plane.

`WorldUnits` — World point units
`"mm"` (default) | character vector | string scalar

World point units, specified as a character vector or string scalar. This name-value argument is used to store the unit type and does not affect any calculations.

Output Arguments

`fisheyeParams` — Fisheye camera parameters
`fisheyeParameters` object

Fisheye camera parameters, returned as a `fisheyeParameters` object.

`imagesUsed` — Images used to estimate camera parameters
numImages-by-1 logical array

Images used to the estimate camera parameters, returned as a *numImages*-by-1 logical array. *numImages* corresponds to the number of images. A logical `true` value indicates the index of an image used to estimate the camera parameters.

`estimationErrors` — Standard errors of estimated parameters
`fisheyeCalibrationErrors` object

Standard errors of estimated parameters, returned as a `fisheyeCalibrationErrors` object.

Version History

Introduced in R2017b

R2025a: MATLAB Compiler support will be removed
Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

undistortFisheyeImage

Correct fisheye image for lens distortion

Syntax

```
J = undistortFisheyeImage(I,intrinsics)
[J,camIntrinsics] = undistortFisheyeImage(I,intrinsics)
[___] = undistortFisheyeImage(___,interp)
[___] = undistortFisheyeImage(___,Name=Value)
```

Description

`J = undistortFisheyeImage(I,intrinsics)` removes lens distortion for image `I` and returns the result as image `J`.

`[J,camIntrinsics] = undistortFisheyeImage(I,intrinsics)` also returns a `cameraIntrinsics` object, which corresponds to a virtual pinhole camera.

`[___] = undistortFisheyeImage(___,interp)` specifies the interpolation method, `interp`, using the preceding syntaxes.

`[___] = undistortFisheyeImage(___,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `"ScaleFactor"=2` increases the zoom in the camera view by a factor of 2.

Examples

Correct Fisheye Image for Lens Distortion

Remove lens distortion from a fisheye image by detecting a checkboard calibration pattern and calibrating the camera. Then, display the results.

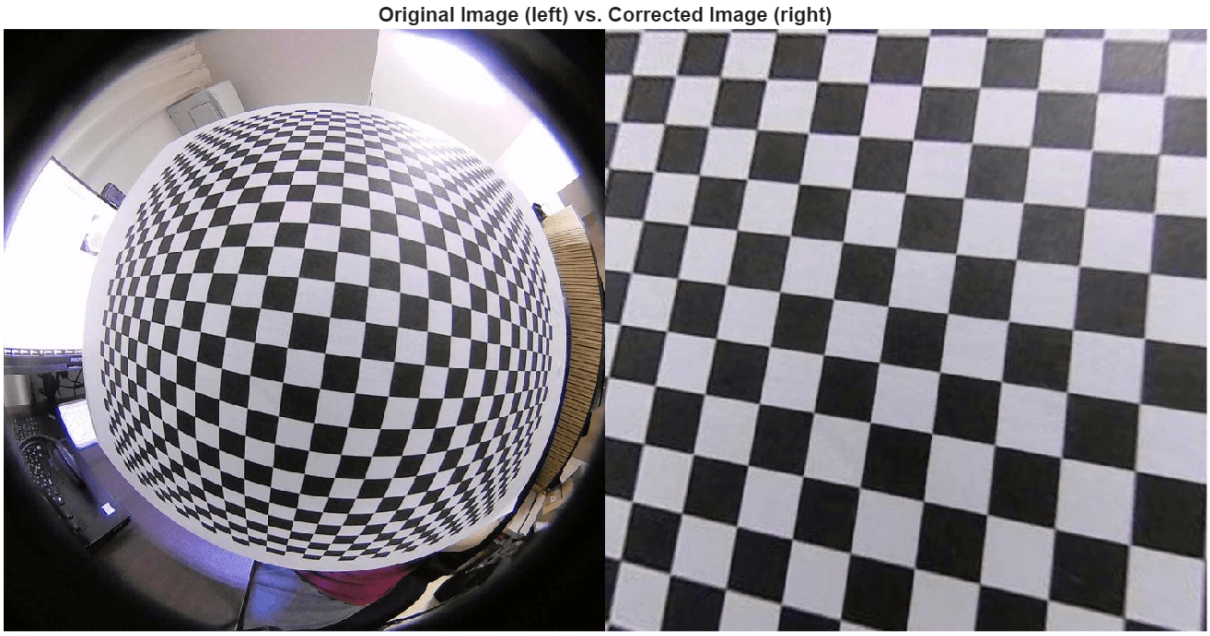
Gather a set of checkerboard calibration images.

```
images = imageDatastore('calibrationImages');
```

Detect the calibration pattern from the images. The 'PartialDetections' Name-Value argument is set to true by default allowing detection of partial checkerboards.

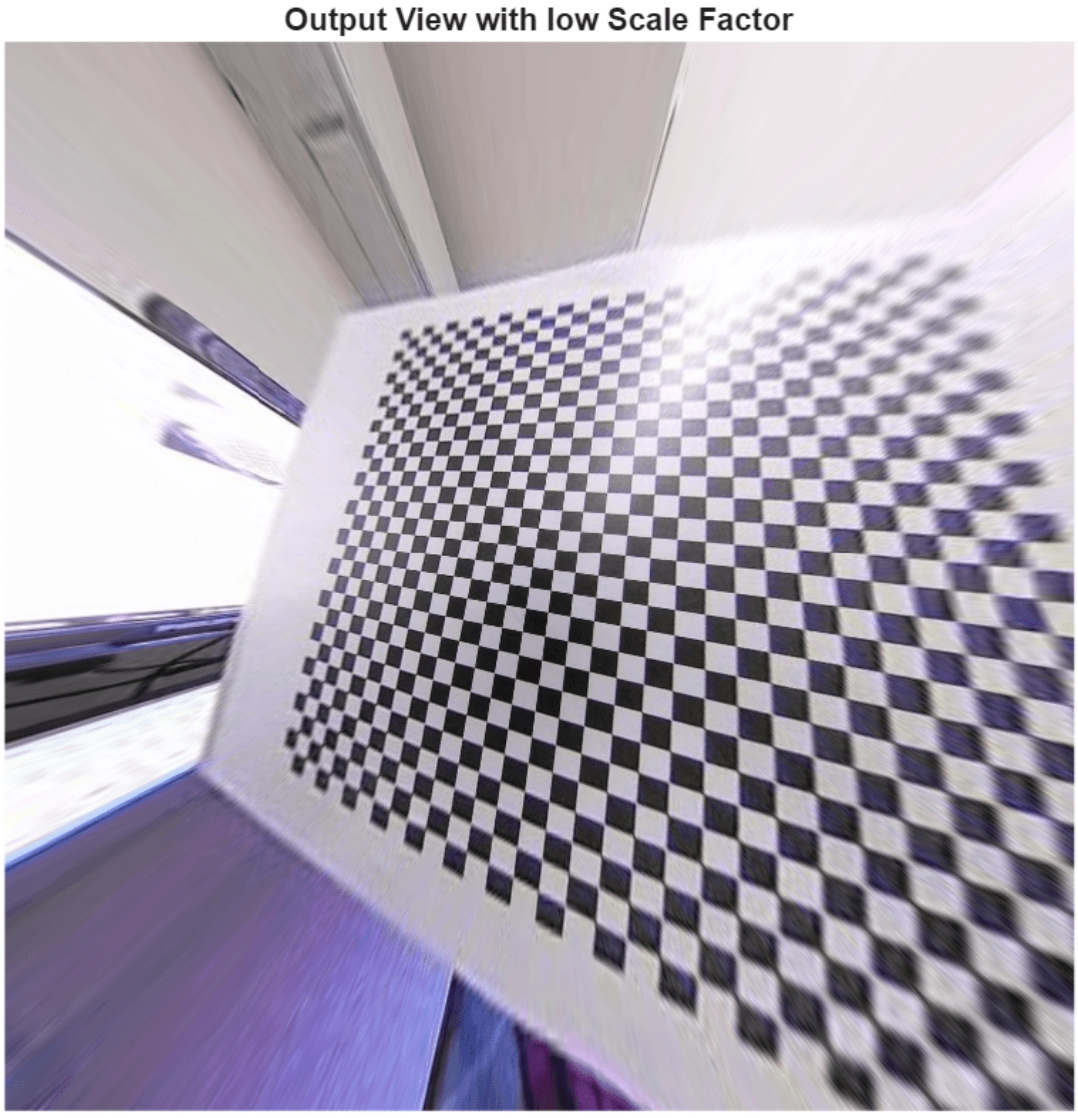
```
[imagePoints,patternDims] = detectCheckerboardPoints(images.Files, 'HighDistortion', true);
```

Generate world coordinates for the corners of the checkerboard squares.



```
squareSize = 20; % millimeters
worldPoints = patternWorldPoints('checkerboard',patternDims,squareSize);
```

Estimate the fisheye camera calibration parameters based on the image and world points. Use the first image to get the image size.



```
I = readimage(images,10);
imageSize = [size(I,1) size(I,2)];
params = estimateFisheyeParameters(imagePoints,worldPoints,imageSize);
```

Remove lens distortion from the first image `I` and display the results.

```
J1 = undistortFisheyeImage(I,params.Intrinsics);
figure
imshowpair(I,J1,'montage')
title('Original Image (left) vs. Corrected Image (right)')
```

```
J2 = undistortFisheyeImage(I,params.Intrinsics,'OutputView','same', 'ScaleFactor', 0.2);
figure
imshow(J2)
title('Output View with low Scale Factor')
```

Input Arguments

`I` — Input image

M-by-*N*-by-3 truecolor image | *M*-by-*N* 2-D grayscale image

Input image, specified as an *M*-by-*N*-by-3 truecolor or *M*-by-*N* 2-D grayscale image. The input image must be real and nonsparse.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

`intrinsics` — Fisheye intrinsic camera parameters

`fisheyeIntrinsics` object

Fisheye intrinsic camera parameters, specified as a `fisheyeIntrinsics` object.

`interp` — Interpolation method
`'bilinear'` (default) | `'nearest'` | `'cubic'`

Interpolation method to use on the input image, specified as `'bilinear'`, `'nearest'` , or `'cubic'`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `"ScaleFactor"=2` increases the zoom in the camera view by a factor of 2

`OutputView` — Size of the output image
`"same"` (default) | `"full"` | `"valid"`

Size of the output image, specified as either `"same"`, `"full"`, or `"valid"`.

The `"full"` output image size is not suitable for fisheye images created with wide-angle lenses, including catadioptic lenses, which generate spherical images.

`ScaleFactor` — Scale factor for focal length
1 (default) | scalar | `[sx sy]` vector

Scale factor for the focal length of a virtual camera perspective, in pixels, specified as a scalar or an `[sx sy]` vector. Specify a vector to scale the *x* and *y* axes individually. Increase the scale to zoom in the perspective of the camera view.

`FillValues` — Output pixel fill values
`0` (default) | scalar | 3-element vector

Output pixel fill values, specified as the comma-separated pair consisting of '`FillValues`' and scalar or 3-element vector. When the corresponding inverse-transformed location in the input image lies completely outside the input image boundaries, you use the fill values for output pixels. When you use a 2-D grayscale input image, `FillValues` must be a scalar. When you use a truecolor image, `FillValues` can be a scalar or a 3-element vector of RGB values.

Output Arguments

`J` — Undistorted image
M-by-*N*-by-3 truecolor image | *M*-by-*N* 2-D grayscale image

Undistorted image, returned as an *M*-by-*N*-by-3 truecolor or *M*-by-*N* 2-D grayscale image.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

`camIntrinsics` — Undistorted intrinsics of virtual camera
`cameraIntrinsics` object

Undistorted intrinsics of a virtual camera, returned as a `cameraIntrinsics` object. The `camIntrinsics` object represents a virtual pinhole camera. You can use this object with the pinhole

model calibration workflow functions. These intrinsics are for a camera that has a perspective that produces the undistorted image.

Tips

- The Computer Vision Toolbox calibration algorithm uses the fisheye camera model proposed by Scaramuzza [1] on page 3-1527.

Version History

Introduced in R2017b

R2024a: Generate C/C++ code using MATLAB Coder

`undistortFisheyeImage` now supports the generation of C/C++ code (requires MATLAB Coder).

undistortFisheyePoints

Correct point coordinates for fisheye lens distortion

Syntax

```
undistortedPoints = undistortFisheyePoints(points,intrinsics)
undistortedPoints = undistortFisheyePoints( ___ ,scaleFactor)
[ ___ ,camIntrinsics] = undistortFisheyePoints( ___ )
[ ___ ,reprojectionErrors] = undistortFisheyePoints( ___ )
```

Description

`undistortedPoints = undistortFisheyePoints(points,intrinsics)` returns point coordinates corrected for fisheye lens distortion.

`undistortedPoints = undistortFisheyePoints( ___ ,scaleFactor)` returns corrected point coordinates using the `scaleFactor` and the previous inputs.

`[ ___ ,camIntrinsics] = undistortFisheyePoints( ___ )` also returns a `cameraIntrinsics` object, which corresponds to a virtual perspective camera that produces undistorted points.

`[ ___ ,reprojectionErrors] = undistortFisheyePoints( ___ )` also returns `reprojectionErrors` used to evaluate the accuracy of undistorted points. The function computes the reprojection errors by applying distortion to the points, and taking the distances between the result and the corresponding input points.

Examples

Undistort Checkerboard Points from Fisheye Image

Undistort and translate checkerboard points detected in a calibration image, and then display the results.

Create an `imageDatastore` object containing checkerboard calibration images.

```
images = imageDatastore(fullfile(toolboxdir('vision'),'visiondata',...
   'calibration','gopro'));
imageFileNames = images.Files;
```

Detect the calibration pattern from the images.

```
[imagePoints,patternDims] = detectCheckerboardPoints(imageFileNames);
```

Generate world coordinates for the corners of the checkerboard squares.

```
squareSize = 29; % millimeters
worldPoints = patternWorldPoints('checkerboard',patternDims,squareSize);
```

Estimate the fisheye parameters from the image and world points. Get the image size from the first image.

```
I = readimage(images,10);
imageSize = [size(I,1) size(I,2)];
params = estimateFisheyeParameters(imagePoints,worldPoints,imageSize);
```

In the first image, detect the checkerboard points.

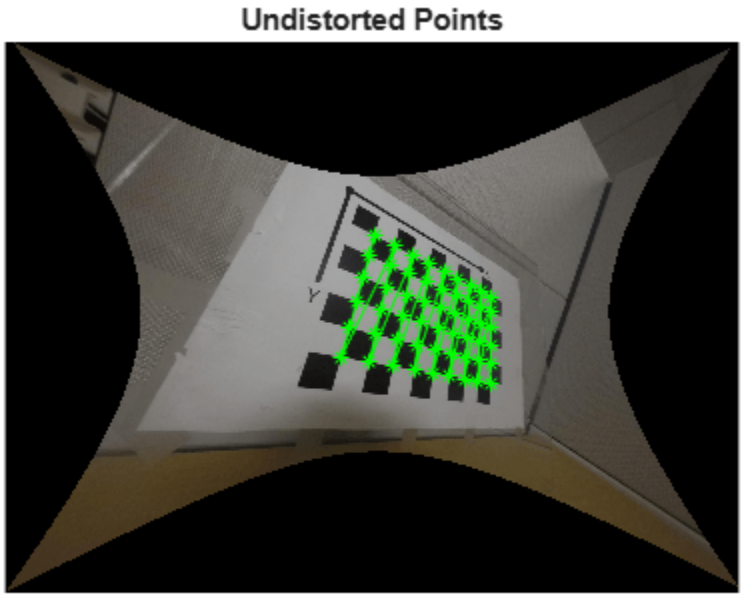
```
points = detectCheckerboardPoints(I);
```

Undistort the points and image.

```
[undistortedPoints,intrinsics1] = undistortFisheyePoints(points,params.Intrinsics);
[J, intrinsics2] = undistortFisheyeImage(I,params.Intrinsics,'OutputView','full');
```

Translate the undistorted points.

```
newOrigin = intrinsics2.PrincipalPoint - intrinsics1.PrincipalPoint;
undistortedPoints = [undistortedPoints(:,1) + newOrigin(1), ...
                     undistortedPoints(:,2) + newOrigin(2)];
```



Display the results.

```
figure
imshow(I)
hold on
plot(points(:,1),points(:,2),'r*-')
title('Detected Points')
hold off
```

```
figure
imshow(J)
```

```
hold on
plot(undistortedPoints(:, 1),undistortedPoints(:, 2),'g*-')
title('Undistorted Points')
hold off
```

Input Arguments

`points` — Input points

M-by-2 matrix

Input points, specified as an *M*-by-2 matrix of *M* [x y] coordinates.

`intrinsics` — Fisheye intrinsic camera parameters

`fisheyeIntrinsics` object

Fisheye intrinsic camera parameters, specified as a `fisheyeIntrinsics` object.

`scaleFactor` — Scale factor for points

1 (default) | scalar | `[sx sy]` vector

Scale factor for points, specified as a scalar or an `[sx sy]` vector. Specify a vector to scale the *x* and *y* axes individually. Increase the scale to zoom in the perspective of the camera view.

Output Arguments

`undistortedPoints` — Undistorted points

M-by-2 matrix

Undistorted points, returned as an *M*-by-2 matrix of *M* number of [x y] coordinates. If `points` is `double`, then `undistortedPoints` is `double`. Otherwise, `undistortedPoints` is `single`.

Data Types: `single` | `double`

`camIntrinsics` — Undistorted intrinsics of virtual camera
`cameraIntrinsics` object

Undistorted intrinsics of a virtual camera, returned as a `cameraIntrinsics` object. These intrinsics are for a camera that has a perspective that produces the undistorted image.

`reprojectionErrors` — Reprojection errors
M-by-1 vector

Reprojection errors, returned as an *M*-by-1 vector. The function computes the reprojection errors by applying distortion to the undistorted points and taking the distances between the results and the corresponding input points. Errors are expressed in pixels.

Version History

Introduced in R2017b

R2025a: Generate CUDA code using GPU Coder

The `undistortFisheyePoints` function now supports the generation of CUDA code (requires GPU Coder).

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

pointsToWorld

(Not recommended) Determine world coordinates of image points

Note `pointsToWorld` is not recommended. Use the `img2world2d` function instead. For more information, see "Version History".

Syntax

```
worldPoints = pointsToWorld(intrinsics,tform,imagePoints)
worldPoints = pointsToWorld(intrinsics,rotationMatrix,translationVector,
imagePoints)
```

Description

`worldPoints = pointsToWorld(intrinsics,tform,imagePoints)` maps undistorted image points `imagePoints`, onto points on the *X*-*Y* plane in world coordinates, `worldPoints` using the `rigid3d` transformation `tform`.

`worldPoints = pointsToWorld(intrinsics,rotationMatrix,translationVector, imagePoints)` returns world points on the *X*-*Y* plane, which correspond to the input image points. Points are converted using the input rotation matrix, translation vector, and camera intrinsics.

Examples

Map Image Points of Fisheye Image to World Coordinates

Map the points of a fisheye image to world coordinates and compare these points to the ground truth points. A series of checkerboard pattern images are used to estimate the fisheye parameters and calibrate the camera.

Create a set of checkerboard calibration images.

```
images = imageDatastore(fullfile(toolboxdir("vision"),"visiondata" ,...
      "calibration","gopro"));
```

Detect the checkerboard corners in the images. Leave the last image for testing.

```
[imagePoints,patternDims] = detectCheckerboardPoints(images.Files(1:end-1));
```

Generate the world coordinates of the checkerboard corners in the pattern-centric coordinate system, with the upper-left corner at (0,0).

```
squareSize = 29; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Estimate the fisheye camera parameters from the image and world points. Use the first image to get image size.

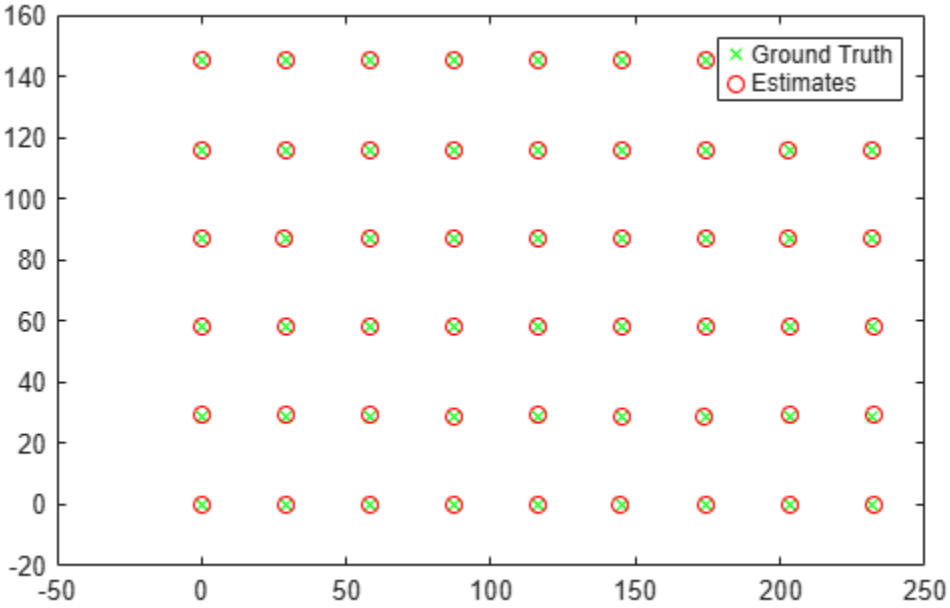
```
I = imread(images.Files{end});
imageSize = [size(I,1) size(I,2)];
```

```
fisheyeParams = estimateFisheyeParameters(imagePoints,worldPoints,imageSize);
intrinsics = fisheyeParams.Intrinsics;
```

Find the reference object in the new image.

```
imagePoints = detectCheckerboardPoints(I,PartialDetections=false);
```

Compute new extrinsics.



```
[R,t] = extrinsics(imagePoints,worldPoints,intrinsics);
```

Map image points to world coordinates in the X-Y plane.

```
newWorldPoints = pointsToWorld(intrinsics,R,t,imagePoints);
```

Compare estimated world points to the ground truth points.

```
plot(worldPoints(:,1),worldPoints(:,2),"gx");
hold on
plot(newWorldPoints(:,1),newWorldPoints(:,2),"ro");
legend("Ground Truth","Estimates");
hold off
```

Input Arguments

`intrinsics` — Camera intrinsics

`cameraIntrinsics` object | `fisheyeIntrinsics` object

Camera parameters, specified as a `cameraIntrinsics` or a `fisheyeIntrinsics` object. The objects store information about a camera's intrinsic calibration parameters, including the lens distortion parameters.

`tform` — Transformation
`rigid3d` object

Transformation of the camera in world coordinates, specified as a `rigid3d` object.

`rotationMatrix` — 3-D rotation
3-by-3 matrix

3-D rotation of the world coordinates relative to the image coordinates, specified as a 3-by-3 matrix. The rotation matrix, together with the translation vector, enable you to transform points from the world coordinate system to the camera coordinate system. The `rotationMatrix` and `translationVector` inputs must be the same data type.

Data Types: `double` | `single`

`translationVector` — 3-D translation
1-by-3 vector

3-D translation of the world coordinates relative to the image coordinates, specified as a 1-by-3 vector. The translation vector, together with the rotation matrix, enable you to transform points from the world coordinate system to the camera coordinate system. The `rotationMatrix` and `translationVector` inputs must be the same data type.

Data Types: `double` | `single`

`imagePoints` — Image points
M-by-2 matrix

Image points, specified as an *M*-by-2 matrix containing *M* [*x*, *y*] coordinates of image points.

When using the `cameraParameters` object as the `cameraParams` input, `pointsToWorld` does not account for lens distortion. Therefore, the `imagePoints` input must contain image points detected in the undistorted image, or they must be undistorted using the `undistortPoints` function. For a `fisheyeIntrinsics` object, the image points are distorted.

Output Arguments

`worldPoints` — World coordinates
M-by-2 matrix

World coordinates, returned as an *M*-by-2 matrix. *M* represents the number of undistorted points in [*x*, *y*] world coordinates.

Version History

Introduced in R2016a

R2022b: Not recommended

Not recommended starting in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `pointsToWorld` function uses the postmultiply convention. Although there are no plans to remove `pointsToWorld` at this time, you can streamline your geometric transformation workflows by switching to the `img2world2d` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

To update your code:

- Change instances of the function name `pointsToWorld` to `img2world2d`.
- Switch the order of the `intrinsics` and the `imagePoints` arguments.
- Specify the transformation as a `rigidtform3d` object using the `tform` argument. `img2world2d` does not support the `rotationMatrix` and `translationVector` input arguments. Note that you create the `rigidtform3d` object using the transpose of `rotationMatrix` or the transpose of the transformation matrix in the `T` property of `tform`.

Discouraged Usage	Recommended Replacement

This example specifies the transformation as a rotation matrix and a translation vector, then determines the world coordinates of image points using the `pointsToWorld` function.
 	
`worldPoints = pointsToWorld(intrinsics, ...`
`    rotationMatrix,translationVector,imagePoints)`
	This example specifies the transformation as a `rigidtform3d` object, then determines the world coordinates of image points using the `img2world2d` function. Note that you create the `rigidtform3d` object using the transpose of the rotation matrix, `rotationMatrix`.
	
	`tform = rigidtform3d(rotationMatrix',translationVecto`
	`worldPoints = img2world2d(imagePoints,tform,intrinsic`

This example specifies the transformation as a `rigid3d` object using the transpose of the geometric transformation matrix `A` in the premultiply convention, then determines the world coordinates of image points using the `pointsToWorld` function.
 	
`A = [1 0 0 0; 0 1 0 0; 0 0 1 -10; 0 0 0 1];`
`tformOld = rigid3d(A');`
`worldPoints = pointsToWorld(intrinsics,tformOld,imagePoints);`
	This example specifies the transformation as a `rigidtform3d` object using the geometric transformation matrix `A`, then determines the world coordinates of image points using the `img2world2d` function
	
	`A = [1 0 0 0; 0 1 0 0; 0 0 1 -10; 0 0 0 1];`
	`tform = rigidtform3d(A);`
	`worldPoints = img2world2d(imagePoints,tform,intrinsic`
	If instead you start with an existing `rigid3d` object `tformOld`, then you can get the geometric transformation matrix in the postmultiply convention by querying the property `T` of `tformOld`.
	
	`T = tformOld.T;`
	`tform = rigidtform3d(T');`
	`worldPoints = img2world2d(imagePoints,tform,intrinsic`

img2world2d

Determine world coordinates of image points

Syntax

```
worldPoints = img2world2d(imagePoints,tform,intrinsics)
```

Description

`worldPoints = img2world2d(imagePoints,tform,intrinsics)` maps undistorted image points `imagePoints`, onto points on the *X*-*Y* plane in world coordinates `worldPoints`, using the rigid transformation `tform`.

Examples

Map Image Points of Fisheye Image to World Coordinates

Map the points of a fisheye image to world coordinates and compare these points to the ground truth points. A series of checkerboard pattern images are used to estimate the fisheye parameters and calibrate the camera.

Load a set of checkerboard calibration images.

```
images = imageDatastore(fullfile(toolboxdir("vision"),"visiondata" ,...
      "calibration","gopro"));
```

Detect the checkerboard corners in the images. Leave the last image for testing.

```
[imagePoints,patternDims] = detectCheckerboardPoints(images.Files(1:end-1));
```

Generate the world coordinates of the checkerboard corners in the pattern-centric coordinate system, with the upper-left corner at (0,0).

```
squareSize = 29; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

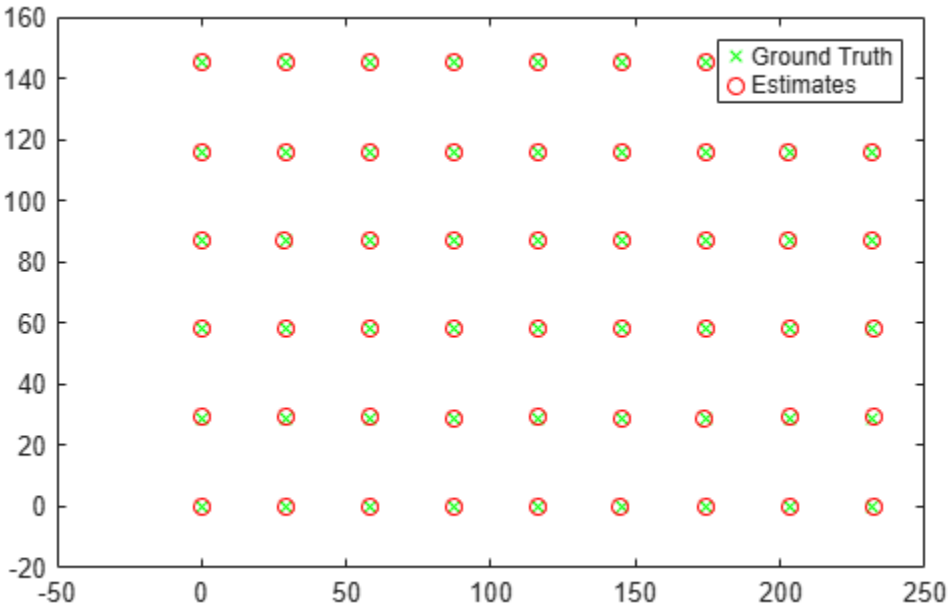
Estimate the fisheye camera parameters from the image and world points. Use the first image to get image size.

```
I = imread(images.Files{end});
imageSize = [size(I,1) size(I,2)];
fisheyeParams = estimateFisheyeParameters(imagePoints,worldPoints,imageSize);
intrinsics = fisheyeParams.Intrinsics;
```

Find the reference object in the new image.

```
imagePoints = detectCheckerboardPoints(I,PartialDetections=false);
```

Calculate new extrinsics.



```
camExtrinsics = estimateExtrinsics(imagePoints,worldPoints,intrinsics);
```

Map image points to world coordinates in the X-Y plane.

```
newWorldPoints = img2world2d(imagePoints,camExtrinsics,intrinsics);
```

Compare estimated world points to the ground truth points.

```
plot(worldPoints(:,1),worldPoints(:,2),"gx");
hold on
plot(newWorldPoints(:,1),newWorldPoints(:,2),"ro");
legend("Ground Truth","Estimates");
hold off
```

Input Arguments

`imagePoints` — Image points

M-by-2 matrix

Image points, specified as an *M*-by-2 matrix containing *M* [*x*, *y*] coordinates of image points.

When you specify the `cameraParams` argument as a `cameraIntrinsics` object, `img2world2d` does not account for lens distortion. Therefore, the `imagePoints` input must contain image points detected in the undistorted image, or they must be undistorted using the `undistortPoints` function. For a `fisheyeIntrinsics` object, the image points are distorted.

`tform` — Transformation

`rigidtform3d` object

Transformation of the camera in world coordinates, specified as a `rigidtform3d` object.

`intrinsics` — Camera intrinsics

`cameraIntrinsics` object | `fisheyeIntrinsics` object | `cameraIntrinsicsKB` object

Camera intrinsics, specified as a `cameraIntrinsics`, `fisheyeIntrinsics`, or a `cameraIntrinsicsKB` object. The object stores information about a camera's intrinsic calibration parameters, including the lens distortion parameters.

Output Arguments

`worldPoints` — World coordinates

M-by-2 matrix

World coordinates, returned as an *M*-by-2 matrix. *M* represents the number of undistorted points in [*x*, *y*] world coordinates.

Version History

Introduced in R2022b

R2022b: Recommended over `pointsToWorld`

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `pointsToWorld` function uses the postmultiply convention. Although there are no plans to remove `pointsToWorld` at this time, you can streamline your geometric transformation workflows by switching to the `img2world2d` function, which supports the premultiply convention. For more information, see "Migrate Geometric Transformations to Premultiply Convention".

R2024a: Added support for the `cameraIntrinsicsKB` object

Support added for the `cameraIntrinsicsKB` object as the `cameraParams` input.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Code generation not supported for `cameraIntrinsicsKB` object input.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

worldToImage

(Not recommended) Project world points into image

Note `worldToImage` is not recommended. Use the `world2img` function instead. For more information, see “Version History”.

Syntax

```
imagePoints = worldToImage(intrinsics,tform,worldPoints)
imagePoints = worldToImage(intrinsics,rotationMatrix,translationVector,
worldPoints)
[imagePoints,validIndex] = worldToImage( ___ )
[ ___ ] = worldToImage( ___ 'ApplyDistortion',distort)
```

Description

`imagePoints = worldToImage(intrinsics,tform,worldPoints)` projects 3-D world points `worldPoints` into points on an image, `imagePoints`. `intrinsics` can be a `cameraIntrinsics` or a `fisheyeIntrinsics` object. `tform` is a `rigid3d` object.

`imagePoints = worldToImage(intrinsics,rotationMatrix,translationVector, worldPoints)` returns the projection of 3-D world points into an image given the camera intrinsics, the rotation matrix, and the translation vector.

`[imagePoints,validIndex] = worldToImage( ___ )` also returns the indices of valid image points that are within the boundary of the image using any of the previous syntax inputs.

`[ ___ ] = worldToImage( ___ 'ApplyDistortion',distort)` returns the projection with the option of applying distortion. This syntax is supported for nonfisheye camera parameters.

Examples

Project World Points into Image

Create a set of calibration images.

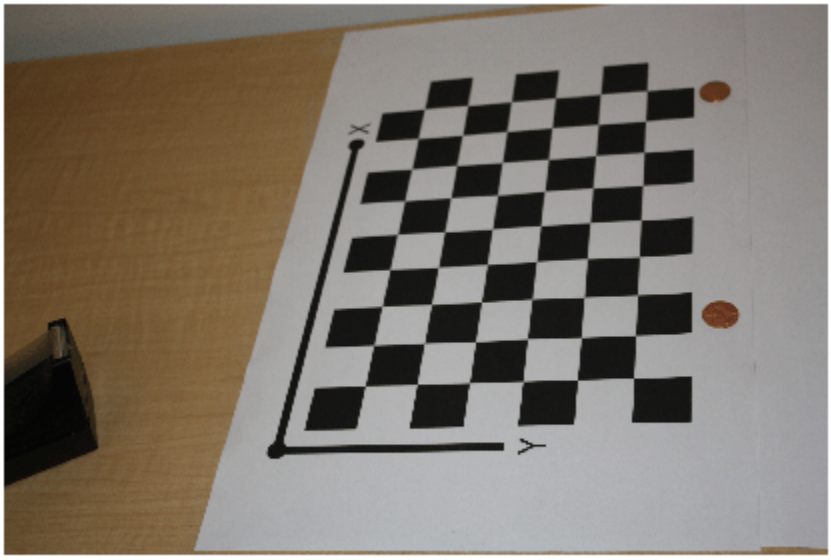
```
images = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
      "calibration","slr"));
```

Detect the checkerboard corners in the images.

```
[imagePoints,patternDims] = detectCheckerboardPoints(images.Files);
```

Generate the world coordinates of the checkerboard corners in the pattern-centric coordinate system, with the upper-left corner at (0,0).

```
squareSize = 29; % in millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```



Calibrate the camera.

```
imageSize = size(readimage(images,1));
cameraParams = estimateCameraParameters(imagePoints,worldPoints, ...
    ImageSize=imageSize(1:2));
```

Load the image at a new location.

```
imOrig = imread(fullfile(toolboxdir("vision"),"visiondata", ...
        "calibration","slr","image9.jpg"));

imshow(imOrig);
```

Undistort the image.

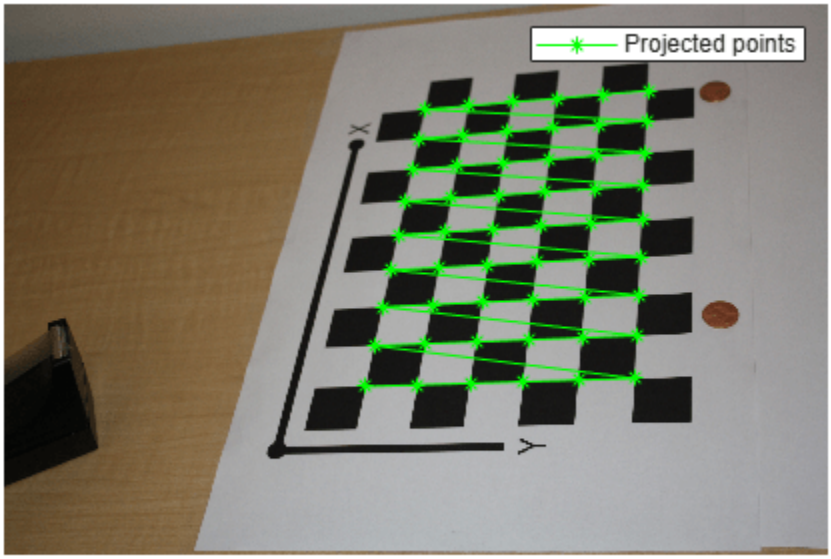
```
imUndistorted = undistortImage(imOrig,cameraParams);
```

Find a reference object in the new image.

```
[imagePoints,patternDims] = detectCheckerboardPoints(imUndistorted);
```

Compute new extrinsics.

```
[R,t] = extrinsics(imagePoints,worldPoints,cameraParams);
```



Add a *z*-coordinate to the world points.

```
zCoord = zeros(size(worldPoints,1),1);
worldPoints = [worldPoints zCoord];
```

Project the world points back into the original image.

```
projectedPoints = worldToImage(cameraParams,R,t,worldPoints);
hold on
```

```
plot(projectedPoints(:,1),projectedPoints(:,2),"g*-");
legend("Projected points");
hold off
```

Input Arguments

`tform` — Transformation

`rigid3d` object

Transformation of the camera in world coordinates, specified as a `rigid3d` object.

`intrinsics` — Camera intrinsics

`cameraIntrinsics` object | `fisheyeIntrinsics` object

Camera parameters, specified as a `cameraIntrinsics` or a `fisheyeIntrinsics` object. The objects store information about a camera's intrinsic calibration parameters, including the lens distortion parameters.

`rotationMatrix` — 3-D rotation

3-by-3 matrix

3-D rotation of the world coordinates relative to the image coordinates, specified as a 3-by-3 matrix. The rotation matrix, together with the translation vector, enable you to transform points from the world coordinate system to the camera coordinate system. The `rotationMatrix` and `translationVector` inputs must be the same data type.

Data Types: `double` | `single`

`translationVector` — 3-D translation
1-by-3 vector

3-D translation of the world coordinates relative to the image coordinates, specified as a 1-by-3 vector. The translation vector, together with the rotation matrix, enable you to transform points from the world coordinate system to the camera coordinate system. The `rotationMatrix` and `translationVector` inputs must be the same data type.

Data Types: `double` | `single`

`worldPoints` — 3-D world points
M-by-3 matrix

3-D world points, specified as an *M*-by-3 matrix containing *M* [*x*,*y*,*z*] coordinates of 3-D world points.

If you use the `tform` input argument then the `worldPoints` coordinates must be in the same units as the `Translation` property of the `tform` object.

`distort` — Apply lens distortion
`false` (default) | `true`

Option to apply lens distortion, specified as `false` or `true`. When you set this argument to `true`, the function applies lens distortion to the output `imagePoints`.

This argument is valid only when using a `cameraParameters` object as the `cameraParams` input.

Output Arguments

`imagePoints` — Image points
M-by-2 matrix

Image points, returned as an *M*-by-2 matrix of *M* [*x*,*y*] point coordinates.

`validIndex` — Valid index
M-by-1 logical array

Valid index returned as an *M*-by-1 logical array that specify the indices of valid image points in the `imagePoints` output that are within the boundary of the image. The world points that correspond to the indices are inside the field of view of the camera.

Version History

Introduced in R2016b

R2022b: Not recommended
Not recommended starting in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `worldToImage` function uses the postmultiply convention. Although there are no plans to remove `worldToImage` at this time, you can streamline your geometric transformation workflows by switching to the `world2img` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

To update your code:

- Change instances of the function name `worldToImage` to `world2img`.
- Switch the order of the `intrinsics` and the `worldPoints` arguments.
- Specify the transformation as a `rigidtform3d` object using the `tform` argument. `world2img` does not support the `rotationMatrix` and `translationVector` input arguments. Note that you create the `rigidtform3d` object using the transpose of `rotationMatrix` or the transpose of the transformation matrix in the `T` property of `tform`.

Discouraged Usage	Recommended Replacement

This example specifies the transformation as a rotation matrix and a translation vector, then projects 3-D world points into points on an image using the `worldToImage` function.
`imagePoints = worldToImage(intrinsics, ...`
`    rotationMatrix,translationVector,worldPoints);`
	This example specifies the transformation as a `rigidtform3d` object, then projects 3-D world points into points on an image using the `world2img` function. Note that you create the `rigidtform3d` object using the transpose of the rotation matrix, `rotationMatrix`.
	`tform = rigidtform3d(rotationMatrix',translationVecto`
	`imagePoints = world2img(worldPoints,tform,intrinsics)`

This example specifies the transformation `rigid3d` object using the transpose of the geometric transformation matrix `A` in the premultiply convention, then projects 3-D world points into points on an image using the `worldToImage` function.
`A = [1 0 0 0; 0 1 0 0; 0 0 1 -10; 0 0 0 1];`
`tformOld = rigid3d(A');`
`imagePoints = worldToImage(intrinsics,tformOld,worldPoints);`
	This example specifies the transformation as a `rigidtform3d` object using the geometric transformation matrix `A`, then projects 3-D world points into points on an image using the `world2img` function.
	`A = [1 0 0 0; 0 1 0 0; 0 0 1 -10; 0 0 0 1];`
	`tform = rigidtform3d(A);`
	`imagePoints = world2img(worldPoints,tform,intrinsics)`
	If instead you start with an existing `rigid3d` object `tformOld`, then you can get the geometric transformation matrix in the postmultiply convention by querying the property `T` of `tformOld`.
	`T = tformOld.T;`
	`tform = rigidtform3d(T');`
	`imagePoints = world2img(worldPoints,tform,intrinsics)`

world2img

Project world points into image

Syntax

```
imagePoints = world2img(worldPoints,tform,intrinsics)
imagePoints = world2img(worldPoints,tform,intrinsics,ApplyDistortion=distort)
[imagePoints,validIndex] = world2img( ___ )
```

Description

`imagePoints = world2img(worldPoints,tform,intrinsics)` projects 3-D world points `worldPoints` into points on an image, `imagePoints`, according to a rigid geometric transformation, `tform`. `intrinsics` can be a `cameraIntrinsics`, `cameraIntrinsicsKB`, or a `fisheyeIntrinsics` object.

`imagePoints = world2img(worldPoints,tform,intrinsics,ApplyDistortion=distort)` returns the projection with distortion applied. Use this syntax only with `cameraIntrinsics` and `cameraIntrinsicsKB` objects.

`[imagePoints,validIndex] = world2img( ___ )` also returns the indices of valid image points that are within the boundary of the image.

Examples

Project World Points into Image

Create a set of calibration images.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata", ...
      "calibration","slr");
images = imageDatastore(dataDir);
imageSize = size(readimage(images,1));
```

Detect the checkerboard corners in the images.

```
[imagePoints,patternDims] = detectCheckerboardPoints(images.Files);
```

Generate the world coordinates of the checkerboard corners in the pattern-centric coordinate system, with the upper-left corner at (0,0).

```
squareSize = 29; % in millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Calibrate the camera.

```
cameraParams = estimateCameraParameters(imagePoints,worldPoints, ...
    ImageSize=imageSize(1:2));
intrinsics = cameraParams.Intrinsics;
```

Load the image at a new location.

```
imOrig = readimage(images,9);
imshow(imOrig)
```

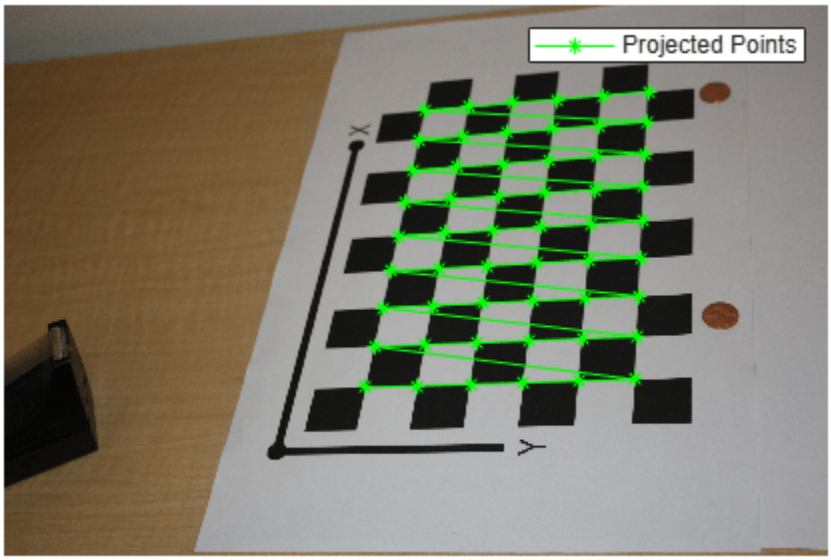
Undistort the image.

```
imUndistorted = undistortImage(imOrig,intrinsics);
```

Find a reference object in the new image.

```
[imagePoints,patternDims] = detectCheckerboardPoints(imUndistorted);
```

Calculate new extrinsics.



```
camExtrinsics = estimateExtrinsics(imagePoints,worldPoints,intrinsics);
```

Add a *z*-coordinate to the world points.

```
zCoord = zeros(size(worldPoints,1),1);
worldPoints = [worldPoints zCoord];
```

Project the world points back into the original image.

```
projectedPoints = world2img(worldPoints,camExtrinsics,intrinsics);
hold on
plot(projectedPoints(:,1),projectedPoints(:,2),"g*-");
legend("Projected Points");
hold off
```

Input Arguments

`worldPoints` — 3-D world points
M-by-3 matrix

3-D world points, specified as an *M*-by-3 matrix containing *M* [*x*,*y*,*z*] coordinates of 3-D world points. The `worldPoints` coordinates must be in the same units as the `Translation` property of the `tform` object.

`tform` — Transformation
`rigidtform3d` object

Transformation of the camera in world coordinates, specified as a `rigidtform3d` object.

`intrinsics` — Camera intrinsics
`cameraIntrinsics` object | `fisheyeIntrinsics` object | `cameraIntrinsicsKB` object

Camera intrinsics, specified as a `cameraIntrinsics`, `fisheyeIntrinsics` or a `cameraIntrinsicsKB` object. The object stores information about a camera's intrinsic calibration parameters, including the lens distortion parameters.

`distort` — Apply lens distortion
`false` (default) | `true`

Apply lens distortion, specified as `false` or `true`. When you set this argument to `true`, the function applies lens distortion to the output `imagePoints`.

This argument is valid only when the `intrinsics` argument is a `cameraIntrinsics` or `cameraIntrinsicsKB` object.

Output Arguments

`imagePoints` — Image points
M-by-2 matrix

Image points, returned as an *M*-by-2 matrix of *M* [*x*,*y*] point coordinates.

`validIndex` — Valid index
M-by-1 logical vector

Valid index returned as an *M*-by-1 logical vector that specify the indices of valid image points in the `imagePoints` output that are within the boundary of the image. The world points that correspond to the indices are inside the field of view of the camera.

Version History

Introduced in R2022b

R2022b: Recommended over `worldToImage`

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `worldToImage` function uses the postmultiply convention. Although there are no plans to remove `worldToImage` at this time, you can streamline your geometric transformation workflows by switching to the `world2img` function, which supports the premultiply convention. For more information, see "Migrate Geometric Transformations to Premultiply Convention".

R2024a: Added support for the `cameraIntrinsicsKB` object

Support added for the `cameraIntrinsicsKB` object as the `cameraParams` input.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Code generation not supported for `cameraIntrinsicsKB` object input.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

toStruct

Convert a trained aggregate channel features (ACF) object detector into structure

Syntax

```
detectorStruct = toStruct(acfObjectDetector)
```

Description

`detectorStruct = toStruct(acfObjectDetector)` returns a structure that stores the properties of the input `acfObjectDetector` object in fields. The output structure contains fields `Classifier` and `TrainingOptions`. Use the structure to create an identical `acfObjectDetector` object for C code generation. You can call the `toStruct`, and then pass the resulting structure to a MATLAB function, which recreates the `acfObjectDetector` object.

Examples

Convert ACF Object Detector to Struct

Load the pretrained ACF stop sign detector from the `stopSignDetector.mat` file, which is present in the current working folder as a supporting file.

```
stopSignDetector= load('stopSignDetectorACF.mat');
detector = stopSignDetector.detector
```

```
detector =

  acfObjectDetector with properties:

            ModelName: 'stopSign'
    ObjectTrainingSize: [34 31]
       NumWeakLearners: 61
```

Convert the detector to a structure.

```
detectorStruct = toStruct(detector)
```

```
detectorStruct =

  struct with fields:

            ModelName: 'stopSign'
    ObjectTrainingSize: [34 31]
       NumWeakLearners: 61
            Classifier: [1×1 struct]
```

```
    TrainingOptions: [1×1 struct]
```

Input Arguments

`acfObjectDetector` — ACF object detector

`acfObjectDetector` object

ACF object detector, specified as an `acfObjectDetector` object. To create this object, call the `trainACFObjectDetector` function with training data as input.

Output Arguments

`detectorStruct` — ACF object properties

structure

ACF object detector, returned as a structure containing the object properties into fields.

Version History

Introduced in R2017a

“Generate Code for Detecting Objects in Images by Using ACF Object Detector”

displayErrors

Display standard errors of camera parameter estimates

Syntax

```
displayErrors(estimationErrors,cameraParams)
```

Description

`displayErrors(estimationErrors,cameraParams)` displays the camera parameters and corresponding standard errors.

Examples

Display Fisheye Camera Calibration Errors

Gather a set of checkerboard calibration images.

```
images = imageDatastore(fullfile(toolboxdir('vision'),'visiondata',...
 'calibration','gopro'));
```

Detect the calibration pattern from the images.

```
[imagePoints,patternDims] = detectCheckerboardPoints(images.Files);
```

Generate world coordinates for the corners of the checkerboard squares.

```
squareSize = 29; % millimeters
worldPoints = patternWorldPoints('checkerboard',patternDims,squareSize);
```

Estimate the fisheye parameters using image and world points. Use the first image to get the image size. Also, store the errors from the calibration.

```
I = readimage(images,1);
imageSize = [size(I,1) size(I,2)];
[params,~,errors] = estimateFisheyeParameters(imagePoints, ...
                                worldPoints,imageSize);
```

Display the standard errors of the estimated camera parameters.

```
displayErrors(errors,params);
```

```

```

Input Arguments

`estimationErrors` — Standard errors of estimated parameters

`cameraCalibrationErrors` object | `fisheyeCalibrationErrors` object

Standard errors of estimated parameters, specified as a `cameraCalibrationErrors` or `fisheyeCalibrationErrors` object.

`cameraParams` — Camera parameters

`cameraParameters` object | `fisheyeParameters` object

Camera parameters, specified as a `cameraParameters` or `fisheyeParameters` object. These objects contain the intrinsic, extrinsic, and lens distortion parameters of a camera.

- To create a `cameraParameters`, use the `estimateCameraParameters` function or the Camera Calibrator app.
- To create a `fisheyeParameters`, use the `estimateFisheyeParameters` function.

info

Information about specified video file

Syntax

```
S = info(videoFReader)
```

Description

`S = info(videoFReader)` returns a MATLAB structure, `S`, with information about the video file specified in the `Filename` property.

Input Arguments

`videoFReader` — Video file reader object

object (default)

Video file reader, specified as a `vision.VideoFileReader` System object.

Output Arguments

`S` — Information about input file

structure

Information about input file, returned as a structure. The fields and possible values for the structure `S` are described below:

Audio	Logical value indicating if the file has audio content.
Video	Logical value indicating if the file has video content.
VideoFrameRate	Frame rate of the video stream in frames per second. The value may vary from the actual frame rate of the recorded video, and takes into consideration any synchronization issues between audio and video streams when the file contains both audio and video content. This implies that video frames may be dropped if the audio stream leads the video stream by more than 1/(actual video frames per second).
VideoSize	Video size as a two-element numeric vector of the form: `[VideoWidthInPixels, VideoHeightInPixels]`
VideoFormat	Video signal format.

Version History

Introduced in R2012a

isDone

End-of-file status (logical)

Syntax

```
status = isDone(videoFReader)
```

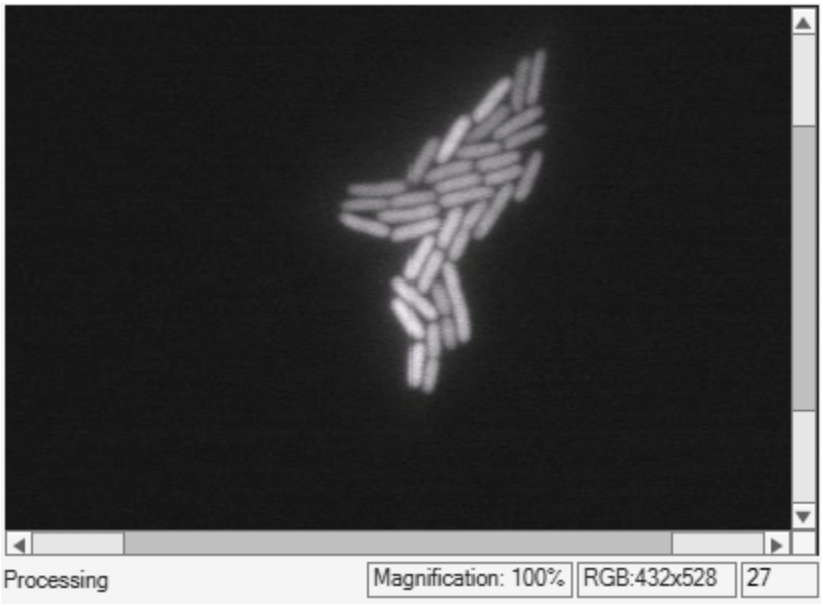
Description

`status = isDone(videoFReader)` returns a logical value indicating that the `VideoFileReader` System object `videoFReader` , has reached the end of the multimedia file after playing it `PlayCount` number of times. After the object plays the file the number of times set by the `PlayCount` property, it sets the status to `true`.

Examples

Read and Play a Video File

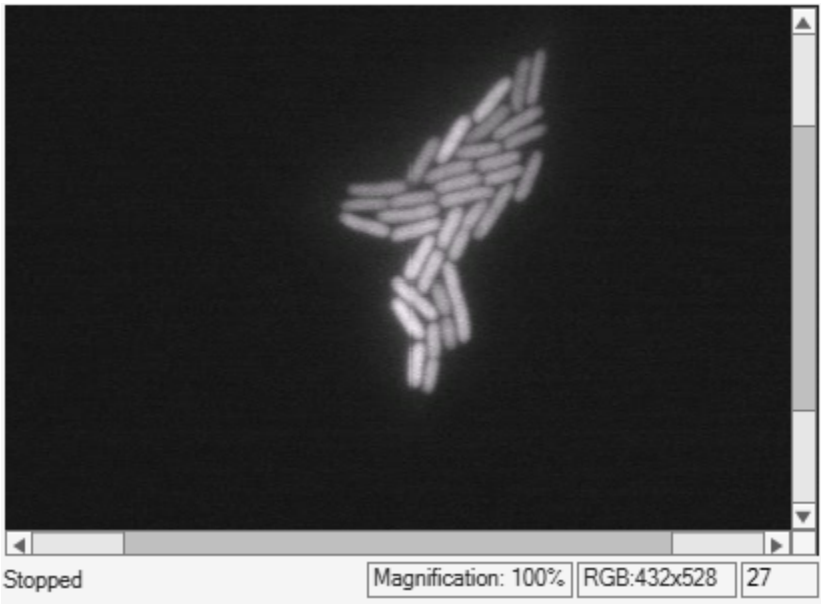
Load the video using a video reader object.



```
vidReader = VideoReader('ecolicells.avi');
```

Create a video player object to play the video file.

```
videoPlayer = vision.VideoPlayer;
```



Use a while loop to read and play the video frames. Pause for 0.1 seconds after displaying each frame.

```
while hasFrame(vidReader)
    videoFrame = readFrame(vidReader);
    videoPlayer(videoFrame);
    pause(0.1)
end
```

Release the objects.

```
release(videoPlayer);
```

Input Arguments

`videoFReader` — Video file reader object

object (default)

Video file reader, specified as a `vision.VideoFileReader` System object.

Output Arguments

`status` — Status of reader file
`true` | `false`

Status of reader file, returned as `true` or `false`.

Version History

Introduced in R2012a

isOpen

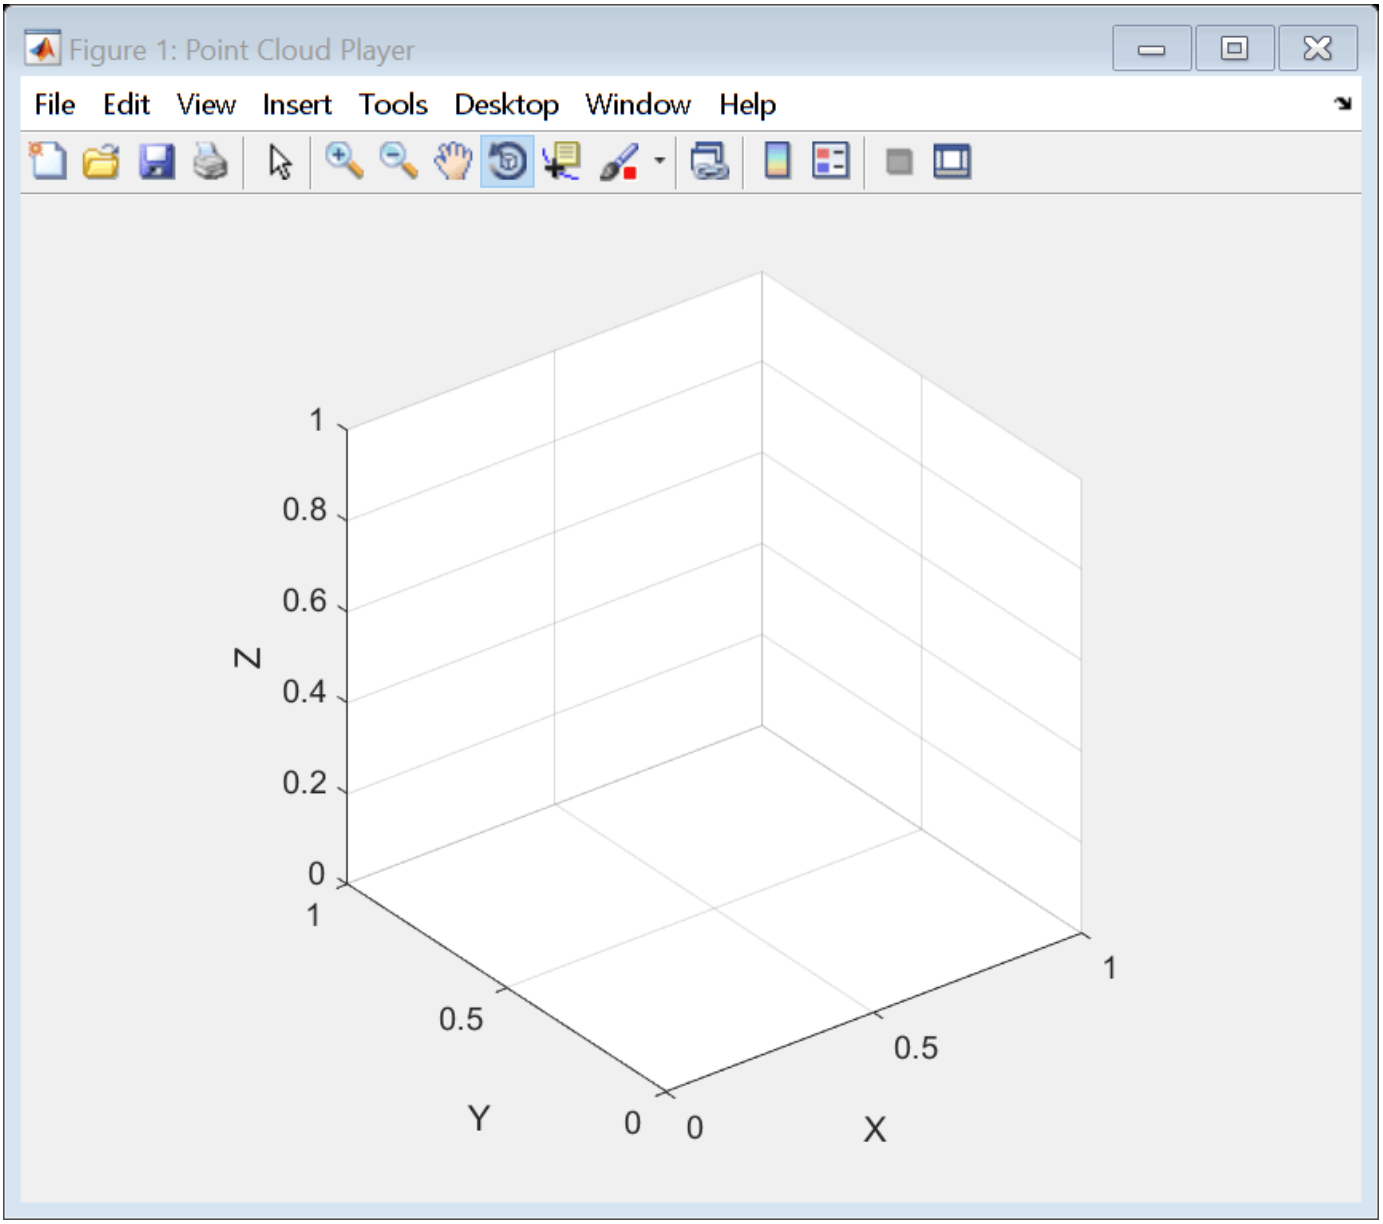
Visible or hidden status for player

Syntax

```
isOpen(player)
```

Description

`isOpen(player)` returns `true` or `false` to indicate whether the player is visible.



Examples

Terminate a Point Cloud Processing Loop

Close the display of continuous point cloud player

Add data to the point cloud player.

```
player = pcplayer([0 1],[0 1],[0 1]);
```

Display continuous player figure. Use the `isOpen` method to check if player figure window is open.

```
while isOpen(player)
   ptCloud = pointCloud(rand(1000,3,'single'));
   view(player, ptCloud);
end
```

Terminate the while-loop by closing `pcplayer` figure window.

Input Arguments

`player` — Player
object

Video player, specified as a `pcplayer`, or `vision.DeployableVideoPlayer` object.

Version History

Introduced in R2012a

segmentGroundFromLidarData

Segment ground points from organized lidar data

Syntax

```
groundPtsIdx = segmentGroundFromLidarData(ptCloud)
groundPtsIdx = segmentGroundFromLidarData(ptCloud,Name=Value)
```

Description

`groundPtsIdx = segmentGroundFromLidarData(ptCloud)` segments organized 3-D lidar data, `ptCloud`, into ground and nonground parts. The lidar sensor must be mounted horizontally such that all ground points are observed in the lidar scan closest to the sensor.

To use this function, the ground plane must be along the *x*-*y* plane. You can use the `pctransform` to rotate the sensor data before using `segmentGroundFromLidarData`.

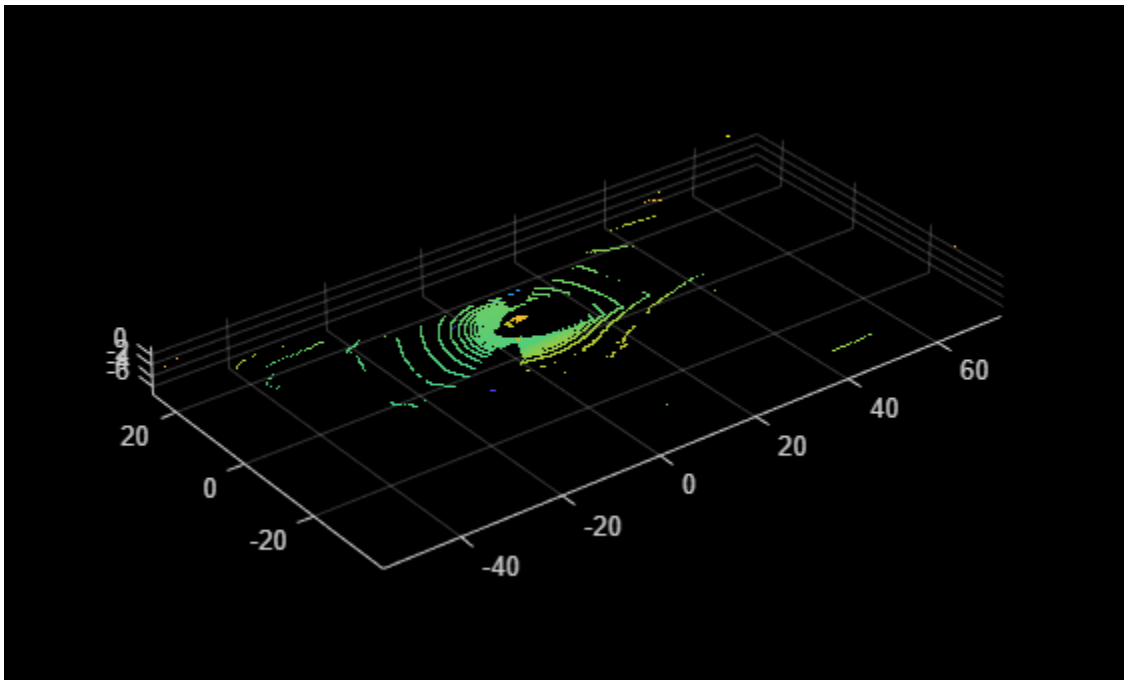
`groundPtsIdx = segmentGroundFromLidarData(ptCloud,Name=Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `segmentGroundFromLidarData(ptCloud,ElevationAngleDelta=5)`

Examples

Segment and Plot Organized Lidar Data

Segment ground points and nonground points from an organized lidar point cloud. Create organized point clouds from these segmentations, and display them.

Load an organized lidar, point cloud.



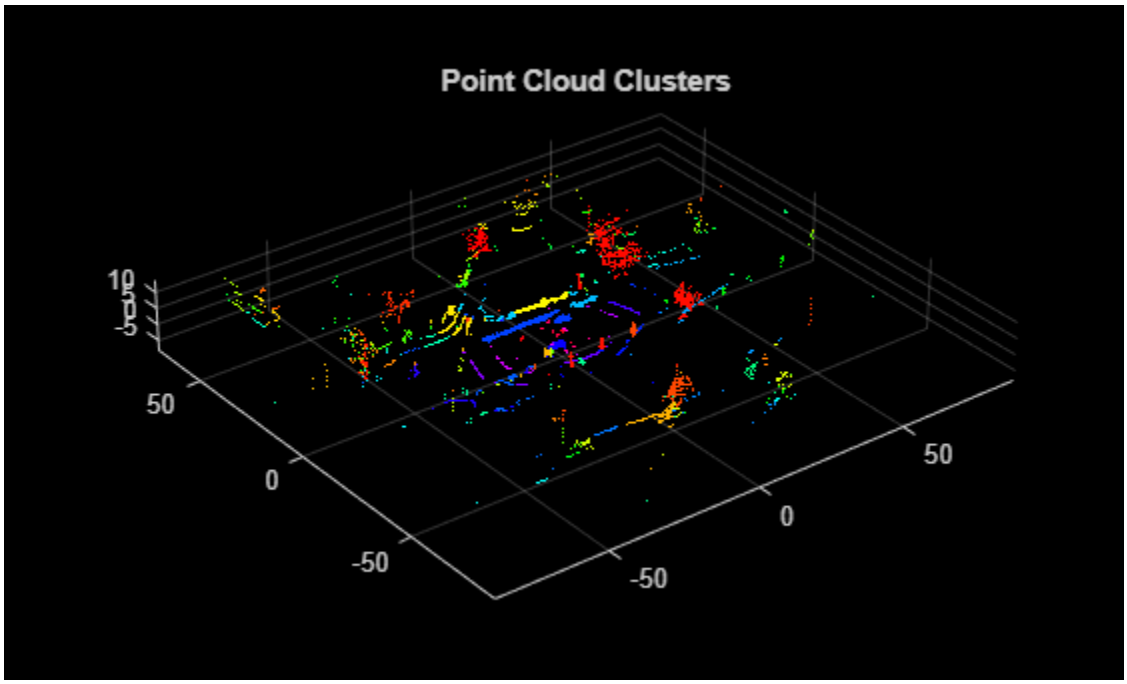
```
ld = load('drivingLidarPoints.mat');
```

Segment ground points from the organized lidar point cloud.

```
groundPtsIdx = segmentGroundFromLidarData(ld.ptCloud);
```

Create an organized point cloud containing only these ground points by using the `select` function. Display this point cloud.

```
groundPtCloud = select(ld.ptCloud,groundPtsIdx);
figure
pcshow(groundPtCloud)
```



Create an organized point cloud containing only the nonground points. Specify a threshold of 0.5 meters.

```
nonGroundPtCloud = select(ld.ptCloud,~groundPtsIdx,'OutputSize','full');
distThreshold = 0.5;
[labels,numClusters] = segmentLidarData(nonGroundPtCloud,distThreshold);
```

Display the nonground points cloud clusters.

```
figure
colormap(hsv(numClusters))
pcshow(nonGroundPtCloud.Location,labels)
title('Point Cloud Clusters')
```

Segment and Plot Ground Plane Using PCAP File

Load Velodyne PCAP® to the workspace.

```
velodyneFileReaderObj = velodyneFileReader('lidarData_ConstructionRoad.pcap','HDL32E');
```

Create a point cloud player using pcplayer. Define its *x*-, *y*-, and *z*-axes limits, in meters, and label its axes.

```
xlimits = [-40 40];
ylimits = [-15 15];
zlimits = [-3 3];
player = pcplayer(xlimits,ylimits,zlimits);
```

Label the pcplayer axes.

```
xlabel(player.Axes,'X (m)')
ylabel(player.Axes,'Y (m)')
zlabel(player.Axes,'Z (m)')
```

Set the colormap for labeling points. Use RGB triplets to specify green for ground-plane points, and red for obstacle points.

```
colors = [0 1 0; 1 0 0];
greenIdx = 1;
redIdx = 2;
```

Iterate through the point clouds in the Velodyne PCAP file, using `readFrame` to read in the data. Segment the ground points from each point cloud. Color all ground points green and nonground points red. Plot the resulting lidar point cloud.

```
colormap(player.Axes,colors)
title(player.Axes,'Segmented Ground Plane of Lidar Point Cloud');

for i = 1:velodyneFileReaderObj.NumberOfFrames
    % Read current frame.
    ptCloud = velodyneFileReaderObj.readFrame(i);

    % Create label array.
    colorLabels = zeros(size(ptCloud.Location,1),size(ptCloud.Location,2));

    % Find the ground points.
    groundPtsIdx = segmentGroundFromLidarData(ptCloud);

    % Map color ground points to green.
    colorLabels(groundPtsIdx (:)) = greenIdx;

    % Map color nonground points to red.
    colorLabels(~groundPtsIdx (:)) = redIdx;

    % Plot the results.
    view(player,ptCloud.Location,colorLabels)
end
```

Input Arguments

ptCloud — Point cloud
`pointCloud` object

Point cloud, specified as a `pointCloud` object. `ptCloud` is an organized point cloud that stores [*x*,*y*,*z*] point coordinates in an *M*-by-*N*-by-3 matrix.

Name-Value Pair Arguments

Example: `ElevationAngleDelta=5` sets the elevation angle threshold to 5 degrees.

`ElevationAngleDelta` — Elevation angle difference threshold

5 (default) | nonnegative scalar

Elevation angle difference threshold to identify ground points, specified as a nonnegative scalar. The function computes the elevation angle difference between one labeled ground point and its 4-connected neighbors. The neighborhood point is labeled as ground if the difference is below the threshold. Typical values for `ElevationAngleDelta` are in the range of [5,15] degrees. Increase this value to encompass more points from uneven ground surfaces.

`InitialElevationAngle` — Initial elevation angle threshold

`30` (default) | non-negative scalar

Initial elevation angle threshold to identify the ground point in the scanning line closest to the lidar sensor, specified as a non-negative scalar. The function marks a point as ground when the elevation angle falls below this value. Typical values for `InitialElevationAngle` are in the range of 15 and 30 degrees.

Output Arguments

`groundPtsIdx` — Ground points index

logical matrix

Ground points index, returned as an *M*-by-*N* logical matrix. Elements with a `true` value, `1`, indicate ground points. Elements with a `false` value, `0`, indicate nonground points.

Version History

Introduced in R2018b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Because of architectural differences between the CPU and GPU, numerical verification does not always match. The GPU floating-point units use fused Floating-Point Multiply-Add (FMAD)

instructions while the CPU does not use these instructions. The CUDA compiler performs these instruction-level optimizations by default impacting the accuracy of the computed results. For example, the CUDA compiler fuses floating-point multiply and add instructions into a single instruction. This Floating-point Multiply-Add (FMAD) operation executes twice as fast compared to two single instructions but results in the loss of numerical accuracy. You can achieve tighter control over these optimizations by using compiler flags. For example, passing `--fmad=false` to the `Compiler Flags` property of the code configuration object instructs the `nvcc` compiler to disable contraction of floating-point multiply and add to a single Floating-Point Multiply-Add (FMAD) instruction. For more information, see “Generate Code by Using the GPU Coder App” (GPU Coder).

focalCrossEntropy

Compute focal cross-entropy loss

Syntax

```
dlY = focalCrossEntropy(dlX,targets)
dlY = focalCrossEntropy(dlX,targets,"DataFormat",FMT)
dlY = focalCrossEntropy( ___ ,Name=Value)
```

Description

`dlY = focalCrossEntropy(dlX,targets)` computes the focal cross-entropy between network predictions and target values for single-label and multi-label classification tasks. The classes are mutually-exclusive classes. The focal cross-entropy loss weights towards poorly classified training samples and ignores well-classified samples. The focal cross-entropy loss is computed as the average logarithmic loss divided by number of non-zero targets.

`dlY = focalCrossEntropy(dlX,targets,"DataFormat",FMT)` also specifies the dimension format `FMT` when `dlX` is not a formatted `dlarray`.

`dlY = focalCrossEntropy( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to the input arguments in previous syntaxes. For example, `ClassificationMode="multilabel"` computes the cross-entropy loss for a multi-label classification task.

Examples

Compute Focal Cross-Entropy Loss Using Formatted `dlarray`

Create the input classification data as 32 observations of random variables belonging to 10 classes or categories.

```
numCategories = 10;
observations = 32;
X = rand(numCategories,observations);
```

Create a formatted deep learning array that has a data format with the labels `'C'` and `'B'`.

```
dlX = dlarray(X,'CB');
```

Use the `softmax` function to set all values in the input data to values between `0` and `1` that sum to `1` over all channels. The values specify the probability of each observation to belong to a particular category.

```
dlX = softmax(dlX);
```

Create the target data as unformatted deep learning array, which holds the correct category for each observation in dlX. Set the targets belonging to the second category as one-hot encoded vectors.

```
targets = dlarray(zeros(numCategories,observations));
targets(2,:) = 1;
```

Compute the focal cross-entropy loss between each prediction and the target.

```
dlY = focalCrossEntropy(dlX,targets,'Reduction','none');
```

Compute Average Focal Cross-Entropy Loss Using Unformatted `dlarray`

Create the input classification data as 32 observations of random variables belonging to 10 classes or categories.

```
numCategories = 10;
observations = 32;
X = rand(numCategories,observations);
```

Create an unformatted deep learning array.

```
dlX = dlarray(X);
```

Use the `softmax` function to set all values in the input data to values between `0` and `1` that sum to `1` over all channels. The values specify the probability for each observation to belong to a particular category.

```
dlX = softmax(dlX,'DataFormat','CB');
```

Create the target data. Set the targets belonging to the second category as one-hot encoded vectors.

```
targets = zeros(numCategories,observations);
targets(2,:) = 1;
```

Compute the average of focal cross-entropy loss computed between the predictions and the targets.

```
dlY = focalCrossEntropy(dlX,targets,'DataFormat','CB')
```

```
dlY =
  1×1 dlarray

    0.4769
```

Compute Average Focal Cross-Entropy Loss for Multi-Label Classification

Create the input classification data as 32 observations of random variables belonging to 10 classes or categories.

```
numCategories = 10;
observations = 32;
X = rand(numCategories,observations);
```

Create a formatted deep learning array that has a data format with the labels 'C' and 'B'.

```
dlX = dlarray(X,'CB');
```

Use the `sigmoid` function to set all values in the input data to values between `0` and `1` that sum to `1` over all channels. The values specify the probability of each observation to belong to a particular category.

```
dlX = sigmoid(dlX);
```

Create the target data, which holds the correct category for each observation in `dlX`. Set the targets belonging to the second and sixth category as one-hot encoded vectors.

```
targets = zeros(numCategories,observations);
targets(2,:) = 1;
targets(6,:) = 1;
```

Compute the average of focal cross-entropy loss computed between the predictions and the targets. Set the '`ClassificationMode`' value to '`multilabel`' for multi-label classification.

```
dlY = focalCrossEntropy(dlX,targets,'ClassificationMode','multilabel')
```

```
dlY =
  1×1 dlarray

    2.4362
```

Input Arguments

`dlX` — Predictions

`dlarray` | numeric array

Predictions, specified as a `dlarray` with or without dimension labels or a numeric array. When `dlX` is not a formatted `dlarray`, you must specify the dimension format using the `DataFormat` name-value argument. If `dlX` is a numeric array, `targets` must be a `dlarray`.

Data Types: `single` | `double`

`targets` — Target classification labels

`dlarray` | numeric array

Target classification labels, specified as a formatted or unformatted `dlarray` or a numeric array.

If `targets` is a formatted `dlarray`, its dimension format must be the same as the format of `dlX`, or the same as the `DataFormat` name-value argument if `dlX` is unformatted.

If `targets` is an unformatted `dlarray` or a numeric array, the size of `targets` must exactly match the size of `dlX`. The format of `dlX` or the value of `DataFormat` is implicitly applied to `targets`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `ClassificationMode="multilabel",DataFormat="CB"` evaluates the focal cross-entropy loss for multi-label classification tasks and specifies the dimension order of the input data as `"CB"`

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `"ClassificationMode","multilabel","DataFormat","CB"` evaluates the focal cross-entropy loss for multi-label classification tasks and specifies the dimension order of the input data as `"CB"`

`Gamma` — Focusing parameter
`2` (default) | positive real number

Focusing parameter of the focal loss function, specified as a positive real number. Increasing the value of `Gamma` increases the sensitivity of the network to misclassified observations.

`Alpha` — Balancing parameter
`0.25` (default) | positive real number

Balancing parameter of the focal loss function, specified as a positive real number. The `Alpha` value scales the loss function linearly and is typically set to `0.25`. If you decrease `Alpha`, increase `Gamma`.

`Reduction` — Type of output loss
`"mean"` (default) | `"none"`

Type of output loss, specified as one of the following:

- `"mean"` — Average of output loss for each prediction. The function computes the average of loss values computed for each predictions in input `dlX`. The function returns the average loss as an unformatted `dlarray`. Observations with all zero target values along the channel dimension are excluded from computing the average loss.
- `"none"` — Output loss for each prediction. The function returns the loss values for each observation in `dlX`. The samples for computing focal cross-entropy loss also contains observations whose target values are all zeros along the channel dimension. If `dlX` is a formatted `dlarray`, output `dlY` is a formatted `dlarray` with same dimension labels as `dlX`. If `dlX` is an unformatted `dlarray`, output `dlY` is an unformatted `dlarray`.

Data Types: `char` | `string`

`ClassificationMode` — Type of classification task
`"single-label"` (default) | `"multilabel"`

Type of classification task, specified as one of these values:

- `"single-label"` — Each observation in the predictions `dlX` is exclusively assigned to one category (single-label classification).
- `"multilabel"`— Each observation in the predictions `dlX` can be assigned to one or more independent categories (multilabel classification).

Note To select the classification mode for binary classification, you must consider the output layer of the network:

- If the final layer has an output size of one, such as with a sigmoid layer, use `"multilabel"`.

- If the final layer has an output size of two, such as with a softmax layer, use `"single-label"`.

`DataFormat` — Dimension order of unformatted data
char vector | string

Dimension order of unformatted input data, specified as a character vector or string `FMT` that provides a label for each dimension of the data. Each character in `FMT` must be one of the following:

- `"S"` — Spatial
- `"C"` — Channel
- `"B"` — Batch (for example, samples and observations)
- `"T"` — Time (for example, sequences)
- `"U"` — Unspecified

You can specify multiple dimensions labeled `"S"` or `"U"`. You can use the labels `"C"`, `"B"`, and `"T"` at most once.

You must specify `DataFormat` when the input data `dlX` is not a formatted `dlarray`.

Example: `DataFomat="SSCB"`

Data Types: `char` | `string`

Output Arguments

`dlY` — Focal cross-entropy loss
`dlarray` scalar

Focal cross-entropy loss, returned as a `dlarray` scalar without dimension labels. The output `dlY` has the same underlying data type as the input `dlX`.

Version History

Introduced in R2020b

R2023b: `TargetCategories` is not recommended
Not recommended starting in R2023b

`TargetCategories` is not recommended. Use `ClassificationMode` instead. To update your code, replace all instances of `TargetCategories="exclusive"` with `ClassificationMode="single-label"` and all instances of `TargetCategories="independent"` with `ClassificationMode="multilabel"`. There are no differences between the properties that require additional updates to your code. The default behavior of the `focalcrossentropy` function remains the same.

bboxerase

Remove bounding boxes

Syntax

```
bboxB = bboxerase(bboxA,window)
[bboxB,indices] = bboxerase(bboxA,window)
___ = bboxerase( ___ ,EraseThreshold=threshold)
```

Description

`bboxB = bboxerase(bboxA,window)` removes bounding boxes in the input `bboxA` that lie within a region of interest (ROI) specified by `window`. The output is the set of bounding boxes retained from the input `bboxA`. This function supports 2-D and 3-D bounding boxes.

Note To perform random erase or cutout data augmentation, use `bboxerase` along with the `imerase` function.

`[bboxB,indices] = bboxerase(bboxA,window)` also returns the indices of the bounding boxes retained from the input set of bounding boxes `bboxIn`.

`___ = bboxerase( ___ ,EraseThreshold=threshold)` additionally specifies the threshold for the amount of overlap between a bounding box region and the specified ROI. A bounding box is removed if the overlap between the bounding box region and the ROI is equal to or greater than the specified threshold.

Examples

Perform Random Erase Augmentation

Read an image.

```
I = imread('peppers.png');
```

Define bounding boxes and labels.

```
bboxA = [410 230 100 90;
         186 78 80 60];
labelsA = ["garlic";"onion"];
```

Find the size of the input image

```
inputSize = size(I);
```

To randomly select a region of interest (ROI), specify a range for the scale and the aspect ratio of the ROI. The scale value for the ROI is set to lie in the range 0.2 and 0.3. Similarly, the minimum value for the aspect ratio is set to lie in the range 1:10 and the maximum value for the aspect ratio is set to lie in the range 30:100.

```
scale = [0.2,0.3];
dimensionRatio = [1,10;30,100];
```

Select the ROI by using the `randomWindow2d` function.

```
window = randomWindow2d(inputSize,'Scale',scale,'DimensionRatio',dimensionRatio);
```

Remove the pixels and the bounding boxes that lie within the randomly selected ROI.

```
J = imerase(I,window);
[bboxB,indices] = bboxerase(bboxA,window);
labelsB = labelsA(indices);
```

Display the original and augmented image.

```
annotatedI = insertObjectAnnotation(I,'Rectangle',bboxA,labelsA);
annotatedJ = insertObjectAnnotation(J,'Rectangle',bboxB,labelsB);
figure
montage({annotatedI,annotatedJ})
title(['Input | Random Erase Output'])
```

Perform Cutout Data Augmentation

Read an image.

```
I = imread('visionteam1.jpg');
```

Define bounding boxes and labels.

```
bboxA = [64 101 117 440;
193 101 67 309;
```

```
282 86 114 375;
618 118 79 345;
486 55 131 528;
475 109 66 361];

labelsA = ["Person 1";"Person 2";"Person 3";"Person 4";"Person 5";"Person 6"];
```

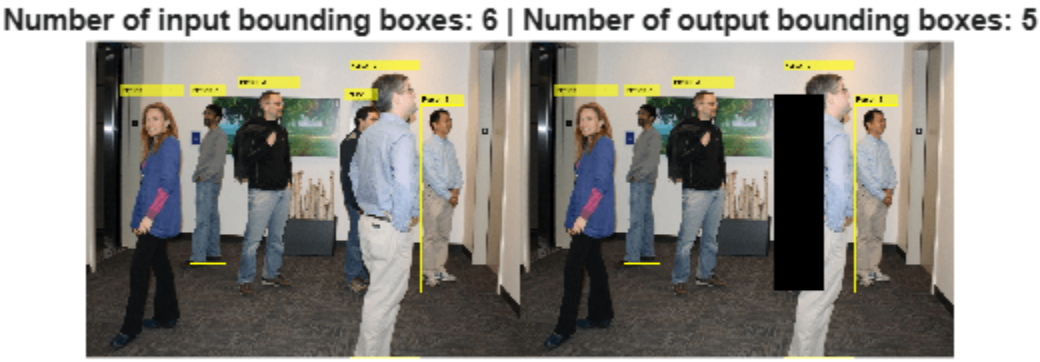
Specify a rectangular region of interest.

```
window = [470 100 90 360];
```

Erase the pixels that lie within the rectangular region by using `imerase` function.

```
J = imerase(I,window);
```

Erase the bounding boxes that lie within the rectangular region. Set the erase threshold value to 0.7. The `bboxerase` function returns the retained bounding boxes and the corresponding indices.



```
[bboxB,indices] = bboxerase(bboxA,window,'EraseThreshold',0.7);
```

Read the class labels corresponding to the retained bounding boxes.

```
labelsB = labelsA(indices);
```

Display the results.

```
figure
I = insertObjectAnnotation(I,'Rectangle',bboxA,labelsA);
J = insertObjectAnnotation(J,'Rectangle',bboxB,labelsB);
imshowpair(I,J,'montage')
title(['Number of input bounding boxes: ', num2str(length(labelsA)), ' | ', 'Number of output bou
```

Input Arguments

`bboxA` — Input set of bounding boxes

M-by-4 matrix

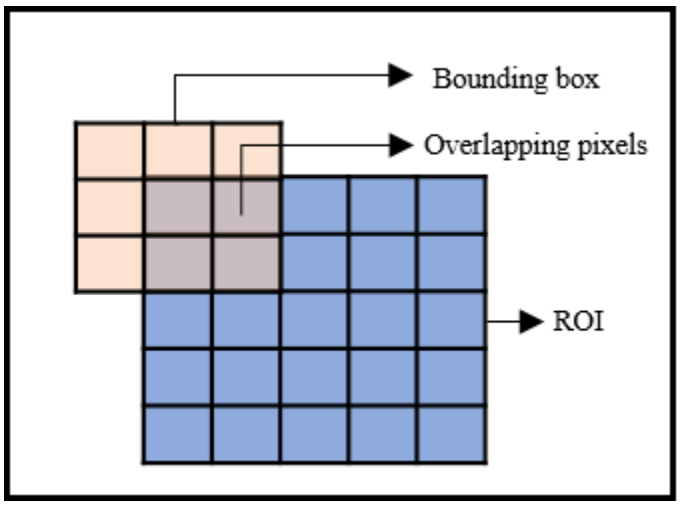
Input set of bounding boxes, specified as *M*-by-4 matrix. *M* is the number of bounding boxes. Each row in the matrix of form [x_{min} y_{min} *width height*]. [x_{min} y_{min}] are the top left coordinates of the bounding box. *width* and *height* are the width and the height of the bounding box respectively.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`window` — Region of interest

4-element vector | `Rectangle` object

Region of interest, specified as one of these values:



- 4 -element vector of form [*x y width height*]. [*x y*] are the top left coordinates of the ROI. *width* and *height* are the width and the height of the ROI respectively.
- `Rectangle` object.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`threshold` — Erase threshold

0.8 (default) | positive scalar

Erase threshold, specified as a positive scalar less than or equal to 1. The erase threshold sets the criteria for removing a bounding box from the input set `bboxA`. The value is the ratio of number of pixels in a bounding box that lie inside the ROI (overlapping pixels) to the total number of pixels in the bounding box.

$$threshold = \frac{Number\ of\ overlapping\ pixels}{Total\ number\ of\ pixels\ in\ bounding\ box}$$

The default value is 0.8. This implies that, a bounding box is removed if 80 % of the pixels in the bounding box lie within the specified ROI.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

bboxB — Output bounding boxes retained from the input
N-by-4 matrix

Output bounding boxes retained from the input, returned as a *N*-by-4 matrix. *N* is the number of bounding boxes retained from the input. Each row of the matrix defines one bounding box of the same type as the input `bboxA`. The value of *N* is always less than or equal to *M*, the number of input bounding boxes.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`indices` — Indices of retained bounding boxes
vector

Indices of retained bounding boxes, returned as a vector of integers. The indices indicate which bounding boxes in the input, `bboxA`, are retained and returned at the output.

Version History

Introduced in R2021a

Object Detector Analyzer

Interactively visualize and evaluate object detection results against ground truth

Description

The Object Detector Analyzer app enables you to visualize and evaluate object detection results against ground truth data. Using the app, you can:

- Evaluate object detection performance either without ground truth data or by comparing detections to ground truth and generating performance metrics. To get started, see Get Started with Object Detector Analyzer App.
- Run a pretrained object detector in the app, or import precomputed object detection results from the workspace. For a list of supported object detectors to run in the app, see "Run Supported Object Detectors" on page 3-1581. For information about the format of precomputed detection results, see "Import Precomputed Detection Results" on page 3-1582.
- Visualize and compare detections and ground truth annotations in an interactive image browser. Inspect individual detections, and overlay their confidence scores, false positives, and false negatives overlaid on images.
- Compute and visualize detector performance metrics: precision-recall curves, confusion matrices, AP, mAP, and mLAMR across data sets, classes, and overlap thresholds, and detection performance by object area. For more information on performance metrics, see "Evaluate Object Detector Performance".
- Interactively adjust the detection threshold and overlap (IoU) threshold to analyze how stricter or more lenient thresholds impact detector performance, enabling you to tune your detector for the optimal trade-off between false negatives and false positives.
- Export all detections or filtered results to the workspace for further analysis.
- Export computed performance metrics as an `objectDetectionMetrics` object. You can use this object to create custom visualizations, compare different detector models, or perform further performance analysis.

To learn more about this app, see Get Started with Object Detector Analyzer App.

Open the Object Detector Analyzer App

- MATLAB Toolstrip: On the **Apps** tab, under **Image Processing and Computer Vision**, click the app icon.
- MATLAB command prompt: Enter `objectDetectorAnalyzer`.

Examples

Visualize Object Detections on a Video

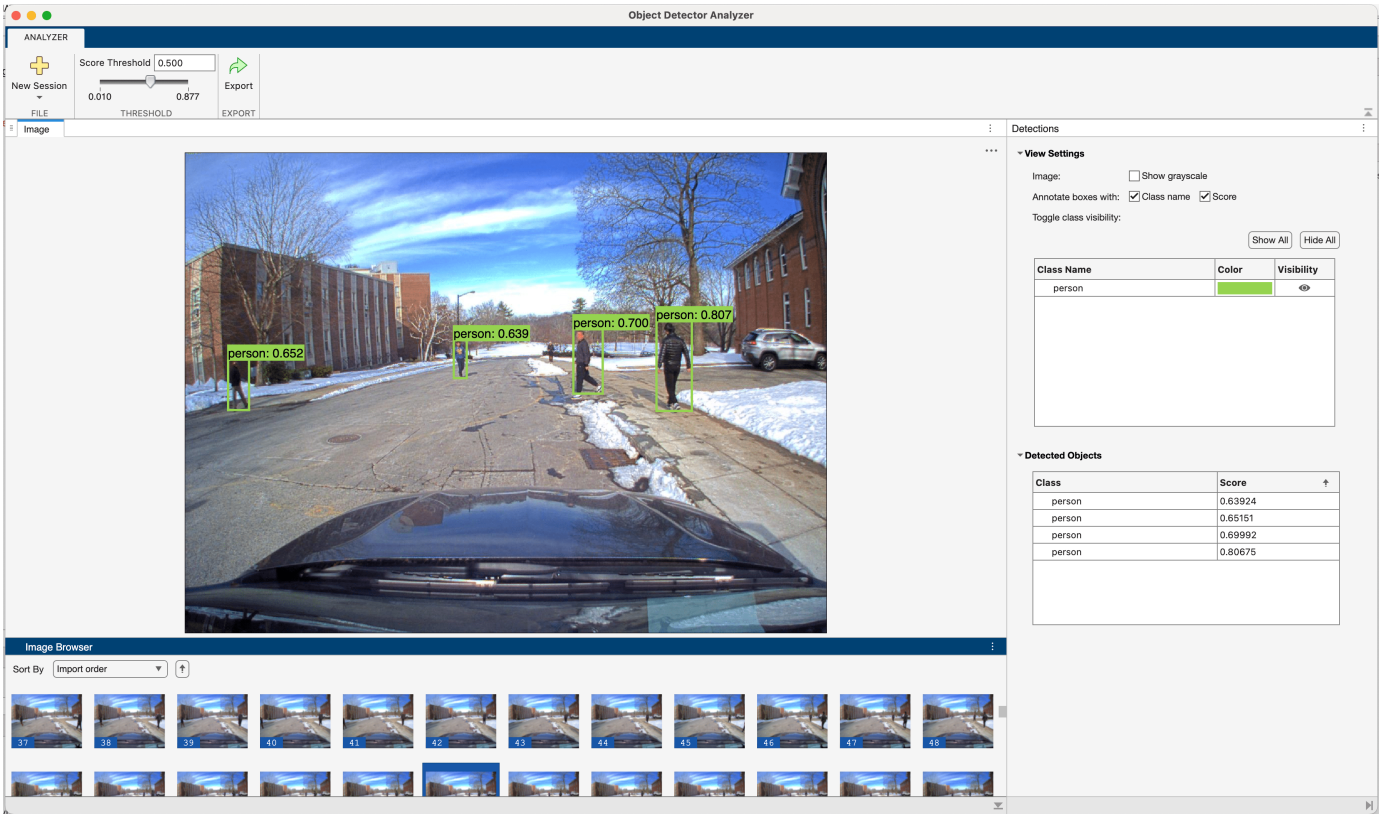
This example shows how to visualize object detections on a video using the Object Detector Analyzer App.

Load detector.

```
detector = peopleDetector();
```

Load a video using `VideoReader`.

```
videoURL = "https://ssd.mathworks.com/supportfiles/vision/data/PedestrianTrackingVideo.avi";
videoFilename = "PedestrianTrackingVideo.avi";
if ~exist("PedestrianTrackingVideo.avi","file")
disp("Downloading Pedestrian Tracking Video (35 MB)")
    websave(videoFilename,videoURL);
end



reader = VideoReader(videoFilename);
```

The Object Detector Analyzer App can import any datastore that produces image data. Use an `arrayDatastore` to produce video frame indices and create a `transform` datastore that calls `VideoReader` `read` object function with the frame indices returned by the `arrayDatastore`. This will read one frame of video data every time data is read from the datastore.

```
frameIndexDS = arrayDatastore((1:reader.NumFrames)',IterationDimension=1,OutputType="same");
videoFrameDS = transform(frameIndexDS,@(frameIdx)read(reader,frameIdx));
```

Launch Object Detector Analyzer App with the detector and the datastore as input. The app will run the detector on the video frames and display the detections on each frame. By default, the video frames are sorted by the number of detections in each frame. You can sort the video frames by Import order using the Sort By dropdown to visualize the video frames in sequence from start to finish.

```
objectDetectorAnalyzer(detector,videoFrameDS)
```

- Get Started with Object Detector Analyzer App
- “Multiclass Object Detection Using YOLO v2 Deep Learning”
- “Visualize Object Detection Results from Pretrained PyTorch Model”

Programmatic Use

`objectDetectorAnalyzer` opens a new session of the app. To start a new analysis session, select **New Session**, then **Evaluate detections without ground truth** or **Evaluate detections against ground truth**.

`objectDetectorAnalyzer(results,imds)` opens the app and visualizes the object detection results, `results`, on all of the test images from the `ImageDatastore` object `imds`. You must specify `results` as a table with *N* rows, where *N* is the number of images, and three columns in this order:

- Bounding boxes for the corresponding image, specified as an *M*-by-4 matrix. Each row of the matrix contains a bounding box of the form [*x y width height*], where *x*, `y`, *width*, *height* specify the upper-left corner coordinates, width, and height of each bounding box, respectively.
- Detection confidence scores for the corresponding image, specified as an *M*-by-1 vector.
- Object labels for the corresponding image, specified as an *M*-by-1 categorical array of class names which correspond to each bounding box.

M is the number of bounding boxes in each image.

`objectDetectorAnalyzer(results,groundTruthData)` opens the app, evaluates the object detection results, `results`, and visualizes them on all of the ground truth images, `groundTruthData`. Specify the ground truth data as a datastore or a `groundTruth` object. You can create a `groundTruth` object by exporting labels you create using the Image Labeler app into the workspace. If `groundTruthData` is a datastore, you must format the datastore such that calling the `read` function on it returns a cell array with these columns.

- The first column must contain the RGB, grayscale, or binary image data for each image.
- The second column must contain the bounding boxes for the corresponding image, specified as an *M*-by-4 matrix. *M* is the number of ground truth objects.
- The third column must contain the object class names for the corresponding image, specified as a categorical vector of size *M*-by-1. *M* is the number of ground truth objects.

More About

Run Supported Object Detectors

This table shows the supported pretrained detectors that you can run directly in the Object Detector Analyzer app. To select a pretrained object detector for your application, see “Choose an Object Detector”.

Detector	Object
Grounding DINO Object Detector	`groundingDinoObjectDetector`
RTM Object Detector	`rtmdetObjectDetector`

Detector	Object
YOLOX Object Detector	`yoloxObjectDetector`
YOLOv4 Object Detector	`yolov4ObjectDetector`
YOLOv3 Object Detector	`yolov3ObjectDetector`
YOLOv2 Object Detector	`yolov2ObjectDetector`
SSD Object Detector	`ssdObjectDetector`
People Detector	`peopleDetector`
RetinaFace Face Detector	`faceDetector`

Import Precomputed Detection Results

You can import precomputed detection results into the Object Detector Analyzer app.

Specify the precomputed detection results as a table with the same number of rows as the number of ground truth images, and these columns:

Bounding Boxes	Scores	Labels
A cell array containing an *M*-by-4 with rows in the format [*x y w h*]. *x* and *y* specify the upper-left corner of each rectangular bounding box. *w* specifies the box width, which is its length along the *x*-axis, and *h* specifies the box height, which is its length along the *y*-axis. *M* is the number of detected bounding boxes.	A cell array containing an *M*-by-1 numeric vector of detection confidence scores. *M* is the number of detected bounding boxes.	A cell array containing an *M*-by-1 categorical array of class labels. *M* is the number of detected bounding boxes.

To learn more, see Get Started with Object Detector Analyzer App.

xyzquat

Convert transformation or rotation to compact 3-D pose representation

Syntax

```
pose = xyzquat(transformation)
pose = xyzquat(rotation)
```

Description

`pose = xyzquat(transformation)` converts a transformation `transformation` to a compact 3-D pose representation `pose`.

`pose = xyzquat(rotation)` converts a rotation `rotation` to a compact 3-D pose representation `pose` with no translation.

Examples

Convert SE(3) Transformation to 3-D Compact Pose

Create SE(3) transformation with an *xyz*-position of `[2 3 1]` and a rotation defined by a numeric quaternion. Use the `eul2quat` function to create the numeric quaternion.

```
trvec = [2 3 1];
quat1 = [0.9659 0.2588 0 0];
pose1 = [trvec quat1]
```

```
pose1 = 1×7

    2.0000    3.0000    1.0000    0.9659    0.2588         0         0
```

```
T = se3(pose1,"xyzquat")
```

```
T = se3
    1.0000         0         0    2.0000
         0    0.8660   -0.5000    3.0000
         0    0.5000    0.8660    1.0000
         0         0         0    1.0000
```

Convert the transformation back into a compact pose.

```
pose2 = xyzquat(T)
```

```
pose2 = 1×7

    2.0000    3.0000    1.0000    0.9659    0.2588         0         0
```

Convert SO(3) Rotation to 3-D Compact Pose

Create SO(3) rotation defined by a numeric quaternion. Use the `eul2quat` function to create the numeric quaternion.

```
quat1 = [0.9659 0.2588 0 0]
```

```
quat1 = 1×4

    0.9659    0.2588         0         0
```

```
R = so3(quat1,"quat")
```

```
R = so3
    1.0000         0         0
         0    0.8660   -0.5000
         0    0.5000    0.8660
```

Convert the rotation into a 3-D compact pose.

```
pose1 = xyzquat(R)
```

```
pose1 = 1×7

         0         0         0    0.9659    0.2588         0         0
```

Input Arguments

`transformation` — Transformation

`se3` object | *N*-element array of `se3` objects

Transformation, specified as an `se3` object or as an *N*-element array of `se3` objects. *N* is the total number of transformations.

`rotation` — Rotation

`so3` object | *N*-element array of `so3` objects

Rotation, specified as an `so3` object or as an *N*-element array of `so3` objects. *N* is the total number of rotations.

Output Arguments

`pose` — 3-D compact pose

M-by-3 matrix

3-D compact pose, returned as an *M*-by-3 matrix, where each row is of the form [*x y z qw qx qy qz*]. *M* is the total number of transformations specified. *x*, *y*, *z* comprise the xyz-position and *qw*, *qx*, *qy*, and *qz* comprise the quaternion rotation.

See Also

`se3` | `so3`

anomalyMap

Predict per-pixel anomaly score map

Syntax

```
map = anomalyMap(detector,I)
map = anomalyMap(detector,I,ExecutionEnvironment=executionEnvironment)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`map = anomalyMap(detector,I)` creates an anomaly score map consisting of per-pixel anomaly scores predicted for test image `I`.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

`map = anomalyMap(detector,I,ExecutionEnvironment=executionEnvironment)` also specifies the hardware resource on which to run the detector.

Examples

Display Anomaly Map over Test Image

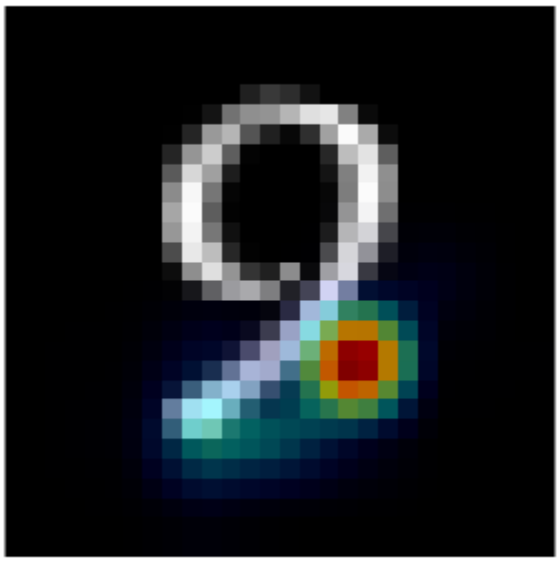
Load a pretrained FCDD anomaly detector. This detector has been trained to classify the digit 8 as normal and all other digits as anomalies.

```
load("digit8AnomalyDetector.mat");
```

Load test images and corresponding labels, then convert the test images to a formatted `dlarray` with the format label "SSCB" for spatial-spatial-channel-batch. The data set consists of grayscale images of handwritten digits 0–9.

```
[Xtest,gtLabels] = digitTest4DArrayData;
```

Select a test image of the digit 9.



```
digitToTest = "9";
digitIdx = find(gtLabels==digitToTest,1);
imTest = Xtest(:,:,:,digitIdx);
```

Predict the per-pixel anomaly scores for the test image.

```
map = anomalyMap(detector,imTest);
```

Display the anomaly map over the test image.

```
overlay = anomalyMapOverlay(imTest,map);
imagesc(overlay)
axis image off
```

Input Arguments

`detector` — Anomaly detector

`efficientADAnomalyDetector` object | `fcddAnomalyDetector` object | `fastFlowAnomalyDetector` object | `patchCoreAnomalyDetector` object

Anomaly detector, specified as an `efficientADAnomalyDetector` object, an `fcddAnomalyDetector` object, a `fastFlowAnomalyDetector` object, or a `patchCoreAnomalyDetector` object.

`I` — Test image

numeric array | formatted `dlarray` object

Test image, specified in one of these formats:

Format	Supported Detectors
M-by-*N*-by-3 numeric array representing a truecolor image.	EfficientAD, FCDD, FastFlow, PatchCore
M-by-*N*-by-3-by-*B* numeric array representing a batch of *B* truecolor images.	EfficientAD, FCDD, FastFlow, PatchCore
Formatted `dlarray` object with two spatial dimensions and one channel dimension. You can specify multiple test images by including a batch dimension.	EfficientAD, FCDD, FastFlow

FCDD anomaly detectors also support grayscale test images, with one color channel instead of three.

`executionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as `"auto"`, `"gpu"`, or `"cpu"`. The table shows the valid hardware resource values.

Resource	Action
`"auto"`	Use a GPU if it is available. Otherwise, use the CPU.
`"gpu"`	Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
`"cpu"`	Use the CPU.

Output Arguments

`map` — Anomaly score map
M-by-*N* numeric matrix | *M*-by-*N*-by-1-by-*B* numeric array | formatted `dlarray` object

Anomaly score map, returned in one of these formats:

- *M*-by-*N* numeric matrix, when the test image `I` is a 2-D grayscale or truecolor image.
- *M*-by-*N*-by-1-by-*B* numeric array representing a batch of images, when `I` is numeric array representing a batch of images.
- Formatted `dlarray` object, when `I` is a formatted `dlarray` object.

The values in the map are unnormalized. Larger values indicate a greater chance of a pixel being an anomaly. To normalize an anomaly map, use the `percentileNormalizer` object.

Data Types: `single`

Version History

Introduced in R2022b

R2024b: Support for EfficientAD anomaly detector

You can now specify the `detector` argument as an `efficientADAnomalyDetector` object.

R2023a: Support for FastFlow and PatchCore anomaly detectors

You can now specify the `detector` argument as a `fastFlowAnomalyDetector` object or a `patchCoreAnomalyDetector` object.

R2023a: Support for C and GPU code generation

`anomalyMap` now supports the generation of C code (requires MATLAB Coder) and optimized CUDA code (requires GPU Coder).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

FCDD, FastFlow, PatchCore	EfficientAD
• The size of `I` must be fixed at code generation time. • The `executionEnvironment` argument is not supported.	• The datastore data format of `I` is not supported.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

FCDD, FastFlow, PatchCore	EfficientAD
• The size of `I` must be fixed at code generation time. • GPU code generation does not support `gpuArray` inputs. • GPU code generation supports inputs that are defined as half-precision floating point data types. For more information, see `half`. • The `executionEnvironment` argument is not supported.	• The datastore data format of `I` is not supported.

`anomalyMapOverlay` | `percentileNormalizer` | `efficientADAnomalyDetector` | `fcddAnomalyDetector` | `fastFlowAnomalyDetector` | `patchCoreAnomalyDetector` | `classify` | `predict`

anomalyMapOverlay

Overlay heatmap on image using per-pixel anomaly scores

Syntax

```
B = anomalyMapOverlay(I,map)
B = anomalyMapOverlay(I,map,Name=Value)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`B = anomalyMapOverlay(I,map)` fuses an overlay of the per-pixel anomaly scores in `map` as a heatmap on a grayscale or RGB background image, `I`.

Note This functionality requires the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

`B = anomalyMapOverlay(I,map,Name=Value)` specifies options using one or more name-value arguments. For example, `anomalyMapOverlay(I,map,Blend="equal")` blends the score map and the background image with equal weighting.

Examples

Display Anomaly Map over Test Image

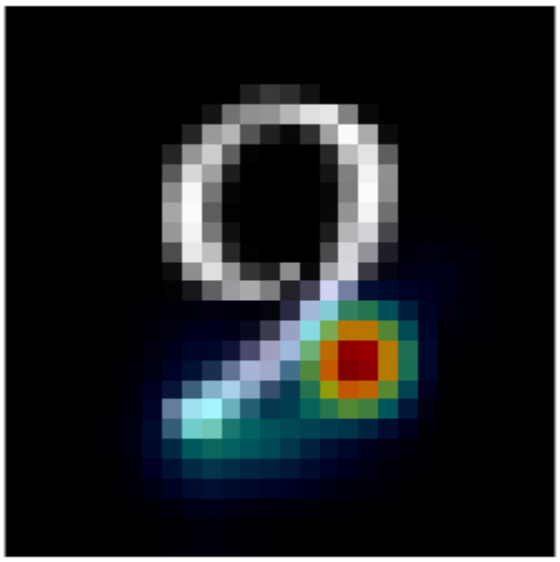
Load a pretrained FCDD anomaly detector. This detector has been trained to classify the digit 8 as normal and all other digits as anomalies.

```
load("digit8AnomalyDetector.mat");
```

Load test images and corresponding labels, then convert the test images to a formatted `dlarray` with the format label "SSCB" for spatial-spatial-channel-batch. The data set consists of grayscale images of handwritten digits 0–9.

```
[Xtest,gtLabels] = digitTest4DArrayData;
```

Select a test image of the digit 9.



```
digitToTest = "9";
digitIdx = find(gtLabels==digitToTest,1);
imTest = Xtest(:,:,:,digitIdx);
```

Predict the per-pixel anomaly scores for the test image.

```
map = anomalyMap(detector,imTest);
```

Display the anomaly map over the test image.

```
overlay = anomalyMapOverlay(imTest,map);
imagesc(overlay)
axis image off
```

Input Arguments

`I` — Background image

M-by-*N*-by-3 numeric array | *M*-by-*N* numeric matrix | *M*-by-*N* logical matrix

Background image, specified in one of these formats:

- *M*-by-*N*-by-3 numeric array representing a truecolor image
- *M*-by-*N* numeric matrix representing a grayscale image
- *M*-by-*N* logical matrix representing a binary image

`map` — Anomaly score map

M-by-*N* numeric matrix

Anomaly score map, specified as an *M*-by-*N* numeric matrix. You can get an anomaly score map using the `anomalyMap` function. Larger values indicate a greater chance that a pixel is an anomaly.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `B = anomalyMapOverlay(I,map,Blend="equal")` blends the score map and the background image with equal weighting.

MapRange — Display range
two-element vector

Display range of the anomaly score map, `map`. The default value is `[min(map(:)) max(map(:))]`.

Blend — Weights to blend map with background image
`"proportional"` (default) | `"equal"` | numeric scalar

Weights to blend the map with background image `I`, specified as `"proportional"`, `"equal"`, or a numeric scalar in the range [0, 1].

Value	Description
`"proportional"`	Overlay `I` and `map` using alpha blending with per-pixel weights proportional to the corresponding values in `map`. The heatmap is more opaque over regions of interest, which have large anomaly scores. The heatmap is more transparent over normal regions, which have small anomaly scores.
`"equal"`	Overlay `I` and `map` using alpha blending with equal weights for the map and background image.
numeric scalar	Overlay `I` and `map` using alpha blending with weight *w* for the map, where *w* is the value of the `Blend` argument. When *w* is `0`, the heatmap is fully transparent and only the background image is visible. When you increase the value of *w*, the heatmap becomes more opaque.

For all values of `Blend`, the weight of the heatmap has an additional multiplicative scale factor, specified by `BlendFactor`. When you account for the additional scale factor, the weight of the heatmap is *w**`BlendFactor` and the weight of the background image is 1 – *w**`BlendFactor`.

BlendFactor — Constant multiplicative scale factor
`1` (default) | numeric scalar

Constant multiplicative factor to apply to the weights of the `Blend` argument, specified as a numeric scalar. Increasing the value of `BlendFactor` increases the brightness of the heatmap over the image.

Example: `BlendFactor=1.2` brightens the heatmap by increasing the weighting by a factor of `1.2`.

Example: `BlendFactor=0.6` darkens the heatmap by decreasing the weighting by a factor of `0.6`.

Colormap — Colormap
`jet(256)` (default) | 256-by-3 numeric matrix

Colormap, specified as a 256-by-3 numeric matrix with values in the range [0, 1]. Each row is a three-element RGB triplet that specifies the red, green, and blue components of a single color of the colormap.

Data Types: `single` | `double`

Output Arguments

B — RGB image with heatmap overlay
M-by-*N*-by-3 numeric array

RGB image with heatmap overlay, returned as an *M*-by-*N*-by-3 numeric array.

Data Types: `uint8`

Version History

Introduced in R2022b

anomalyThreshold

Optimal anomaly threshold for set of anomaly scores and corresponding labels

Syntax

```
t = anomalyThreshold(gtLabels,scores,anomalyLabels)
t = anomalyThreshold(gtLabels,scores,anomalyLabels,optimMethod)
t = anomalyThreshold(gtLabels,scores,anomalyLabels,MaxFalsePositiveRate=
maxFPR)
t = anomalyThreshold(gtLabels,scores,anomalyLabels,MaxFalseNegativeRate=
maxFNR)
[t,anomalyROC] = anomalyThreshold( ___ )
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`t = anomalyThreshold(gtLabels,scores,anomalyLabels)` calculates the optimal anomaly threshold given per-image anomaly scores and corresponding ground truth labels. `anomalyLabels` indicates which class labels in `gtLabels` belong to the anomaly (positive) class. When performing anomaly detection, images with scores below the calculated threshold are considered normal images and images with scores above the threshold are considered anomalous images.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

`t = anomalyThreshold(gtLabels,scores,anomalyLabels,optimMethod)` also specifies the optimization method.

`t = anomalyThreshold(gtLabels,scores,anomalyLabels,MaxFalsePositiveRate=maxFPR)` also specifies the maximum false positive rate.

`t = anomalyThreshold(gtLabels,scores,anomalyLabels,MaxFalseNegativeRate=maxFNR)` also specifies the maximum false negative rate.

`[t,anomalyROC] = anomalyThreshold( ___ )` also returns the receiver operating characteristic (ROC) curve and performance metrics.

Examples

Calculate Optimal Anomaly Threshold

Load calibration images and corresponding labels, then create a datastore that reads the calibration data. The data set consists of grayscale images of handwritten digits 0–9.

```
[Xcal,gtLabels] = digitTest4DArrayData;
dsCal = arrayDatastore(Xcal,IterationDimension=4);
```

Load a pretrained FCDD anomaly detector. This detector has been trained to classify the digit 8 as normal and all other digits as anomalies. Therefore, specify the set of anomaly labels as the set of digits between 0 and 9, excluding 8.

```
load("digit8AnomalyDetector.mat");
anomalyLabels = setdiff(string(0:9),"8");
```

Predict the anomaly score of each calibration image.

```
scores = predict(detector,dsCal);
```

Calculate the optimal threshold and corresponding ROC metrics from the anomaly scores and ground truth labels.

```
[T,roc] = anomalyThreshold(gtLabels,scores,anomalyLabels)
```

```
T = single

2.9632e-04

roc =
  rocmetrics with properties:

    Metrics: [4980×4 table]

Properties, Methods
```

Set the `Threshold` property of the FCDD anomaly detector as the optimal threshold.

```
net.Threshold = T;
```

Input Arguments

`gtLabels` — Ground truth labels

numeric vector | logical vector | categorical vector

Ground truth labels for each image, specified as a numeric vector, logical vector, or categorical vector. The `anomalyThreshold` function converts the labels into a logical vector according to the set of anomaly labels in `anomalyLabels`.

`scores` — Predicted anomaly scores

numeric vector

Predicted anomaly score for each image, specified as a numeric vector of the same length as `gtLabels`.

`anomalyLabels` — Anomaly labels

numeric vector | logical vector | categorical vector | string vector

Anomaly labels, specified as a vector of the same data type as `gtLabels`. When `gtLabels` is categorical, `anomalyLabels` can be of data type string whose values correspond to categories in `gtLabels`.

The `anomalyThreshold` function converts all ground truth labels in `gtLabels` that belong to the set of anomaly labels to a logical `true`, indicating an anomaly (positive detection). The function converts all other ground truth labels to a logical `false`, indicating normality (negative detection).

`optimMethod` — Optimization method
`"YoudensIndexROC"` (default) | `"NearestZeroOneROC"` | `"MaxF1Score"`

Optimization method, specified as one of the values in the table.

Optimization Method	Description
`"YoudensIndexROC"`	The optimal threshold is the point on the ROC curve with the maximum difference between the true positive rate (TPR) and false positive rate (FPR). The difference between TPR and FPR is also known as Youden's index or Youden's J statistic.
`"NearestZeroOneROC"`	The optimal threshold is the point on the ROC curve nearest to the coordinate (0, 1), where the FPR is 0 and the TPR is 1. This point minimizes the Euclidean distance between the ROC curve and the (0,1) point.
`"MaxF1Score"`	The optimal threshold is the point on the precision-recall (PR) curve that maximizes the F1 score. This value is the harmonic mean of the precision and recall values.

Data Types: `char` | `string`

`maxFPR` — Maximum false positive rate
`0` (default) | number in the range [0, 1]

Maximum false positive rate (FPR), specified as a number in the range [0, 1]. The optimal threshold is the point on the ROC curve where the FPR is less than or equal to `maxFPR`.

`maxFNR` — Maximum false negative rate
`0` (default) | number in the range [0, 1]

Maximum false negative rate (FNR), specified as a number in the range [0, 1]. The optimal threshold is the point on the ROC curve where the FNR is less than or equal to `maxFNR`.

Output Arguments

`t` — Optimal threshold
numeric scalar

Optimal threshold, returned as a numeric scalar of the same data type as `scores`.

`anomalyROC` — ROC curve and performance metrics
`rocmetrics` object

ROC curve and performance metrics, returned as a `rocmetrics` object.

Tips

- You can plot ROC and PR curves returned by `anomalyROC` using the `plot` function.

classify

Classify image as normal or anomalousJAB

Syntax

```
isAnomaly = classify(detector,I)
isAnomaly = classify(detector,I,Name=Value)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`isAnomaly = classify(detector,I)` predicts whether test image `I` is anomalous or normal, given an anomaly detector with an anomaly threshold.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

`isAnomaly = classify(detector,I,Name=Value)` specifies options using one or more name-value arguments. For example, `classify(detector,I,MiniBatchSize=32)` limits the batch size to 32.

Examples

Calculate Metrics for Trained FCDD Anomaly Detector

Load test images and corresponding labels, then create a datastore that reads the test data. The data set consists of grayscale images of handwritten digits 0–9.

```
[Xtest,gtLabels] = digitTest4DArrayData;
dsTest = arrayDatastore(Xtest,IterationDimension=4);
```

Load a pretrained FCDD anomaly detector. This detector has been trained to classify the digit 8 as normal and all other digits as anomalies. Therefore, specify the set of anomaly labels as the set of digits between 0 and 9, excluding 8.

```
load("digit8AnomalyDetector.mat");
anomalyLabels = setdiff(string(0:9),"8");
```

Classify each test image as normal or anomalous.

```
predLabels = classify(detector,dsTest);
```

Calculate metrics for the anomaly detection results.

```
metrics = evaluateAnomalyDetection(predLabels,gtLabels,anomalyLabels)
```

```

```

Input Arguments

`detector` — Anomaly detector

`efficientADAnomalyDetector` object | `fcddAnomalyDetector` object | `fastFlowAnomalyDetector` object | `patchCoreAnomalyDetector` object

Anomaly detector, specified as an `efficientADAnomalyDetector` object, an `fcddAnomalyDetector` object, a `fastFlowAnomalyDetector` object, or a `patchCoreAnomalyDetector` object. You must set the `Threshold` property of the detector before calling this function.

`I` — Test image

numeric array | datastore | formatted `dlarray` object

Test image, specified in one of these formats:

Format	Supported Detectors
M-by-*N*-by-3 numeric array representing a truecolor image.	EfficientAD, FCDD, FastFlow, PatchCore
M-by-*N*-by-3-by-*B* numeric array representing a batch of *B* truecolor images.	EfficientAD, FCDD, FastFlow, PatchCore

Format	Supported Detectors
Datastore that reads and returns truecolor images. The images must all have the same size.	EfficientAD, FCDD, FastFlow, PatchCore
Formatted `dlarray` object with two spatial dimensions and one channel dimension. You can specify multiple test images by including a batch dimension.	EfficientAD, FCDD, FastFlow

FCDD anomaly detectors also support grayscale test images, with one color channel instead of three.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `isAnomaly = classify(detector,I,MiniBatchSize=32)` limits the batch size to 32.

`MiniBatchSize` — Size of batches
128 (default) | positive integer

Size of batches for calculating predictions, specified as a positive integer. Larger batch sizes lead to faster processing but take up more memory.

`ScoreFunction` — Function for computing scalar score from anomaly map
function handle

Function for computing a scalar score from an anomaly map when `detector` is an `efficientADAnomalyDetector` object, an `fcddAnomalyDetector` object, or a `fastFlowAnomalyDetector` object, specified as a function handle. The function handle `ScoreFunction` must represent a function that accepts the input data `I` and returns an output in the form of a numeric scalar. `I` must be 2-D numeric image data, `dlarray` data with two spatial dimensions, or a datastore. The default value of `ScoreFunction` depends on the type of detector specified:

Detector Specified in `detector` Argument	Default `ScoreFunction` Value
FastFlow	`@(I)max(I,[],[1 2])`
EfficientAD	`@(I)max(I,[],[1 2 3])`
FCDD	`@(I)mean(I,[1 2])`
PatchCore	Not supported

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as `"auto"`, `"gpu"`, or `"cpu"`. The table shows the valid hardware resource values.

Resource	Action
`"auto"`	Use a GPU if it is available. Otherwise, use the CPU.

Resource	Action
`"gpu"`	Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
`"cpu"`	Use the CPU.

Output Arguments

`isAnomaly` — Test image is anomaly
N-element logical vector

Test image is anomaly, returned as an *N*-element logical vector, where *N* is the number of test images in `I`. The value `true` indicates an anomaly (positive detection). The value `false` indicates normality (negative detection).

Data Types: `logical`

Version History

Introduced in R2022b

R2024b: Support for EfficientAD anomaly detector

You can now specify the `detector` argument as an `efficientADAnomalyDetector` object.

R2023a: Support for FastFlow and PatchCore anomaly detectors

You can now specify the `detector` argument as a `fastFlowAnomalyDetector` object or a `patchCoreAnomalyDetector` object.

R2023a: Support for C and GPU code generation

`classify` now supports the generation of C code (requires MATLAB Coder) and optimized CUDA code (requires GPU Coder).

R2024a: Option to specify custom anomaly score function for FastFlow and FCDD detectors

Specify a custom anomaly score function, which the `classify` function uses to compute a scalar score from the anomaly map, by using the `ScoreFunction` name-value argument.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

FCDD, FastFlow, PatchCore	EfficientAD
• The size of `I` must be fixed at code generation time. • The only name-value argument supported for code generation is `MiniBatchSize`. The name-value argument must be a compile-time constant.	• The datastore data format of `I` is not supported.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

FCDD, FastFlow, PatchCore	EfficientAD
• The size of `I` must be fixed at code generation time. • GPU code generation does not support `gpuArray` inputs. • GPU code generation supports inputs that are defined as half-precision floating point data types. For more information, see `half`. • The only name-value argument supported for code generation is `MiniBatchSize`. The name-value argument must be a compile-time constant.	• The datastore data format of `I` is not supported.

evaluateAnomalyDetection

Evaluate anomaly detection results against ground truth

Syntax

```
metrics = evaluateAnomalyDetection(predLabels,gtLabels,anomalyLabels)
metrics = evaluateAnomalyDetection(predLabels,gtLabels,anomalyLabels,Verbose=
tf)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`metrics = evaluateAnomalyDetection(predLabels,gtLabels,anomalyLabels)` calculates various metrics to evaluate the quality of the anomaly detection results `predLabels` against the ground truth `gtLabels`. `anomalyLabels` indicates which class labels in `gtLabels` belong to the anomaly (positive) class

Note This functionality requires the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

`metrics = evaluateAnomalyDetection(predLabels,gtLabels,anomalyLabels,Verbose=tf)` also displays the evaluation progress information in the command window.

Examples

Calculate Metrics for Trained FCDD Anomaly Detector

Load test images and corresponding labels, then create a datastore that reads the test data. The data set consists of grayscale images of handwritten digits 0–9.

```
[Xtest,gtLabels] = digitTest4DArrayData;
dsTest = arrayDatastore(Xtest,IterationDimension=4);
```

Load a pretrained FCDD anomaly detector. This detector has been trained to classify the digit 8 as normal and all other digits as anomalies. Therefore, specify the set of anomaly labels as the set of digits between 0 and 9, excluding 8.

```
load("digit8AnomalyDetector.mat");
anomalyLabels = setdiff(string(0:9),"8");
```

Classify each test image as normal or anomalous.

```
predLabels = classify(detector,dsTest);
```

Calculate metrics for the anomaly detection results.

```
metrics = evaluateAnomalyDetection(predLabels,gtLabels,anomalyLabels)

Evaluating anomaly detection results

    Normal       465         35
    Anomaly     1134       3366
```

Input Arguments

`predLabels` — Predicted labels

logical vector

Predicted labels, specified as a logical vector. The label value `0` (`false`) corresponds to the normal (negative) class. The value `1` (`true`) corresponds to the anomaly (positive) class. You can get the predicted labels using the `classify` function.

Data Types: `logical`

`gtLabels` — Ground truth labels

numeric vector | logical vector | categorical vector

Ground truth labels for each image, specified as a numeric vector, logical vector, or categorical vector. The `evaluateAnomalyDetection` function converts the labels into a logical vector according to the set of anomaly labels in `anomalyLabels`.

`anomalyLabels` — Anomaly labels

numeric vector | logical vector | categorical vector | string vector

Anomaly labels, specified as a vector of the same data type as `gtLabels`. When `gtLabels` is categorical, `anomalyLabels` can be of data type string whose values correspond to categories in `gtLabels`.

The `evaluateAnomalyDetection` function converts all ground truth labels in `gtLabels` that belong to the set of anomaly labels to a logical `true`, indicating an anomaly (positive detection). The function converts all other ground truth labels to a logical `false`, indicating normality (negative detection).

`tf` — Display evaluation progress
`1` (default) | `0`

Display evaluation progress information in the command window, specified as a numeric or logical `1` (`true`) or `0` (`false`). The displayed information includes a progress bar, elapsed time, estimated time remaining, and data set metrics.

Data Types: `logical`

Output Arguments

`metrics` — Anomaly detection metrics
`anomalyDetectionMetrics` object

Anomaly detection metrics, returned as an `anomalyDetectionMetrics` object.

Version History

Introduced in R2022b

predict

Predict unnormalized anomaly scores

Syntax

```
scores = predict(detector,I)
scores = predict(detector,I,Name=Value)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`scores = predict(detector,I)` calculates the unnormalized anomaly scores predicted by an anomaly detector during inference for a set of test images, `I`. Use this function to get predictions from the output layers of the detector during inference.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

`scores = predict(detector,I,Name=Value)` specifies options using one or more name-value arguments. For example, `predict(detector,I,MiniBatchSize=32)` limits the batch size to 32.

Examples

Calculate Optimal Anomaly Threshold

Load calibration images and corresponding labels, then create a datastore that reads the calibration data. The data set consists of grayscale images of handwritten digits 0–9.

```
[Xcal,gtLabels] = digitTest4DArrayData;
dsCal = arrayDatastore(Xcal,IterationDimension=4);
```

Load a pretrained FCDD anomaly detector. This detector has been trained to classify the digit 8 as normal and all other digits as anomalies. Therefore, specify the set of anomaly labels as the set of digits between 0 and 9, excluding 8.

```
load("digit8AnomalyDetector.mat");
anomalyLabels = setdiff(string(0:9),"8");
```

Predict the anomaly score of each calibration image.

```
scores = predict(detector,dsCal);
```

Calculate the optimal threshold and corresponding ROC metrics from the anomaly scores and ground truth labels.

```
[T,roc] = anomalyThreshold(gtLabels,scores,anomalyLabels)

T = single

2.9632e-04

roc =
  rocmetrics with properties:

    Metrics: [4980×4 table]

Properties, Methods
```

Set the `Threshold` property of the FCDD anomaly detector as the optimal threshold.

```
net.Threshold = T;
```

Input Arguments

`detector` — Anomaly detector

`efficientADAnomalyDetector` object | `fcddAnomalyDetector` object | `fastFlowAnomalyDetector` object | `patchCoreAnomalyDetector` object

Anomaly detector, specified as an `efficientADAnomalyDetector` object, an `fcddAnomalyDetector` object, a `fastFlowAnomalyDetector` object, or a `patchCoreAnomalyDetector` object.

`I` — Test image

numeric array | datastore | formatted `dlarray` object

Test image, specified in one of these formats:

Format	Supported Detectors
M-by-*N*-by-3 numeric array representing a truecolor image.	EfficientAD, FCDD, FastFlow, PatchCore
M-by-*N*-by-3-by-*B* numeric array representing a batch of *B* truecolor images.	EfficientAD, FCDD, FastFlow, PatchCore
Datastore that reads and returns truecolor images. The images must all have the same size.	EfficientAD, FCDD, FastFlow, PatchCore
Formatted `dlarray` object with two spatial dimensions and one channel dimension. You can specify multiple test images by including a batch dimension.	EfficientAD, FCDD, FastFlow

FCDD anomaly detectors also support grayscale test images, with one color channel instead of three.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `isAnomaly = predict(detector,I,MiniBatchSize=32)` limits the batch size to 32.

`MiniBatchSize` — Size of batches
128 (default) | positive integer

Size of batches for calculating predictions, specified as a positive integer. Larger batch sizes lead to faster processing but take up more memory.

`ScoreFunction` — Function for computing scalar score from anomaly map
function handle

Function for computing a scalar score from an anomaly map when `detector` is an `efficientADAnomalyDetector` object, an `fcddAnomalyDetector` object, or a `fastFlowAnomalyDetector` object, specified as a function handle. The function handle `ScoreFunction` must represent a function that accepts the input data `I` and returns an output in the form of a numeric scalar. `I` must be 2-D numeric image data, `dlarray` data with two spatial dimensions, or a datastore. The default value of `ScoreFunction` depends on the type of detector specified:

Detector Specified in `detector` Argument	Default `ScoreFunction` Value
FastFlow	`@(I)max(I,[],[1 2])`
EfficientAD	`@(I)max(I,[],[1 2 3])`
FCDD	`@(I)mean(I,[1 2])`
PatchCore	Not supported

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as `"auto"`, `"gpu"`, or `"cpu"`. The table shows the valid hardware resource values.

Resource	Action
`"auto"`	Use a GPU if it is available. Otherwise, use the CPU.
`"gpu"`	Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
`"cpu"`	Use the CPU.

Output Arguments

`scores` — Predicted anomaly scores
numeric scalar | numeric vector | formatted `dlarray` object

Predicted anomaly scores, returned as a numeric scalar, numeric vector, or formatted `dlarray` object. `scores` contains one element for each image in `I`.

Version History

Introduced in R2022b

R2024b: Support for EfficientAD anomaly detector

You can now specify the `detector` argument as an `efficientADAnomalyDetector` object.

R2023a: Support for FastFlow and PatchCore anomaly detectors

You can now specify the `detector` argument as a `fastFlowAnomalyDetector` object or a `patchCoreAnomalyDetector` object.

R2023a: Support for C and GPU code generation

`predict` now supports the generation of C code (requires MATLAB Coder) and optimized CUDA code (requires GPU Coder).

R2024a: Option to specify custom anomaly score function for FastFlow and FCDD detectors

Specify a custom anomaly score function, which the `predict` function uses to compute a scalar score from the anomaly map, by using the `ScoreFunction` name-value argument.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

FCDD, FastFlow, PatchCore	EfficientAD
• The size of `I` must be fixed at code generation time. • The only name-value argument supported for code generation is `MiniBatchSize`. The name-value argument must be a compile-time constant.	• The datastore data format of `I` is not supported.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

FCDD, FastFlow, PatchCore	EfficientAD
• The size of `I` must be fixed at code generation time. • GPU code generation does not support `gpuArray` inputs. • GPU code generation supports inputs that are defined as half-precision floating point data types. For more information, see `half`. • The only name-value argument supported for code generation is `MiniBatchSize`. The name-value argument must be a compile-time constant.	• The datastore data format of `I` is not supported.

normalize

Normalize anomaly score map using percentiles

Syntax

```
normalizedMap = normalize(normalizer,map)
normalizedMap = normalize(normalizer,map,Name=Value)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`normalizedMap = normalize(normalizer,map)` normalizes an anomaly map, `map`, using the map percentile statistics computed by the `percentileNormalizer` object `normalizer`.

Note This functionality requires the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

`normalizedMap = normalize(normalizer,map,Name=Value)` specifies options for anomaly map normalization using one or more name-value arguments. For example, `NormalOutputRange=[0 0.2]` specifies the normalized map output range of a normal image as `[0, 0.2]`.

Input Arguments

`normalizer` — Percentile normalizer

`percentileNormalizer` object

Percentile normalizer, specified as a `percentileNormalizer` object.

`map` — Anomaly score map

M-by-*N* numeric matrix

Anomaly score map, specified as an *M*-by-*N* numeric matrix. You can produce an anomaly score map using the `anomalyMap` function. Larger values indicate a greater chance that the corresponding pixel is an anomaly.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `normalize(normalizer,map,NormalOutputRange=[0 0.2])` specifies the normalized map output range of a normal image as `[0, 0.2]`.

`NormalOutputRange` — Normalized map output range of normal image

`[0 0.1]` (default) | two-element row vector

Normalized map output range of a normal image, specified as a two-element row vector. The `percentileNormalizer` function linearly maps this range to the range specified by the `NormalPercentileRange` name-value argument. To learn more, see “Linear Mapping for Anomaly Map Normalization” on page 2-1648.

`OutputClipRange` — Clipping of normalized heat map output range
`[ ]` (default) | two-element row vector

Clipping of the normalized heat map output range, specified by a two-element row vector. This argument specifies the limits of the output normalized anomaly scores, and both values must be within the range specified by the `NormalOutputRange` name-value argument.

Output Arguments

`normalizedMap` — Normalized anomaly score map
M-by-*N* numeric matrix

Normalized anomaly score map, returned as an *M*-by-*N* numeric matrix.

Tips

- The normalized anomaly score values returned in the `normalizedMap` argument are unbounded. To limit the range of the normalized anomaly scores, such as to [0, 1] for use with `anomalyMapOverlay`, specify the range using the `OutputClipRange` name-value argument.

Version History

Introduced in R2024b

splitAnomalyData

Split data into training, validation and testing sets for anomaly detection

Syntax

```
[dsTrain,dsVal,dsTest] = splitAnomalyData(ds,anomalyLabels)
[dsTrain,trainLabels,dsVal,valLabels,dsTest,testLabels] = splitAnomalyData(
ds,gtLabels,anomalyLabels)
[ ___ ] = splitAnomalyData( ___ ,Name=Value)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`[dsTrain,dsVal,dsTest] = splitAnomalyData(ds,anomalyLabels)` automatically splits the input image datastore, `ds`, into three datastores for training, validation and testing of anomaly detection networks. `anomalyLabels` indicates which class labels in `gtLabels` belong to the anomaly (positive) class. By default, 70% of the total input data is used for training, 10% are used for validation, and 20% are used for testing. By default, the training datastore does not include anomaly images.

Note This functionality requires the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

`[dsTrain,trainLabels,dsVal,valLabels,dsTest,testLabels] = splitAnomalyData(ds,gtLabels,anomalyLabels)` automatically splits the input datastore, `ds`, into three datastores and their labels for training, validation and testing of anomaly detection networks. `gtLabels` represents the ground-truth labels for each corresponding image in the datastore and `anomalyLabels` determine which labels in `gtLabels` belong to the anomaly class.

`[ ___ ] = splitAnomalyData( ___ ,Name=Value)` uses name-value arguments to perform custom proportioning of the images. You can specify either the proportion of images in each datastore on page 3-0 or the proportion of anomaly and normal images on page 3-0 .

If you specify name-value arguments for both proportioning strategies, then `splitAnomalyData` uses the arguments that specify the proportion of images in each datastore. In this case, the function ignores the arguments that specify the proportion of anomaly and normal images.

Examples

Split Datastore of Labeled Anomaly Images

Load a data set that consists of images of digits from 0 to 9.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata","digits","synthetic");
ds = imageDatastore(dataDir,IncludeSubfolders=true, ...
    LabelSource="foldernames");
```

Specify the digits that count as anomalous. For instance, consider images of the digit 8 to be normal, and all other digits to be anomalous.

```
anomalyLabels = ["0","1","2","3","4","5","6","7","9"];
```

Split the training data into training, validation, and testing datastores.

```
[dsTrain,dsVal,dsTest] = splitAnomalyData(ds,anomalyLabels);
```

```
Splitting anomaly dataset
-------------------------
* Finalizing... Done.
* Number of files and proportions per class in all the datasets:
```

	Input		Train		Validation		Test	
	NumFiles	Ratio	NumFiles	Ratio	NumFiles	Ratio	NumFiles	Ratio
0	101	0.1	0	0	34	0.10863	67	0.10686
1	101	0.1	0	0	34	0.10863	67	0.10686
2	101	0.1	0	0	34	0.10863	67	0.10686
3	101	0.1	0	0	34	0.10863	67	0.10686
4	101	0.1	0	0	33	0.10543	68	0.10845
5	101	0.1	0	0	34	0.10863	67	0.10686
6	101	0.1	0	0	33	0.10543	68	0.10845
7	101	0.1	0	0	34	0.10863	67	0.10686
8	101	0.1	70	1	10	0.031949	21	0.033493
9	101	0.1	0	0	33	0.10543	68	0.10845

Input Arguments

`ds` — Data set

datastore

Data set of normal and anomaly images, specified as a datastore. If you do not specify the `gtLabels` argument, then `ds` must be an image datastore containing labeled images.

`gtLabels` — Ground truth labels

numeric vector | logical vector | categorical vector

Ground truth labels for each image, specified as a numeric vector, logical vector, or categorical vector. The `splitAnomalyData` function converts the labels into a logical vector according to the set of anomaly labels in `anomalyLabels`.

`anomalyLabels` — Anomaly labels

numeric vector | logical vector | categorical vector | string vector

Anomaly labels, specified as a vector of the same data type as `gtLabels`. When `gtLabels` is categorical, `anomalyLabels` can be of data type string whose values correspond to categories in `gtLabels`.

The `splitAnomalyData` function converts all ground truth labels in `gtLabels` that belong to the set of anomaly labels to a logical `true`, indicating an anomaly (positive detection). The function converts all other ground truth labels to a logical `false`, indicating normality (negative detection).

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `[dsTrain,dsVal,dsTest] = splitAnomalyData(ds,anomalyLabels,DataAllocationRatio=[0.8 0.1 0.1])` assigns 80% of the total input data for training, 10% for validation, and 10% for testing

Specify Proportion of Images in Each Datastore

`DataAllocationRatio` — Proportion of input data to include in each datastore
`[0.7 0.1 0.2]` (default) | 1-by-3 numeric vector

Proportion of input data to include in the train, validation and test datastores respectively, specified as a 1-by-3 numeric vector. The function ignores class labels when splitting the data. The elements of the vector must sum to a number between 0 and 1. If the elements sum to a number less than 1, then the `splitAnomalyData` function does not allocate the remaining data to a training, validation, or testing datastore.

`KeepAnomalyLabelsInTrainingDatastore` — Include anomaly images in training datastore
`false` or `0` (default) | `true` or `1`

Include anomaly images in the training datastore, specified as a numeric or logical `false` (`0`) or `true` (`1`).

`KeepUnusedAnomalyLabels` — Include all anomaly images in validation and testing datastores
`true` or `1` (default) | `false` or `0`

Include all anomaly images in the validation and testing datastores, specified as a numeric or logical `true` (`1`) or `false` (`0`). This argument applies only when the value of `KeepAnomalyLabelsInTrainingDatastore` is `false`.

By default, `KeepUnusedAnomalyLabels` is `true` and the `splitAnomalyData` function distributes all anomaly images to the validation and testing datastores. Therefore, the validation datastore `dsVal` and testing datastore `dsTest` have a higher proportion of anomaly to normal labels than the input datastore `ds`.

When `KeepUnusedAnomalyLabels` is `false`, `splitAnomalyData` function omits some anomaly files from `dsVal` and `dsTest`. Therefore, `dsVal` and `dsTest` use the same proportion of anomaly to normal images as `ds`. Specify `KeepUnusedAnomalyLabels` as `false` for stratified partitions.

Specify Proportion of Normal and Anomaly Images

`NormalLabelsRatio` — Ratio of files with normal class labels
`[]` (default) | 1-by-3 numeric vector

Ratio of files with normal class labels to include in the training, validation, and testing datastores, specified as a 1-by-3 numeric vector. The elements of the vector must sum to a number between 0 and

1. If the elements sum to a number less than 1, then the `splitAnomalyData` function does not allocate the remaining normal data to a training, validation, or testing datastore.

Example: `NormalLabelsRatio=[0.8 0.1 0.1]` assigns 80% of the normal data for training, 10% for validation, and 10% for testing

`AnomalyLabelsRatio` — Ratio of files with anomaly class labels
`[]` (default) | 1-by-3 numeric vector

Ratio of files with normal class labels to include in the training, validation, and testing datastores, specified as a 1-by-3 numeric vector. The elements of the vector must sum to a number between 0 and 1. If the elements sum to a number less than 1, then the `splitAnomalyData` function does not allocate the remaining anomaly data to a training, validation, or testing datastore.

Example: `AnomalyLabelsRatio=[0.1 0.1 0.5]` assigns 10% of the anomaly data for training, 10% for validation, and 50% for testing, and omits the remaining 30% of the anomaly data

Other Partitioning Options

`Verbose` — Display statistics
`true` or `1` (default) | `false` or `0`

Display statistics of the partitioned data for each class, specified as a numeric or logical `true` (`1`) or `false` (`0`).

Output Arguments

`dsTrain` — Training datastore
datastore

Training datastore, returned as a datastore of the same type as `ds`.

`dsVal` — Validation datastore
datastore

Validation datastore, returned as a datastore of the same type as `ds`.

`dsTest` — Testing datastore
datastore

Testing datastore, returned as a datastore of the same type as `ds`.

`trainLabels` — Labels of data in training datastore
numeric vector | logical vector | categorical vector

Labels of data in training datastore, returned as a numeric vector, logical vector, or categorical vector.

`valLabels` — Labels of data in validation datastore
numeric vector | logical vector | categorical vector

Labels of data in validation datastore, returned as a numeric vector, logical vector, or categorical vector.

`testLabels` — Labels of data in testing datastore
numeric vector | logical vector | categorical vector

Labels of data in testing datastore, returned as a numeric vector, logical vector, or categorical vector.

`trainFCDDAnomalyDetector` | `trainFastFlowAnomalyDetector`

trainEfficientADAnomalyDetector

Train EfficientAD anomaly detection network

Syntax

```
detector = trainEfficientADAnomalyDetector(normalData,detectorIn,options)
detector = trainEfficientADAnomalyDetector( ___ ,NormalizationDataRatio=Ratio)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`detector = trainEfficientADAnomalyDetector(normalData,detectorIn,options)` trains the input EfficientAD anomaly detection network `detectorIn`. The training data consists of the specified normal images `normalData`.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Note It is recommended that you also have Parallel Computing Toolbox to use with a CUDA enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

`detector = trainEfficientADAnomalyDetector( ___ ,NormalizationDataRatio=Ratio)` specifies the data ratio to use for anomaly map normalization, in addition to the input arguments from the previous syntax.

Input Arguments

`detectorIn` — EfficientAD anomaly detector to train

`efficientADAnomalyDetector` object

EfficientAD anomaly detector to train, specified as an `efficientADAnomalyDetector` object.

`normalData` — Training data

datastore

Training data, specified as a datastore. The training data consists of samples of normal images. Do not include anomaly images in the training data.

`options` — Training options

`TrainingOptionsSGDM` object | `TrainingOptionsRMSProp` object | `TrainingOptionsADAM` object

Training options, specified as a `TrainingOptionsSGDM`, `TrainingOptionsRMSProp`, or `TrainingOptionsADAM` object returned by the `trainingOptions` function. To specify the solver name and other options for network training, use the `trainingOptions` function.

Tip When you perform tile-based training and GPU memory is limited, reduce the mini-batch size using the `MiniBatchSize` argument of the `trainingOptions` function, at the expense of slower computation speed.

`Ratio` — Proportion of data to use for anomaly map normalization

`0.1` (default) | numeric scalar in range [0, 1]

Proportion of training data to use for anomaly map normalization and optionally, optimization of anomaly score for logical anomalies, specified as a numeric scalar in the range [0, 1]. For example, a data ratio of 0.1 specifies that the detector must use only 10% of the training data for anomaly map normalization. To not perform the normalization, set the value to 0. Use a higher percentage of training data for normalization when your training data size is large.

Note When you specify the `OptimizeScoreForLogicalAnomalies` name-value argument as `true`, the `trainEfficientADAnomalyDetector` function additionally optimizes the anomaly score for improved detection of logical anomalies using the specified portion of training data.

Output Arguments

`detector` — Trained EfficientAD anomaly detector

`efficientADAnomalyDetector` object

Trained EfficientAD anomaly detector, returned as an `efficientADAnomalyDetector` object.

Tips

- For a given training image size and number of training images, if the peak memory usage for creating a memory bank exceeds the available memory, EfficientAD outputs a warning. To address insufficient memory, try reducing image resolution, using fewer training images, or enhancing GPU performance.

trainFastFlowAnomalyDetector

Train FastFlow anomaly detection network

Syntax

```
detector = trainFastFlowAnomalyDetector(normalData,detectorIn,options)
[detector,info] = trainFastFlowAnomalyDetector(normalData,detectorIn,options)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`detector = trainFastFlowAnomalyDetector(normalData,detectorIn,options)` trains the input FastFlow anomaly detection network `detectorIn`. The training data consists of normal images in `normalData`. The `options` argument controls options for training.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Note It is recommended that you also have Parallel Computing Toolbox to use with a CUDA-enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

`[detector,info] = trainFastFlowAnomalyDetector(normalData,detectorIn,options)` also returns information on the training progress, such as the training accuracy and learning rate for each iteration.

Examples

Train FastFlow Anomaly Detector

Load a data set that consists of images of digits from 0 to 9. Consider images of the digit 8 to be normal, and all other digits to be anomalous.

```
trainDir = fullfile(toolboxdir("vision"),"visiondata","digits","synthetic");
dsNormal = imageDatastore(fullfile(trainDir,"8"));
```

Create a `fastFlowAnomalyDetector` object.

```
untrainedDetector = fastFlowAnomalyDetector;
```

Specify training options for Adam optimization.

```
options = trainingOptions("adam", ...
   InitialLearnRate = 1e-2, ...
```

```
    MaxEpochs=40, ...
    VerboseFrequency=4, ...
    MiniBatchSize=250, ...
    Shuffle="every-epoch", ...
    Plots="none");
```

Train the anomaly detector.

```
detector = trainFastFlowAnomalyDetector(dsNormal,untrainedDetector,options);
```

```

T = single

-0.0833

roc =
  rocmetrics with properties:

    Metrics: [111×4 table]

Properties, Methods
```

```
detector.Threshold = T;
```

Input Arguments

`detectorIn` — FastFlow anomaly detector to train

`fastFlowAnomalyDetector` object

FastFlow anomaly detector to train, specified as a `fastFlowAnomalyDetector` object.

`normalData` — Training data

datastore

Training data, specified as a datastore. The training data consists of samples of normal images. Do not include anomaly images in the training data.

`options` — Training options
`TrainingOptionsSGDM` object | `TrainingOptionsRMSProp` object | `TrainingOptionsADAM` object

Training options, specified as a `TrainingOptionsSGDM`, `TrainingOptionsRMSProp`, or `TrainingOptionsADAM` object returned by the `trainingOptions` function. To specify the solver name and other options for network training, use the `trainingOptions` function. You must set the `BatchNormalizationStatistics` property of the object as `"moving"`.

Note If you specify the `OutputFcn` function handle using the `OutputFcn` name-value argument, it must use a per-epoch `info` structure with these fields:

- `Epoch`
- `Iteration`
- `TimeElapsed`
- `LearnRate`
- `TrainingLoss`

Output Arguments

`detector` — Trained FastFlow anomaly detector
`fastFlowAnomalyDetector` object

Trained FastFlow anomaly detector, returned as a `fastFlowAnomalyDetector` object.

`info` — Training progress information
structure array

Training progress information, returned as a structure array with these fields.

- `Epoch` — Epoch
- `Iteration` — Iteration
- `TimeElapsed` — Total elapsed duration
- `LearnRate` — Learning rate for each iteration
- `TrainingLoss` — Loss at the end of each iteration
- `ValidationLoss` — Loss on the validation data

If you specify AUC as a metric to track using the `Metrics` property of the `trainingOptions` function, then the structure array will additionally include this field:

- `ValidationAUC` — Area under the ROC curve (AUC) metric values for the validation data

---

Note If you specify the `ValidationData` training option to return `ValidationLoss` and `ValidationAUC`, you must specify your data in one of these formats:

- A two-element cell array `{dsNormal, dsDefect}`, where `dsNormal` is a datastore of normal images, and `dsDefect` is a datastore of anomalous images.
- A single datastore. You must organize the datastore so that calling the `read` and `readall` functions on it returns a table or two-element cell array of the form `{I, Labels}`, where `I` is the image data and `Labels` is the corresponding label data. In the label data, each element is a logical `1` (`true`) for anomaly images, or a logical `0` (`false`) for normal images.

Version History

Introduced in R2023a

R2025a: MATLAB Compiler support will be removed
Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

Topics
“Getting Started with Anomaly Detection Using Deep Learning”

trainFCDDAnomalyDetector

Train fully convolutional data description (FCDD) anomaly detection network

Syntax

```
detector = trainFCDDAnomalyDetector(normalData,anomalyData,untrainedDetector,
options)
detector = trainFCDDAnomalyDetector(normalData,anomalyData,untrainedDetector,
options,Name=Value)
[detector,info] = trainFCDDAnomalyDetector( ___ )
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`detector = trainFCDDAnomalyDetector(normalData,anomalyData,untrainedDetector, options)` trains the FCDD anomaly detection network `untrainedDetector`. The training data consists of normal images in `normalData` and anomaly images in `anomalyData`. The `options` argument controls options for training.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Note It is recommended that you also have Parallel Computing Toolbox to use with a CUDA-enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

`detector = trainFCDDAnomalyDetector(normalData,anomalyData,untrainedDetector, options,Name=Value)` uses additional options specified by one or more name-value arguments.

`[detector,info] = trainFCDDAnomalyDetector( ___ )` also returns information on the training progress, such as the training accuracy and learning rate for each iteration.

Examples

Train FCDD Anomaly Detector

Load a data set that consists of images of digits from `0` to `9`.

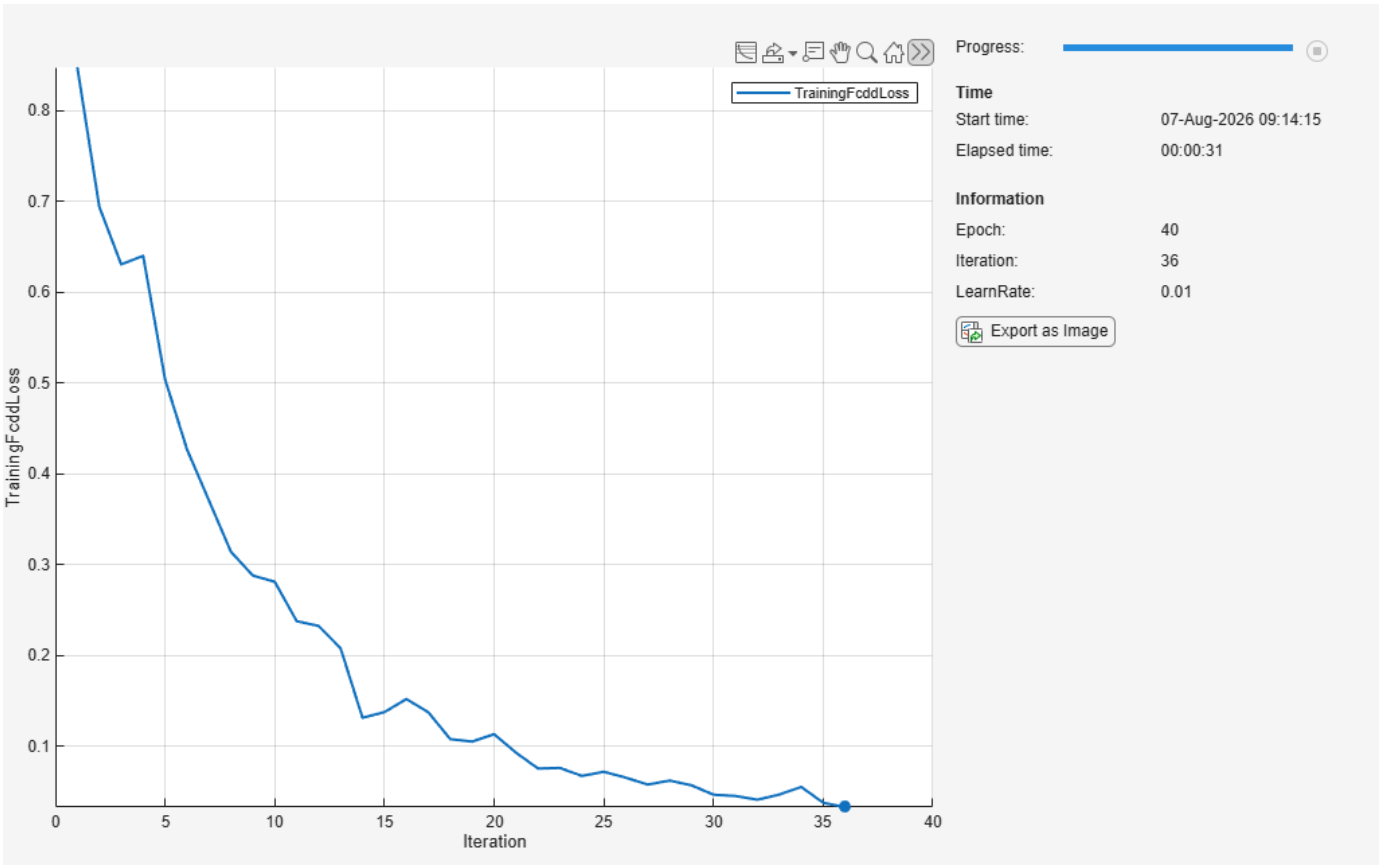
```
dataDir = fullfile(toolboxdir("vision"),"visiondata","digits","synthetic");
dsTrain = imageDatastore(dataDir,IncludeSubfolders=true, ...
    LabelSource="foldernames");
```

Split the training data into normal and anomaly images. For instance, set the images of the digit `8` to be normal, and all other digits to be anomalous.

```
trainingLabels = dsTrain.Labels;
normalDataIdx = find(trainingLabels == "8");
anomalyDataIdx = find(trainingLabels ~= "8");
dsNormal = subset(dsTrain,normalDataIdx);
dsAnomaly = subset(dsTrain,anomalyDataIdx);
```

Create an `fcddAnomalyDetector` object with a ResNet-18 backbone.

```
backbone = pretrainedEncoderNetwork("resnet18",3);
untrainedDetector = fcddAnomalyDetector(backbone);
```



Specify training options for SGDM optimization.

```
options = trainingOptions("sgdm", ...
    Plots="training-progress", ...
    InitialLearnRate = 0.01, ...
    MaxEpochs=40, ...
    MiniBatchSize=300, ...
    ResetInputNormalization=false, ...
    Shuffle="every-epoch");
```

Train the anomaly detector.

```
detector = trainFCDDAnomalyDetector(dsNormal,dsAnomaly,untrainedDetector,options);
```

```
    Epoch    Iteration    TimeElapsed    LearnRate    TrainingFcddLoss
    _____    _________    ___________    _________    ________________
```

Input Arguments

`untrainedDetector` — Untrained FCDD anomaly detector
`fcddAnomalyDetector` object

Untrained FCDD anomaly detector, specified as an `fcddAnomalyDetector` object.

`normalData` — Labeled ground truth normal images
datastore

Labeled ground truth normal images, specified as a datastore.

`anomalyData` — Labeled ground truth anomaly images
datastore

Labeled ground truth anomaly images, specified as a datastore.

`options` — Training options
`TrainingOptionsSGDM` object | `TrainingOptionsRMSProp` object | `TrainingOptionsADAM` object

Training options, specified as a `TrainingOptionsSGDM`, `TrainingOptionsRMSProp`, or `TrainingOptionsADAM` object returned by the `trainingOptions` function. To specify the solver name and other options for network training, use the `trainingOptions` function.

You must set the `BatchNormalizationStatistics` property of the object as `"moving"`.

Note If you specify the `OutputFcn` function handle using the `OutputFcn` name-value argument, it must use a per-epoch `info` structure with these fields:

- `Epoch`
- `Iteration`
- `TimeElapsed`
- `LearnRate`
- `TrainingLoss`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `detector = trainFCDDAnomalyDetector(normalData,anomalyData,untrainedDetector,options,FreezeBackbone=false)` does not freeze the backbone of the FCDD network during training.

`UseMaskData` — Use mask data
`false` or `0` (default) | `true` or `1`

Use mask data in the anomaly training data to form the pixelwise loss, specified as a numeric or logical `false` (`0`) or `true` (`1`). When `true`, the anomaly training data in `anomalyData` must be a

datastore that returns pairs of images as a two-element cell array of the form `{anomalyImage,anomalyMask}`. The first element, `anomalyImage`, is a sample image of an anomaly. The second element, `anomalyMask`, is a logical image of the same size as `anomalyImage` and has `true` valued pixels at locations where `anomalyImage` has anomaly content.

`FreezeBackbone` — Freeze backbone of FCDD network
`true` or `1` (default) | `false` or `0`

Freeze the backbone of the FCDD network during training, specified as a numeric or logical `true` (`1`) or `false` (`0`). When `true`, the weight of layers in the backbone does not change during training.

Output Arguments

`detector` — Trained FCDD anomaly detector
`fcddAnomalyDetector` object

Trained FCDD anomaly detector, returned as an `fcddAnomalyDetector` object.

`info` — Training progress information
structure array

Training progress information, returned as a structure array with these fields.

- `Epoch` — Epoch
- `Iteration` — Iteration
- `TimeElapsed` — Total elapsed duration
- `LearnRate` — Learning rate for each iteration
- `TrainingFcddLoss` — FCDD loss at the end of each iteration
- `OutputNetworkIteration` — Iteration number of returned network

Version History

Introduced in R2022b

R2025a: MATLAB Compiler support will be removed
Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

trainPatchCoreAnomalyDetector

Train PatchCore anomaly detection network

Syntax

```
detector = trainPatchCoreAnomalyDetector(normalData,detectorIn)
detector = trainPatchCoreAnomalyDetector( ___ ,Name=Value)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`detector = trainPatchCoreAnomalyDetector(normalData,detectorIn)` trains the input PatchCore anomaly detection network `detectorIn`. The training data consists of normal images in `normalData`.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Note It is recommended that you also have Parallel Computing Toolbox to use with a CUDA-enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

`detector = trainPatchCoreAnomalyDetector( ___ ,Name=Value)` specifies options that control aspects of network creation and training as one or more name-value arguments, in addition to all input arguments from the previous syntax.

Examples

Train PatchCore Anomaly Detector

Load a data set that consists of images of digits from 0 to 9. Consider images of the digit 8 to be normal, and all other digits to be anomalous.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata","digits","synthetic");
dsNormal  = imageDatastore(fullfile(dataDir,"8"));
```

Create a `patchCoreAnomalyDetector` object.

```
untrainedDetector = patchCoreAnomalyDetector(Backbone="resnet18");
```

Train the anomaly detector.

```
detector = trainPatchCoreAnomalyDetector(dsNormal,untrainedDetector);
```

```
Computing Input Normalization Statistics.
Training PatchCore Model.
------------------------

Step 1: Computing embeddings for each minibatch
Done creating uncompressed train embeddings.
Step 2: Compress train embeddings at 0.1 factor to create a coreset...

Computing coreset samples
Done compressing train embeddings (coreset).
Done training PatchCore model.
```

Set the anomaly threshold of the detector using a calibration data set.

```
calDir = fullfile(toolboxdir("vision"),"visiondata","digits","handwritten");
dsCal = imageDatastore(calDir,IncludeSubfolders=true,LabelSource="foldernames");
gtLabels = dsCal.Labels;
anomalyLabels = setdiff(string(0:9),"8");
scores = predict(detector,dsCal);
[T,roc] = anomalyThreshold(gtLabels,scores,anomalyLabels)
```

```
T = single

1.1555

roc =
  rocmetrics with properties:

    Metrics: [121×4 table]

Properties, Methods
```

```
detector.Threshold = T;
```

Input Arguments

`detectorIn` — PatchCore anomaly detector to train

`patchCoreAnomalyDetector` object

PatchCore anomaly detector to train, specified as a `patchCoreAnomalyDetector` object.

`normalData` — Training data

datastore

Training data, specified as a datastore. The training data consists of samples of normal images. Do not include anomaly images in the training data.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example:
`trainPatchCoreAnomalyDetector(normalData,detectorIn,CompressionRatio=0.1)`
specifies that the detector must use only 10% of the features extracted from training images.

`CompressionRatio` — Compression ratio
`0.1` (default) | numeric scalar in range `[0, 1]`

Compression ratio, specified as a number in the range `[0, 1]`. This value indicates the decimal amount of compression used on the features extracted from training images to construct a memory bank. For example, a compression ratio of 0.1 specifies that the detector must use only 10% of the features. This ratio is a trade off between memory and accuracy. A smaller `CompressionRatio` value increases compression, but decreases accuracy.

`MiniBatchSize` — Size of mini-batch
`128` (default) | positive integer

Size of the mini-batch to use for each training iteration, specified as a positive integer. A mini-batch is a subset of the training set that the training function uses to evaluate the gradient of the loss function and update the weights.

`ExecutionEnvironment` — Hardware resource for running neural network
`"auto"` (default) | `"cpu"` | `"gpu"`

Hardware resource for running the neural network, specified as one of these options:

- `"auto"` — Use a GPU if one is available. Otherwise, use the CPU.
- `"gpu"` — Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA-enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Use the CPU.

For more information on when to use the different execution environments, see “Scale Up Deep Learning in Parallel, on GPUs, and in the Cloud” (Deep Learning Toolbox).

`ResetInputNormalization` — Reset input layer normalization
`1` or `true` (default) | `0` or `false`

Reset input layer normalization using training images, specified as a logical `1` (`true`) or `0` (`false`):

- `1` (`true`) — Reset the input layer normalization statistics using the `normalData` data set, and recalculate them at training time.
- `0` (`false`) — Recalculate the input layer normalization statistics at training time.

`SubsamplingStrategy` — Subsampling method
`"greedycoreset"` (default) | `"random"`

Subsampling method used to reduce redundancy in the feature bank that occurs during training, specified as one of these options:

- `"greedycoreset"` — Greedy coreset subsampling method.
- `"random"` — Random subsampling method.

The greedy coreset subsampling method has higher accuracy at the expense of slower run time. The random subsampling method can increase run speed at the expense of a decrease in comparative

accuracy. When using the random subsampling method, increasing the number of training images can improve accuracy, but also increases the model size and inference time.

`Verbose` — Display training progress information
`1` or `true` (default) | `0` or `false`

Display training progress information in the command window, specified as a logical `1` (`true`) or `0` (`false`).

Output Arguments

`detector` — Trained PatchCore anomaly detector
`patchCoreAnomalyDetector` object

Trained PatchCore anomaly detector, returned as a `patchCoreAnomalyDetector` object.

Tips

- For a given training image size and number of training images, if the peak memory usage for creating a memory bank exceeds the available memory, PatchCore outputs a warning. To decrease memory usage, try reducing image resolution, using fewer training images, or enhancing GPU performance (in this order to balance the ease of implementation with the target outcome of lowering memory usage).

Version History

Introduced in R2023a

R2025a: MATLAB Compiler support will be removed
Warns starting in R2025a

Support for using MATLAB Compiler will be removed in a future release.

R2024a: Option to specify subsampling strategy

Specify the subsampling method by using the `SubsamplingStrategy` name-value argument. For example, `SubsamplingStrategy="greedycoreset"` specifies the greedy coreset subsampling method.

viewAnomalyDetectionResults

View anomaly detection results

Syntax

```
viewAnomalyDetectionResults(detector,I,gtLabels,scores,anomalyLabels)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`viewAnomalyDetectionResults(detector,I,gtLabels,scores,anomalyLabels)` displays the anomaly detection results for a set of test images `I`. The function displays the predicted scores against the ground truth `gtLabels`. `anomalyLabels` indicates which class labels in `gtLabels` belong to the anomaly (positive) class

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

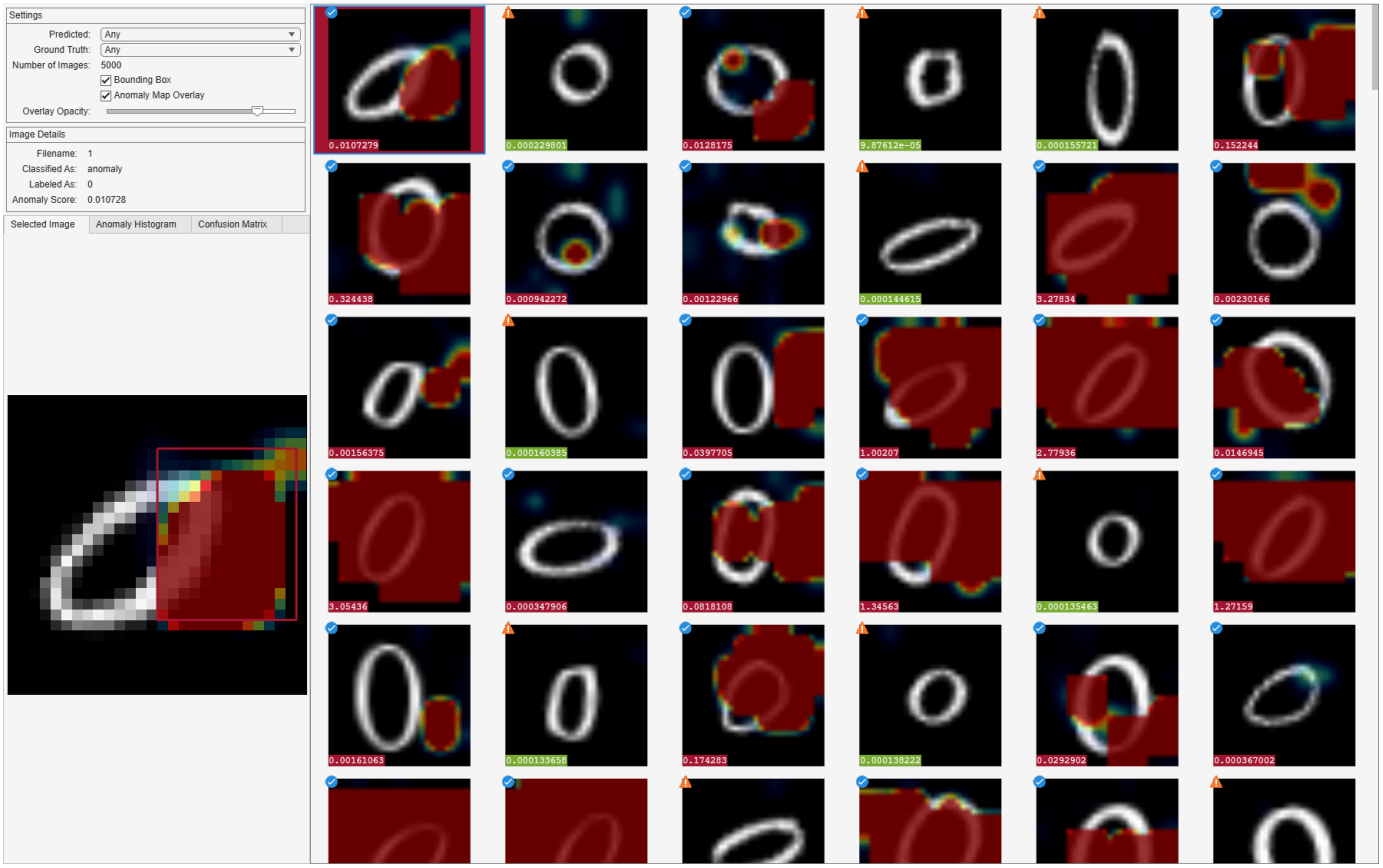
Examples

View Anomaly Detection Results

Load test images and corresponding labels, then create a datastore that reads the test data. The data set consists of grayscale images of handwritten digits 0–9.

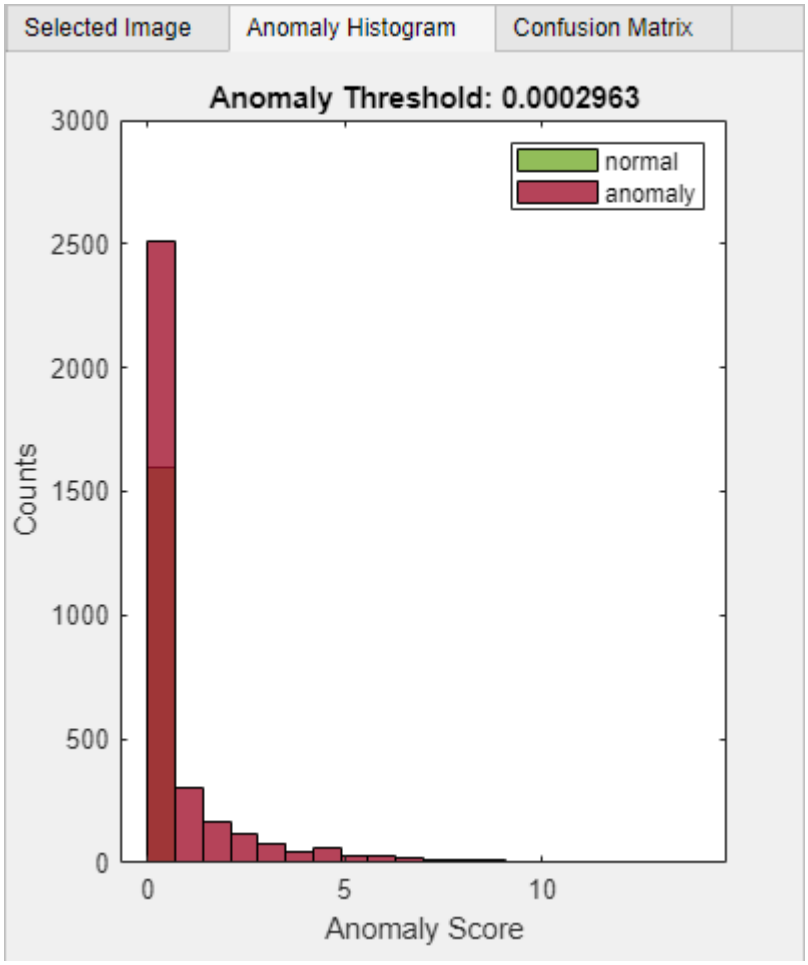
```
[Xtest,gtLabels] = digitTest4DArrayData;
dsTest = arrayDatastore(Xtest,IterationDimension=4);
```

Load a pretrained FCDD anomaly detector. This detector has been trained to classify the digit 8 as normal and all other digits as anomalies. Therefore, specify the set of positive labels as the set of digits between 0 and 9, excluding 8.



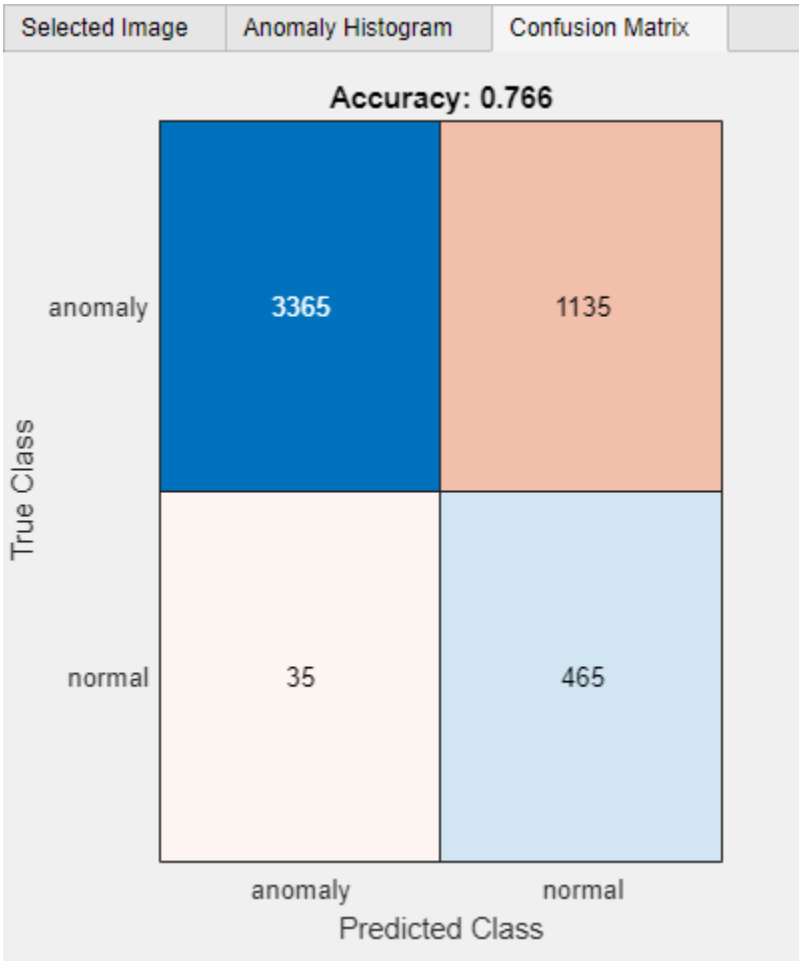
```
load("digit8AnomalyDetector.mat")
anomalyLabels = setdiff(string(0:9),"8");
```

Predict anomaly scores for each test image using the FCDD anomaly detector.

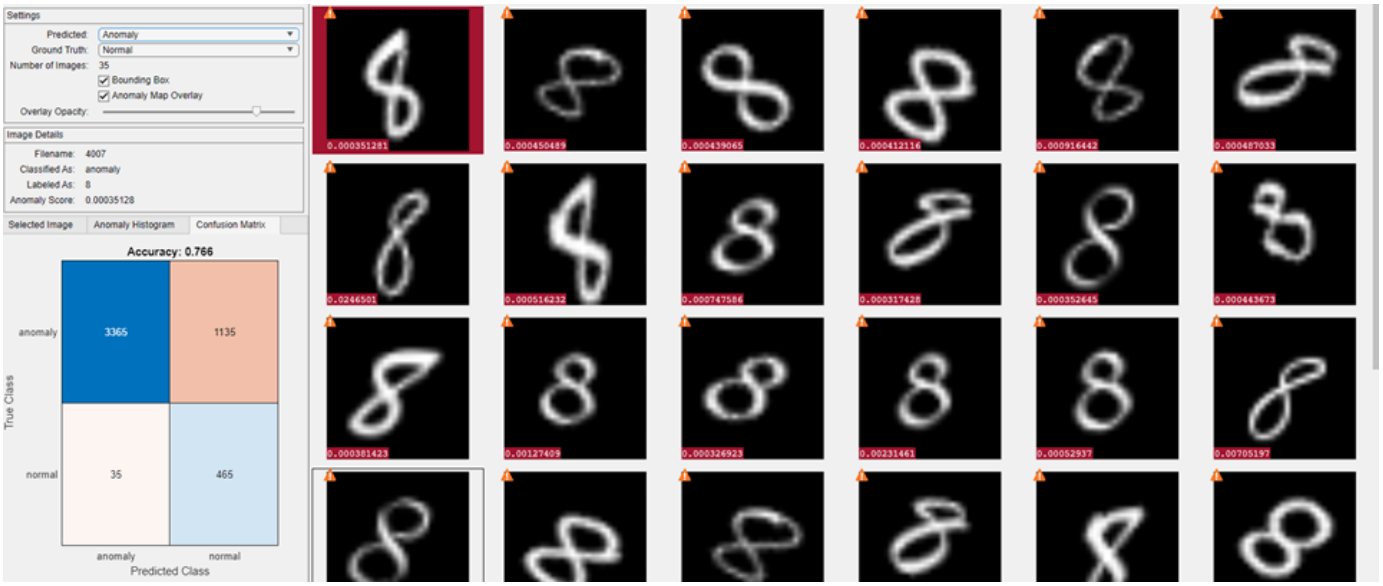


```
predScores = predict(detector,dsTest);
```

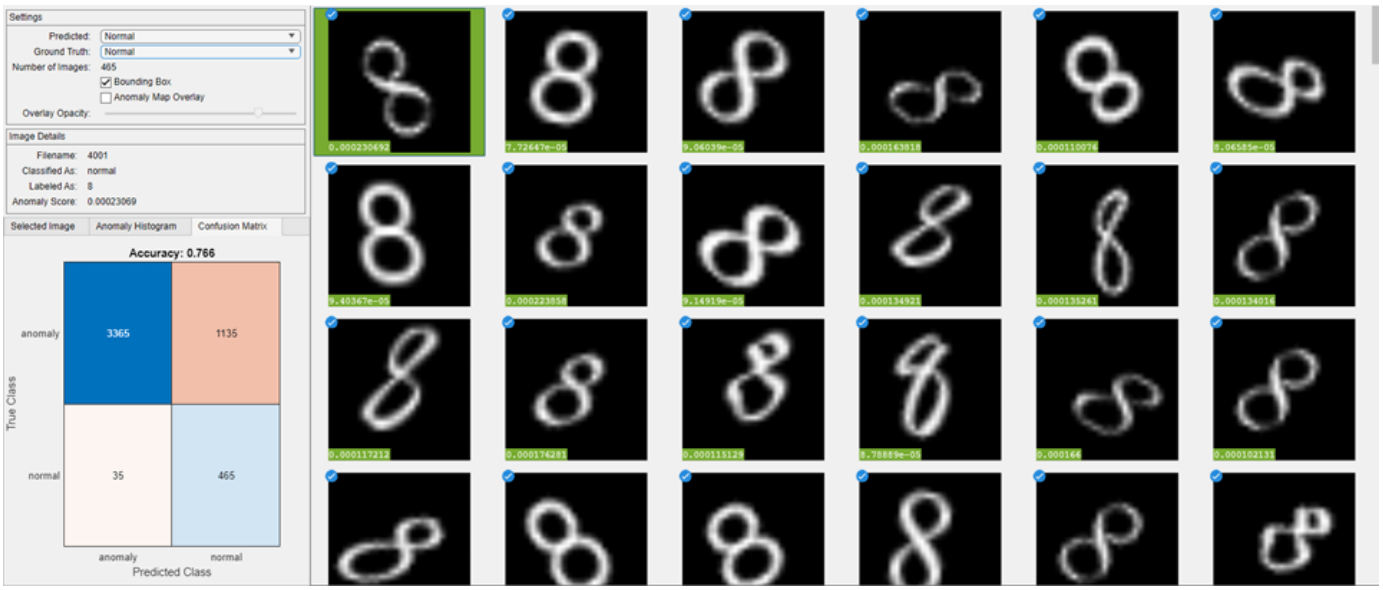
View the anomaly detection results.



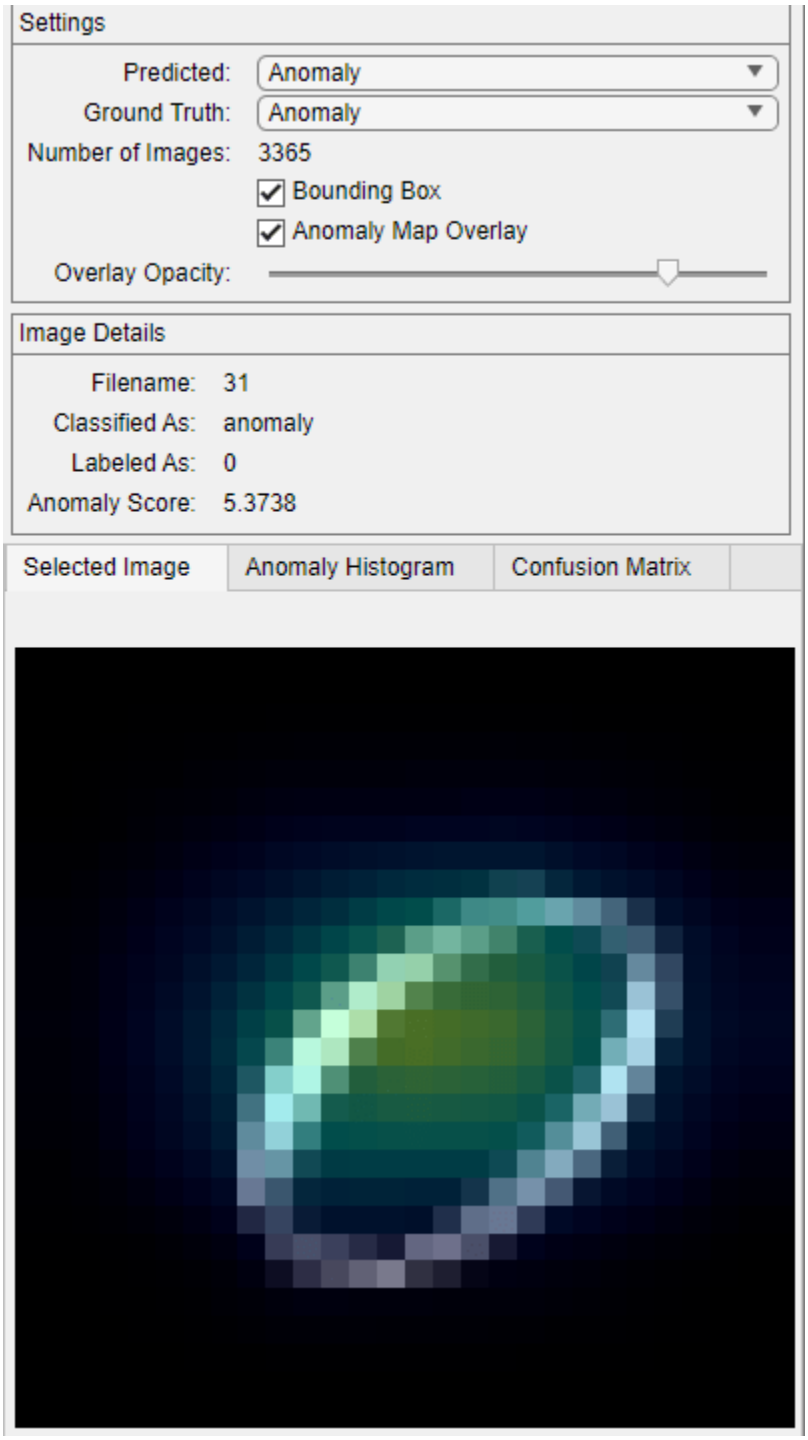
```
viewAnomalyDetectionResults(detector,dsTest,gtLabels,predScores,anomalyLabels);
```



Select the **Anomaly Histogram** tab to view the **Anomaly Score vs. Counts** histogram plot. Note the **Anomaly Threshold** of `0.0002963` on the anomaly histogram plot. Above this threshold, the detector classifies the test image as an anomaly.



Select the **Confusion Matrix** tab to view the performance of the trained anomaly detector. You can also use this matrix to set predicted and ground truth filters. The accuracy of `0.766` represents the ratio of correctly classified images to the total number of images in the data set.



Analyze the false positive images by setting the **Predicted** parameter to `Anomaly` and the **Ground Truth** parameter to `Normal` in the **Settings** pane. On each thumbnail of false positive images, the score appears against a red background because of the positive classification. The icon in the top left corner of the thumbnail is a yellow triangle with a white exclamation mark, which indicates the image is misclassified.

Analyze the true negative images by setting the **Predicted** parameter to `Normal` and the **Ground Truth** parameter to `Normal`. On each thumbnail of true negative images, the score appears against a green background because of the negative classification. The icon in the top left corner of the thumbnail is a blue circle with a white checkmark, which indicates the image is correctly classified.

Analyze the true positive images by setting the **Predicted** parameter to `Anomaly` and the **Ground Truth** parameter to `Anomaly`. Select the image with the filename `31`. The anomaly map overlay displays the anomaly heatmap over the image. Clear **Anomaly Map Overlay** in the **Settings** pane and observe the difference in the **Selected Image** tab.

Input Arguments

`detector` — Anomaly detector

`efficientADAnomalyDetector` object | `fcddAnomalyDetector` object | `fastFlowAnomalyDetector` object | `patchCoreAnomalyDetector` object

Anomaly detector, specified as an `efficientADAnomalyDetector` object, an `fcddAnomalyDetector` object, a `fastFlowAnomalyDetector` object, or a `patchCoreAnomalyDetector` object. You must set the `Threshold` property of the detector before calling this function.

`I` — Images

datastore

Images, specified as a datastore.

`gtLabels` — Ground truth labels

numeric vector | logical vector | categorical vector

Ground truth labels for each image, specified as a numeric vector, logical vector, or categorical vector. The `viewAnomalyDetectionResults` function converts the labels into a logical vector according to the set of anomaly labels in `anomalyLabels`.

`scores` — Predicted anomaly scores

numeric scalar | numeric vector | formatted `dlarray` object

Predicted anomaly scores, returned as a numeric scalar, numeric vector, or formatted `dlarray` object. `scores` contains one element for each image in `I`.

`anomalyLabels` — Anomaly labels

numeric vector | logical vector | categorical vector | string vector

Anomaly labels, specified as a vector of the same data type as `gtLabels`. When `gtLabels` is categorical, `anomalyLabels` can be of data type string whose values correspond to categories in `gtLabels`.

The `viewAnomalyDetectionResults` function converts all ground truth labels in `gtLabels` that belong to the set of anomaly labels to a logical `true`, indicating an anomaly (positive detection). The function converts all other ground truth labels to a logical `false`, indicating normality (negative detection).

More About

Anomaly Detection Figure Window

The `viewAnomalyDetectionResults` function opens an interactive figure window that enables you to explore the classification results and anomaly score maps for a set of images. Annotations on the image thumbnails can help you interpret the classification.

- The number in the colored box indicates the overall anomaly score of the image. When the number is in a green box, the score is below the anomaly threshold and the image is predicted to be normal, or negative. When the number is in a red box, the score is above the anomaly threshold and the image is predicted to be anomalous, or positive.

- The icon in the upper right corner indicates whether the predicted and ground truth classification agree. When the icon is a blue circle with a white check mark, the prediction and ground truth agree, and the prediction is a true positive or a true negative. When the icon is a yellow triangle with a white exclamation mark, the prediction and ground truth disagree, and the prediction is a false positive or false negative.

Version History

Introduced in R2022b

R2023a: Support for FastFlow and PatchCore anomaly detectors

You can now specify the `detector` argument as a `fastFlowAnomalyDetector` object or a `patchCoreAnomalyDetector` object.

`anomalyMapOverlay`

vision.loadFastFlowAnomalyDetector

Load FastFlow anomaly detector model for code generation

Syntax

```
net = vision.loadFastFlowAnomalyDetector(filename)
```

Description

`net = vision.loadFastFlowAnomalyDetector(filename)` loads a pretrained `fastFlowAnomalyDetector` object saved in the `filename` MAT file. `filename` must be a compile-time constant.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Examples

Generate C Code from MAT File Containing FastFlow Anomaly Detector

Use the `vision.loadFastFlowAnomalyDetector` function to load a FastFlow anomaly detector and generate C code for this network. This example assumes you have a pretrained `fastFlowAnomalyDetector` object saved as a variable named `detector` in the file `trainedFastFlow8Detector.mat`. In order to run the example, you must train the detector and save the trained detector in a MAT file with this name. For an example of how to train a FastFlow anomaly detector, see `trainFastFlowAnomalyDetector`.

Load a pretrained `fastFlowAnomalyDetector` object from a MAT file.

```
load("trainedFastFlow8Detector.mat");
```

Create an entry-point function `myFastFlow.m` that accepts an image as input. The entry-point function performs these operations:

- Define a persistent variable called `myDetector`. The persistent variable prevents reconstructing and reloading the network object during subsequent calls to the `myFastFlow` function.
- Load the detector in the file `trainedFastFlow8Detector.mat` into the `myDetector` variable using the `vision.loadFastFlowAnomalyDetector` function.
- Perform operations, such as prediction and classification, on the input image using the detector.

```
function [score,label] = myFastFlow(in)
  persistent myDetector;
    if isempty(myDetector)
        myDetector = vision.loadFastFlowAnomalyDetector("trainedFastFlow8Detector.mat");
    end
  score = predict(myDetector,in);
```

```
  if score < myDetector.Threshold
    label = "normal";
  else
    label = "anomaly";
  end
end
```

Specify the size of the training images as the size of the input to the entry-point function. The example assumes the network was trained on truecolor images of size 16-by-16 pixels.

```
inputSize = [16 16 3];
```

Create a `coder.config` configuration object for MEX code generation and set the target language to C. On the configuration object, set `DeepLearningConfig` with no target library. The `codegen` function must determine the size, class, and complexity of MATLAB function inputs. Use the `-args` option to specify the size of the input to the entry-point function. Use the `-config` option to pass the code configuration object.

```
cfg = coder.config("mex");
cfg.TargetLang = "C";
cfg.DeepLearningConfig = coder.DeepLearningConfig;
codegen -args {ones(inputSize,"single")} -config cfg myFastFlow -report;
```

The `codegen` command places all the generated files in the `codegen` folder. The folder contains the C code for the entry-point function `myFastFlow.c`, header and source files containing the C class definitions for the network, weight, and bias files.

Read a test image from a graphics file. The image must be the same size as `inputSize`. Convert the image to data type `single` as expected by the generated code.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata","digits","handwritten","4");
imTest = imread(dataDir+filesep+"digit_4_5.png");
imTest = im2single(imTest);
```

Predict the anomaly score and label of the test image by calling the generated code.

```
[predScore,predLabel] = myFastFlow_mex(imTest)
```

```
predScore =

  single

     -0.0033

predLabel =

    "anomaly"
```

Input Arguments

`filename` — Filename

string scalar

Filename of the MAT file containing the pretrained `fastFlowAnomalyDetector` object, specified as a string scalar. The MAT file must exist on the MATLAB path and contain only the network to be loaded.

This input argument must be a compile-time constant.

Data Types: `string`

Output Arguments

net — Network

`fastFlowAnomalyDetector` object

Network, returned as a `fastFlowAnomalyDetector` object.

`coder.loadDeepLearningNetwork` | `coder.DeepLearningConfig`

vision.loadFCDDAnomalyDetector

Load FCDD anomaly detector model for code generation

Syntax

```
net = vision.loadFCDDAnomalyDetector(filename)
```

Description

`net = vision.loadFCDDAnomalyDetector(filename)` loads a pretrained `fcddAnomalyDetector` object saved in the `filename` MAT file. `filename` must be a compile-time constant.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Examples

Generate C Code from MAT File Containing FCDD Anomaly Detector

Load a pretrained `fcddAnomalyDetector` object from a MAT file. This detector was trained on grayscale images of size 28-by-28.

```
load("digit8AnomalyDetector.mat");
```

Create an entry-point function `myFCDD` that accepts an image as input. The entry-point function performs these operations:

- Define a persistent variable called `myDetector`. The persistent variable prevents reconstructing and reloading the network object during subsequent calls to the `myFCDD` function.
- Load the detector in the file `digit8AnomalyDetector.mat` into the `myDetector` variable using the `vision.loadFCDDAnomalyDetector` function.
- Perform operations, such as prediction and classification, on the input image using the detector.

Show the contents of the entry-point function. This function is attached to the example as a supporting file.

```
type myFCDD.m
```

```
function [score,label] = myFCDD(in)
  persistent myDetector;
    if isempty(myDetector)
        myDetector = vision.loadFCDDAnomalyDetector("digit8AnomalyDetector.mat");
    end
  score = predict(myDetector,in);
  if score < myDetector.Threshold
```

```
    label = "normal";
  else
    label = "anomaly";
  end
end
```

Specify the size of the training images as the size of the input to the entry-point function.

```
inputSize = [28 28];
```

Create a `coder.config` configuration object for MEX code generation and set the target language to C. On the configuration object, set the `DeepLearningConfig` property with no target library. The `codegen` function must determine the size, class, and complexity of MATLAB function inputs. Use the `-args` option to specify the size of the input to the entry-point function. Use the `-config` option to pass the code configuration object.

```
cfg = coder.config("mex");
cfg.TargetLang = "C";
cfg.DeepLearningConfig = coder.DeepLearningConfig;
codegen -args {ones(inputSize,"single")} -config cfg myFCDD -report;
```

```
Code generation successful: View report
```

The `codegen` command places all the generated files in the `codegen` folder. The folder contains the C code for the entry-point function `myFCDD.c`, header and source files containing the C class definitions for the convoluted neural network (CNN), weight, and bias files.

Load the test data. The test images must be the same size as the training images.

```
[XTest,YTest] = digitTest4DArrayData;
```

Select a test image. Convert the image to data type `single`, as expected by the generated code.

```
idxToTest = 1;
imTest = XTest(:,:,:,idxToTest);
imTest = im2single(imTest);
```

Predict the anomaly score and label of the test image by calling the generated code.

```
[predScore,predLabel] = myFCDD_mex(imTest)
```

```
predScore = single

0.0107

predLabel =
"anomaly"
```

Input Arguments

`filename` — Filename

string scalar

Filename of the MAT file containing the pretrained `fcddAnomalyDetector` object, specified as a string scalar. The MAT file must exist on the MATLAB path and contain only the network to be loaded.

This input argument must be a compile-time constant.

Data Types: `string`

Output Arguments

net — Network
`fcddAnomalyDetector` object

Network, returned as an `fcddAnomalyDetector` object.

vision.loadPatchCoreAnomalyDetector

Load PatchCore anomaly detector model for code generation

Syntax

```
net = vision.loadPatchCoreAnomalyDetector(filename)
```

Description

`net = vision.loadPatchCoreAnomalyDetector(filename)` loads a pretrained `patchCoreAnomalyDetector` object saved in the `filename` MAT file. `filename` must be a compile-time constant.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Examples

Generate C Code from MAT File Containing PatchCore Anomaly Detector

Use the `vision.loadPatchCoreAnomalyDetector` function to load a PatchCore anomaly detector and generate C code for this network. This example assumes you have a pretrained `patchCoreAnomalyDetector` object saved as a variable named `detector` in the file `trainedPatchCore8Detector.mat`. For an example of training a PatchCore anomaly detector, see `trainPatchCoreAnomalyDetector`.

Load the pretrained `patchCoreAnomalyDetector` object from the MAT file.

```
load("trainedPatchCore8Detector.mat");
```

Create an entry-point function `myPatchCore.m` that accepts an image as input. The entry-point function performs these operations:

- Define a persistent variable called `myDetector`. The persistent variable prevents reconstructing and reloading the network object during subsequent calls to the `myPatchCore` function.
- Load the detector in the file `trainedPatchCore8Detector.mat` into the `myDetector` variable using the `vision.loadPatchCoreAnomalyDetector` function.
- Perform operations, such as prediction and classification, on the input image using the detector.

```
function [score,label] = myPatchCore(in)
  persistent myDetector;
    if isempty(myDetector)
        myDetector = vision.loadPatchCoreAnomalyDetector("trainedPatchCore8Detector.mat");
    end
  score = predict(myDetector,in);
  if score < myDetector.Threshold
```

```
    label = "normal";
  else
    label = "anomaly";
  end
end
```

Specify the size of the training images as the size of the input to the entry-point function. The example assumes the network was trained on truecolor images of size 16-by-16 pixels.

```
inputSize = [16 16 3];
```

Create a `coder.config` configuration object for MEX code generation and set the target language to C. On the configuration object, set `DeepLearningConfig` with no target library. The `codegen` function must determine the size, class, and complexity of MATLAB function inputs. Use the `-args` option to specify the size of the input to the entry-point function. Use the `-config` option to pass the code configuration object.

```
cfg = coder.config("mex");
cfg.TargetLang = "C";
cfg.DeepLearningConfig = coder.DeepLearningConfig;
codegen -args {ones(inputSize,"single")} -config cfg myPatchCore -report;
```

The `codegen` command places all the generated files in the `codegen` folder. The folder contains the C code for the entry-point function `myPatchCore.c`, header and source files containing the C class definitions for the network, weight, and bias files.

Read a test image from a graphics file. The image must be the same size as `inputSize`. Convert the image to data type `single` as expected by the generated code.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata","digits","handwritten","4");
imTest = imread(dataDir+filesep+"digit_4_5.png");
imTest = im2single(imTest);
```

Predict the anomaly score and label of the test image by calling the generated code.

```
[predScore,predLabel] = myPatchCore_mex(imTest)
```

```
predScore =

  single

    2.6989

predLabel =

    "anomaly"
```

Input Arguments

`filename` — Filename

string scalar

Filename of the MAT file containing the pretrained `patchCoreAnomalyDetector` object, specified as a string scalar. The MAT file must exist on the MATLAB path and contain only the network to be loaded.

This input argument must be a compile-time constant.

Data Types: `string`

Output Arguments

net — Network
`patchCoreAnomalyDetector` object

Network, returned as a `patchCoreAnomalyDetector` object.

Version History

Introduced in R2023a

See Also

`coder.loadDeepLearningNetwork` | `coder.DeepLearningConfig`

extractpatches

Extract patches from image at specified ROIs

Syntax

```
patches = extractpatches(I,bboxes)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`patches = extractpatches(I,bboxes)` extracts patches from image `I` at the ROI locations specified by the bounding boxes `bboxes`.

Note This functionality requires the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Examples

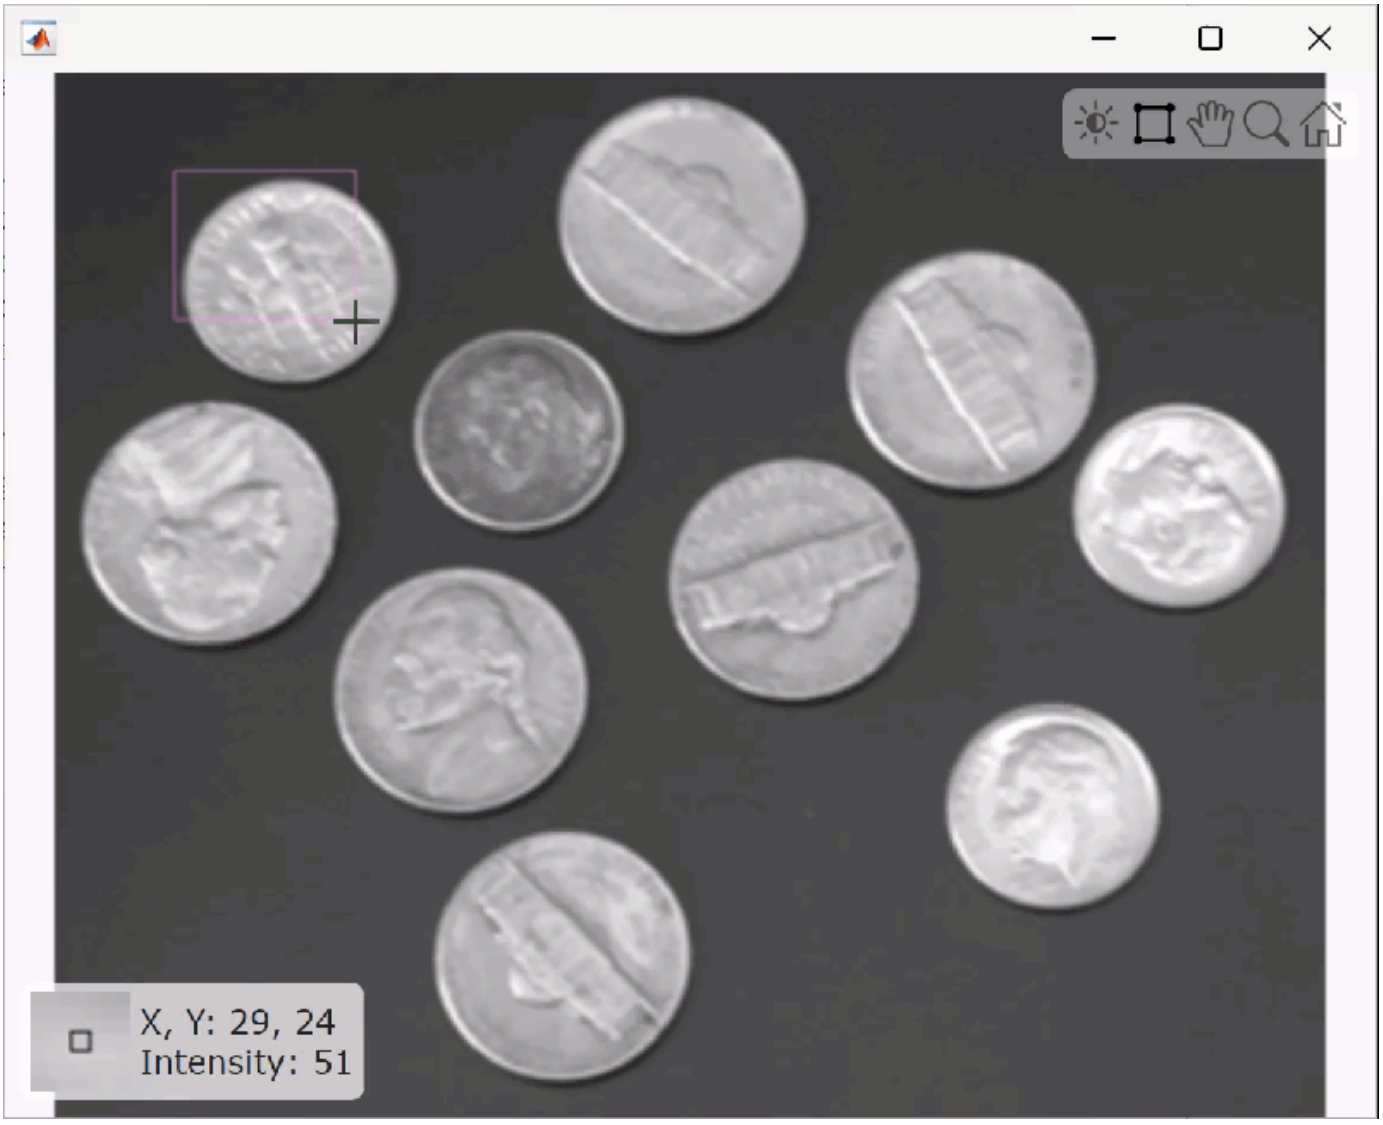
Select Exemplar Patches for Counting Objects

Load an image containing objects to count into the workspace.

```
I = imread("coins.png");
```

Display the image using the `imageshow` function.

```
hImage = imageshow(I);
```



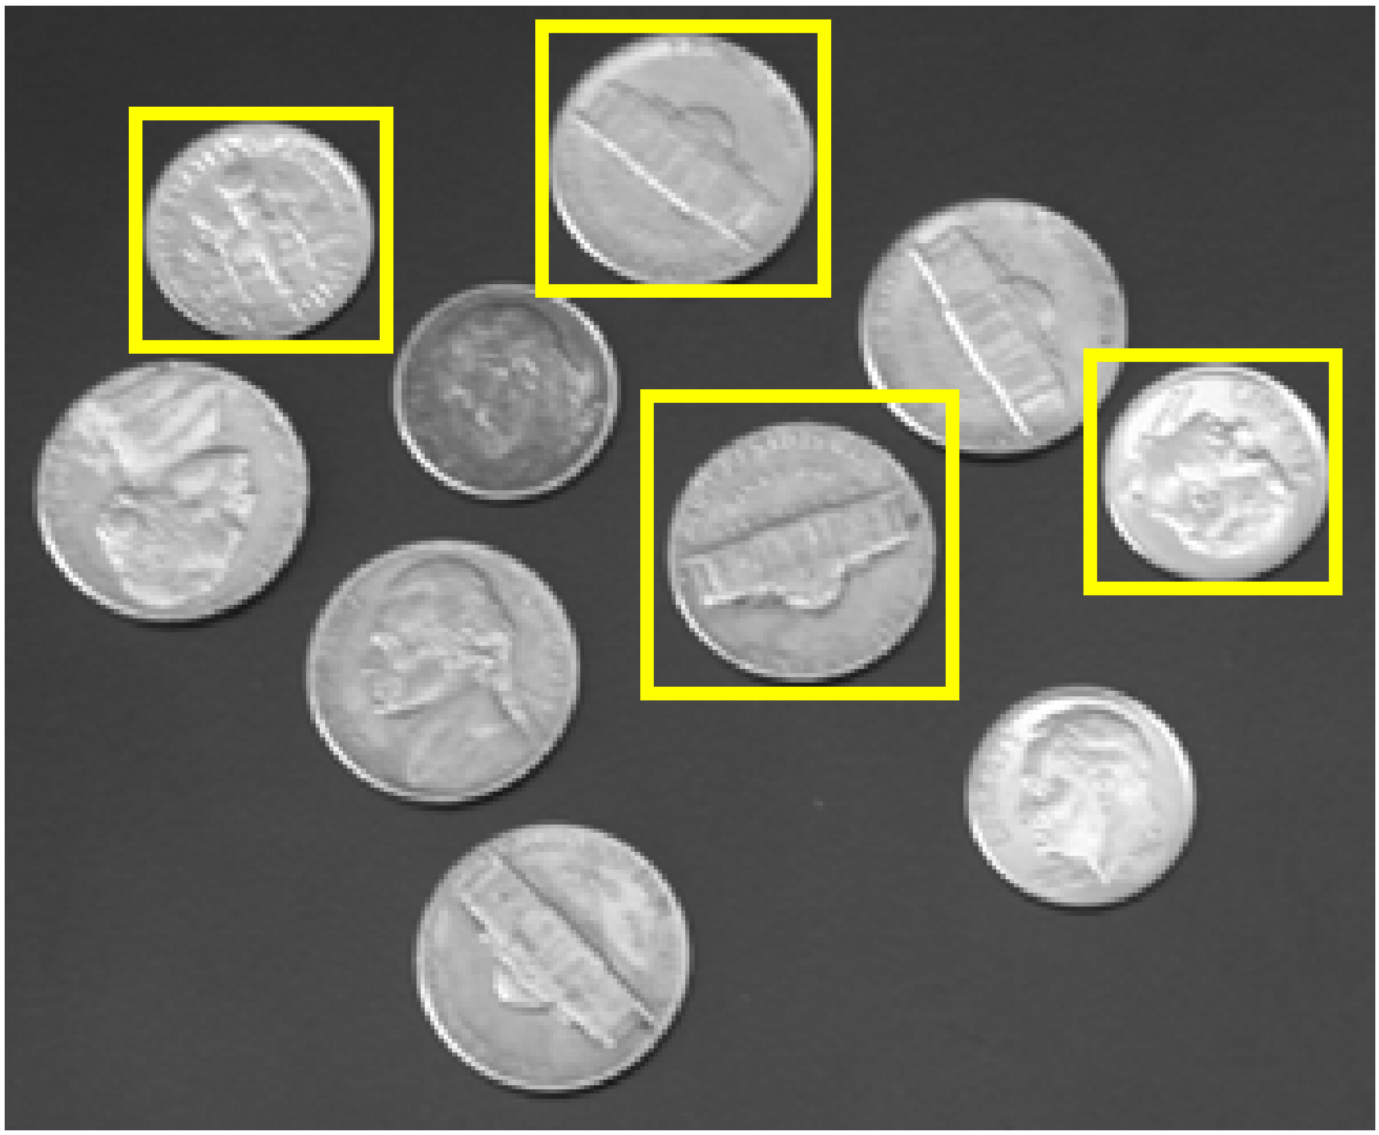
To interactively define bounding box ROIs on the image, use the `uiselectboxes` function. Click a start point in the image and drag boxes around the desired objects. Click **Accept** in the top-right corner of the figure window when you are satisfied with your selections.

```
bboxes = uiselectboxes(hImage)
```

```
bboxes = 4×4

    195.4484     28.4718    69.5974    63.5455
    321.0263    101.0952    55.9805    58.2500
    224.9516    116.2251    65.0584    61.2760
    165.1886     85.9653    55.2240    52.1980
```

This GIF shows how to interactively select bounding boxes by creating and dragging the boxes to different positions on the image.



Extract the patch tiles from the image using the `extractpatches` function.

```
tiles = extractpatches(I,bboxes)
```

```
tiles=4×1 cell array
    64×70 uint8
    58×56 uint8
    62×65 uint8
    52×55 uint8
```

Display the bounding boxes defining the image patches overlaid on the image using the `insertShape` function.

```
annotatedImage = insertShape(I,"rectangle",bboxes,"LineWidth",3);
imshow(annotatedImage)
```

Input Arguments

I — Input image

H-by-*W* numeric matrix | *H*-by-*W*-by-3 numeric array

Input image from which to extract patches, specified as one of these options:

Image Type	Data Format
Grayscale	*H*-by-*W* numeric matrix
RGB	*H*-by-*W*-by-3 numeric array

bboxes — Axis-aligned rectangular bounding box ROIs

M-by-4 numeric matrix

Axis-aligned rectangular bounding box ROIs that enclose patches, specified as an *M*-by-4 numeric matrix. *M* is the number of bounding box ROIs. Each row of the matrix represents a bounding box, and is of the form [*x y w h*], where:

- *x* and `y` specify the upper-left corner of the rectangle.
- *w* specifies the width of the rectangle, which is its length along the *x*-axis.
- *h* specifies the height of the rectangle, which is its length along the *y*-axis.

You can interactively select bounding box ROIs for an image using the `uiselectboxes` function.

Output Arguments

`patches` — Image patches

M-by-1 cell array

Image patches, returned as an *M*-by-1 cell array. *M* is the number of bounding box ROIs specified using the `bboxes` name-value argument. Each element of the array is an image patch, returned as one of these values depending on the format of the input image `I`.

- RGB — Each patch is a *P*-by-*Q*-by-3 numeric array.
- Grayscale — Each patch is a *P*-by-*Q* numeric matrix.

P and *Q* are the height and width dimensions of each patch, respectively.

uiselectboxes

Select bounding box ROIs from image

Syntax

```
bboxes = uiselectboxes(hImage)
bboxes = uiselectboxes(hImage,Color=boxColor)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`bboxes = uiselectboxes(hImage)` enables you to interactively select rectangular bounding box ROIs on the displayed image `hImage`.

Note This functionality requires the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

`bboxes = uiselectboxes(hImage,Color=boxColor)` specifies the color of created bounding box ROI boundaries.

Examples

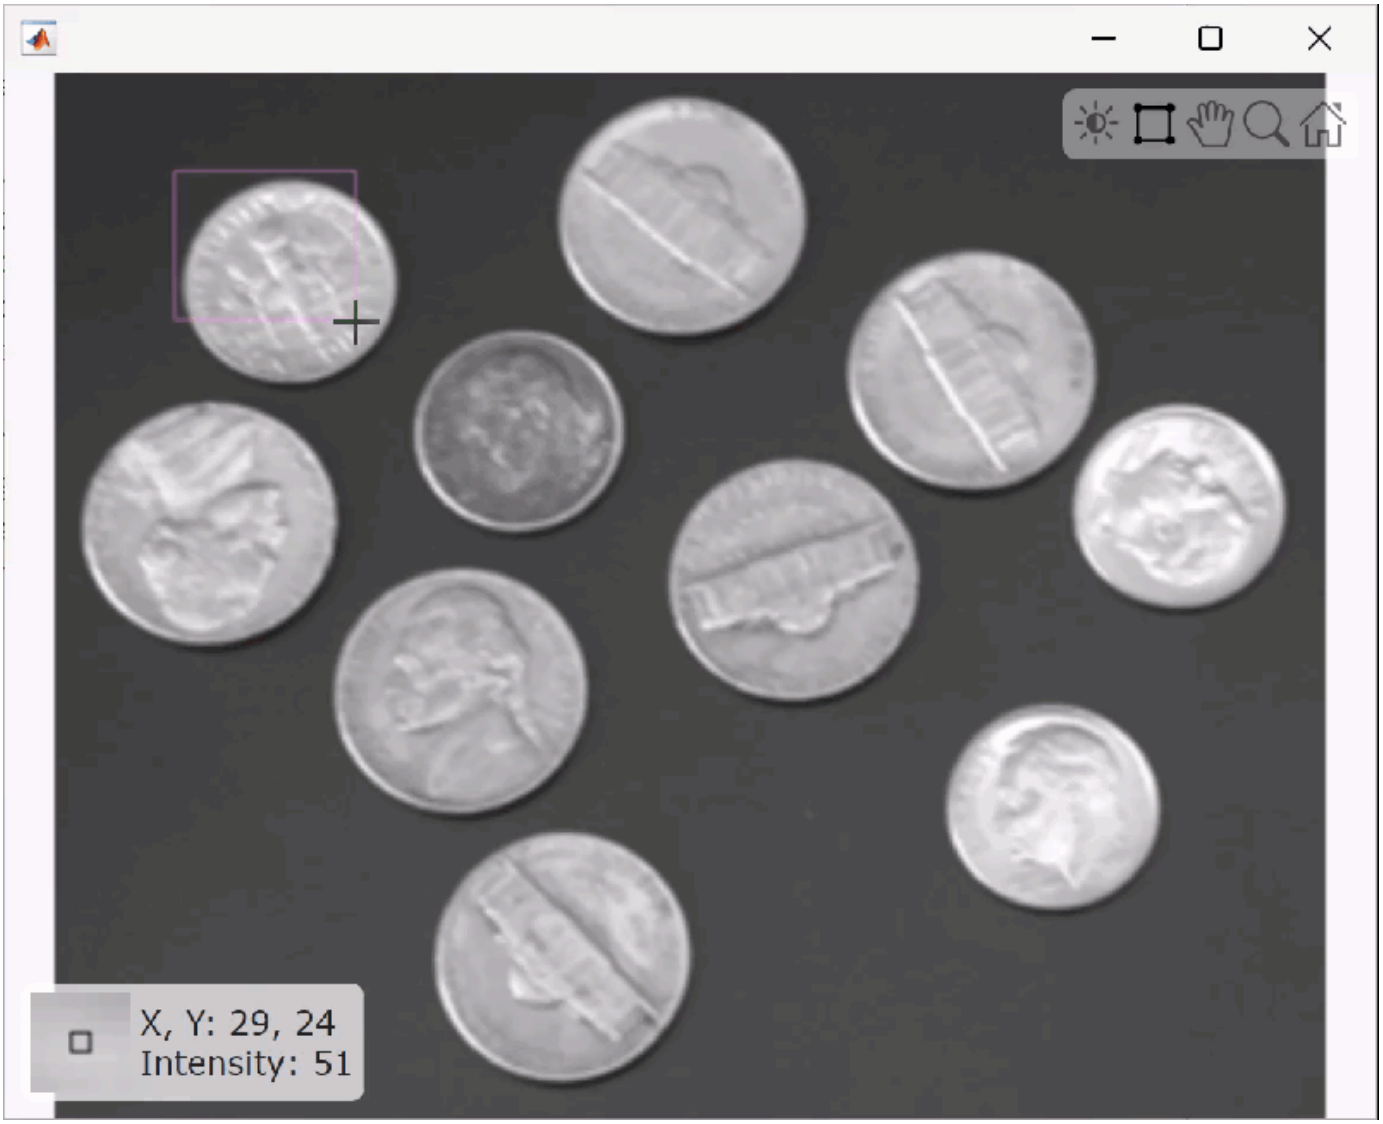
Select Exemplar Patches for Counting Objects

Load an image containing objects to count into the workspace.

```
I = imread("coins.png");
```

Display the image using the `imageshow` function.

```
hImage = imageshow(I);
```



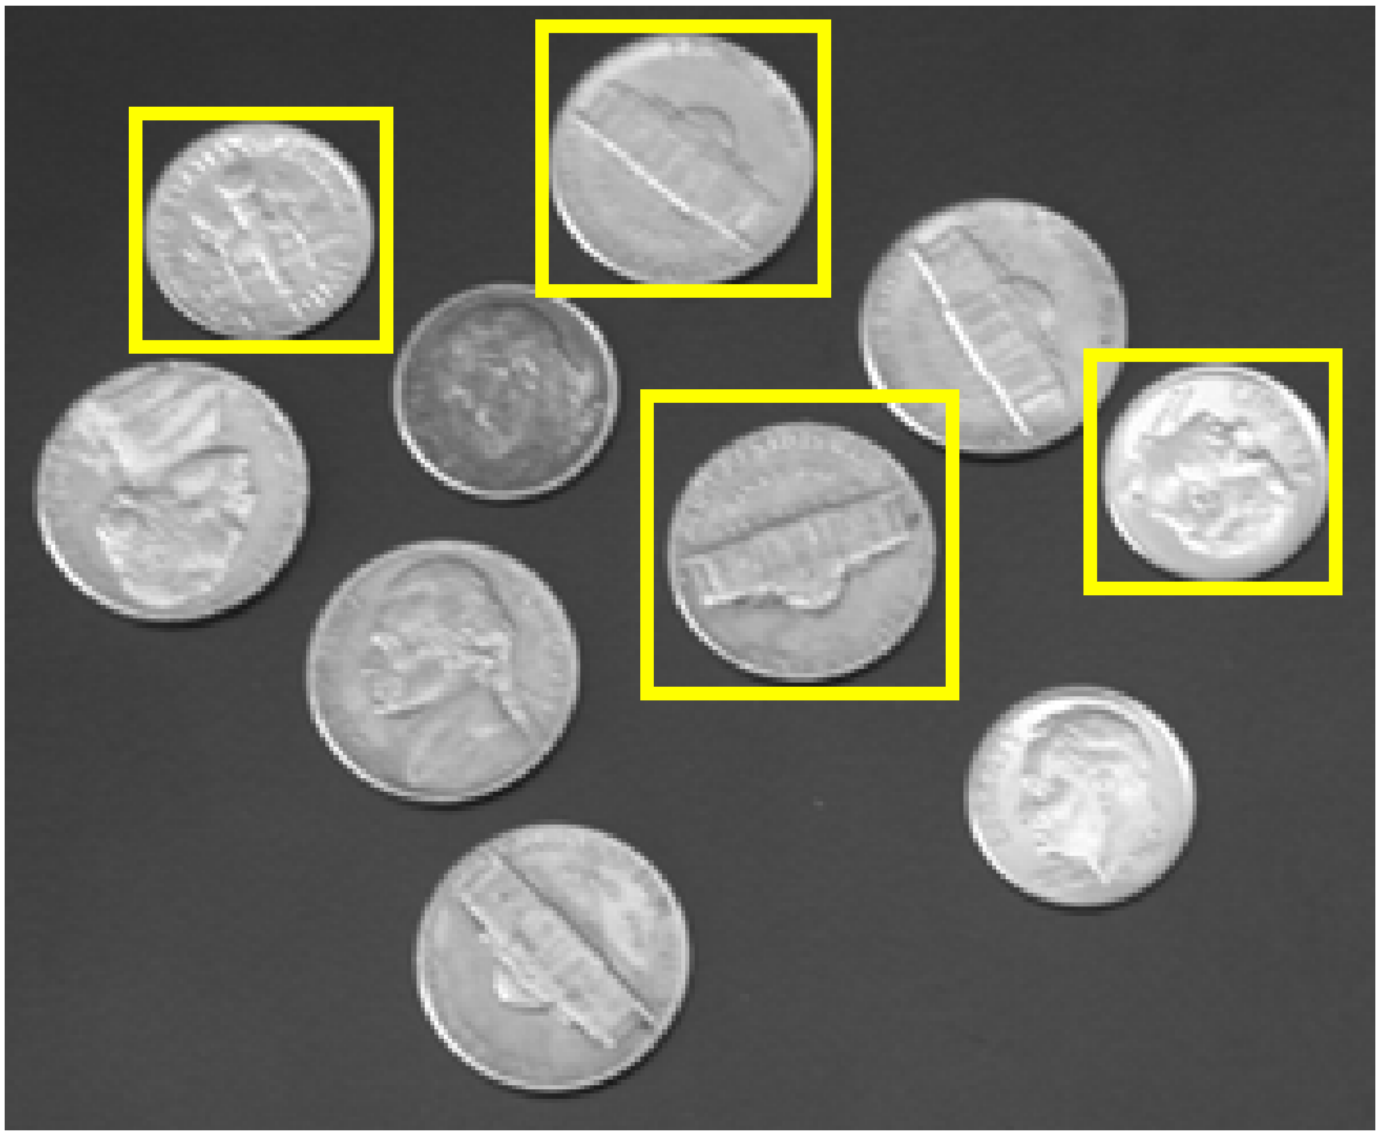
To interactively define bounding box ROIs on the image, use the `uiselectboxes` function. Click a start point in the image and drag boxes around the desired objects. Click **Accept** in the top-right corner of the figure window when you are satisfied with your selections.

```
bboxes = uiselectboxes(hImage)
```

```
bboxes = 4×4

    195.4484     28.4718    69.5974    63.5455
    321.0263    101.0952    55.9805    58.2500
    224.9516    116.2251    65.0584    61.2760
    165.1886     85.9653    55.2240    52.1980
```

This GIF shows how to interactively select bounding boxes by creating and dragging the boxes to different positions on the image.



Extract the patch tiles from the image using the `extractpatches` function.

```
tiles = extractpatches(I,bboxes)
```

```
tiles=4×1 cell array
    64×70 uint8
    58×56 uint8
    62×65 uint8
    52×55 uint8
```

Display the bounding boxes defining the image patches overlaid on the image using the `insertShape` function.

```
annotatedImage = insertShape(I,"rectangle",bboxes,"LineWidth",3);
imshow(annotatedImage)
```

Input Arguments

`hImage` — Input image

`Image` object

Input image object, specified as an `Image` object. To create an `Image` object, use the `imageshow` function. The image must be RGB or grayscale.

`boxColor` — Bounding box boundary color

`[1.0 0.56 1.0]` (default) | RGB triplet | hexadecimal color code | short or long color name

Bounding box boundary color, specified as an RGB triplet, hexadecimal color code, or a short or long color name. For a custom color, specify an RGB triplet or a hexadecimal color code.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1]. For example, `[0.4 0.6 0.7]`.
- A hexadecimal color code is a string scalar or character vector that starts with a hash symbol (`#`) followed by three or six hexadecimal digits, which can range from `0` to `F`. The values are not case sensitive. Therefore, the color codes `"#FF8800"`, `"#ff8800"`, `"#F80"`, and `"#f80"` are equivalent.

Output Arguments

bboxes — Axis-aligned rectangular bounding box ROIs

M-by-4 numeric matrix

Axis-aligned rectangular bounding box ROIs, returned as an *M*-by-4 numeric matrix. *M* is the number of bounding box ROIs. Each row of the matrix represents a bounding box, returned as a 4-element row vector, and is of the form [*x y w h*], where:

- *x* and `y` specify the upper-left corner of the rectangle.
- *w* specifies the width of the rectangle, which is its length along the *x*-axis.
- *h* specifies the height of the rectangle, which is its length along the *y*-axis.

visionTransformer

Pretrained vision transformer (ViT) neural network

Syntax

```
[net,classNames] = visionTransformer
[net,classNames] = visionTransformer(modelName)
[net,classNames] = visionTransformer( ___ ,Name=Value)
```

Description

`[net,classNames] = visionTransformer` returns a base-sized ViT neural network (86.8 million parameters) with a patch size of 16. The network is fine tuned using the ImageNet 2012 data set at a resolution of 384-by-384.

This feature requires a Deep Learning Toolbox license and the Computer Vision Toolbox Model for Vision Transformer Network support package. You can download this support package from the Add-On Explorer. For more information, see “Get and Manage Add-Ons”.

`[net,classNames] = visionTransformer(modelName)` returns the ViT neural network with the specified model name.

`[net,classNames] = visionTransformer( ___ ,Name=Value)` specifies additional options using one or more name-value arguments.

Examples

Load ViT Neural Network

Load a pretrained ViT neural network using the `visionTransformer` function. If the Computer Vision Toolbox™ Model for Vision Transformer Network support package is not installed, then the function provides a link to the required support package in the Add-On Explorer. To install the support package, click the link, and then click **Install**.

Load a pretrained ViT neural network and the class names. If the required support package is installed, then the function returns a `dlnetwork` object and a string array of class names.

```
[net,classNames] = visionTransformer;
```

View the neural network.

```
net
```

```
net =
  dlnetwork with properties:

         Layers: [143×1 nnet.cnn.layer.Layer]
    Connections: [167×2 table]
     Learnables: [200×3 table]
          State: [1×3 table]
```

```
     InputNames: {'imageinput'}
    OutputNames: {'softmax'}
    Initialized: 1

  View summary with summary.
```

View the number of classes.

```
numClasses = numel(classNames)
```

```
numClasses =
1000
```

Input Arguments

`modelName` — Model name

`"base-16-imagenet-384"` (default) | `"small-16-imagenet-384"` | `"tiny-16-imagenet-384"`

Model name, specified as one of these values:

Model Name	Neural Network Name	Parameter Memory	Parameters (Millions)	Image Input Size	Input Value Range	Input Layer Normalization
`"base-16-imagenet-384"`	Base-sized ViT with a patch size of 16, fine-tuned using the ImageNet 2012 data set at a resolution of 384-by-384.	331 MB	86.8	384-by-384	[0, 255]	`"zscore"`
`"small-16-imagenet-384"`	Small-sized ViT with a patch size of 16, fine-tuned using the ImageNet 2012 data set at a resolution of 384-by-384.	85 MB	22.1	384-by-384	[0, 255]	`"zscore"`

Model Name	Neural Network Name	Parameter Memory	Parameters (Millions)	Image Input Size	Input Value Range	Input Layer Normalization
`"tiny-16-imagenet-384"`	Tiny-sized ViT with a patch size of 16, fine-tuned using the ImageNet 2012 data set at a resolution of 384-by-384	22 MB	5.7	384-by-384	[0, 255]	`"zscore"`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `visionTransformer(DropoutProbability=0.2)` returns a pretrained vision transformer neural network with a dropout probability set of 0.2.

`DropoutProbability` — Probability of dropping out input elements in dropout layers
`0.1` (default) | scalar in the range [0, 1)

Probability of dropping out input elements in dropout layers, specified as a scalar in the range [0, 1).

When you train a neural network with dropout layers, the layer randomly sets input elements to zero using the dropout mask `rand(size(X)) < p`, where `X` is the layer input and `p` is the layer dropout probability. The layer then scales the remaining elements by `1/(1-p)`.

This operation helps to prevent the network from overfitting [2], [3]. A higher number results in the network dropping more elements during training. At prediction time, the output of the layer is equal to its input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`AttentionDropoutProbability` — Probability of dropping out input elements in attention layers
`0.1` (default) | scalar in the range [0, 1)

Probability of dropping out input elements in attention layers, specified as a scalar in the range [0, 1).

When you train a neural network with attention layers, the layer randomly sets attention scores to zero using the dropout mask `rand(size(scores)) < p`, where `scores` is the layer input and `p` is the layer dropout probability. The layer then scales the remaining elements by `1/(1-p)`.

This operation helps to prevent the network from overfitting [2], [3]. A higher number results in the network dropping more elements during training. At prediction time, the output of the layer is equal to its input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`net` — Pretrained ViT neural network
`dlnetwork` object

Pretrained ViT neural network, returned as a `dlnetwork` object.

`classNames` — Class names
string array

Class names, returned as a string array.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You can generate generic C/C++ code that does not depend on third-party libraries and deploy the generated code to hardware platforms.

  Code generation that requires any third-party libraries is not supported. To generate code, save the pretrained network to a MAT file and load it using `coder.loadDeepLearningNetwork`. For more information, see “Load Pretrained Networks for Code Generation” (MATLAB Coder).

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- You can generate CUDA code that is independent of deep learning libraries and deploy the generated code to platforms that use NVIDIA GPU processors.

Code generation that requires any deep learning libraries is not supported. To generate code, save the pretrained network to a MAT file and load it using `coder.loadDeepLearningNetwork`. For more information, see “Load Pretrained Networks for Code Generation” (GPU Coder).

vision.loadYOLOXObjectDetector

Load YOLOX object detector model for code generation

Syntax

```
net = vision.loadYOLOXObjectDetector(filename)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`net = vision.loadYOLOXObjectDetector(filename)` loads a pretrained YOLOX object detector model net from the MAT file `filename`. `filename` must be a compile-time constant.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Examples

Generate C++ Code from MAT File Containing YOLOX Object Detector

Use the `vision.loadYOLOXObjectDetector` function to load a YOLOX object detector and generate C code for the network. You must have a pretrained `yoloxObjectDetector` object saved as a variable named `detector` in the file `trainedYoloxObjectDetector.mat`. For an example of training a YOLOX object detector, see `trainYOLOXObjectDetector`.

Load the pretrained `yoloxObjectDetector` object from the MAT file.

```
load("trainedYoloxObjectDetector.mat");
```

Create an entry-point function `myYoloxObject.m` that accepts an image as input. The entry-point function performs these operations:

- Defines a persistent variable called `myDetector`. The persistent variable prevents reconstructing and reloading the network object during subsequent calls to the `myYoloxObject` function.
- Loads the detector from the file `trainedYoloxObjectDetector.mat` into the `myDetector` variable using the `vision.loadYOLOXObjectDetector` function.
- Detects object bounding boxes, scores, and labels on the input test image `imTest` using the detector.

```
function [bboxes,scores,labels] = myYoloxObject(imTest)
  persistent myDetector;
    if isempty(myDetector)
        myDetector = vision.loadYOLOXObjectDetector("trainedYoloxObjectDetector.mat");
    end
```

```
  [bboxes,scores,labels] = detect(myDetector,imTest);
end
```

Read a test image from a graphics file.

```
imTest = imread("highway.png");
```

Create a `coder.config` configuration object for MEX code generation and set the target language to C++. On the configuration object, set the `DeepLearningConfig` property to the target library `"mkldnn"`, for MKL-DNN targets. For more information about the supported target libraries for C++ code generation in deep learning networks, see “Generate Generic C/C++ Code for Deep Learning Networks” (MATLAB Coder).

The `codegen` function must determine the size, class, and complexity of MATLAB function inputs. Use the `-args` option to specify the input test image `imTest` to the entry-point function. Use the `-config` option to pass the code configuration object `myYoloxObject` to `codegen`.

```
cfg = coder.config("mex");
cfg.TargetLang = "C++";
cfg.DeepLearningConfig = coder.DeepLearningConfig(TargetLibrary = "mkldnn");
codegen -args {imTest} -config cfg myYoloxObject -report;
```

The `codegen` command places all the generated files in the `codegen` folder. The folder contains the C code for the entry-point function `myYoloxObject.c`, as well as header and source files containing the C class definitions for the network, weight, and bias files.

Note The YOLOX object detector deep learning network architecture contains the `spaceToDepthLayer`. Code generation for `spaceToDepthLayer` is not supported for the target library `"none"`.

Predict the bounding boxes, detection confidence scores, and object labels in the test image by calling the code generated mex file `myYoloxObject_mex`.

```
[predBboxes,predScores,predLabels] = myYoloxObject_mex(imTest)
```

```
predBboxes
```

```
predBboxes =

  3×4 single matrix

   97.9102  104.5984   39.9582   32.5561
   97.6418  104.9113   41.7848   32.5751
  146.5345   88.3480   82.4816   73.4598
```

```
predScores
```

```
predScores =

  3×1 single column vector

    0.4241
    0.7093
    0.9108
```

```
predLabels

predLabels =

  3×1 categorical array

     car
     truck
     truck
```

Input Arguments

`filename` — Filename

character vector | string scalar

Filename of the MAT file containing the pretrained YOLOX object detector, specified as a character vector or string scalar. The MAT file must exist on the MATLAB path and contain only the network to be loaded.

This input argument must be a compile-time constant.

Data Types: `char` | `string`

Output Arguments

`net` — YOLOX object detector network

`yoloxObjectDetector` object

YOLOX object detector network, returned as a `yoloxObjectDetector` object.

Version History

Introduced in R2023b

insertObjectKeypoints

Insert object keypoints in image

Syntax

```
RGB = insertObjectKeypoints(I,keypoints)
RGB = insertObjectKeypoints( ___ ,Name=Value)
```

Description

`RGB = insertObjectKeypoints(I,keypoints)` inserts a set of object keypoints, `keypoints` into the specified image, `I` and returns the result as a truecolor output image, `RGB`.

`RGB = insertObjectKeypoints( ___ ,Name=Value)` specifies one or more name-value arguments, in addition to any combination of input arguments from the previous syntax, to configure the keypoints to be inserted in the image. For example, `KeypointSize=3` inserts keypoints with the size of 3 pixels in the image.

Examples

Insert Object Keypoints and Connections

Read an input image.

```
I = imread("visionteam.jpg");
```

Run the `detect` method of YOLOv4 object detector to detect bounding boxes around persons in the image. Here, persons are considered as objects.

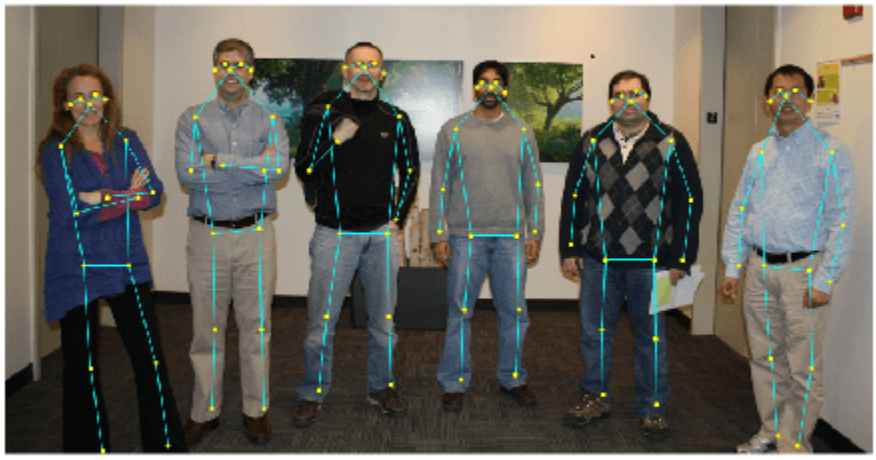
```
detector = yolov4ObjectDetector("csp-darknet53-coco");
[bboxes,scores,labels] = detect(detector,I,Threshold=0.4);
personIndices = labels=="person";
personBoxes = bboxes(personIndices,:);
```

Run the `detect` method of a pretrained HRNet object keypoint detector to detect keypoints of every person in the image.

```
keypointDetector = hrnetObjectKeypointDetector;
[keypoints,keypointScores,valid] = detect(keypointDetector,I,personBoxes);
```

Create an object skeleton from keypoint connections. Each row in the skeleton corresponds to categorical keypoint class indices of a keypoint connection.

```
objectSkeleton = keypointDetector.KeypointConnections
```



```
objectSkeleton = 17×2

     2     4
     2     1
     3     5
     3     1
```

```
     1     6
     1     7
     6     8
     8    10
     7     9
     9    11
     6    12
     7    13
    12    13
    12    14
    14    16
     ⋮
```

Insert the keypoints and skeleton on the respective person and display results.

```
detectedKeypoints = insertObjectKeypoints(I,keypoints,KeypointColor="yellow",KeypointSize=2,...
                                                  Connections=objectSkeleton,ConnectionColor="c",LineWid
imshow(detectedKeypoints);
```

Insert Object Keypoints with Label Annotations

Read an input image.

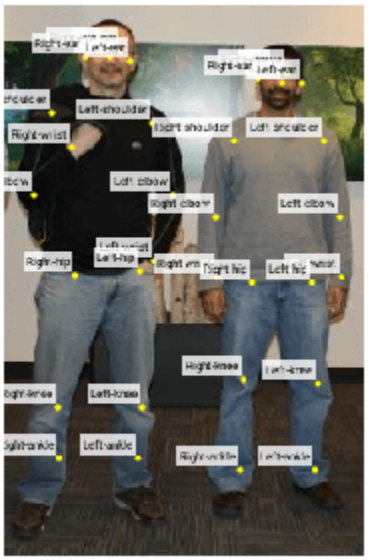
```
I = imread("visionPeople.jpg");
```

Specify a bounding box to detect the persons in the image.

```
bboxes = uint8([1.39,19.30,122.39,341.61;131.78,27.06,108.36,324.50]);
```

Detect keypoints of the person by using the `detect` method of pretrained HRNet object keypoint detector.

```
keypointDetector = hrnetObjectKeypointDetector("human-full-body-w32");
[keypoints,keypointScores,valid] = detect(keypointDetector,I,bboxes);
```



Read categorical class labels of keypoints from the keypoint detector object.

```
labels = keypointDetector.KeyPointClasses
```

```
labels = 17×1 categorical
     Nose
     Left-eye
     Right-eye
     Left-ear
     Right-ear
     Left-shoulder
     Right-shoulder
     Left-elbow
     Right-elbow
     Left-wrist
     Right-wrist
     Left-hip
     Right-hip
     Left-knee
     Right-knee
     Left-ankle
     Right-ankle
```

Insert and display detected keypoints along with the labels in the image.

```
detectedKeypoints = insertObjectKeypoints(I,keypoints,KeypointColor="yellow",KeypointSize=2,keypo
                                          TextBoxColor="white",TextBoxOpacity=0.8,FontSize=8);
imshow(detectedKeypoints);
```

Input Arguments

`I` — Input image

matrix | array

Input image, specified as an *X*-by-*Y* matrix for a grayscale image, or an *X*-by-*Y*-by-3 array for a RGB color image.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16`

`keypoints` — Object keypoints

array

Object keypoints, specified as an *M*-by-2-by-*P* array for *P* objects in the image. *M* is the number of keypoints corresponding to each object in the input image *I*. Each row of the *M*-by-2 matrix is a keypoint location in the format [*x y*].

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `insertObjectKeypoints(__,KeypointColor=[255 0 0])` inserts all the keypoints in red color.

`Connections` — Keypoint indices of keypoint connections

`[]` (default) | matrix

Keypoint indices of keypoint connections specified as an *L*-by-2 matrix. *L* is the number of keypoint connections in an object. Each row in the matrix has two indices of connected keypoints. These two keypoints are connected by a line segment.

Data Types: `double`

`KeypointVisibility` — Keypoint visibility value

`true` (default) | *M*-by-*P* matrix

Keypoint visibility value, specified as an *M*-by-*P* logical matrix. *M* is the number of keypoints in an object. *P* is the total number of objects in the image.

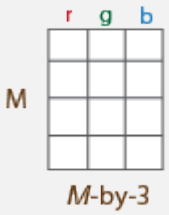
- Keypoints with the keypoint visibility value set to `true` or `1` in the matrix are inserted in the image.
- Keypoints with the keypoint visibility value set to `false` or `0` in the matrix are not inserted in the image.

By default, all keypoints have a keypoint visibility value set to `true` or `1`.

Data Types: `logical`

`KeypointColor` — Keypoint color

`[0.850 0.325 0.098]` (default) | character vector | cell array of character vectors | string scalar | string array | *M*-by-3 matrix



Keypoint color, specified as a character vector, cell array of character vectors, *M*- element vector, or *M*-by-3 matrix of RGB values.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color.

You can specify a different color for each keypoint or one color for all keypoints. To specify one color for all keypoints, set `KeypointColor` to a color string or an [*R G B*] vector.

Specification	Format	Example
One color for all keypoints	String or character color name	`"r"` `"red"`
	1-by-3 vector (RGB triplet)	 `[1 0 0]`
Different color for each keypoint	*M*-element vector	`["red","yellow","blue"]`

Specification	Format	Example

	M-by-3 matrix, as a list of RGB values	`[1 0 0`
		` 0 1 1`
		` 1 0 1]`
		

Supported colors are listed in the table.

Color Name	Short Name	RGB Triplet	Appearance
`"red"`	`"r"`	`[1 0 0]`	
`"green"`	`"g"`	`[0 1 0]`	
`"blue"`	`"b"`	`[0 0 1]`	
`"cyan"`	`"c"`	`[0 1 1]`	
`"magenta"`	`"m"`	`[1 0 1]`	
`"yellow"`	`"y"`	`[1 1 0]`	
`"black"`	`"k"`	`[0 0 0]`	
`"white"`	`"w"`	`[1 1 1]`	

Data Types: `logical` | `uint8` | `uint16` | `int16` | `double` | `single`

`KeypointLabel` — Keypoint labels
`[]` (default) | *M*-element vector

Keypoint labels, specified as an *M*-element categorical vector. *M* is the number of keypoints in an object.

Data Types: `categorical`

`KeypointSize` — Keypoint size
2 (default) | positive integer

Keypoint size, specified as a positive integer in pixels.

Data Types: `categorical`

`Opacity` — Opacity of keypoints and connections
1 (default) | scalar in the range `[0 1]`

Opacity of keypoints and connections, specified as a scalar value in the range [0 1]. The value `1` makes the keypoints and connections completely opaque and the value `0` makes them completely transparent.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ConnectionColor` — Color of line segment connecting keypoints
`[0 0.447 0.741]` (default) | character vector | cell array of character vectors | string scalar | string array | *M*-by-3 matrix

Color of line segment connecting keypoints, specified as a character vector, cell array of character vectors, *M*- element vector, or *M*-by-3 matrix of RGB values.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color.

You can specify a different color for each keypoint connection or one color for all connections. To specify one color for all keypoint connections, set `ConnectionColor` to a color string or an [*R G B*] vector.

For a description of RGB color and how to specify it, see `KeypointColor`.

Data Types: `logical` | `uint8` | `uint16` | `int16` | `double` | `single`

`LineWidth` — Line width of keypoint connection
2 (default) | positive integer

Line width of keypoint connection, specified as a positive integer. The unit is pixels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`TextBoxColor` — Text box color of keypoint label
`"yellow"` (default) | character vector | cell array of character vectors | string scalar | string array | *M*-by-3 matrix

Text box color of keypoint label, specified as a character vector, cell array of character vectors, *M*-element vector, or *M*-by-3 matrix of RGB values. *M* is the number of keypoints in an object.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color.

You can specify a different color for each text box or one color for all text boxes. To specify one color for all text boxes, set `TextBoxColor` to a color string or an [*R G B*] vector.

For a description of RGB color and how to specify it, see `KeypointColor`.

Data Types: `logical` | `uint8` | `uint16` | `int16` | `double` | `single`

`TextBoxOpacity` — Text box background opacity of keypoint label
0.6 (default) | scalar in the range [`0` `1`]

Text box background opacity of keypoint label, specified as a scalar. Specify the opacity value in the range [`0` `1`].

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`FontColor` — Font color of keypoint label
`"black"` (default) | character vector | cell array of character vectors | string scalar | string array | *M*-by-3 matrix

Font color of keypoint label, specified as a character vector, cell array of character vectors, vector, or *M*-by-3 matrix of RGB values. *M* is the number of keypoints in an object.

You can specify a different font color for each keypoint label or one font color for all keypoint labels. To specify one color for all keypoint labels, set `FontColor` to a color string or an [*R G B*] vector. For a description of RGB color and how to specify it, see `KeypointColor`.

Data Types: `logical` | `uint8` | `uint16` | `int16` | `double` | `single`

`Font` — Font face of text
`"Roboto-Regular"` (default) | character vector | string scalar

Font face of text, specified as a character vector. The font face must be one of the available truetype fonts installed on your system. To get a list of available fonts on your system, type `listTrueTypeFonts` at the MATLAB command prompt.

Data Types: `char` | `string`

`FontSize` — Font size of keypoint label text
12 (default) | integer in the range [8 72]

Font size of keypoint label text, specified as an integer that corresponds to points in the range [8 72].

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`RGB` — Output image
truecolor image

Output image, returned as a RGB color image of same datatype as the input image, with the same *X*-by-*Y*-by-3 dimensions as `I`.

Limitations

Value to the `LineWidth`, `TextBoxColor`, `TextBoxOpacity`, `Font`, `FontColor`, `FontSize` arguments should be specified only when the `KeypointLabel` argument is non-empty.

Version History

Introduced in R2023b

R2026a: Default value of `Font` changed to `Roboto-Regular`
Behavior changed in R2026a

Starting in R2026a, the default value of the `Font` name-value argument is `Roboto-Regular`. In previous releases, the default value was `LucidaSansRegular`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- `Font`, `FontSize`, `KeypointColor` and `KeypointConnections` name-value arguments must be compile-time constants.
- Non-ASCII characters are not supported.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

Topics

“Choose Function to Visualize Detected Objects”

loadHRNETObjectKeypointDetector

Load HRNet object keypoint detector model for code generation

Syntax

```
net = loadHRNETObjectKeypointDetector(filename)
```

Description

`net = loadHRNETObjectKeypointDetector(filename)` loads a pretrained HRNet object keypoint detector model net from the MAT file `filename`. `filename` must be a compile-time constant.

Note This functionality requires Deep Learning Toolbox and the Computer Vision Toolbox Model for Object Keypoint Detection. You can download and install the Computer Vision Toolbox Model for Object Keypoint Detection from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Examples

Generate C++ Code from MAT File Containing HRNet Object Keypoint Detector

Use the `loadHRNETObjectDetector` function to load an HRNet object detector and generate C code for the network. You must have a pretrained `hrnetObjectKeypointDetector` object saved as a variable named `detector` in the file `trainedHRNetObjectKeypointDetector.mat`.

Load the pretrained `hrnetObjectKeypointDetector` object from the MAT file.

```
load("trainedHRNetObjectKeypointDetector.mat");
```

Create an entry-point function `myHRNetObject.m` that accepts an image and the bounding boxes of image objects as input. The entry-point function performs these operations:

- Defines a persistent variable called `myDetector`. The persistent variable prevents reconstructing and reloading the network object during subsequent calls to the `myHRNetObject` function.
- Loads the detector from the file `trainedHRNetObjectKeypointDetector.mat` into the `myDetector` variable using the `loadHRNETObjectDetector` function.
- Detects object keypoints, confidence scores, and validity of the objects in the input test image `imTest` using the detector.

```
function [keypoints,scores,valid] = myHRNetObject(imTest,bboxes)
  persistent myDetector;
    if isempty(myDetector)
        myDetector = loadHRNETObjectKeypointDetector("trainedHRNetObjectKeypointDetector.mat");
    end
  [keypoints,scores,valid] = detect(myDetector,imTest,bboxes);
end
```

Read a test image from a graphics file.

```
imTest = imread("visionTeam.jpg");
```

Specify the bounding boxes of objects in the test image.

```
bboxes = [28.999092    48.454803    136.47928    364.54520;
157.66484    34.789597    101.99452    375.76184;
261.84634    39.663254    123.77393    345.26978;
388.49371    49.597092    111.15561    328.06561;
506.54700    51.744110    140.14929    351.37390;
656.18372    49.514694    134.45197    363.48529];
```

Create a `coder.config` configuration object for MEX code generation and set the target language to C++. On the configuration object, set the `DeepLearningConfig` property to the target library `"mkldnn"`, for MKL-DNN targets. For more information about the supported target libraries for C++ code generation in deep learning networks, see “Generate Generic C/C++ Code for Deep Learning Networks” (MATLAB Coder).

Note The HRNet object keypoint detector deep learning network architecture contains the `spaceToDepthLayer`. Code generation for `spaceToDepthLayer` is not supported for target library `"none"`.

The `codegen` function must determine the size, class, and complexity of MATLAB function inputs. Use the `-args` option to specify the input test image `imTest` and object bounding boxes `bboxes` to the entry-point function. Use the `-config` option to pass the code configuration object `myHRNetObject` to `codegen`.

```
cfg = coder.config("mex");
cfg.TargetLang = "C++";
cfg.DeepLearningConfig = coder.DeepLearningConfig(TargetLibrary = "mkldnn");
codegen -args {imTest,bboxes} -config cfg myHRNetObject -report;
```

The `codegen` command places all the generated files in the `codegen` folder. The folder contains the C code for the entry-point function `myHRNetObject.c`, header and source files containing the C class definitions for the network, weight, and bias files.

Compute the object keypoint locations, keypoint confidence scores, and keypoint validity in the test image by calling the code-generated MEX file `myHRNetObject_mex`.

```
[objKeypoints,keypointScores,keypointValid] = myHRNetObject_mex(imTest,bboxes)
```

```

```

Input Arguments

`filename` — Filename

character vector | string scalar

Filename of the MAT file containing the pretrained HRNet object keypoint detector, specified as a character vector or string scalar. The MAT file must exist on the MATLAB path and contain only the network to be loaded.

This input argument must be a compile-time constant.

Data Types: `char` | `string`

Output Arguments

`net` — HRNet object keypoint detector network

`hrnetObjectKeypointDetector` object

HRNet object keypoint detector network, returned as a `hrnetObjectKeypointDetector` object.

Version History

Introduced in R2023b

trainHRNetObjectKeypointDetector

Train HRNet object keypoint detector

Syntax

```
trainedKeypointDetector = trainHRNetObjectKeypointDetector(trainingData,
keypointDetector,options)
trainedKeypointDetector = trainHRNetObjectKeypointDetector(trainingData,
checkpoint,options)
[trainedKeypointDetector,info] = trainHRNetObjectKeypointDetector( ___ )
[ ___ ] = trainHRNetObjectKeypointDetector( ___ ,Name=Value)
```

Description

`trainedKeypointDetector = trainHRNetObjectKeypointDetector(trainingData, keypointDetector,options)` trains an object keypoint detector using the specified high resolution deep learning network (HRNet) `keypointDetector`. You can specify `keypointDetector` as a pretrained or custom HRNet object keypoint detector. The `options` input specifies training parameters for the keypoint detection network.

You can also use this syntax to fine-tune a pretrained HRNet object keypoint detector.

`trainedKeypointDetector = trainHRNetObjectKeypointDetector(trainingData, checkpoint,options)` resumes training from the saved detector checkpoint.

You can use this syntax to:

- Add more training data and continue training a keypoint detector.
- Improve training accuracy by increasing the maximum number of iterations.

`[trainedKeypointDetector,info] = trainHRNetObjectKeypointDetector( ___ )` returns information on the training progress, such as the training loss and learning rate for each iteration, using any combination of input arguments from previous syntaxes.

`[ ___ ] = trainHRNetObjectKeypointDetector( ___ ,Name=Value)` specifies options using one or more name-value arguments. For example, `ExperimentMonitor=[]` specifies not to track metrics using Experiment Manager.

Note This functionality requires Deep Learning Toolbox and the Computer Vision Toolbox Model for Object Keypoint Detection. You can install the Computer Vision Toolbox Model for Object Keypoint Detection from the Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Examples

Train HRNet Keypoint Detection Network for Hand Keypoints Detection

Fine-tune a pretrained HRNet object keypoint detector to detect the keypoints of a human hand in an image. The keypoint detector uses an HRNet-W32 deep learning network, trained on the COCO keypoint detection data set.

Download and load the hand pose data set using `helperDownloadHandPoseDataset` helper function. The hand pose data set is a labeled data set that contains 2500 images from the Large-Scale Multiview Hand Pose Dataset [1 on page 3-1685]. Extract a subset of the downloaded hand pose data set that contains the first 100 images. Each image in the data set contains a human hand with 21 annotated keypoints.

```
downloadFolder = tempdir;
dataset = helperDownloadHandPoseDataset(downloadFolder);
data = load(dataset);
handPoseDataset = data.handPoseDataset(1:100,:);
```

The training data is a table with three columns in which the first, second, and third columns contain the image filenames, keypoint locations, and hand bounding boxes, respectively. Each entry in the keypoint locations column consists of an *N*-by-2 matrix, where *N* is the number of keypoints present in the hand in the corresponding image. Each image contains only one hand, which is one object. Therefore, each row represents one object in an image. Add the full data path to the locally stored hand pose data folder.

```
handPoseDataset.imageFilename = fullfile(downloadFolder,"2DHandPoseDataAndGroundTruth","2DHandPos
```

Create an `ImageDatastore` object for loading the image data.

```
handPoseImds = imageDatastore(handPoseDataset.imageFilename);
```

Create an `ArrayDatastore` object for loading the ground truth keypoint location data.

```
handPoseArrds = arrayDatastore(handPoseDataset(:,2));
```

Create a `boxLabelDatastore` object for loading the bounding box locations.

```
handPoseBlds = boxLabelDatastore(handPoseDataset(:,3));
```

Combine the image, array, and box label datastores into a single datastore.

```
trainingData = combine(handPoseImds,handPoseArrds,handPoseBlds);
```

Specify the keypoint classes in a human hand.

```
keypointClasses = ["forefinger3","forefinger4","forefinger2","forefinger1", ...
    "middleFinger3","middleFinger4","middleFinger2","middleFinger1", ...
    "pinkyFinger3","pinkyFinger4","pinkyFinger2","pinkyFinger1", ...
    "ringFinger3","ringFinger4","ringFinger2","ringFinger1", ...
    "thumb3","thumb4","thumb2","thumb1","wrist"]';
```

Create an `hrnetObjectKeypointDetector` object, and configure it to detect the specified keypoints classes.

```
handKeypointDetector = hrnetObjectKeypointDetector("human-full-body-w32",keypointClasses);
handKeypointDetector.Network
```

```
ans =
  dlnetwork with properties:
```

```
         Layers: [1036×1 nnet.cnn.layer.Layer]
    Connections: [1196×2 table]
     Learnables: [1170×3 table]
          State: [584×3 table]
     InputNames: {'input_1'}
    OutputNames: {'finallayer'}
    Initialized: 1

  View summary with summary.
```

Specify training options for the hand keypoint detector.

```
options = trainingOptions("adam", ...
    MaxEpochs=20, ...

Input Arguments

`trainingData` — Labeled ground truth images

datastore

Labeled ground truth images, specified as a datastore. Your data must be set up so that using the `read` or `readall` function on the datastore returns a cell array with three columns in the order {*ImageData*,*Keypoint*,*BoundingBox*}. This table describes the format of each cell in a row.

ImageData	Keypoint	BoundingBox
Grayscale, RGB, or multi-channel image that serves as a network input, specified as an *H*-by-*W* numeric matrix, *H*-by-*W*-by-3 numeric array, or *H*-by-*W*-by-*C* numeric array, respectively, where: • *H* is the height of the image. • *W* is the width of the image. • *C* is number of channels in the image.	Keypoint locations, defined in spatial coordinates as an *N*-by-2 or *N*-by-3 numeric matrix with rows of the form [*x y*] or [*x y v*], respectively, where: • *N* is the number of keypoint classes. • *x* and `y` specify the spatial coordinates of a keypoint. • *v* specifies the visibility of a keypoint.	Bounding box, defined in spatial coordinates as a 1-by-4 numeric vector of the form [*x y w h*], where: • *x* and `y` specify the upper-left corner of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis. • *h* specifies the height of the rectangle, which is its length along the *y*-axis.

Use the `combine` function on an `ImageDatastore`, an `arrayDatastore` and a `boxLabelDatastore` datastore, in that order, to create a combined datastore that returns these three data columns using `read`.

`keypointDetector` — Pretrained or untrained HRNet object keypoint detector

`hrnetObjectKeypointDetector` object

Pretrained or untrained HRNet object keypoint detector, specified as an `hrnetObjectKeypointDetector` object.

`options` — Training options

`TrainingOptionsSGDM` object | `TrainingOptionsRMSProp` object | `TrainingOptionsADAM` object

Training options, specified as a `TrainingOptionsSGDM`, `TrainingOptionsRMSProp`, or `TrainingOptionsADAM` object returned by the `trainingOptions` function. To specify the solver name and other options for network training, use the `trainingOptions` function. You must set the `BatchNormalizationStatistics` property of the object to `"moving"`.

`checkpoint` — Saved detector checkpoint
`hrnetObjectKeypointDetector` object

Saved detector checkpoint, specified as an `hrnetObjectKeypointDetector` object. To periodically save a detector checkpoint during training as a MAT file, specify a location for the file using the `CheckpointPath` property of the training options object `options`. To control how frequently the detector saves checkpoints, use the `CheckPointFrequency` and `CheckPointFrequencyUnit` properties of the training options object.

To load a checkpoint for a previously trained detector, load the MAT file from the checkpoint path. For example, this code loads the checkpoint MAT file of a detector from the `"checkpath"` folder in the current working directory to which the detector saves checkpoints during training.

```
data = load("checkpath/net_checkpoint__6__2023_11_17__16_03_08.mat");
checkpoint = data.net;
```

The name of each MAT file includes the iteration number and timestamp at which the detector saves the checkpoint. The file stores the detector in the `net` variable. To continue training the network, specify the detector extracted from the file to the `trainHRNetObjectKeypointDetector` function.

```
HRNetDetector = trainHRNetObjectKeypointDetector(trainingData,checkpoint,options);
```

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `trainHRNetObjectKeypointDetector(trainingData,ExperimentMonitor=[])` specifies not to track metrics with Experiment Manager.

`ExperimentMonitor` — Detector training experiment monitoring
`[]` (default) | `experiments.Monitor` object

Detector training experiment monitoring, specified as an `experiments.Monitor` object for use with the Experiment Manager app. You can use this object to track the progress of training, update information fields in the training results table, record values of the metrics used by the training, or produce training plots. For more information on using this app, see the “Train Object Detectors in Experiment Manager” example.

The app monitors this information during training:

- Training loss at each iteration
- Learning rate at each iteration
- Validation loss at each iteration, if the `options` input contains validation data

Output Arguments

`trainedKeypointDetector` — Trained HRNet object keypoint detector
`hrnetObjectKeypointDetector` object

Trained HRNet object keypoint detector, returned as an `hrnetObjectKeypointDetector` object.

`info` — Training progress information
structure array

Training progress information, returned as a structure array with these fields. Each field corresponds to a stage of training.

- `TrainingLoss` — Training loss at each iteration. The `trainHRNetObjectKeypointDetector` function computes the mean squared error (MSE) loss between predicted and ground truth keypoint heatmaps. For more information, see “Getting Started with HRNet”.
- `BaseLearnRate` — Learning rate at each iteration.
- `OutputNetworkIteration` — Iteration number of the returned network.

Each field is a numeric vector with one element per training iteration. If the function does not calculate a metric at a specific iteration, the corresponding element of that vector has a value of `NaN`.

Version History

trainNerfacto

Create and train Nerfacto Neural Radiance Field (NeRF) model

Syntax

```
nerf = trainNerfacto(trainingData,cameraPoses,intrinsics,outputFolder)
nerf = trainNerfacto(pretrainedModelFolder)
nerf = trainNerfacto( ___ ,Name=Value)
```

Description

Add-On Required: This feature requires the Computer Vision Toolbox Interface for Nerfstudio Library add-on.

`nerf = trainNerfacto(trainingData,cameraPoses,intrinsics,outputFolder)` creates and trains a Nerfacto Neural Radiance Field (NeRF) model [1] from the Nerfstudio Library [2] on a collection of images taken from different camera poses. The function also creates a model folder which contains the model weights and other parameters in the path that you specified using the `outputFolder` argument.

Note This feature requires the Computer Vision Toolbox Interface for Nerfstudio Library add-on, a Deep Learning Toolbox license, a Parallel Computing Toolbox license, and a CUDA enabled NVIDIA GPU with at least 16 GB of available GPU memory.

`nerf = trainNerfacto(pretrainedModelFolder)` resumes training of a pretrained Nerfacto NeRF model.

`nerf = trainNerfacto( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination input of arguments from previous syntaxes. For example, `MaxIterations=1000` specifies to perform a maximum of 1000 training iterations on the NeRF model.

Examples

Train Neural Radiance Field Model and Generate Novel Views

Training Data Requirements

To train a NeRF model [1 on page 3-1692] from the Nerfstudio Library [2 on page 3-1692] on a scene, your training set must contain:

- At least 100 images of the scene from multiple overlapping views of the region of interest.
- Camera poses associated with each image.
- Intrinsic parameters of camera used to capture the images.

To calculate the intrinsic parameters of camera through calibration, use the Camera Calibrator app. For information on estimating camera poses and related geometric information, see the “Structure from Motion from Multiple Views” example.

Download Training Data

The training data is located in the `sfmTrainingDataTUMRGBD` folder, which is stored in the `tum_rgbd_nerfacto.zip` file. Download and extract the `tum_rgbd_nerfacto.zip` file in the current directory by running this code.

The `tum_rgbd_nerfacto.zip` file contains the `sfmTrainingDataTUMRGBD` folder. The folder contains the `cameraInfo.mat` file which contains the camera poses associated with each image and the intrinsic parameter of camera, and the `images` folder which contains indoor images from the TUM RGB-D dataset [3 on page 3-1692].

Download and extract `tum_rgbd_nerfacto.zip`.

```
if ~exist("tum_rgbd_data.zip","file")
    websave("tum_rgbd_data.zip","https://ssd.mathworks.com/supportfiles/3DReconstruction/tum_rgbd
    unzip(fullfile("tum_rgbd_data.zip"), pwd);
end
```

Set Up Training Data

Specify the path to the `images` folder, and then create an `imageDatastore` object using the path.

```
trainingImageFolder = fullfile("sfmTrainingDataTUMRGBD","images");
imds = imageDatastore(trainingImageFolder);
disp("Number of images: " + length(imds.Files))
```

```
Number of images: 104
```

Show the first training image.

```
figure
sampleTrainingImage = preview(imds);
imshow(sampleTrainingImage)
title("Sample Training Image")
```

Load the camera poses corresponding to the training images, and the intrinsic parameters of the camera used to capture the images.

```
camInfo = load(fullfile("sfmTrainingDataTUMRGBD","cameraInfo.mat"));
trainIntrinsics = camInfo.intrinsics;
trainPoses = camInfo.cameraPoses;
```

Display the camera poses. Observe that there are 104 camera poses, which corresponds to the 104 training images in the image datastore `imds`.

```
disp(trainPoses)
```

```
  1×104 rigidtform3d array with properties:

    Dimensionality
    Translation
    R
    A
```

Display the camera intrinsics. The `trainNerfacto` function assumes that all images were taken by a single camera, thus sharing the same intrinsics parameters for all training images.

```
disp(trainIntrinsics)
```

```
  cameraIntrinsics with properties:

            FocalLength: [535.1307 532.1860]
         PrincipalPoint: [323.3722 239.7986]
              ImageSize: [480 640]
       RadialDistortion: [-0.0032 0.0192]
    TangentialDistortion: [-0.0029 -0.0023]
                    Skew: 0
                       K: [3×3 double]
```

Train NeRF Model

Use the `trainNerfacto` function to create and train a NeRF model on the training images across up to 1000 iterations. Store intermediate model checkpoints and configurations in the `nerfTUMTrainingOutput` folder. Training requires about 30 minutes on a Linux machine with an NVIDIA GeForce RTX 3090 GPU that has 24 GB of memory.

```
outputFolder = fullfile(pwd,"nerfTUMTrainingOutput");
nerf = trainNerfacto(imds,trainPoses,trainIntrinsics,outputFolder,MaxIterations = 1000);
```

Write Novel Views from Trained NeRF Model to Image Files

Write the views captured by the first 20 camera poses to a local folder, `generatedTrainingViewsTUM`, by using the `writeViews` function.

```
imdsGen = writeViews(nerf,trainPoses(1:20),"generatedTrainingViewsTUM");
```

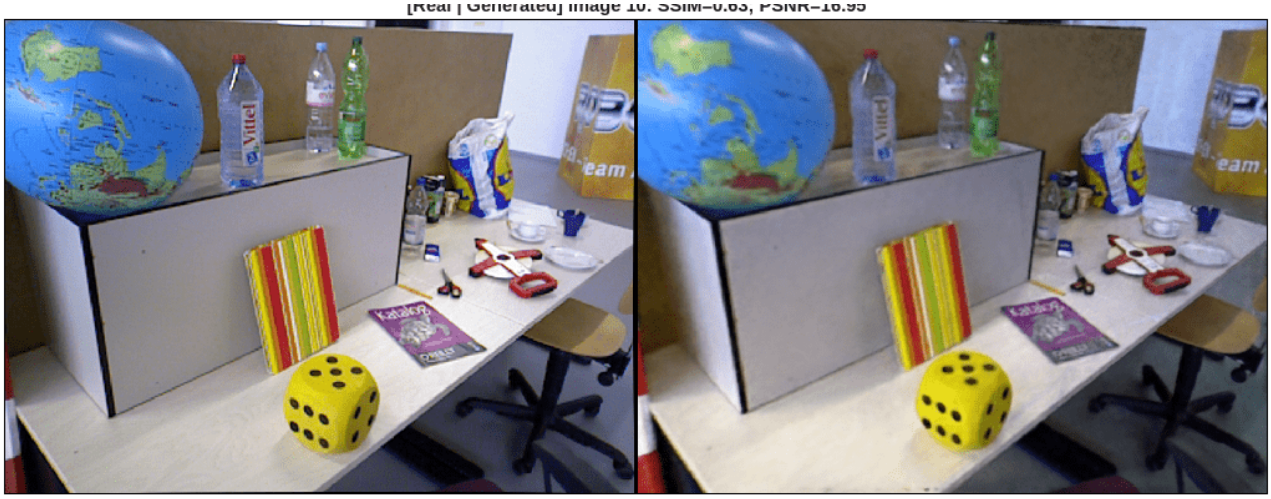
Display a side-by-side comparison between the training images and the generated images of the scene at a camera pose. Each comparison includes these metrics that quantify the similarity between the training images and the generated images:

- Structural Similarity Index Metrics (SSIM) — Value in the range [0,1], where a value of 1 indicates the perfect similarity.

- Peak Signal-to-Noise Ratio (PSNR) — Values are in decibels, where higher values indicate better similarity.

`imageIdx` selects the camera pose to compare.

```
numImg = numel(imdsGen.Files);



imageIdx =  10                                                  ;

% Load image generated by the trained NeRF
imageGen = readimage(imdsGen, imageIdx);

% Load the corresponding real image used in training
imageReal = readimage(imds,imageIdx);

% Compute image similarity metrics - SSIM and PSNR
ssimVal = ssim(rgb2gray(imageGen), rgb2gray(imageReal));
psnrVal = psnr(imageGen, imageReal);

% Visualize the images and their similarity maps
figure
montage({imageReal,imageGen}, BorderSize=[2 2])
title("[Real | Generated] Image " + imageIdx + ": SSIM="+num2str(ssimVal,2) + "; PSNR="+num2str(p
truesize;
```

Tips to Improve Training Results

Although the generated images are photorealistic, there are minor differences in the image texture and high-frequency details between the generated images and the training images. To achieve better quality results:

- Capture a larger set of high resolution images.
- Ensure the image set has good lighting.
- Ensure the image set has no motion blur or moving objects.
- Train the `nerfacto` object with a higher number of maximum training iterations (at the cost of longer computation time).

Input Arguments

`trainingData` — Training image collection

`imageDatastore` object

Training image collection, specified as an `imageDatastore` object. The image collection must contain three channel `uint8` RGB images in JPEG or PNG formats. All images must be in the same format.

Tip To improve the quality of the trained Nerfacto NeRF model, ensure that your training image collection:

- Contains at least 100 images that capture the subject from multiple overlapping views with good lighting
- Contains no motion blur or moving object

`cameraPoses` — Camera poses of training images

M-by-1 vector of `rigidtform3d` objects

Camera poses of the training images, specified as an *M*-by-1 vector of `rigidtform3d` objects, where *M* is the number images in the training image collection. Each element of the vector specifies the camera pose of the corresponding training image.

Tip For sequential training images, such as video frames, use the `monovslam` object to obtain the camera poses for each training image. To learn more about how to estimate camera poses from non-sequential training images, see “Structure from Motion from Multiple Views”.

`intrinsics` — Intrinsic parameters of camera

`cameraIntrinsics` object

Intrinsic parameters of the camera used to capture the training images, specified as a `cameraIntrinsics` object. Camera intrinsic parameters include the focal length, principal point, and skew of the camera.

Tip Use the Camera Calibrator app to obtain the camera intrinsic parameters from your training images. For an example of how to obtain camera intrinsic parameters using the app, see “Using the Single Camera Calibrator App”.

`outputFolder` — Output model folder path

string scalar | character vector

Output model folder path, specified as a string scalar or character vector. The function stores the trained NeRF model and the associated configuration file in this folder. The folder that you specify must be empty and writeable. If a folder that you specify in the path does not exist, the `trainNerfacto` function creates that folder.

Data Types: `char` | `string`

`pretrainedModelFolder` — Pretrained model folder path

string scalar | character vector

Pretrained model folder path, specified as a string scalar or a character vector. This path must match the path in the “ModelFolder” on page 2-0 property of the nerfacto object for the pretrained model.

Data Types: `char` | `string`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `trainNerfacto(trainingData,cameraPoses intrinsics,OutputFolder,MaxIterations=1000)` specifies to perform a maximum of 1000 training iterations.

`MaxIterations` — Maximum training iterations

`30000` (default) | positive integer

Maximum number of training iterations, specified as a positive integer.

Tip This hyperparameter has the highest impact to the quality of the trained Nerfacto NeRF model. Increasing this value improves the quality of the scene reconstruction that the Nerfacto NeRF model generates, but increases the training time.

Data Types: `single` | `double`

`CheckpointFrequency` — Checkpoint saving interval

5 (default) | positive integer

Checkpoint saving interval, specified as a positive integer. This parameter specifies the iterations interval at which checkpoints are saved during model training.

Data Types: `single` | `double`

`SaveAllCheckpoints` — Keep all saved checkpoints
`false` or `0` (default) | `true` or `1`

Keep all saved checkpoints, specified as a logical `0` (`false`) or `1` (`true`). If you specify this value as `false`, the function only saves the most recent checkpoint and deletes all other checkpoints once training is complete.

Data Types: `logical`

`NumImagesToSample` — Number of images to sample in each iteration
inf (default) | positive integer

Number of images to sample in each training iteration, specified as a positive integer. By default, pixels are randomly sampled from all training images. Reducing this value reduces memory consumption during training.

Data Types: `single` | `double`

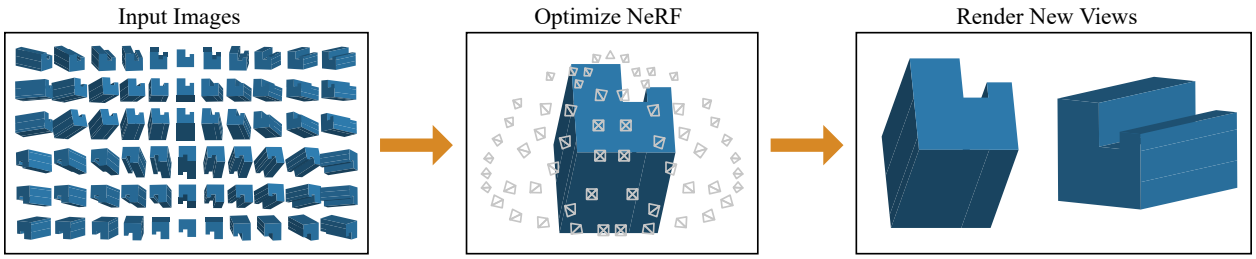
`OptimizeCameras` — Refine camera poses during training
`true` or `1` (default) | `false` or `0`

Refine camera poses during training, specified as a logical `1` (`true`) or `0` (`false`). Specify this value as `true` improves the training result If the initial camera poses of the training data are not accurate. If the initial camera poses are highly accurate, setting this value to `false` may improve the training result.

Data Types: `logical`

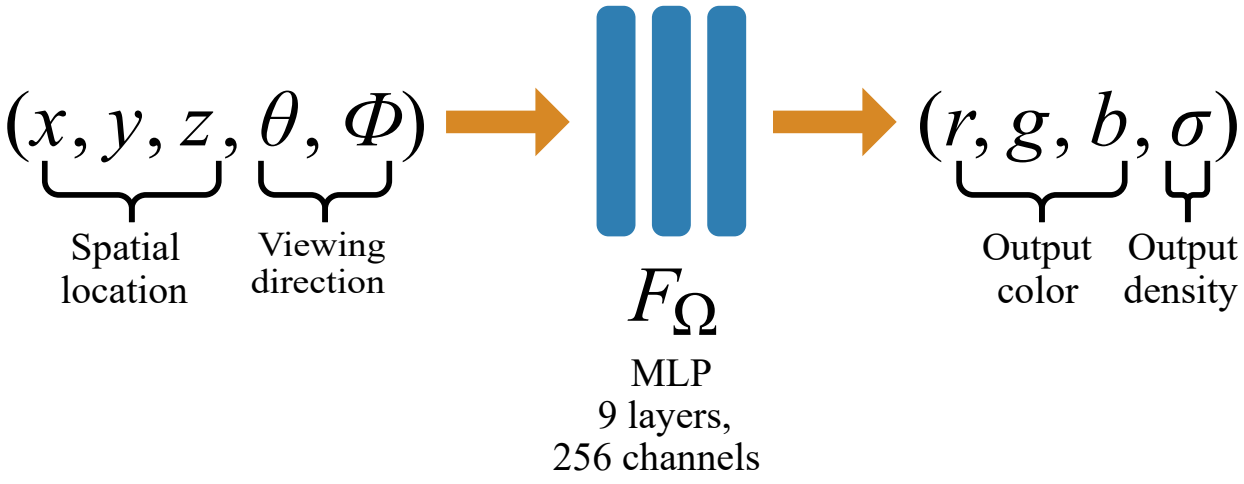
Output Arguments

`nerf` — Trained Nerfacto NeRF model
`nerfacto` object



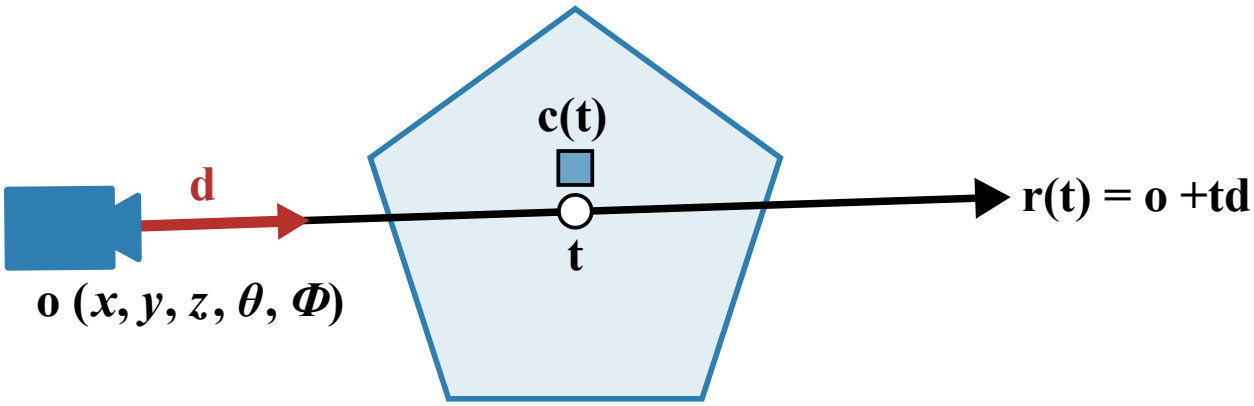
Trained Nerfacto NeRF model, returned as a `nerfacto` object.

Tips

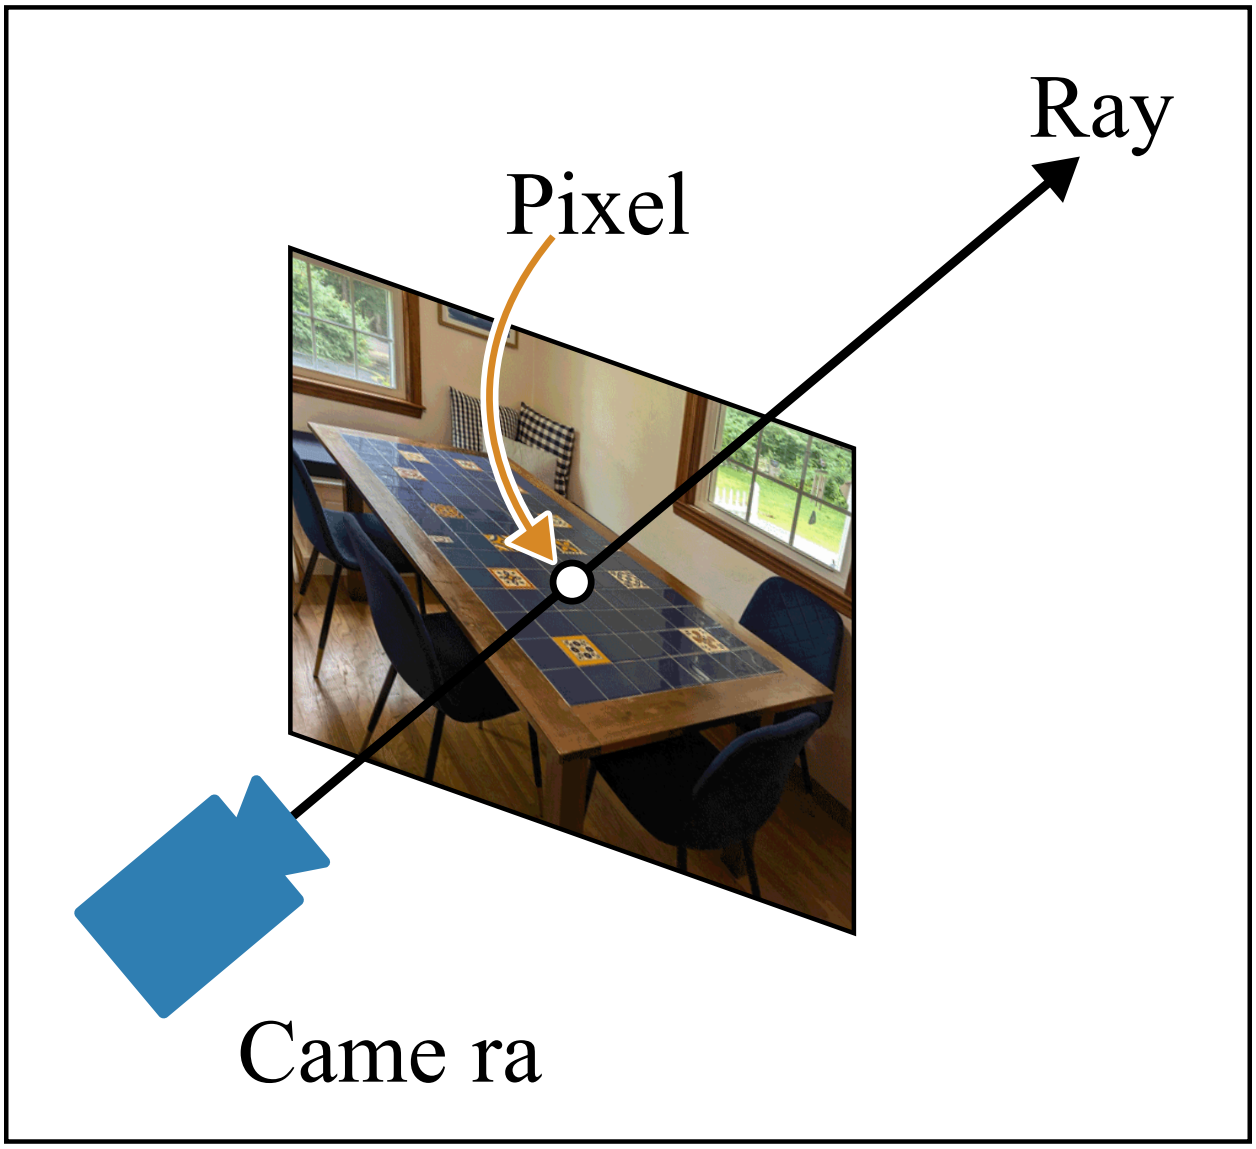


Training a Nerfacto NeRF model using high-resolution training images can cause out-of-memory errors. To resolve this, reduce the size of your training images using the `imresize` function, then obtain the camera poses and camera intrinsic parameters of the resized images.

Algorithms

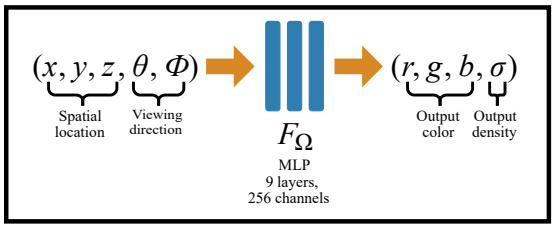


By training a NeRF model on a set of sparse input images and camera poses, you can create an internal representation of a 3D scene. You can use a trained NeRF model to generate a dense, colored point cloud, and render images from novel viewpoints.



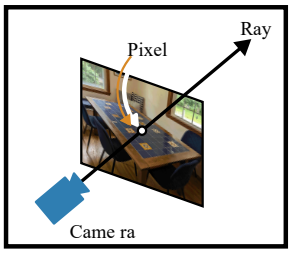
Input Images
Optimize NeRF
Render New Views

A NeRF model represents a scene as a continuous 5D vector-valued function instantiated as a neural network with weights Ω. The function accepts the position and direction of a light ray and returns the color and density of 3D points along the ray.



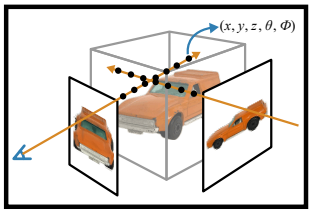
(x, y, z, θ, Φ)
Spatial location
Viewing direction
F_Ω
MLP
9 layers,
256 channels
(r, g, b, σ)
Output color
Output density

When generating a novel view, the NeRF model first uses the neural network to calculate the color and density of 3D points along each ray from a virtual camera. The ray is defined as $r(t) = o + td$, where o is the origin coordinates of the ray, and d is the unit vector in the ray direction defined by the camera angles θ and ϕ. The neural network return the color $c(t)$ if the ray $r(t)$ hits a particle at distance t along the ray. The model then uses volumetric rendering to project the output colors and densities into an image.



c(t)
d
r(t) = o +td
t
o (x, y, z, θ, Φ)

Ray
Pixel
Came ra



During training, a NeRF model first samples a batch of rays that consist of multiple spatial locations and viewing directions. The neural network F_Ω then predicts the color and density at 3D points along each ray, and the NeRF model uses volumetric rendering to project the output colors and densities onto an image. The model calculates the training loss by matching the image pixels of the rendered image against the captured images in the training data.

Predict color and density at 3D points along ray using neu ral net

Calculate color at each pixel using volumetric rendering

Calculate t raining loss by comparing rendered vs actual image pixels

Version History

Introduced in R2026a

generatePointCloud

Generate dense, colored point cloud using trained Nerfacto Neural Radiance Field (NeRF) model

Syntax

```
ptCloud = generatePointCloud(nerf)
ptCloud = generatePointCloud(nerf,MaxNumPoints=numPoints)
```

Description

Add-On Required: This feature requires the Computer Vision Toolbox Interface for Nerfstudio Library add-on.

`ptCloud = generatePointCloud(nerf)` generates a dense, colored point cloud using a trained Nerfacto NeRF model [1] from the Nerfstudio Library [2].

Note This feature requires the Computer Vision Toolbox Interface for Nerfstudio Library add-on, a Deep Learning Toolbox license, a Parallel Computing Toolbox license, and a CUDA enabled NVIDIA GPU with at least 16 GB of available GPU memory.

`ptCloud = generatePointCloud(nerf,MaxNumPoints=numPoints)` specifies the maximum number of points in the dense, colored point cloud

Examples

Generate Point Cloud Using Neural Radiance Field Model

Download Pretrained NeRF Model

The `tum_rgbd_nerfacto.zip` file contains the `trainedNerfactoTUMRGBD` folder. The folder contains the `saved-nerfacto-tum-rgbd.mat` supporting file, which contains a `nerfacto` object that has been trained on a sequence of indoor images from the TUM RGB-D data set [1 on page 3-1706], and the `nerfactoModelFolder` folder, which contains the data and configuration files required for the Nerfstudio Library [2 on page 3-1706] to load and execute the trained NeRF model [3 on page 3-1706].

Download and extract `tum_rgbd_nerfacto.zip`.

```
if ~exist("tum_rgbd_nerfacto.zip","file")
    websave("tum_rgbd_nerfacto.zip","https://ssd.mathworks.com/supportfiles/3DReconstruction/tum_
    unzip("tum_rgbd_nerfacto.zip",pwd);
end
```

Specify the path to the folder containing the `saved-nerfacto-tum-rgbd` MAT file, and then load the pretrained `nerfacto` object into the workspace.

```
modelRoot = fullfile(pwd, "trainedNerfactoTUMRGBD");
load(fullfile(modelRoot, "saved-nerfacto-tum-rgbd.mat"))
```

```
Warning: The model folder for the nerfacto object could not be loaded. Update the model folder lo
  '\\mathworks\devel\sandbox\user\Shared\EX_25b\EX_nerfacto_feature\train_nerfacto_small'
```

MATLAB® displays a warning when you first load the pretrained `nerfacto` object into the workspace because the path to the model folder associated with the object, `nerfactoModelFolder`, changes when you extract the `nerfacto_saved_model.zip`.

To resolve this issue, use the `changePath` function to update the `ModelFolder` property of the trained `nerfacto` object to the current path of `nerfactoModelFolder`. This process can take a few minutes.

```
nerf = changePath(nerf, fullfile(modelRoot, "nerfactoModelFolder"));
```

```
Changing nerfacto object model folder path.
nerfacto object model folder path change complete.
```

Display the `nerfacto` object properties to verify that the `ModelFolder` property is set to the current path of `nerfactoModelFolder` on your system.

```
disp(nerf)
```

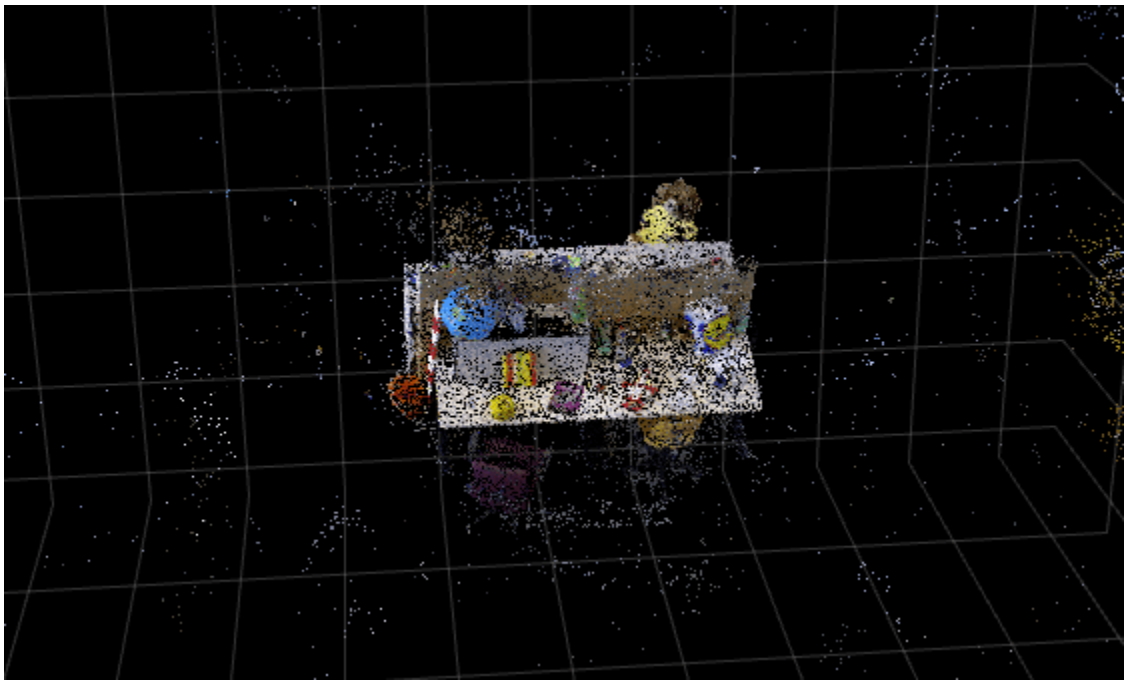
```
  nerfacto with properties:

      ModelFolder: "/home/user/Documents/MATLAB/ExampleManager/user.Bdoc.EX_26a_v1/vision-ex9089
    MaxIterations: 30000
       Intrinsics: [1×1 cameraIntrinsics]
```

Generate Point Cloud with Pretrained NeRF Model

Use the `generatePointCloud` function to generate a dense, colored point cloud of the scene. Set the maximum number of points in the point cloud to 100,000 by specifying the `MaxNumPoints` name-value argument. This value achieves a balance between the quality of the point cloud, the computing time, and storage space.

```
ptCloud = generatePointCloud(nerf, MaxNumPoints=100000);
```



```
Generating point cloud from nerfacto object.

Setting up the Nerfstudio pipeline...
[12:27:23 PM] Auto image downscale factor of 1                                                  nerfs
Setting up training dataset...
Caching all 104 images.
Loading latest checkpoint from load_dir
nerfacto object point cloud generation complete.
```

Visualize Point Cloud

Visualize the point cloud by using the `pcshow` function, and specify the vertical axis and vertical axis direction to match the coordinate system of the TUM RGB-D data set used to train the `nerfacto` object. Modify the view of the point cloud visualization to focus on the scene region of interest by specifying the of low-level camera properties of the axes object. For more information on configuring these properties, see “Low-Level Camera Properties”.

```
figure
ax = pcshow(ptCloud, VerticalAxis="y",VerticalAxisDir="down");
ax.CameraPosition = [-1.5185 -6.5178 -11.9106];
ax.CameraUpVector = [0.0520 -0.8878 0.4572];
ax.CameraViewAngle = 15;
```

```
xlabel("X")
ylabel("Y")
zlabel("Z")
title("Point Cloud from NeRF")
```

Tip: You can use the `pcdenoise` function to clean up the outliers and noise in the point cloud.

Input Arguments

`nerf` — Trained Nerfacto NeRF model
`nerfacto` object

Trained Nerfacto NeRF model, specified as a `nerfacto` object.

`numPoints` — Maximum number of points in generated dense, colored point cloud
`500000` (default) | positive integer

Maximum number of points in the generated dense colored point cloud, specified as a positive integer. Increasing this value results in a higher quality point cloud, but increases the point cloud size and processing time.

Note The generated point cloud might contain fewer points than the maximum number of points specified because the Nerfacto NeRF model rejects outlier points during point cloud generation.

Data Types: `single` | `double`

Output Arguments

`ptCloud` — Dense, colored point cloud
`pointCloud` object

Dense, colored point cloud, returned as a `pointCloud` object. The object contains the location, color, and normal vector for each point in the point cloud.

Version History

Introduced in R2026a

generateViews

Generate novel views using Nerfacto Neural Radiance Field (NeRF) model

Syntax

```
I = generateViews(nerf,cameraPoses)
I = generateViews( ___ ,Intrinsics=virtualCameraIntrinsics)
```

Description

Add-On Required: This feature requires the Computer Vision Toolbox Interface for Nerfstudio Library add-on.

`I = generateViews(nerf,cameraPoses)` generates novel views using the trained Nerfacto NeRF model [1] from the Nerfstudio library [2], for the specified virtual camera poses `cameraPoses`.

Note This feature requires the Computer Vision Toolbox Interface for Nerfstudio Library add-on, a Deep Learning Toolbox license, a Parallel Computing Toolbox license, and a CUDA enabled NVIDIA GPU with at least 16 GB of available GPU memory.

`I = generateViews( ___ ,Intrinsics=virtualCameraIntrinsics)` specifies the intrinsic parameters of the virtual camera in addition to all input arguments from the previous syntax.

Examples

Generate Novel Views using Neural Radiance Field Model

Download Pretrained NeRF Model

The `tum_rgbd_nerfacto.zip` file contains the `trainedNerfactoTUMRGBD` folder. The folder contains the `saved-nerfacto-tum-rgbd.mat` supporting file, which contains a `nerfacto` object that has been trained on a sequence of indoor images from the TUM RGB-D data set [1 on page 3-1712], and the `nerfactoModelFolder` folder, which contains the data and configuration files required for the Nerfstudio Library [2 on page 3-1712] to load and execute the trained NeRF model [3 on page 3-1712].

Download and extract `tum_rgbd_nerfacto.zip`.

```
if ~exist("tum_rgbd_nerfacto.zip","file")
    websave("tum_rgbd_nerfacto.zip","https://ssd.mathworks.com/supportfiles/3DReconstruction/tum_
    unzip("tum_rgbd_nerfacto.zip", pwd);
end
```

Specify the path to the folder containing the `saved-nerfacto-tum-rgbd` MAT file, and then load the pretrained `nerfacto` object into the workspace.

```
modelRoot = fullfile(pwd, "trainedNerfactoTUMRGBD");
load(fullfile(modelRoot, "saved-nerfacto-tum-rgbd.mat"))
```

```
Warning: The model folder for the nerfacto object could not be loaded. Update the model folder lo
  '\\mathworks\devel\sandbox\user\Shared\EX_25b\EX_nerfacto_feature\train_nerfacto_small'
```

MATLAB® displays a warning when you first load the pretrained `nerfacto` object into the workspace because the path to the model folder associated with the object, `nerfactoModelFolder`, changes when you extract the `nerfacto_saved_model.zip`.

To resolve this issue, use the `changePath` function to update the `ModelFolder` property of the trained `nerfacto` object to the current path of `nerfactoModelFolder`. This process can take a few minutes.

```
nerf = changePath(nerf, fullfile(modelRoot, "nerfactoModelFolder"));
```

```
Changing nerfacto object model folder path.
nerfacto object model folder path change complete.
```

Display the `nerfacto` object properties to verify that the `ModelFolder` property is set to the current path of `nerfactoModelFolder` on your system.

```
disp(nerf)
```

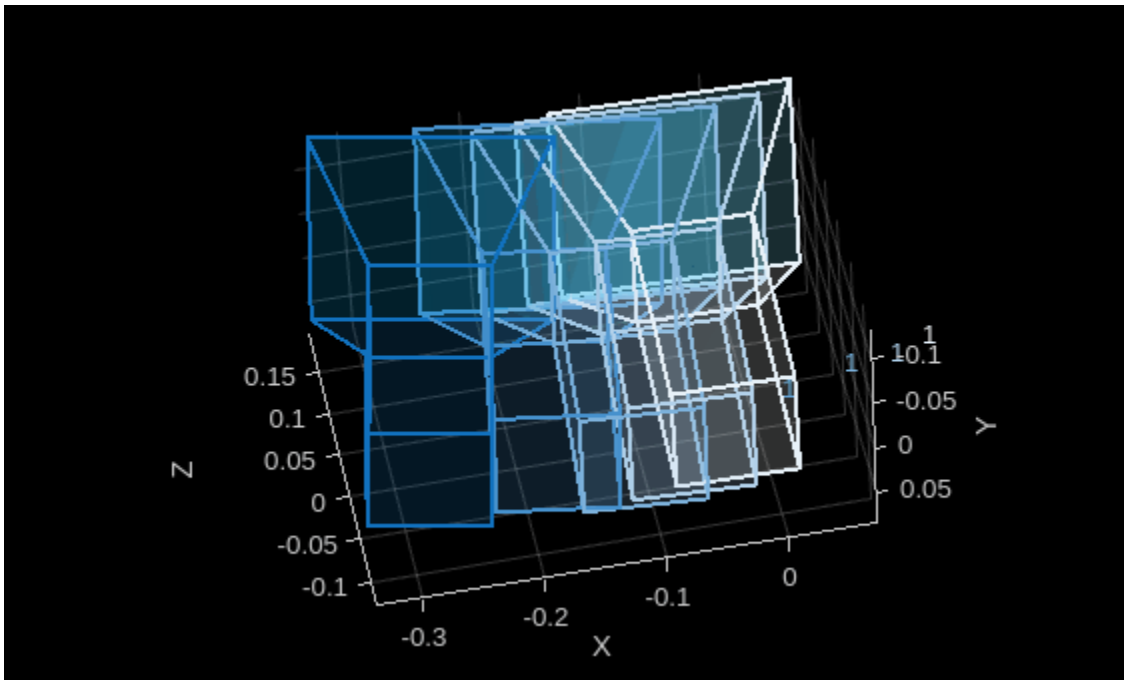
```
  nerfacto with properties:

     ModelFolder: "/home/user/Documents/MATLAB/ExampleManager/user.Bdoc.EX_26a_v1/vision-ex39493
   MaxIterations: 30000
      Intrinsics: [1×1 cameraIntrinsics]
```

Load Camera Poses

This example contains a set of predefined camera poses that are stored as an array of `rigidtform3d` objects in the `camera-poses-tum.mat` file. These represent the position and orientation of the camera in the 3-D world coordinate system of the scene.

Load the `camera-poses-tum.mat` file into workspace, which contains the camera poses `camPoses`.



```
load("camera-poses-tum.mat","camPoses");
```

Display the camera poses by using the `plotCamera` function.

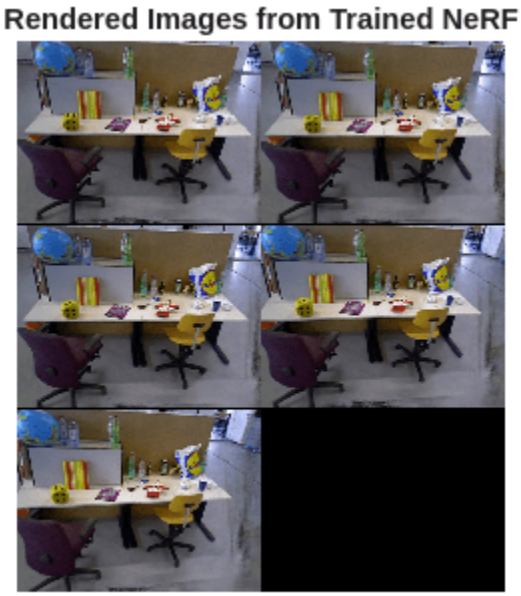
```
figure
pcshow([NaN NaN NaN], VerticalAxis="y", VerticalAxisDir="down");
xlabel("X")
ylabel("Y")
zlabel("Z")
hold on

colors = sky(length(camPoses));
for i = 1:length(camPoses)
plotCamera(camPoses(i), Size=0.1, Color=colors(i,:), Opacity=0.1);
end

hold off
```

Generate Novel Views with Pretrained NeRF Model

Generate the views captured by the camera poses `camPoses` by using the `generateViews` function.



```
images = generateViews(nerf,camPoses);
```

```
Generating views from nerfacto object.
Loading latest checkpoint from load_dir
nerfacto object view generation complete.
```

Tip: If you want to generate a large number of novel views, use the `writeViews` function instead of `generateViews` to avoid an out-of-memory error.

Display the generated images. The images show the globe and chairs in front of the desk that are present in the images used to train this NeRF model.

```
figure
montage(images, BorderSize=[2 2])
title("Rendered Images from Trained NeRF")
```

Input Arguments

`nerf` — Trained Nerfacto NeRF model

`nerfacto` object

Trained Nerfacto NeRF model, specified as a `nerfacto` object.

`cameraPoses` — Virtual camera poses

M-by-1 vector of `rigidtform3d` objects

Virtual camera poses, specified as an *M*-by-1 vector of `rigidtform3d` objects, where *M* is the number novel views that you want to generate. Each element of the vector specifies a virtual camera

pose for a novel view that you want to generate in the world coordinate system. You must specify the virtual camera poses in the same world coordinate system as the camera poses of the training images.

Tip Generating a large number of views can cause an out of memory error because the `generateViews` function stores the generated images in memory. To generate a large number of views, use the `writeViews` function, which stores the generated images as files, instead.

`virtualCameraIntrinsics` — Virtual camera intrinsic parameters

`nerf.Instrinsics` (default) | `cameraIntrinsics` object

Virtual camera intrinsic parameters, specified as a `cameraIntrinsics` object. This function supports the intrinsic parameters of a pinhole camera model, which consist of focal length, principal point, and skew, and ignores other parameter values such as lens distortion.

By default, the `generateViews` function generates novel views using a virtual camera with the same intrinsic parameter as the camera that captures the training images. However, you can specify a virtual camera with intrinsic parameters that are different from the camera intrinsic parameters of the training images, such as to generate novel views with a higher resolution or wider field-of-view compared to the training images.

Output Arguments

`I` — Novel views

H-by-*W*-by-3-by-*M* array

Novel views, returned as an *H*-by-*W*-by-3-by-*M* array, where *M* is the number of novel views. Each image is of size *H*-by-*W*-by-3, where *H* and *W* are the height and width of the image, in pixels.

writeViews

Write novel views from Nerfacto Neural Radiance Field (NeRF) model to image files

Syntax

```
imds = writeViews(nerf,cameraPoses)
imds = writeViews(nerf,cameraPoses,outputFolder)
imds = writeViews( ___ ,Name=Value)
```

Description

Add-On Required: This feature requires the Computer Vision Toolbox Interface for Nerfstudio Library add-on.

`imds = writeViews(nerf,cameraPoses)` writes novel views generated using the trained Nerfacto NeRF model [1] from the Nerfstudio Library [2] for the virtual camera poses `cameraPoses` to a folder named `render` in the current working directory. The function returns an image datastore that contains the paths to the image files.

Note This feature requires the Computer Vision Toolbox Interface for Nerfstudio Library add-on, a Deep Learning Toolbox license, a Parallel Computing Toolbox license, and a CUDA enabled NVIDIA GPU with at least 16 GB of available GPU memory.

`imds = writeViews(nerf,cameraPoses,outputFolder)` specifies the path of the folder to which to write the novel view images.

`imds = writeViews( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination input of arguments from previous syntaxes.

For example, `ImageFormat="jpg"` specifies to write the generated novel view images to `.jpg` files.

Examples

Write Novel Views from Neural Radiance Field Model to Image Files

Download Pretrained NeRF Model

The `tum_rgbd_nerfacto.zip` file contains the `trainedNerfactoTUMRGBD` folder. The folder contains the `saved-nerfacto-tum-rgbd.mat` supporting file, which contains a `nerfacto`object that has been trained on a sequence of indoor images from the TUM RGB-D data set [1 on page 3-1718], and the `nerfactoModelFolder` folder, which contains the data and configuration files required for the Nerfstudio Library [2 on page 3-1718] to load and execute the trained NeRF model [3 on page 3-1718].

Download and extract `tum_rgbd_nerfacto.zip`.

```
if ~exist("tum_rgbd_nerfacto.zip","file")
    websave("tum_rgbd_nerfacto.zip","https://ssd.mathworks.com/supportfiles/3DReconstruction/tum_
```

```
    unzip("tum_rgbd_nerfacto.zip",pwd);
end
```

Specify the path to the folder containing the `saved-nerfacto-tum-rgbd` MAT file, and then load the pretrained `nerfacto` object into the workspace.

```
modelRoot = fullfile(pwd,"trainedNerfactoTUMRGBD");
load(fullfile(modelRoot,"saved-nerfacto-tum-rgbd.mat"))
```

```
Warning: The model folder for the nerfacto object could not be loaded. Update the model folder lo
  '\\mathworks\devel\sandbox\user\Shared\EX_25b\EX_nerfacto_feature\train_nerfacto_small'
```

MATLAB® displays a warning when you first load the pretrained `nerfacto` object into the workspace because the path to the model folder associated with the object, `nerfactoModelFolder`, changes when you extract the `nerfacto_saved_model.zip`.

To resolve this issue, use the `changePath` function to update the `ModelFolder` property of the trained `nerfacto` object to the current path of `nerfactoModelFolder`. This process can take a few minutes.

```
nerf = changePath(nerf, fullfile(modelRoot,"nerfactoModelFolder"));
```

```
Changing nerfacto object model folder path.
nerfacto object model folder path change complete.
```

Display the `nerfacto` object properties to verify that the `ModelFolder` property is set to the current path of `nerfactoModelFolder` on your system.

```
disp(nerf)
```

```
  nerfacto with properties:

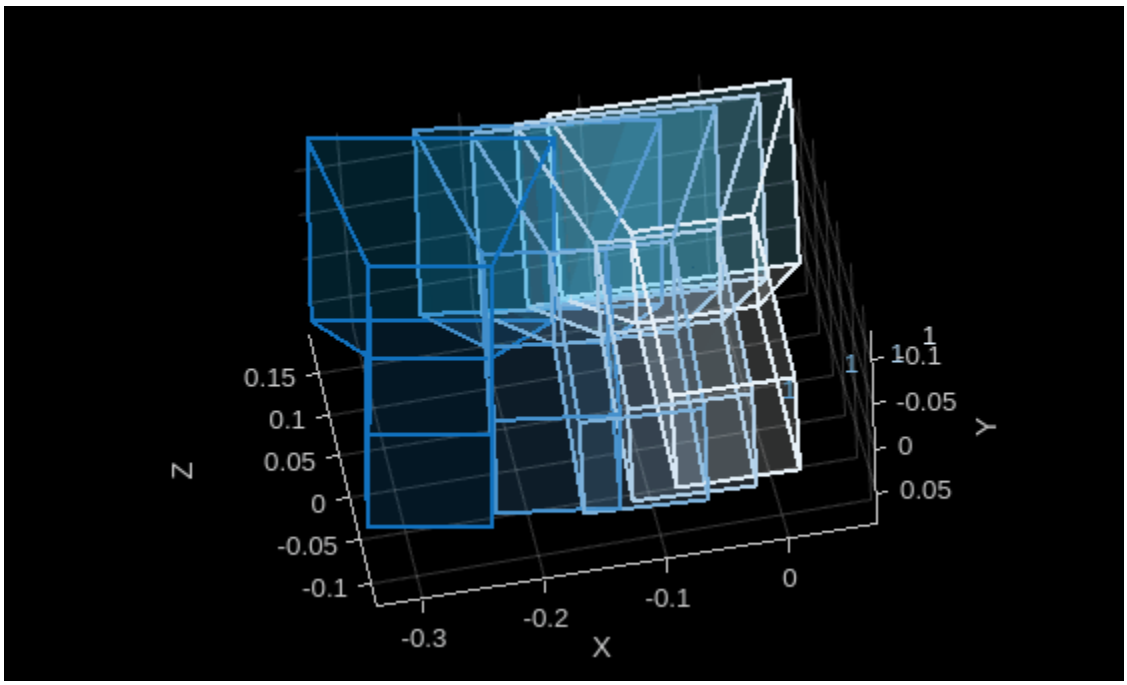
      ModelFolder: "/home/user/Documents/MATLAB/ExampleManager/user.Bdoc.EX_26a_v1/vision-ex6257
    MaxIterations: 30000
       Intrinsics: [1×1 cameraIntrinsics]
```

Load Camera Poses

This example contains a set of predefined camera poses that are stored as an array of `rigidtform3d` objects in the `camera-poses-tum.mat` file. These represent the position and orientation of the camera in the 3-D world coordinate system of the scene.

Load the `camera-poses-tum.mat` file into workspace, which contains the camera poses `camPoses`.

```
load("camera-poses-tum.mat","camPoses");
```



Plot the camera poses by using the `plotCamera` function.

```
figure
pcshow([NaN NaN NaN],VerticalAxis="y",VerticalAxisDir="down");
xlabel("X")
ylabel("Y")
zlabel("Z")
hold on

colors = sky(length(camPoses));
for i = 1:length(camPoses)
plotCamera(camPoses(i),Size=0.1,Color=colors(i,:),Opacity=0.1);
```

```
end

hold off
```

Write Novel Views from Pretrained NeRF Model to Image Files

Write the views captured by the camera poses `camPoses` to a local folder, `generatedNeRFViews`, by using the `writeViews` function.

```
imdsGen = writeViews(nerf,camPoses,"generatedNeRFViews");
```

```
Generating views from nerfacto object.
Loading latest checkpoint from load_dir
nerfacto object view generation complete.
```

Display the generated image of the scene at a camera pose. `imageIdx` selects the camera pose.

```
numImg = numel(imdsGen.Files);
```

```
imageIdx = 3 ;
```

```
imageGen = readimage(imdsGen,imageIdx);

figure
imshow(imageGen)
title("Generated Image " + imageIdx)
```

Tips to Improve Training Results

Although the generated images are photorealistic, there are minor differences in the image texture and high-frequency details between the generated images and the training images. To achieve better quality results:

- Capture a larger set of high resolution images.
- Ensure the image set has good lighting.
- Ensure the image set has no motion blur or moving objects.
- Train the `nerfacto` object with a higher number of maximum training iterations (at the cost of longer computation time).

Vision - ECCV 2020, edited by Andrea Vedaldi, Horst Bischof, Thomas Brox, and Jan-Michael Frahm. Springer International Publishing, 2020. https://doi.org/10.1007/978-3-030-58452-8_24.

Input Arguments

`nerf` — Trained Nerfacto NeRF model

`nerfacto` object

Trained Nerfacto NeRF model, specified as a `nerfacto` object.

`cameraPoses` — Virtual camera poses

M-by-1 vector of `rigidtform3d` objects

Virtual camera poses, specified as an *M*-by-1 vector of `rigidtform3d` objects, where *M* is the number novel views that you want to generate. Each element of the vector specifies a virtual camera pose for a novel view that you want to generate in the world coordinate system. You must specify the virtual camera poses in the same world coordinate system as the camera poses of the training images.

Tip Use the `generateViews` function to instead generate a small number of novel view images stored in memory.

`outputFolder` — Output images folder path

string scalar | character vector

Output images folder path, specified as a string scalar or character vector. If you specify a folder in the path that does not exist, the `writeViews` function creates that folder.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `writeViews(nerf,cameraPoses,ImageFormat="jpg")` writes the generated novel view images to the `.jpg` format.

`ImageFormat` — Output image file format

`"jpeg"` (default) | `"jpg"` | `"png"`

Output image file format, specified as one of these options:

- `"jpeg"` — Stores the output images as `.jpeg` files.
- `"jpg"` — Stores the output images as `.jpg` files.
- `"png"` — Stores the output images as `.png` files.

Data Types: `char` | `string`

`JPEGQuality` — Quality of generated JPEG images

`100` (default) | scalar in range `[0, 100]`

Quality of the generated JPEG images, specified as a scalar in the range `[0, 100]`. Specifying a smaller value results in images with lower quality and more compression, while specifying a larger value results in images with higher quality and less compression.

Dependencies

To specify this value, you must specify `ImageFormat` as `"jpeg"`

Data Types: `single` | `double`

`Intrinsics` — Virtual camera intrinsic parameters
`nerf.Instrinsics` (default) | `cameraIntrinsics` object

Virtual camera intrinsic parameters, specified as a `cameraIntrinsics` object. This function supports the intrinsic parameters of a pinhole camera model, which consist of focal length, principal point, and skew, and ignores other parameter values such as lens distortion.

By default, the `writeViews` function generates novel views using a virtual camera with the same intrinsic parameter as the camera that captures the training images. However, you can specify a virtual camera with intrinsic parameters that are different from the camera intrinsic parameters of the training images, such as to generate novel views with a higher resolution or wider field-of-view compared to the training images.

Output Arguments

`imds` — Output image datastore
`imageDatastore` object

Output image datastore, returned as an `imageDatastore` object. The `writeViews` function stores the images in the datastore in the corresponding order to the specified virtual camera poses.

Version History

Introduced in R2026a

changePath

Update model folder property of trained Nerfacto NeRF model

Syntax

```
nerfUpdated = changePath(nerf,newFolderPath)
```

Description

Add-On Required: This feature requires the Computer Vision Toolbox Interface for Nerfstudio Library add-on.

`nerfUpdated = changePath(nerf,newFolderPath)` updates the model folder property of a trained Nerfacto NeRF model [1] from the Nerfstudio library [2].

You can use this function to update the `ModelFolder` property of a trained `nerfacto` object , `nerf`, when you move the associated model folder to a new location, `newFolderPath`. This allows the object to access the model folder to generate a dense colored point cloud and create novel views of the scene.

Note This feature requires the Computer Vision Toolbox Interface for Nerfstudio Library add-on, a Deep Learning Toolbox license, a Parallel Computing Toolbox license, and a CUDA enabled NVIDIA GPU with at least 16 GB of available GPU memory.

Examples

Generate Novel Views using Neural Radiance Field Model

Download Pretrained NeRF Model

The `tum_rgbd_nerfacto.zip` file contains the `trainedNerfactoTUMRGBD` folder. The folder contains the `saved-nerfacto-tum-rgbd.mat` supporting file, which contains a `nerfacto` object that has been trained on a sequence of indoor images from the TUM RGB-D data set [1 on page 3-1725], and the `nerfactoModelFolder` folder, which contains the data and configuration files required for the Nerfstudio Library [2 on page 3-1725] to load and execute the trained NeRF model [3 on page 3-1725].

Download and extract `tum_rgbd_nerfacto.zip`.

```
if ~exist("tum_rgbd_nerfacto.zip","file")
    websave("tum_rgbd_nerfacto.zip","https://ssd.mathworks.com/supportfiles/3DReconstruction/tum_
    unzip("tum_rgbd_nerfacto.zip", pwd);
end
```

Specify the path to the folder containing the `saved-nerfacto-tum-rgbd` MAT file, and then load the pretrained `nerfacto` object into the workspace.

```
modelRoot = fullfile(pwd, "trainedNerfactoTUMRGBD");
load(fullfile(modelRoot, "saved-nerfacto-tum-rgbd.mat"))
```

```
Warning: The model folder for the nerfacto object could not be loaded. Update the model folder lo
  '\\mathworks\devel\sandbox\user\Shared\EX_25b\EX_nerfacto_feature\train_nerfacto_small'
```

MATLAB® displays a warning when you first load the pretrained `nerfacto` object into the workspace because the path to the model folder associated with the object, `nerfactoModelFolder`, changes when you extract the `nerfacto_saved_model.zip`.

To resolve this issue, use the `changePath` function to update the `ModelFolder` property of the trained `nerfacto` object to the current path of `nerfactoModelFolder`. This process can take a few minutes.

```
nerf = changePath(nerf, fullfile(modelRoot, "nerfactoModelFolder"));
```

```
Changing nerfacto object model folder path.
nerfacto object model folder path change complete.
```

Display the `nerfacto` object properties to verify that the `ModelFolder` property is set to the current path of `nerfactoModelFolder` on your system.

```
disp(nerf)
```

```
  nerfacto with properties:

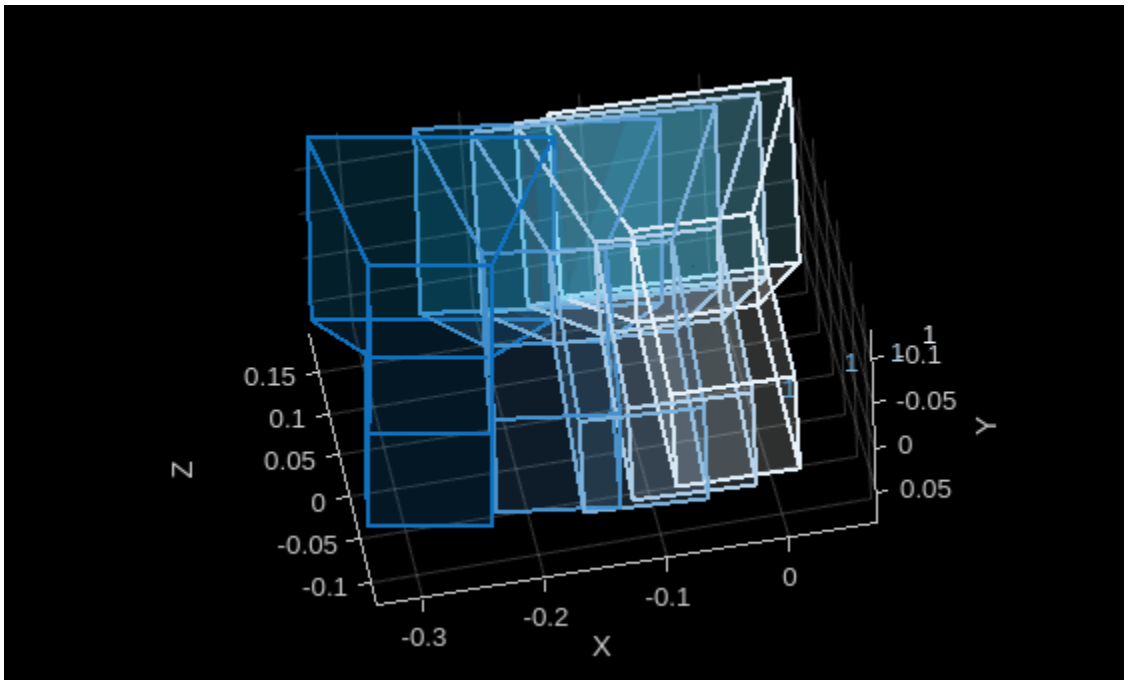
Load Camera Poses

This example contains a set of predefined camera poses that are stored as an array of `rigidtform3d` objects in the `camera-poses-tum.mat` file. These represent the position and orientation of the camera in the 3-D world coordinate system of the scene.

Load the `camera-poses-tum.mat` file into workspace, which contains the camera poses `camPoses`.



```
load("camera-poses-tum.mat","camPoses");
```

Display the camera poses by using the `plotCamera` function.

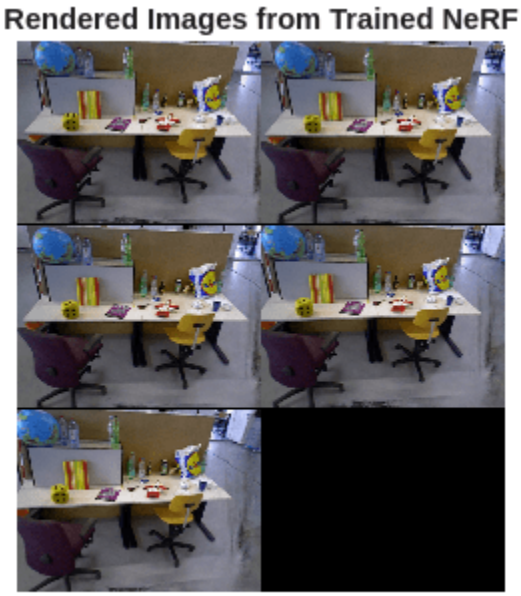
```
figure
pcshow([NaN NaN NaN], VerticalAxis="y", VerticalAxisDir="down");
xlabel("X")
ylabel("Y")
zlabel("Z")
hold on

colors = sky(length(camPoses));
for i = 1:length(camPoses)
plotCamera(camPoses(i), Size=0.1, Color=colors(i,:), Opacity=0.1);
end

hold off
```

Generate Novel Views with Pretrained NeRF Model

Generate the views captured by the camera poses `camPoses` by using the `generateViews` function.



```
images = generateViews(nerf,camPoses);
```

```
Generating views from nerfacto object.
Loading latest checkpoint from load_dir
nerfacto object view generation complete.
```

Tip: If you want to generate a large number of novel views, use the `writeViews` function instead of `generateViews` to avoid an out-of-memory error.

Display the generated images. The images show the globe and chairs in front of the desk that are present in the images used to train this NeRF model.

```
figure
montage(images, BorderSize=[2 2])
title("Rendered Images from Trained NeRF")
```

Input Arguments

`nerf` — Trained Nerfacto NeRF model

`nerfacto` object

Trained Nerfacto NeRF model, specified as a `nerfacto` object.

`newFolderPath` — New model folder path

string scalar | character vector

New model folder path, specified as a string scalar or character vector.

Data Types: `char` | `string`

Output Arguments

`nerfUpdated` — Trained Nerfacto NeRF model with updated model folder path

`nerfacto` object

Trained Nerfacto NeRF model with the updated model folder path, returned as a `nerfacto` object.

Version History

Introduced in R2026a
