Blocks

2-D Autocorrelation

2-D autocorrelation of input matrix

Libraries:
Computer Vision Toolbox / Statistics

Description

The 2-D Autocorrelation block computes the 2-D autocorrelation of the input vector or matrix.

Ports

Input

Port_1 — Input array
vector | matrix

Input array, specified as a vector or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`
Complex Number Support: Yes

Output

Port_1 — Autocorrelation of input
vector | matrix

Autocorrelation of the input array, returned as a vector or matrix. The data type of the output is the same as that of the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`
Complex Number Support: Yes

Parameters

For details on fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Lock data type settings against change by the fixed-point tools — Prevent fixed-point tools from overriding data types
`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

Algorithms

If the input $A$is a vector with dimension M-by-1 then the equation for 1-D discrete autocorrelation is:

where $0 \le n \le 2M - 1$.

The output is an autocorrelation vector of size $(2M - 1, 1)$.

If the input A is a matrix with dimension M-by-N then the equation for the 2-D discrete autocorrelation is:

where $0 \le i < 2M - 1$ and $0 \le j < 2N - 1$.

The dimension of the output autocorrelation matrix is $(2M - 1, 2N - 1)$.

2-D Convolution

Compute 2-D discrete convolution of two input matrices

Libraries:
Computer Vision Toolbox / Filtering

Description

The 2-D Convolution block computes the two-dimensional convolution of two input matrices. Assume that matrix A has dimensions (*Ma*, *Na*) and matrix B has dimensions (*Mb*, *Nb*). When the block calculates the full output size, the equation for the 2-D discrete convolution is:

$$C(i,j) = \sum_{m=0}^{(Ma-1)} \sum_{n=0}^{(Na-1)} A(m,n) * B(i-m, j-n)$$

where $0 \le i < Ma + Mb - 1$ and $0 \le j < Na + Nb - 1$.

Ports

Input

I1 — Input matrix
matrix

Input matrix, specified as either a matrix of intensity values or a matrix that represents one plane of an RGB video stream.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

I2 — Input matrix
matrix

Input matrix, specified as either a matrix of intensity values or a matrix that represents one plane of an RGB video stream.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Output — Convolution
matrix

Convolution of the input matrices, returned as a matrix.

Dependencies

- The dimensions of the output are dictated by the **Output size** parameter.
- If the data type of the input is floating point, the output of the block is also floating point.
- If `all(size(I1)<size(I2))`, the block returns an error.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Main Tab

Output size — Output size
matrix

Dimensions of the output.

The table describes the block output, given the following input dimensions:

- **I1** — (*Ma*, *Na*)
- **I2** — (*Mb*, *Nb*)

Output size	Output	Output Dimension
`Full`	Full two-dimensional convolution	(*Ma*+*Mb*-1, *Na*+*Nb*-1).
`Same as input port I1`	Central part of the convolution with the same dimensions as the input at port **I1**	
`Valid`	Only the parts of the convolution that are computed without the zero-padded edges of any input.	(*Ma*-*Mb*+1, *Na*-*Nb*+1)

Normalized output — Normalized output
matrix

Normalize output by dividing the output by `sqrt(sum(dot(I1p,I1p))*sum(dot(I2,I2)))`, where `I1p` is the portion of the **I1** matrix that aligns with the **I2** matrix.

Note When you select the **Normalized output** check box, the block input cannot be fixed point.

Data Types Tab

For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

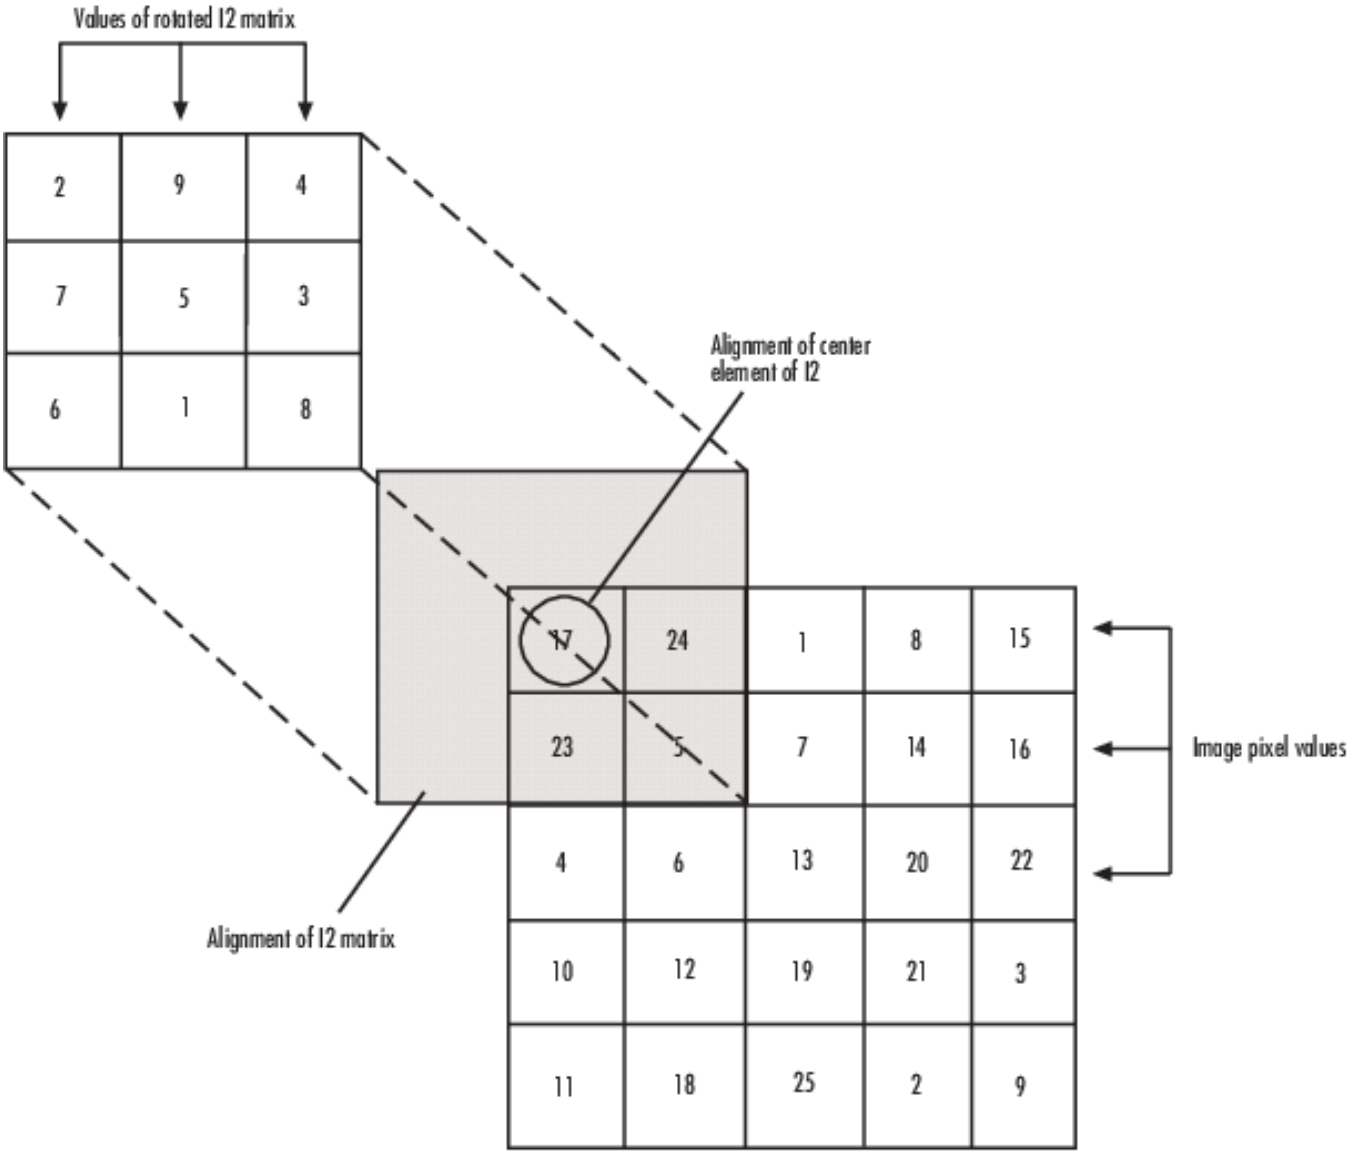
Algorithms

2-D Convolution

In convolution, the value of an output element is computed as a weighted sum of neighboring elements.

For example, suppose the first input matrix represents an image and is defined as:

```
I1 = [17  24   1   8  15
     23   5   7  14  16
      4   6  13  20  22
     10  12  19  21   3
     11  18  25   2   9]
```



The second input matrix also represents an image and is defined as:

```
I2 = [8   1   6
     3   5   7
     4   9   2]
```

The following figure shows how to compute the (1,1) output element by using these steps:

1. Rotate the second input matrix, **I2**, 180 degrees around its center element.
2. Slide the center element of **I2** so that it lies on top of the (0,0) element of **I1**.
3. Multiply each element of the rotated **I2** matrix by the element of **I1** underneath.
4. Sum the individual products from step 3.

The (1,1) output element is $0 \cdot 2 + 0 \cdot 9 + 0 \cdot 4 + 0 \cdot 7 + 17 \cdot 5 + 24 \cdot 3 + 0 \cdot 6 + 23 \cdot 1 + 5 \cdot 8 = 220$.

Computing the (1,1) Output of Convolution

The normalized convolution of the (1,1) output element is `220/sqrt(sum(dot(I1p,I1p))*sum(dot(I2,I2)))` = 0.3459, where `I1p = [0 0 0; 0 17 24; 0 23 5]`.

Output Sizes

The equations below describe how the block computes the convolution depending on how you set the **Output size** parameter. For the cases below, the inputs are set as:

- **I1** — dimensions (4,3)
- **I2** — dimensions (2,2)
- When **Output size** is set to `Full`, the block uses the following equations:

$$C_{\text{full}_{\text{rows}}} = I1_{\text{rows}} + I2_{\text{rows}} - 1 = 5$$

$$C_{\text{full}_{\text{columns}}} = I1_{\text{columns}} + I2_{\text{columns}} - 1 = 4$$

The resulting matrix is:

$$C_{\text{full}} = \begin{bmatrix} c_{00} & c_{01} & c_{02} & c_{03} \\ c_{10} & c_{11} & c_{12} & c_{13} \\ c_{20} & c_{21} & c_{22} & c_{23} \\ c_{30} & c_{31} & c_{32} & c_{33} \\ c_{40} & c_{41} & c_{42} & c_{43} \end{bmatrix}$$

- When **Output size** is set to `Same as input port I1`, the output is the central part of *Cfull* with the same dimensions as the input at port **I1**, (4,3). However, since a 4-by-3 matrix cannot be extracted from the exact center of *Cfull*, the block leaves more rows and columns on the top and left side of the *Cfull* matrix and outputs:

$$C_{\text{same}} = \begin{bmatrix} c_{11} & c_{12} & c_{13} \\ c_{21} & c_{22} & c_{23} \\ c_{31} & c_{32} & c_{33} \\ c_{41} & c_{42} & c_{43} \end{bmatrix}$$

- When the **Output size** is set to `Valid`, the block uses the following equations to determine the number of rows and columns of the output matrix:

$$C_{\text{valid}_{\text{rows}}} = I1_{\text{rows}} - I2_{\text{rows}} + 1 = 3$$

$$C_{\text{valid}_{\text{columns}}} = I1_{\text{columns}} - I2_{\text{columns}} + 1 = 2$$

In this case, it is always possible to extract the exact center of *Cfull*. Therefore, the block outputs:

$$C_{\text{full}} = \begin{bmatrix} c_{11} & c_{12} \\ c_{21} & c_{22} \\ c_{31} & c_{32} \end{bmatrix}$$

2-D FIR Filter

2-D Correlation

Compute 2-D correlation of two input matrices

Libraries:
Computer Vision Toolbox / Statistics

Description

The 2-D Correlation block computes the two-dimensional cross-correlation between two input matrices.

Ports

Input

I1 — First input matrix
matrix

First input matrix, specified as an *M*-by-*N* matrix. The two input matrices must have data types in the same category such as `double`, `single`, unsigned integer (`uint8`,`uint16`,`uint32`,`uint64`), or integer (`int8`,`int16`,`int32`,`int64`).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`
Complex Number Support: Yes

I2 — Second input matrix
matrix

Second input matrix, specified as a *P*-by-*Q* matrix. The two input matrices must have data types in the same category such as `double`, `single`, unsigned integer (`uint8`,`uint16`,`uint32`,`uint64`), or integer (`int8`,`int16`,`int32`,`int64`).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`
Complex Number Support: Yes

Output

Port_1 — Calculated cross-correlation
scalar | vector | matrix

Calculated cross-correlation, returned as a scalar, vector, or matrix. The size of the cross-correlation output depends on the **Output size** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`
Complex Number Support: Yes

Parameters

Main

Output size — Size of cross-correlation output

`Full` (default) | `Same as input port I1` | `Valid`

Size of the cross-correlation output.

- If you choose `Full`, the output has the dimensions (M+P-1)-by-(N+Q-1).
- If you choose `Same as input port I1`, the output has the same dimensions as the input at port **I1**. The block returns the central part of cross-correlation matrix, which is the same size as the input at port **I1**.
- If you choose `Valid`, the output has the dimensions (M-P+1)-by-(N-Q+1). The block returns only parts of the cross-correlation matrix that are computed without zero-padded edges.

Normalized output — Normalize cross-correlation output

`off` (default) | `on`

Select this parameter, if the data types of the inputs are floating-point. The values of the cross-correlation output are normalized to [0, 1].

Data Types

For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Lock data type settings against change by the fixed-point tools — Prevent fixed-point tools from overriding data types
`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Block Characteristics

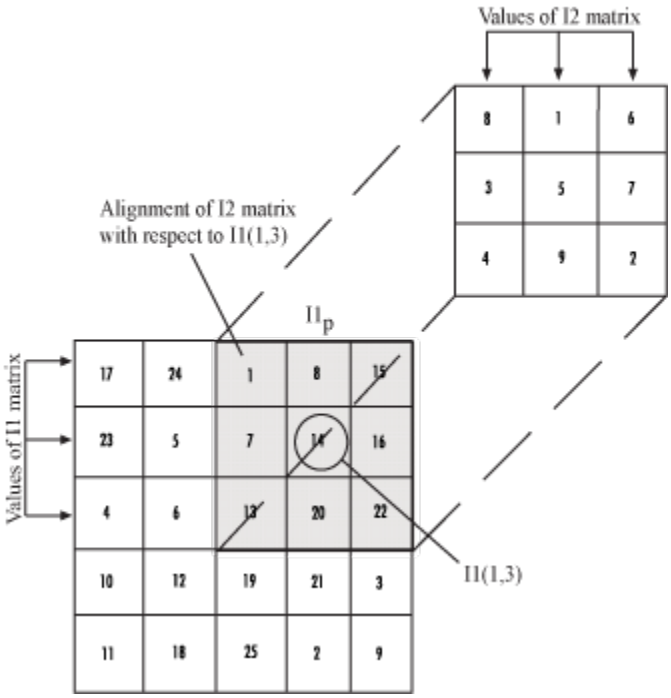
Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

Algorithms

Given two input matrices, *I1* and *I2*, that are size M-by-N and P-by-Q, the 2-D cross-correlation value at the point `(k,l)` is given by

$$C(k,l) = \sum_{m=0}^{M-1} \sum_{n=0}^{N-1} I1(m,n)\overline{I2}(m+k,n+l).$$

The normalized cross-correlation value at the point `(k,l)` is calculated as



$$C_N(k,l) = \frac{\sum_{m=0}^{M-1}\sum_{n=0}^{N-1} I1(m,n)\overline{I2}(m+k,n+l)}{\sqrt{\sum_{m=0}^{M-1}\sum_{n=0}^{N-1} I1(m,n)^2}\sqrt{\sum_{m=0}^{M-1}\sum_{n=0}^{N-1} \overline{I2}(m+k,n+l)^2}},$$

where,

$0 \le k < M+P-1$

$0 \le l < N+Q-1$

Suppose *I1* and *I2* are matrices with dimensions (4,3) and (2,2). The following figure shows how the block computes cross-correlation value for the point `I1(1,3)`, which refers to the second row and fourth column in zero-based indexing.

The cross-correlation value for the point `I1(1,3)` is computed using these steps:

1. Slide the center element of *I2* so that it lies on top of the (1,3) element of *I1*.
2. Multiply each weight in *I2* by the element of *I1* underneath.
3. Sum the individual products from step 2.

The cross-correlation value for the point `I1(1,3)` is
$1 \cdot 8 + 8 \cdot 1 + 15 \cdot 6 + 7 \cdot 3 + 14 \cdot 5 + 16 \cdot 7 + 13 \cdot 4 + 20 \cdot 9 + 22 \cdot 2 = 585$.

The normalized cross-correlation value for the point `I1(1,3)` is

$$\frac{585}{\sqrt{\sum I1_p^2}\sqrt{\sum I2^2}} = 0.8070.$$

2-D DCT

Compute 2-D discrete cosine transform (DCT)

Libraries:
Computer Vision Toolbox / Transforms

Description

The 2-D DCT block calculates the two-dimensional discrete cosine transform of an image. Suppose $f(x,y)$ is the input image of dimension M-by-N, the equation for the 2-D DCT is

$$F(m,n) = \frac{2}{\sqrt{MN}} C(m)C(n) \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} f(x,y) \cos\frac{(2x+1)m\pi}{2M} \cos\frac{(2y+1)n\pi}{2N}$$

where $C(m) = C(n) = 1/\sqrt{2}$ for $m, n = 0$ and $C(m), C(n) = 1$ otherwise.

The number of rows and columns of the input image must be power of 2. You can also use this block to compute 1-D DCT of a vector.

Ports

Input

Port_1 — Input data
matrix | vector

Input data, specified as a numeric matrix or a vector. The size of the input data must be power of 2.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Output

Port_1 — Output data
matrix | vector

Output data containing the DCT coefficients, returned as a matrix or vector. The size and the datatype of the output is same as that of the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Main Tab

Sine and cosine computation — Specify how the block computes the sine and cosine terms

`Table lookup` (default) | `Trigonometric fcn`

Use this parameter to specify how the block computes the sine and cosine terms in the DCT algorithm.

- If you select `Trigonometric fcn`, the block computes the sine and cosine values during the simulation.
- If you select `Table lookup`, the block computes and stores the trigonometric values before the simulation starts. In this case, the block requires extra memory. `Table lookup` is the default.

Data Types Tab

Fixed-point operational parameters

Rounding mode — Rounding mode for fixed-point representation

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Use this parameter to specify the rounding mode for the block to use when the specified data type and scaling cannot exactly represent the result of a fixed-point calculation. See Rounding Modes for more information on the available values.

Note The sine table values do not obey this parameter; they always round to `Nearest`.

Saturate on integer overflow — Specify overflow mode

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation.

For details on saturate and wrap, see “Overflow Handling” for fixed-point operations.

Note The sine table values do not obey this parameter; instead, they are always saturated.

Fixed-point data types

Sine Table — Data type of sine table

`Inherit: Same word length as input` (default) | `fixdt(1,16)` | `<data type expression>`

Use this parameter to specify the word length of the values of the sine table. The fraction length of the sine table values always equals the word length minus one.

The sine table values do not obey the **Rounding mode** and **Saturate on integer overflow** parameters; instead, they are always saturated and rounded to `Nearest`.

Product output — Data type of product output

`Inherit: Inherit via internal rule` (default) | `Inherit: Same as input` | `fixdt(1,16,0)` | `<data type expression>`

Use this parameter to specify the product output data type. See “Fixed-Point Data Types” on page 1-17 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block.

Accumulator — Data type of accumulator

`Inherit: Inherit via internal rule` (default) | `Inherit: Same as input` | `Inherit: Same as product output` | `fixdt(1,16,0)` | `<data type expression>`

Use this parameter to specify the accumulator data type. See “Fixed-Point Data Types” on page 1-17 for illustrations depicting the use of the accumulator data type in this block.

Output — Data type of output

`Inherit: Inherit via internal rule` (default) | `Inherit: Same as input` | `fixdt(1,16,0)` | `<data type expression>`

Use this parameter to specify the output data type. See “Fixed-Point Data Types” on page 1-17 for illustrations depicting the use of the output data type in this block. When you set this parameter to

- `Inherit: Inherit via internal rule`, the block calculates the output word length and fraction length automatically. The internal rule first calculates an ideal output word length and fraction length using the following equations:

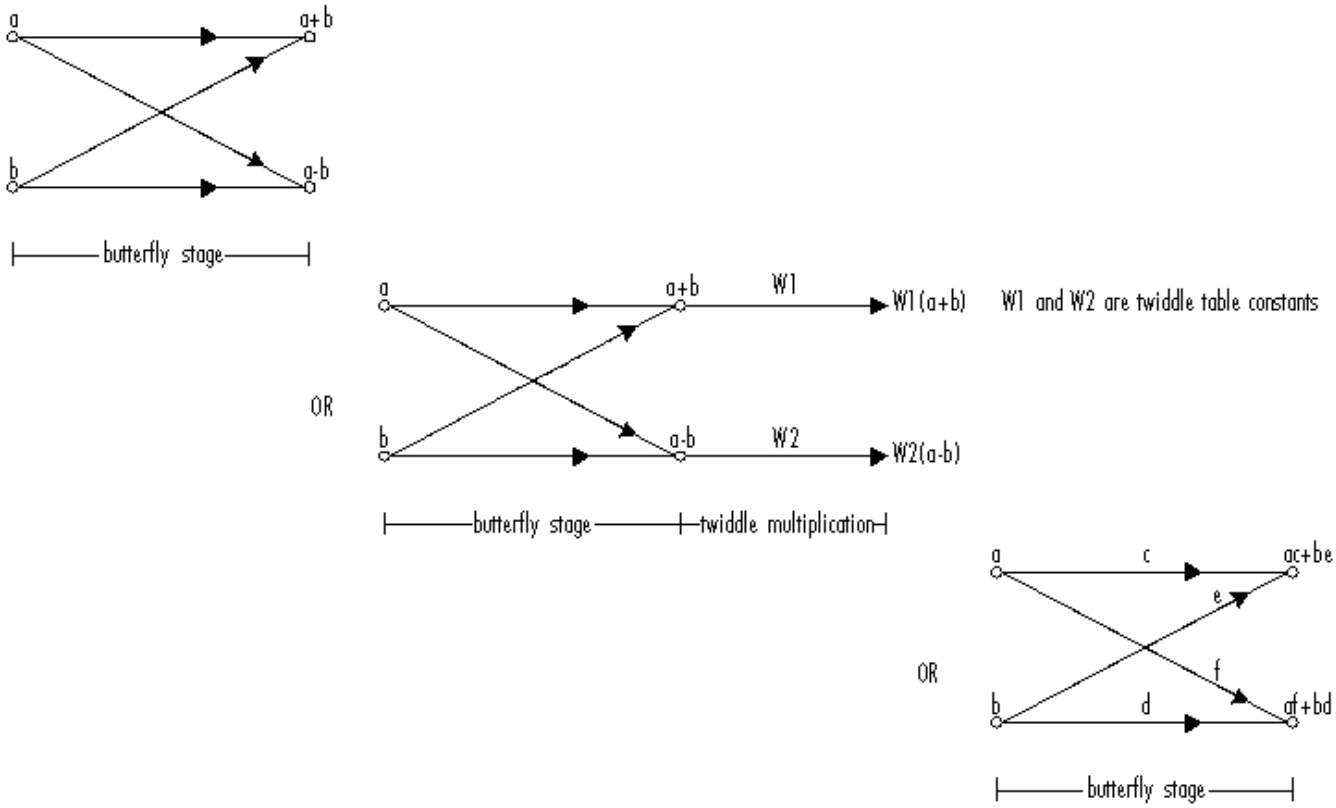
  $$WL_{idealoutput} = WL_{input} + floor(\log_2(DCTlength - 1)) + 1$$

  $$FL_{idealoutput} = FL_{input}$$

  Using these ideal results, the internal rule then selects word lengths and fraction lengths that are appropriate for your hardware. For more information, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

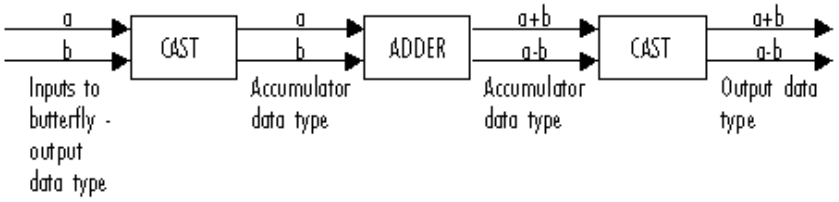
Lock data type settings against change by the fixed-point tools — Data type override
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask. For more information, see `fxptdlg`, a reference page on the Fixed-Point Tool.



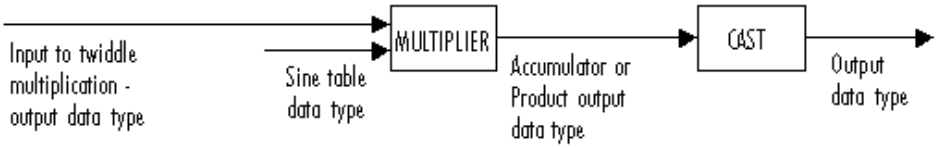
Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`no`



More About

Fixed-Point Data Types



The following diagram shows the data types used in the 2-D DCT block for fixed-point signals. Inputs are first cast to the output data type and stored in the output buffer. Each butterfly stage processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type.

Butterfly Stage Data Types

Twiddle Multiplication Data Types

The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, refer to "Multiplication Data Types". You can set the sine table, product output, accumulator, and output data types in the block mask as discussed in the next section.

2-D FFT

Compute 2-D fast Fourier transform (FFT)

Libraries:
Computer Vision Toolbox / Transforms

Description

The 2-D FFT block computes the discrete Fourier transform (DFT) of a two-dimensional input matrix using the fast Fourier transform (FFT) algorithm. The equation for the two-dimensional DFT $F(m, n)$ of an M-by-N input matrix, $f(x, y)$, is:

$$F(m,n) = \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} f(x,y) e^{-j\frac{2\pi mx}{M}} e^{-j\frac{2\pi ny}{N}}$$

where $0 \le m \le M-1$ and $0 \le n \le N-1$.

The block supports FFT implementation based on the FFTW library and an implementation based on a collection of Radix-2 algorithms. You can either manually select one of these implementations or let the block select one automatically.

Ports

Input

Port_1 — Input data
vector | matrix

Input data, specified as a vector or matrix of intensity values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`
Complex Number Support: Yes

Output

Port_1 — Output data
vector | matrix

Output data containing the 2-D FFT of the input, returned as a vector or matrix. The size and data type of the output are the same as those of the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`
Complex Number Support: Yes

Parameters

Main

FFT implementation — FFT implementation

`Auto` (default) | `Radix-2` | `FFTW`

Specify the type of implementation to use to compute the FFT as one of these options:

- `FFTW` — Select this option to support an arbitrary-length input signal. The block restricts generated code with the `FFTW` implementation to host computers capable of running MATLAB®.
- `Radix-2` — Select this option to support bit-reversed processing, fixed and floating-point data, or portable C-code generation using "Simulink Coder". The dimensions of the input matrix, *M* and *N*, must be powers of two. To work with other input sizes, use the Image Pad block to pad or truncate these dimensions to powers of two, or, if possible, choose the `FFTW` implementation. For more information about the algorithms used by the `Radix-2` mode, see "Radix-2 Implementation" on page 1-23.
- `Auto` — Select this option to let the block choose the FFT implementation. For non-power-of-two transform lengths, the block restricts generated code to MATLAB host computers.

Output in bit-reversed order — Bit-reversed output

`off` (default) | `on`

Select this parameter to get the output data in bit-reversed order relative to the order of the input data. If you clear this parameter, the output data appears in linear order relative to the order of the input data. For more information on the bit-reversed order of output, see "Bit-Reversed Order" on page 1-21.

Dependencies

To enable this parameter, set the **FFT implementation** parameter to `Auto` or `Radix-2`.

Scale result by FFT length — Scale output data

`off` (default) | `on`

When you select this parameter, the block divides the output by the FFT length. This option is useful when you want the output of the FFT to stay in the same amplitude range as its input. This is particularly useful when working with fixed-point data types.

Data Types

For details on the fixed-point block parameters, see "Specify Fixed-Point Attributes for Blocks" (DSP System Toolbox).

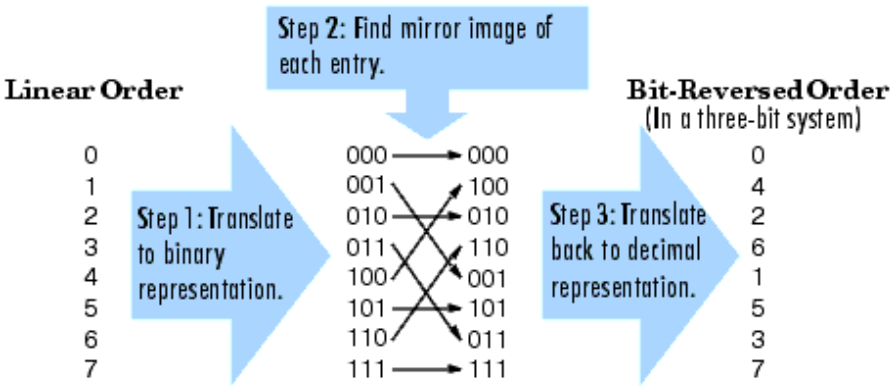
Lock data type settings against change by the fixed-point tools — Data type override

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in this block. For more information, see "Lock the Output Data Type Setting" (Fixed-Point Designer).

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`



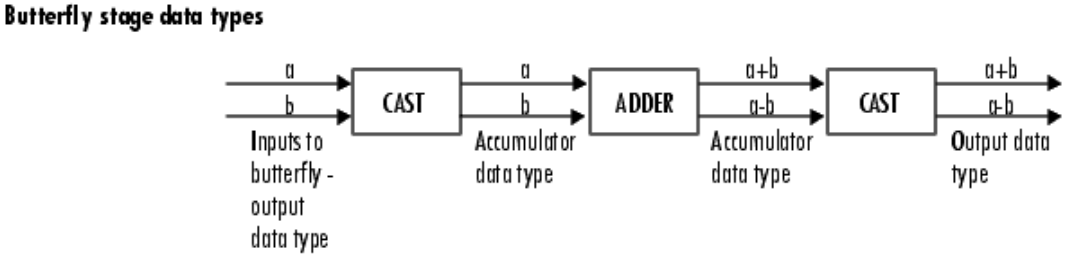
More About

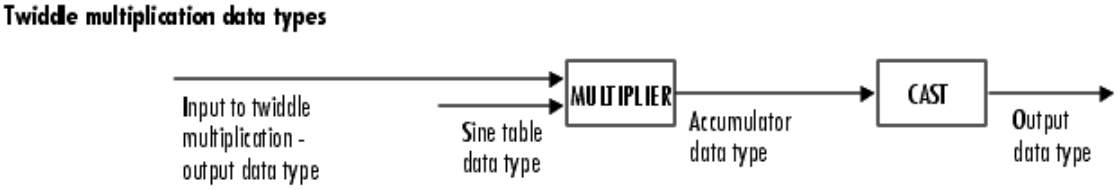
Bit-Reversed Order

Two numbers are bit-reversed values of each other when the binary representation of one is the mirror image of the binary representation of the other. For example, in a three-bit system, one and four are bit-reversed values of each other because the three-bit binary representation of one, `001`, is the mirror image of the three-bit binary representation of four, `100`. The diagram shows the row indices in linear order. To put them in bit-reversed order:

1. Translate the indices into their binary representations with the minimum number of bits. In this example, the minimum number of bits is three because the binary representation of the largest row index, 7, is `111`.
2. Find the mirror image of each binary entry, and write it beside the original binary representation.
3. Translate each binary mirror image to its decimal representation.

   The row indices now appear in bit-reversed order.





When you select the **Output in bit-reversed order** parameter of the 2-D FFT block, the block bit-reverses the order of both the rows and columns. All output values remain the same, but they appear in a different order.

Fixed-Point Data Types

These diagrams show the data types used in the 2-D FFT block for fixed-point signals. The block first casts inputs to the output data type and stores them in the output buffer. Each butterfly stage then processes signals in the accumulator data type, with the final butterfly casting its output back into the output data type. The block multiplies by a twiddle factor before each butterfly stage, in a decimation-in-time FFT, and after each butterfly stage in a decimation-in-frequency FFT.

The multiplier output appears in the accumulator data type because both of the inputs to the multiplier are complex. For details on the complex multiplication performed, refer to “Multiplication Data Types”.

Algorithms

FFTW Implementation

The FFTW implementation provides an optimized FFT calculation, including support for power-of-two and non-power-of-two transform lengths in both simulation and code generation. Generated code using the FFTW implementation can run only on computers capable of running MATLAB. The input must be of a floating-point data type.

Radix-2 Implementation

The Radix-2 implementation supports bit-reversed processing, fixed or floating-point data, and enables the block to provide portable C-code generation using “Simulink Coder”. The dimensions of the input matrix, *M* and *N*, must be powers of two. To work with other input sizes, use the Image Pad block to pad or truncate these dimensions to powers of two.

The block implements one or more of these algorithms for Radix-2 implementation.

- Butterfly operation
- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm

Radix-2 Algorithms for Real and Complex Signals

Complexity of Input	Output Ordering	Algorithms Used for FFT Computation
Complex	Linear	Bit-reversed operation and Radix-2 DIT
Complex	Bit-reversed	Radix-2 DIF
Real	Linear	Bit-reversed operation and Radix-2 DIT in conjunction with the half-length and double-signal algorithms
Real	Bit-reversed	Radix-2 DIF in conjunction with the half-length and double-signal algorithms

Radix-2 Optimization for Table of Trigonometric Values

In certain situations, the Radix-2 algorithm computes all the possible trigonometric values of the twiddle factor:

$$e^{j\frac{2\pi k}{K}},$$

where K is the greater value of either M or N, and k is an integer in the range `[0, K – 1]`. The block stores these values in a table and retrieves them during simulation. This table summarizes the number of table entries each for fixed-point and floating-point Radix-2 FFT algorithms:

Number of Table Entries for N-Point FFT	
Floating point	$3N/4$
Fixed point	N

Version History

No.98CH36181)*, 3:1381–84. Seattle, WA, USA: IEEE, 1998. https://doi.org/10.1109/ICASSP.1998.681704.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- When these conditions apply, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB:
  - **FFT implementation** is set to `FFTW`.
  - **Inherit FFT length from input dimensions** is cleared, and the length of each dimension of the input matrix is a power of two.

  Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed ZIP file. Using this ZIP file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed.
- When the length of each dimension of the input matrix is a power of two, you can generate standalone C and C++ code from this block.

Functions

`fft2` | `ifft2` | `bitrevorder`

2-D FIR Filter

2-D FIR filter on input matrix

Libraries:
Computer Vision Toolbox / Filtering

Description

The 2-D FIR Filter block filters a 2-D grayscale image using a 2-D finite impulse response (FIR) filter represented as a 2-D coefficient matrix or a pair of separable filter coefficient vectors.

Ports

Input

I — Input image
matrix

Input image, specified as a numeric matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`
Complex Number Support: Yes

H — Filter coefficients
matrix

Filter coefficients, specified as a numeric matrix. The input to the **H** port must have the same data type as the input to the **I** port.

Dependencies

To enable this port, set the **Coefficient source** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`
Complex Number Support: Yes

HV — Vertical filter coefficients
vector

Vertical filter coefficients, specified as a numeric vector. The input to the **HV** port must have the same data type as the input to the **I** port.

Dependencies

To enable this port, specify these parameter values.

- **Separable filter coefficients** — `on`
- **Coefficient source** — `Input port`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`
Complex Number Support: Yes

HH — Horizontal filter coefficients
vector

Horizontal filter coefficients, specified as a numeric vector. The input to the **HH** port must have the same data type as the input to the **I** port.

Dependencies

To enable this port, specify these parameter values.

- **Separable filter coefficients** — `on`
- **Coefficient source** — `Input port`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`
Complex Number Support: Yes

PVal — Pad value
scalar

Pad value, specified as a numeric scalar. The input to the **PVal** port must have the same data type as the input to the **I** port.

Dependencies

To enable this port, specify these parameter values.

- **Output size** — `Full` or `Same as input port I`
- **Padding options** — `Constant`
- **Pad value source** — `Input port`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`
Complex Number Support: Yes

Output

Output — Filtered output image
matrix

Filtered output image, returned as a numeric matrix of the same data type as the input image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Main

Separable filter coefficients — Filter coefficients are separable

`off` (default) | `on`

Select this parameter if your filter coefficients are separable. Using separable filter coefficients reduces the number of calculations the block must perform to compute the output. You can use `isfilterseparable` to check if your filter is separable and compute the vertical and horizontal filter coefficients.

Coefficient source — Source of filter coefficients

`Specify via dialog` (default) | `Input port`

Specify the source of the filter coefficients as one of these options.

- `Specify via dialog` — Specify the filter coefficients using the **Coefficients** parameter or, if you select the **Separable filter coefficients** parameter, by using the **Vertical coefficients (across height)** and **Horizontal coefficients (across width)** parameters.
- `Input port` — Specify the filter coefficients using the **H** port, or if you select the **Separable filter coefficients** parameter, by using the **HV** and **HH** ports.

Coefficients — Filter coefficients

`[1 0; 0 -1]` (default) | numeric matrix

Specify the filter coefficients as a numeric matrix.

Dependencies

To enable this parameter, specify these parameter values.

- **Separable filter coefficients** — `off`
- **Coefficient source** — `Specify via dialog`

Vertical coefficients (across height) — Vertical filter coefficients

`[4 0]` (default) | numeric vector

Specify the vertical filter coefficients as a numeric vector.

Dependencies

To enable this parameter, specify these parameter values.

- **Separable filter coefficients** — `on`
- **Coefficient source** — `Specify via dialog`

Horizontal coefficients (across height) — Horizontal filter coefficients

`[4 0]` (default) | numeric vector

Specify the horizontal filter coefficients as a numeric vector.

Dependencies

To enable this parameter, specify these parameter values.

- **Separable filter coefficients** — `on`
- **Coefficient source** — `Specify via dialog`

Output size — Size of filtered image

`Full` (default) | `Same as input port I` | `Valid`

For an input image having dimensions *M*-by-*N* and a filter having dimensions *P*-by-*Q*, specify the size of the filtered image as one of these options.

- `Full` — The block uses padding to return a filtered image with full dimensions *(M+P–1)*-by-*(N+Q–1)*.
- `Same as input port I` — The block uses padding to return a filtered image with dimensions *M*-by-*N*, the same size as the input image.
- `Valid` — The block filters the input image only where the coefficient matrix fits entirely within it without padding, and returns a filtered image with dimensions *(M–P+1)*-by-*(N–Q+1)*.

Padding options — Padding method

`Constant` (default) | `Replicate` | `Symmetric` | `Circular`

Specify the padding method as one of these options.

- `Constant` — Pads the input image with a constant value.
- `Replicate` — Pads the input image by repeating its border values.
- `Symmetric` — Pads the input image by mirror-reflecting the image across its border.
- `Circular` — Pads the input image by assuming the image is periodic.

Dependencies

To enable this parameter, specify the **Output size** parameter as either `Full` or `Same as input port I`.

Pad value source — Source of padding value

`Specify via dialog` (default) | `Input port`

Specify the source of the padding value as one of these options.

- `Specify via dialog` — Specify the pad value using the **Pad value** parameter.
- `Input port` — Specify the pad value using the **PVal** port.

Dependencies

To enable this parameter, specify these parameter values.

- **Output size** — `Full` or `Same as input port I`

- **Padding options** — `Constant`

Pad value — Padding value

`0` (default) | numeric scalar

Specify the padding value as a numeric scalar.

Dependencies

To enable this parameter, specify these parameter values.

- **Output size** — `Full` or `Same as input port I`
- **Padding options** — `Constant`
- **Pad value source** — `Specify via dialog`

Filtering based on — Method of filtering

`Convolution` (default) | `Correlation`

Specify the method of filtering as `Convolution` or `Correlation`.

Data Types

For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Lock data type settings against change by the fixed-point tools — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

2-D Histogram

Generate histogram from input

Libraries:
Computer Vision Toolbox / Statistics

Description

The 2-D Histogram block computes the frequencies of the elements in the input image. The block calculates the histogram values for either the entire input or for each column of the input image. It sorts all the of input values into bins according to their pixel values. The histogram value for a given bin represents the frequency of the input values bracketed by that bin. The block is also capable of computing a running histogram across a sequence of inputs. The block is also capable of computing a running histogram across a sequence of inputs.

Ports

Input

Port_1 — Input image
vector | matrix | 3-D array

Input image, specified as a vector, matrix, or 3-D array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Rst — Reset value
scalar

Reset value for an input sequence, specified as a scalar. This value dictates the event that causes the block to reset the running histogram. The sample time of the **Rst** input must be a positive integer and a multiple of the input sample time.

Dependencies

To enable this port, select the **Running histogram** parameter and set the **Trigger type** parameter to `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero sample`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

Port_1 — Histogram output
vector | matrix | 3-D array

Histogram output, returned as a vector, matrix, or 3-D array.

If the **Find the histogram over** parameter is set to `Entire input`, then the output is always a vector. If the **Find the histogram over** parameter is set to `Each column`, then the output has the same number of dimension as the input.

Data Types: `single` | `double` | `uint32`

Parameters

Main

Lower limit of histogram — Lower limit of lowest-valued bin
`0` (default) | real-valued scalar

Specify a real-valued scalar for the lower boundary, B_m, of the lowest-valued bin. `NaN` and `inf` are not valid values for B_m.

Tunable: Yes

Upper limit of histogram — Upper limit of highest-valued bin
`1` (default) | real-valued scalar

Specify a real-valued scalar for the upper boundary, B_m, of the highest-valued bin. `NaN` and `inf` are not valid values for B_M.

Tunable: Yes

Number of bins — Number of bins in histogram
`256` (default) | real-valued scalar

Specify the number of bins in the histogram.

Find the histogram over — Dimension along which to compute histogram
`Entire input` (default) | `Each column`

Specify the dimension of the input image along which the block computes the histogram values. For any given value, *n*, of the **Number of bins** parameter, this parameter affects the output of the block as follows.

- `Entire input` — The block computes the histogram over the entire input. It outputs an *n*-element column vector.
- `Each column` — The block computes the histogram over each column of the input.
  - If the input is an *M*-by-*N* matrix, the block outputs an *n*-by-*N* matrix. The *j*th column of the output matrix contains the histogram for the data in the *j*th column of the *M*-by-*N* input matrix.
  - If the input is an *M*-by-*N*-by-*P* array, the block outputs an *n*-by-*N*-by-*P* array. If the input is a three-channel color image, the value of P is 3, and the block computes the histogram for each color channel separately.

Normalized — Normalize histogram output
`off` (default) | `on`

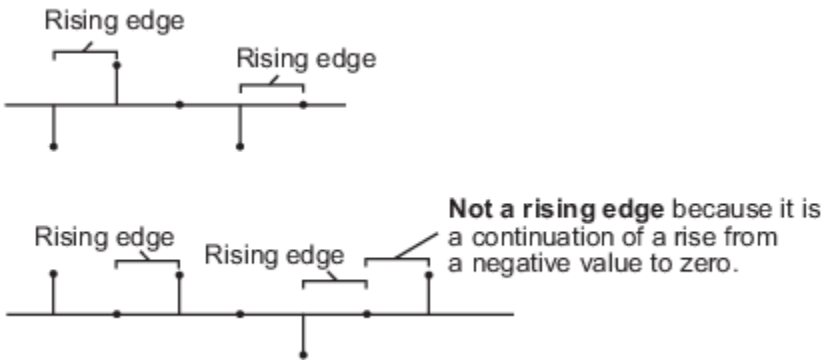
Select the **Normalized** parameter to normalize the output histogram value within a range of [0, 1].

Note Use of this parameter is not supported for fixed-point signals.

Running histogram — Frequency distribution for successive inputs
`off` (default) | `on`

Select the **Running histogram** parameter to compute the frequency distribution of both the past and present data for successive inputs. The block resets the histogram (by emptying all of the bins) when it detects a reset event at the optional **Rst** port. There's an additional dimension to the output size which is equal to $((T_{sim}/T_s)+1)$ where T_{sim} is the simulation time and T_s is the sample time for block execution. The output depends on the value of the **Find the histogram over** parameter.

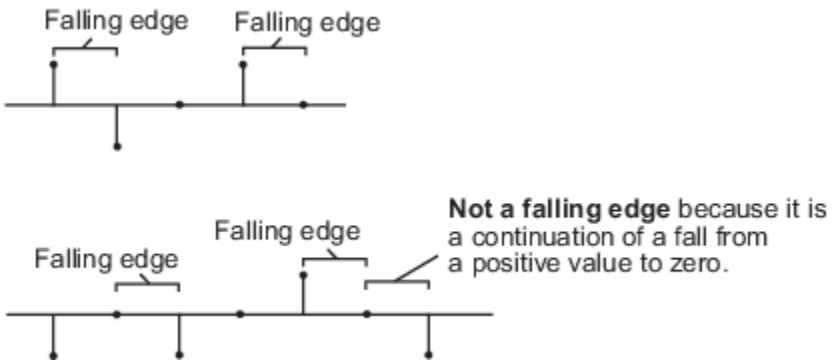
- `Entire input` — The block computes a running histogram for the data in the first dimension of the input. The block outputs an *n*-by-1-by-$((T_{sim}/T_s)+1)$, where *n* is the value of **Number of bins** parameter.
- `Each column` — The block computes a running histogram for each column of the *M*-by-*N* matrix. The block outputs an *n*-by-*N*-by-$((T_{sim}/T_s)+1)$ array, where *n* is the value of the **Number of bins** parameter.



Note When the block is used in running mode and the input data type is non-floating point, the output of the histogram is stored as a `uint32` data type. The largest number that can be represented by this data type is $2^{32}-1$. If the range of the `uint32` data type is exceeded, the output data wraps back to 0.

Trigger type — Reset condition of running histogram
`None` (default) | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero sample`

Specify the event that, when detected at the optional **Rst** port, resets the running histogram. The reset signal and the input data signal must have the same rate.



Specify the reset event as:

- `None` — Disables the **Rst** port
- `Rising edge` — Triggers a reset event when the **Rst** input does one of the following:
  - Rises from a negative value to either a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero

- `Falling edge` — Triggers a reset event when the **Rst** input does one of the following:
  - Falls from a positive value to either a negative value or zero

- Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero

- `Either edge` — Triggers a reset event when the **Rst** input is a rising edge or falling edge
- `Non-zero sample` — Triggers a reset event at each sample time that the **Rst** input is not zero

Dependencies

To enable this parameter, select the **Running histogram** parameter.

Data Types

For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Lock data type settings against change by the fixed-point tools — Prevent fixed-point tools from overriding data types
`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`no`

Algorithms

The histogram bins have equal width of:

$$\Delta = \frac{B_M - B_m}{n},$$

where

- B_M — Represents the upper boundary of the highest-valued bin.

- B_m — Represents the lower boundary of the lowest-valued bin.
- n — Represents the number of bins.

The centers are located at:

$$B_m + \left(k + \frac{1}{2}\right)\Delta \quad k = 0, 1, 2, \ldots, n - 1 .$$

For input values that fall between two bins, the block places them in the lower-valued bin. For input values greater than the upper limit of the histogram or less than the lower limit of the histogram, the block places them in the highest-valued or lowest-valued bin, respectively.

2-D IDCT

Compute 2-D inverse discrete cosine transform (IDCT)

Libraries:
Computer Vision Toolbox / Transforms

Description

The 2-D IDCT block calculates the two-dimensional inverse discrete cosine transform of the input signal. The equation for the two-dimensional IDCT of an input signal is:

$$f(x,y) = \frac{2}{\sqrt{MN}} \sum_{m=0}^{M-1} \sum_{n=0}^{N-1} C(m)C(n)F(m,n)\cos\frac{(2x+1)m\pi}{2M}\cos\frac{(2y+1)n\pi}{2N},$$

where $F(m,n)$ is the discrete cosine transform (DCT) of the signal $f(x,y)$. If $m = n = 0$, then $C(m) = C(n) = 1/\sqrt{2}$. Otherwise $C(m) = C(n) = 1$.

Ports

Input

Port_1 — Input data
matrix | vector

Specify input data as a vector or matrix of intensity values. The number of elements in the input data must be a power of two.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

Port_1 — Output data
matrix | vector

Output data containing the 2-D IDCT of the input, returned as a matrix or vector. The size and data type of the output are the same as those of the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Main

Sine and cosine computation — How the block computes sine and cosine terms

`Table lookup` (default) | `Trigonometric fcn`

Specify how the block computes the sine and cosine terms to find the 2-D IDCT.

- `Table lookup` — The block computes and stores the trigonometric values before the simulation starts. This option requires more memory than the `Trigonometric fcn` option.
- `Trigonometric fcn` — The block computes the sine and cosine values during the simulation.

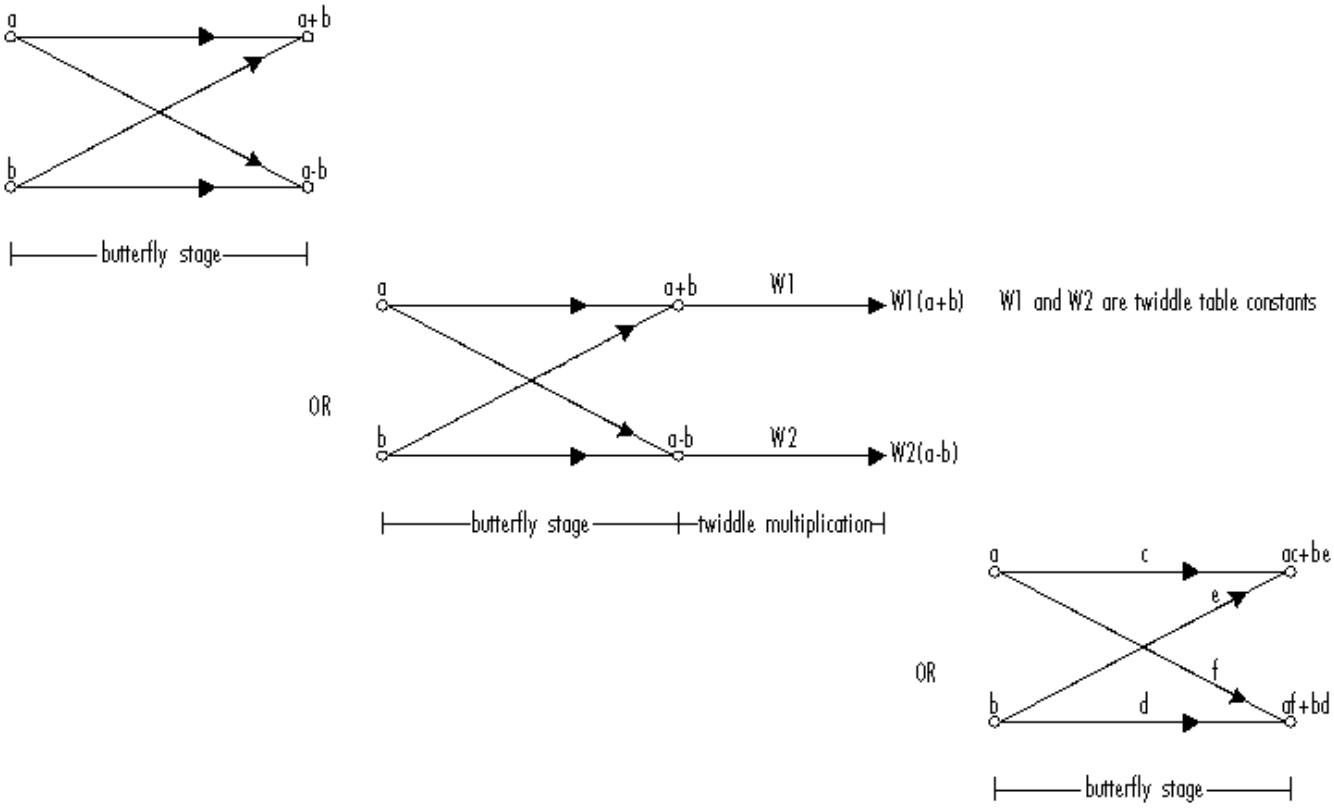
Data Types

For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Lock data type settings against change by the fixed-point tools — Data type override

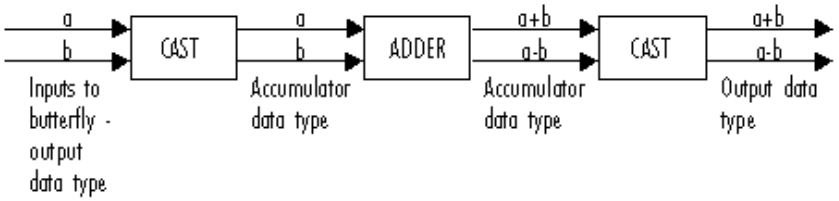
`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).



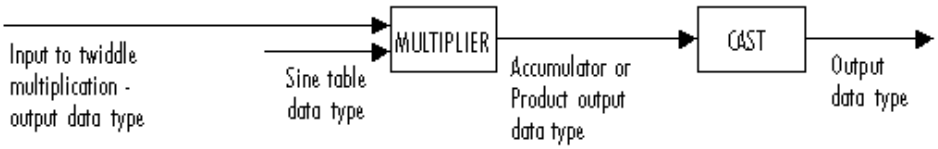
Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`no`



More About

Fixed-Point Data Types



The following diagram shows the data types used in the 2-D IDCT block for fixed-point signals. Inputs are first cast to the output data type and stored in the output buffer. Each butterfly stage processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type.

Butterfly Stage Data Types

Twiddle Multiplication Data Types

When at least one of the inputs to the multiplier is real, the output of the multiplier is in the product output data type. When both of the inputs to the multiplier are complex, the multiplication result is in the accumulator data type. For more information on the multiplication of real and complex numbers, see “Multiplication Data Types”.

`dct2` | `idct2`

2-D IFFT

Compute 2-D inverse fast Fourier transform (IFFT)

Libraries:
Computer Vision Toolbox / Transforms

Description

The 2-D IFFT block computes the inverse discrete Fourier transform (IDFT) of a two-dimensional input matrix using the fast Fourier transform (FFT) algorithm. The equation for the 2-D IDFT $f(x, y)$ of an M-by-N input matrix, $F(m, n)$, is:

$$f(x,y) = \frac{1}{MN}\sum_{m=0}^{M-1}\sum_{n=0}^{N-1} F(m,n)e^{j\frac{2\pi mx}{M}}e^{j\frac{2\pi ny}{N}},$$

where $0 \le x \le M-1$ and $0 \le y \le N-1$.

The block supports FFT implementation based on the FFTW library and an implementation based on a collection of Radix-2 algorithms. You can either manually select one of these implementations or let the block select one automatically.

Ports

Input

Port_1 — Input data
vector | matrix

Input data, specified as a vector or matrix of intensity values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`
Complex Number Support: Yes

Output

Port_1 — Output data
vector | matrix

Output data containing the 2-D IFFT of the input, returned as a vector or matrix. The size and data type of the output are the same as those of the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`
Complex Number Support: Yes

Parameters

Main

FFT implementation — FFT implementation

`Auto` (default) | `Radix-2` | `FFTW`

Specify the type of implementation to compute the FFT as one of these options:

- `FFTW` — Select this option to use to support an arbitrary-length input signal. The block restricts generated code with the `FFTW` implementation to host computers capable of running MATLAB.
- `Radix-2` — Select this option to support bit-reversed processing, fixed and floating-point data, or portable C-code generation using "Simulink Coder". The dimensions of the input matrix, *M* and *N*, must be powers of two. To work with other input sizes, use the Image Pad block to pad or truncate these dimensions to powers of two, or, if possible, choose the `FFTW` implementation. For more information about the algorithms used by the `Radix-2` mode, see "Radix-2 Implementation" on page 1-23.
- `Auto` — Select this option to let the block choose the FFT implementation. For non-power-of-two transform lengths, the block restricts generated code to MATLAB host computers.

Input is in bit-reversed order — Bit-reversed input

`off` (default) | `on`

Specify whether the input to the block is in bit-reversed order or linear order. Select this parameter when you specify the input in bit-reversed order. Otherwise, clear this parameter. The block yields invalid output when you do not set this parameter correctly. For more information on the bit-reversed order of input, see "Bit-Reversed Order" on page 1-42.

Dependencies

To enable this parameter, set the **FFT implementation** parameter to `Auto` or `Radix-2`.

Input is conjugate symmetric — Conjugate symmetric input

`on` (default) | `off`

Select this parameter to specify that the block input is conjugate symmetric, and you want real-valued outputs. Otherwise, clear this parameter.

The 2-D FFT block yields conjugate symmetric output when you input real-valued data. Taking the 2-D IFFT of a conjugate symmetric input matrix produces real-valued output. Therefore, if the input to the 2-D IFFT block is conjugate symmetric, and you select this parameter, the block produces real-valued outputs. When you select this parameter, the block optimizes its computation method. You cannot select this parameter for fixed-point.

If you specify conjugate symmetric input data and do not select this parameter, the block outputs complex-valued data with small imaginary parts. The block outputs invalid data if you select this parameter with input data that is not conjugate symmetric input data.

Divide output by product of FFT length in each input dimension — Scale output data

`on` (default) | `off`

Select this parameter to compute the scaled IFFT, which divides the output by the product of the dimension lengths of the FFT input dimension, as shown in this equation.

$$f(x,y) = \frac{1}{MN}\sum_{m=0}^{M-1}\sum_{n=0}^{N-1} F(m,n)e^{j\frac{2\pi mx}{M}}e^{j\frac{2\pi ny}{N}},$$

where $0 \le x \le M-1$ and $0 \le y \le N-1$.

When you clear this parameter, the block computes the unscaled version of the IFFT, as shown in this equation.

$$f(x,y) = \sum_{m=0}^{M-1}\sum_{n=0}^{N-1} F(m,n)e^{j\frac{2\pi mx}{M}}e^{j\frac{2\pi ny}{N}}$$

Data Types

For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

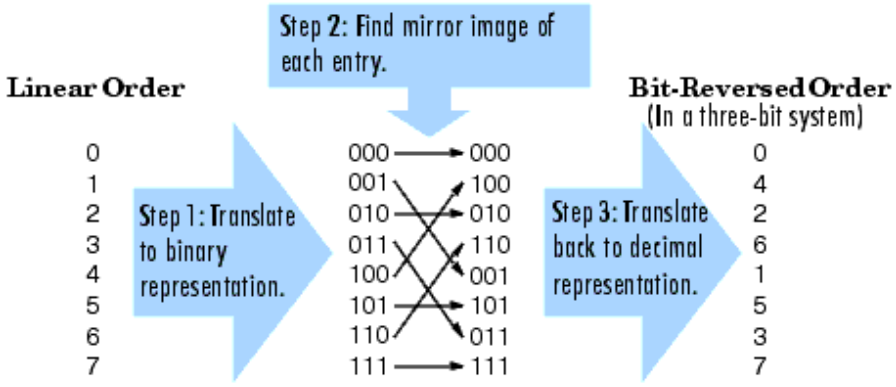
Lock data type settings against change by the fixed-point tools — Data type override

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`



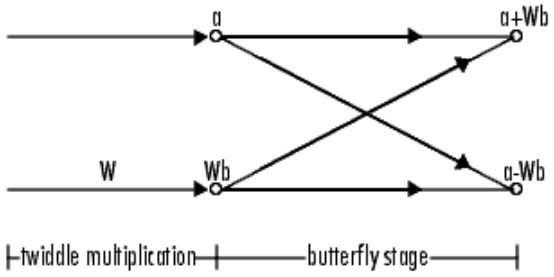
More About

Bit-Reversed Order

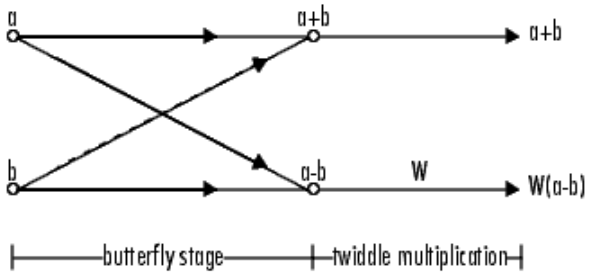
Two numbers are bit-reversed values of each other when the binary representation of one is the mirror image of the binary representation of the other. For example, in a three-bit system, one and four are bit-reversed values of each other because the three-bit binary representation of one, `001`, is the mirror image of the three-bit binary representation of four, `100`. The diagram shows the row indices in linear order. To put them in bit-reversed order:

1. Translate the indices into their binary representations with the minimum number of bits. In this example, the minimum number of bits is three because the binary representation of the largest row index, 7, is `111`.
2. Find the mirror image of each binary entry, and write it beside the original binary representation.
3. Translate each binary mirror image to its decimal representation.

   The row indices now appear in bit-reversed order.

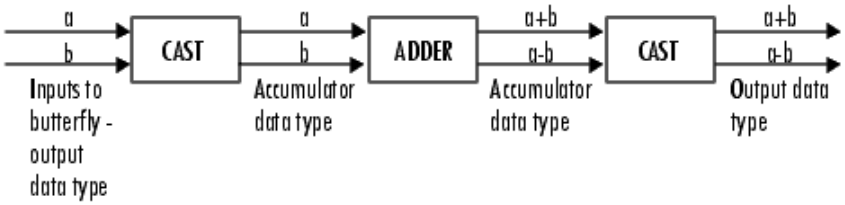


When you select the **Output in bit-reversed order** parameter of the 2-D FFT block, the block bit-reverses the order of both the rows and columns. All output values remain the same, but they appear in a different order.



Fixed-Point Data Types

These diagrams show the data types used in the 2-D FFT block for fixed-point signals. The block first casts inputs to the output data type and stores them in the output buffer. Each butterfly stage then processes signals in the accumulator data type, with the final butterfly casting its output back into the output data type. The block multiplies by a twiddle factor before each butterfly stage, in a decimation-in-time FFT, and after each butterfly stage in a decimation-in-frequency FFT.



Decimation-in-time IFFT

Decimation-in-frequency IFFT

Butterfly stage data types

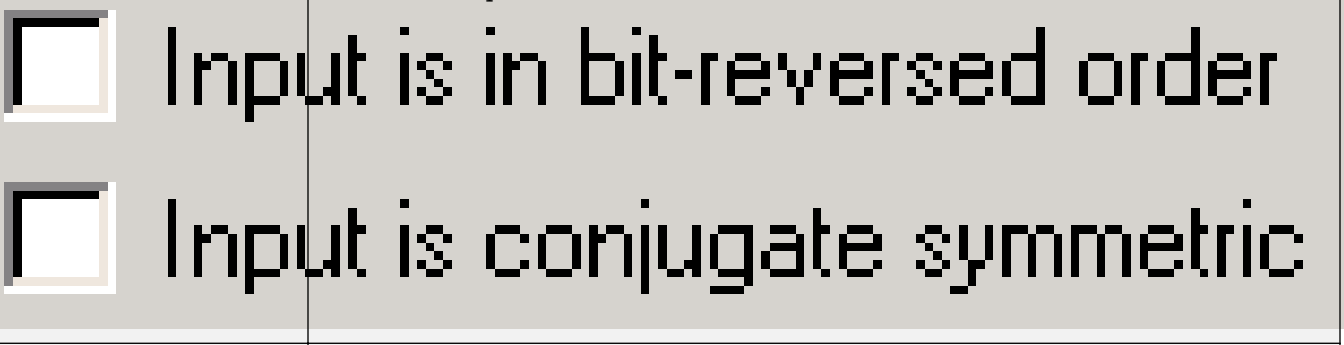
Twiddle multiplication data types

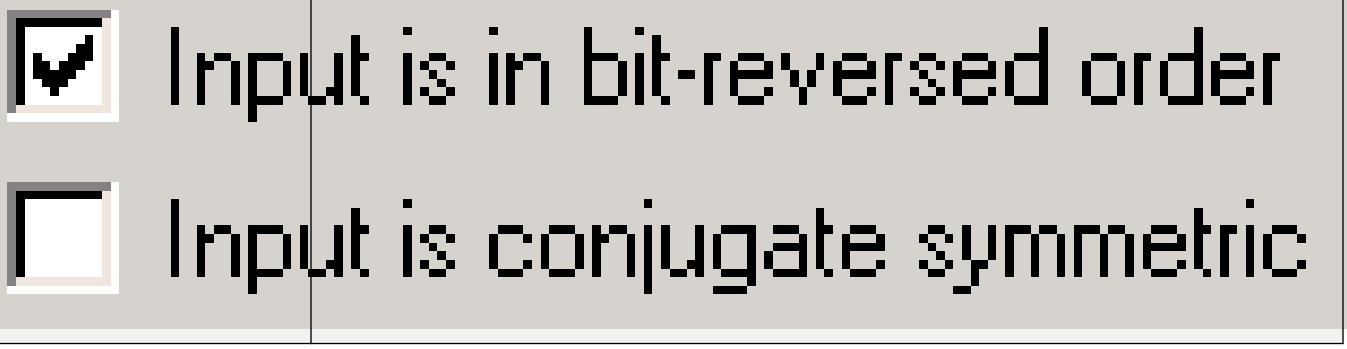
The multiplier output appears in the accumulator data type because both of the inputs to the multiplier are complex. For details on the complex multiplication performed, refer to “Multiplication Data Types”.

Algorithms

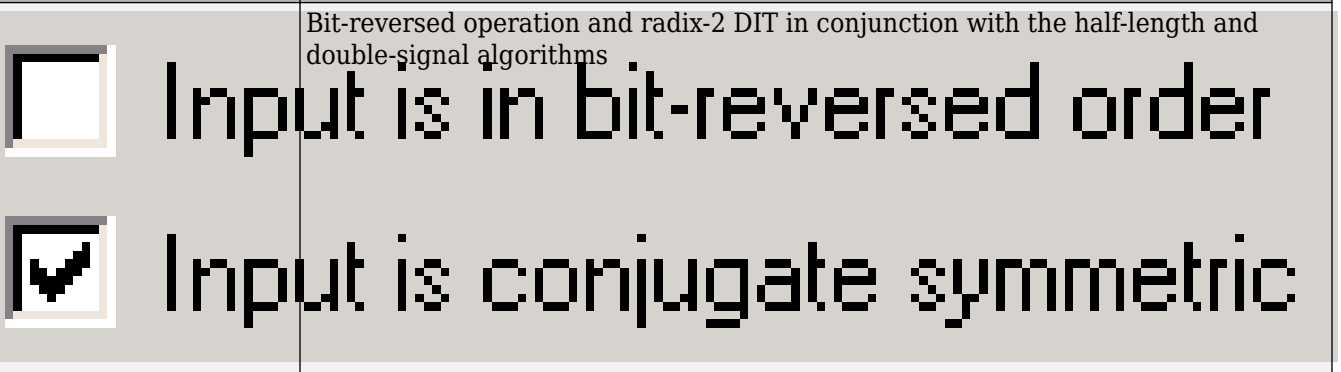
FFTW Implementation

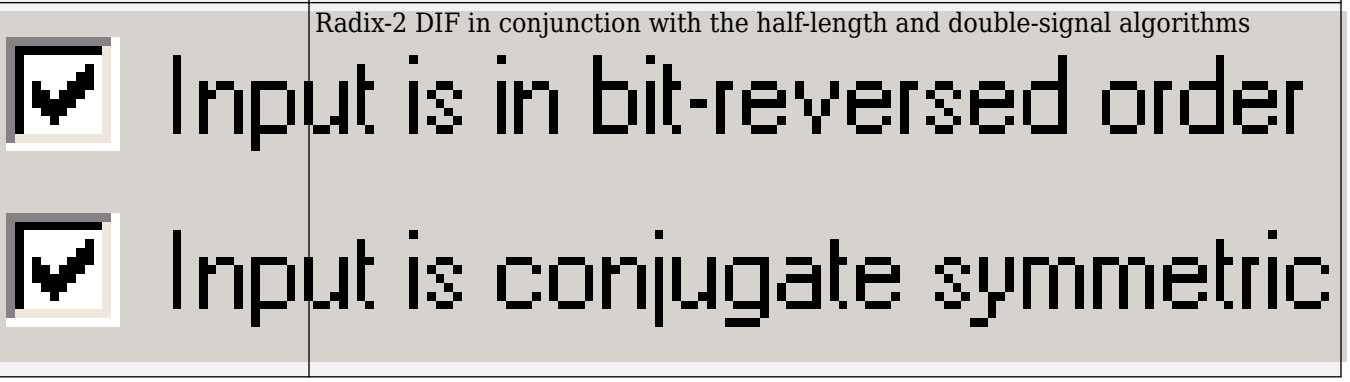
The FFTW implementation provides an optimized FFT calculation, including support for power-of-two and non-power-of-two transform lengths in both simulation and code generation. Generated code using the FFTW implementation can run only on computers capable of running MATLAB. The input must be of a floating-point data type.





Radix-2 Implementation





The Radix-2 implementation supports bit-reversed processing, fixed or floating-point data, and enables the block to provide portable C-code generation using “Simulink Coder”. The dimensions of the input matrix, *M* and *N*, must be powers of two. To work with other input sizes, use the Image Pad block to pad or truncate these dimensions to powers of two.

The block implements one or more of these algorithms for Radix-2 implementation.

- Butterfly operation
- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm

Radix-2 Algorithms for Real and Complex Signals

Parameter Settings	Algorithms Used for FFT Computation
	Bit-reversed operation and radix-2 DIT
	Radix-2 DIF

Parameter Settings	Algorithms Used for FFT Computation
	Bit-reversed operation and radix-2 DIT in conjunction with the half-length and double-signal algorithms
	Radix-2 DIF in conjunction with the half-length and double-signal algorithms

Note The **Input is conjugate symmetric** parameter is not supported for fixed-point signals.

In certain situations, the Radix-2 algorithm computes all the possible trigonometric values of the twiddle factor:

$$e^{j\frac{2\pi k}{K}},$$

where K is the greater value of either M or N, and k is an integer in the range [`0`, K – `1`]. The block stores these values in a table and retrieves them during simulation. This table summarizes the number of table entries each for fixed-point and floating-point Radix-2 FFT algorithms:

Number of Table Entries for N-Point FFT	
Floating point	$3N/4$
Fixed point	N

No.98CH36181)*, 3:1381–84. Seattle, WA, USA: IEEE, 1998. https://doi.org/10.1109/ICASSP.1998.681704.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- When these conditions apply, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB:
  - **FFT implementation** is set to `FFTW`.
  - **Inherit FFT length from input dimensions** is cleared, and the length of each dimension of the input matrix is a power of two.

  Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed ZIP file. Using this ZIP file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed.
- When the length of each dimension of the input matrix is a power of two, you can generate standalone C and C++ code from this block.

2-D Mean

Find 2-D mean of input array

Libraries:
Computer Vision Toolbox / Statistics

Description

The 2-D Mean block computes the mean value of an input. It can compute the mean either along a specified dimension of the input or across the entire input. The block can also compute the running mean values in a sequence of inputs over a period of time.

Ports

Input

I — Input array
vector | matrix | *N*-D array

Input array, specified as a vector, matrix, or *N*-D array. This port is unnamed unless you select the **Enable ROI processing** parameter or select the **Running mean** parameter and set the **Reset port** parameter to a value other than `None`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`
Complex Number Support: Yes

Rst — Reset running mean
scalar

Reset the running mean, specified as a scalar. This port specifies the event that causes the block to reset the running mean. The sample time of the **Rst** input must be a positive integer and a multiple of the block sample time.

Dependencies

To enable this port, select the **Running mean** parameter and set the **Reset port** parameter to one of these options:

- `Rising edge`
- `Falling edge`
- `Either edge`
- `Non-zero sample`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

ROI — Region of interest
vector | matrix

Region of interest (ROI), specified as a four-element vector, *m*-by-4 matrix, or *M*-by-*N* matrix. This port accepts different input values depending on the setting of the **ROI type** parameter.

Note The block supports the **ROI** port for 2-D input images only.

Dependencies

To enable this port, select **Enable ROI processing** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Label — Label matrix
matrix

Label matrix, specified as a matrix of nonnegative integers. The label matrix represents the objects in a 2-D image on a per pixel basis. The pixels labeled `0` represent the background, pixels labeled `1` make up the first object, the pixels labeled `2` make up the second object, and so on. The size of the label matrix must be the same as the size of the 2-D input image.

Dependencies

To enable this port, select **Enable ROI processing** parameter and set the **ROI type** parameter to `Label matrix`.

Data Types: `uint8` | `uint16` | `uint32`

Label Numbers — Label values of ROIs
vector

Label values of ROIs, specified as an *M*-element vector. Use this vector to specify which objects the block calculates statistics for. Each element of the vector must correspond to a labeled object in the label matrix. *M* must be less than or equal to the number of objects in the label matrix.

Dependencies

To enable this port, select **Enable ROI processing** parameter and set the **ROI type** parameter to `Label matrix`.

Data Types: `uint8` | `uint16` | `uint32`

Output

Out — Mean value of input
scalar | vector | matrix | *N*-D array

Mean value of the input, returned as a scalar, vector, matrix, or *N*-D array. The size of this output depends on the size of the input and the parameter settings of the block. This port is unnamed unless you select the **Output flag indicating if ROI is within image bounds** or **Output flag indicating if input label numbers are valid** parameter

Compute Mean Value of Input Array

The block computes the mean value along the specified dimension of the input or across the entire input. The block returns output as:

- Scalar — The input is of any size, and the **Find the mean value over** parameter is set to `Entire input`.
- Vector — The input is a matrix, and the **Find the mean value over** parameter is set to `Each row`, `Each column`, or `Specified dimension`. If `Specified dimension` is selected, the value of the **Dimension** parameter must be either `1` or `2`.
- (*N*–1)-D array — The input is an *N*-D array, the **Find the mean value over** parameter is set to `Specified dimension`, and the value of the **Dimension** parameter is *N*.
- *N*-D array with one singleton dimension — The input is an *N*-D array, and the **Find the mean value over** parameter is set to `Each row`, `Each column`, or `Specified dimension`. If `Specified dimension` is selected, the value of the **Dimension** parameter must be an integer less than *N*.

  Example: For a 3-D input array of size *M*-by-*N*-by-*P*, the dimension of the returned output is:

  - An 1-by-*N*-by-*P* array if you set the **Find the mean value over** parameter to `Entire row`.
  - An *M*-by-1-by-*P* array if you set the **Find the mean value over** parameter to `Entire column`.
  - An *M*-by-*N* matrix if you set the **Find the mean value over** parameter to `Specified dimension` and the **Dimension** parameter to `3`.

Compute Mean Value of Sequence of Inputs

Select the **Running mean** parameter. The block finds the mean value of each element of the input across the entire sequence and compiles them into a single array. The output is of the same size as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Flag — Validation of ROI
scalar | vector

Validation of ROI, returned as a scalar or vector of logical values. If the **ROI type** parameter is set to `Rectangles` or `Lines`, the output signifies whether or not the specified ROIs lie within the input image, either completely or partially. If the **ROI type** parameter is set to `Label matrix`, the output signifies whether or not the label numbers specified in the **Label Numbers** input are present in the input label matrix. The size of this output depends on whether the **Output** parameter is set to `Individual statistics for each ROI` or `Single statistic for all ROIs`.

ROI type	`Individual statistics for each ROI`	`Single statistic for all ROIs`

`Rectangles` or `Lines`	The port returns an *M*-element vector of logical values, where *M* is the number of regions specified at the **ROI** port. When an ROI is either completely or partially inside the input image, the corresponding element of the vector is `1`. When the ROI is completely outside the input image, the corresponding element of the vector is `0`.	The port returns a logical scalar. The scalar is `0` when all the ROIs are completely outside the input image. Otherwise, the scalar is `1`.
`Label matrix`	The port returns an *M*-element vector of logical values, where *M* is the number of elements in the input specified at the **Label Numbers** port. When a specified label number is present or absent in the label matrix, the corresponding element of the vector is `1` or `0` respectively.	The port returns a logical scalar. The scalar is `0` when all elements of the vector specified at the **Label Numbers** port are absent from the label matrix. Otherwise. the scalar is `1`.

Note If an ROI is partially outside the image, the block computes the mean values for only the portion of the ROI that lies within the image bounds.

Dependencies

To enable this port, set the **ROI type** parameter to `Rectangles`, `Lines`, or `Label matrix`. For either `Rectangles` or `Lines`, select the **Output flag indicating if ROI is within image bounds** parameter. For Label matrix, select the **Output flag indicating if input label numbers are valid** parameter.

Data Types: `Boolean`

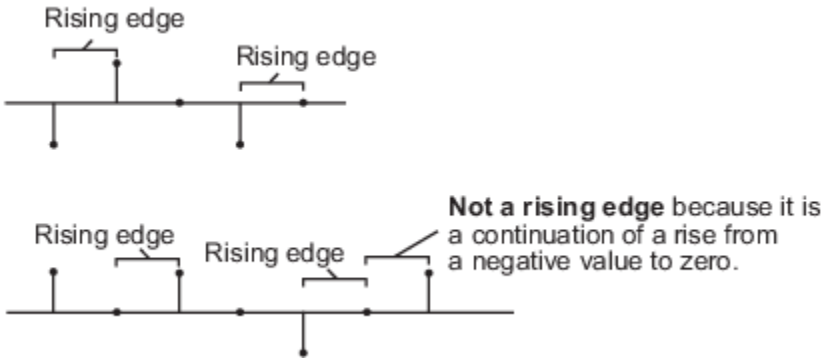
Parameters

Main

Running mean — Running mean values

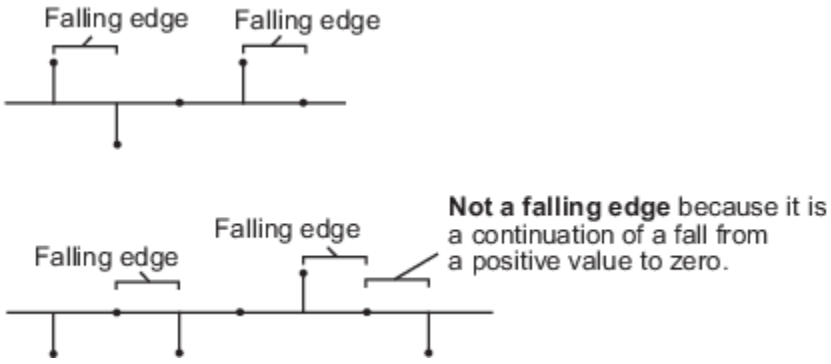
`off` (default) | `on`

Select this parameter to compute running mean values across a sequence of inputs over a period of time.



Reset port — Reset event

`None` (default) | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero sample`



Specifies what the block detects as a reset event. The block resets the running mean when a reset event occurs at the **Rst** port. The reset sample time must be a positive integer and a multiple of the input sample time.

Specify the reset event as one of these options.

- `None` — Disable the **Rst** port.
- `Rising edge` — Trigger a reset event when the **Rst** input does one of the following.
  - Rises from a negative value to either a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero

- `Falling edge` — Trigger a reset event when the **Rst** input does one of the following.
  - Falls from a positive value to either a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero

- `Either edge` — Trigger a reset event when the **Rst** input is either a rising edge or a falling edge.
- `Non-zero sample` — Trigger a reset event at each sample time that corresponds to a non-zero **Rst** input.

Note When running simulations in Simulink® multitasking mode, reset signals have a one-sample latency. In this case, when the block detects a reset event, there is a one-sample delay at the **Rst** port before the block applies the reset.

Dependencies

To enable this parameter, select the **Running mean** parameter.

Find the mean value over — Dimension along which mean is computed

`Entire input` (default) | `Each row` | `Each column` | `Specified dimension`

Specify the dimension of the input along which the block computes the mean.

- `Entire input` — Computes mean over the entire input.
- `Each row` — Computes mean over each row.
- `Each column` — Computes mean over each column.
- `Specified dimension`— Computes mean over the dimension specified in the **Dimension** parameter.
  - If the **Dimension** parameter is set to `1`, the output is the same as when `Each column` is selected.
  - If the **Dimension** parameter is set to `2`, the output is the same as when `Each row` is selected.

Dependencies

To enable this parameter, clear the **Running mean** parameter.

Dimension — Custom dimension

`1` (default) | positive scalar

Specify the dimension (one-based value) of the input array over which the block computes the mean. The value of this parameter must not exceed the number of dimensions in the input array.

Dependencies

To enable this parameter, set the **Find the mean value over** parameter to `Specified dimension`.

Enable ROI processing — Compute mean value within ROI

`off` (default) | `on`

Select to compute the mean within the specified ROIs in the image.

Dependencies

To enable this parameter, set the **Find the mean value over** parameter to `Entire input`.

ROI type — Type of ROI

`Rectangles` (default) | `Lines` | `Label matrix` | `Binary mask`

Specify the ROI format that represents the regions in the image over which to compute the mean. The type of ROIs can be a rectangles, lines, a label matrix, or a binary mask.

ROI type	Inputs to the ROI Port	Description

`Rectangles`	• Four-element row vector [*x y width height*] • *M*-by-4 matrix: $\begin{bmatrix} x_1 & y_1 & width_1 & height_1 \\ x_2 & y_2 & width_2 & height_2 \\ \vdots & \vdots & \vdots & \vdots \\ x_M & y_M & width_M & height_M \end{bmatrix}$, where *M* is the number of rectangular ROIs. Each row of the matrix corresponds to a different rectangle.	• *x* and *y* are the one-based coordinates of the upper left corner of the rectangle. • *width* and *height* are the width and height, in pixels, of the rectangle. The values of *width* and *height* must be greater than zero.
`Lines`	• Four-element row vector [x_1 y_1 x_2 y_2] • *M*-by-4 matrix: $\begin{bmatrix} x_{11} & y_{11} & x_{12} & y_{12} \\ x_{21} & y_{21} & x_{22} & y_{22} \\ \vdots & \vdots & \vdots & \vdots \\ x_{M1} & y_{M1} & x_{M2} & y_{M2} \end{bmatrix}$ where *M* is the number of linear ROIs. Each row of the matrix corresponds to a different line.	• x_1 and y_1 are the coordinates of the beginning of the line. • x_2 and y_2 are the coordinates of the end of the line.
`Label matrix`	*M*-by-*N* matrix	Matrix of the same size as the input image. The matrix contains label values that represent different objects in an image. The pixels labeled `0` represent the background. The pixels labeled `1` make up one object, the pixels labeled `2` make up a second object, and so on.
`Binary mask`	*M*-by-*N* matrix	Matrix of the same size as the input image. The binary mask classifies image pixels as belonging to either the region of interest or the background. Binary mask values of `1` indicate that the corresponding image pixel belongs to the ROI. Binary mask values of `0` indicate that the corresponding image pixel is part of the background.

Dependencies

To enable this parameter, select the **Enable ROI processing** parameter.

ROI portion to process — Portion of ROI for which to compute mean

`Entire ROI` (default) | `ROI perimeter`

Specify the portion of the ROI for which the block computes the 2-D mean.

- `Entire ROI` — The block computes the mean value over the entire region of the rectangular ROI.
- `ROI perimeter` — The block computes the mean value along the perimeter of the rectangular ROI.

Dependencies

To enable this parameter, set the **ROI type** parameter to `Rectangles`.

Output — Compute individual or universal mean for ROIs

`Individual statistics for each ROI` (default) | `Single statistic for all ROIs`

Specify whether to calculate the 2-D mean individually for each ROI or across all ROIs.

- To compute separate mean values for each ROI, set this parameter to `Individual statistics for each ROI`. The block outputs a vector of mean values corresponding to different ROIs. The length of the output vector is equal to the number of ROIs.
- To compute the universal mean value across all specified ROIs, set this parameter to `Single statistic for all ROIs`. The block outputs a scalar representing the mean value across all specified ROIs.

Dependencies

To enable this parameter, set the **ROI type** parameter to `Rectangles`, `Lines`, or `Label matrix`.

Output flag indicating if ROI is within image bounds — Enable flag output port

`off` (default) | `on`

Select to enable the Flag output port.

Dependencies

To enable this parameter, set the **ROI type** parameter to `Rectangles` or `Lines`.

Output flag indicating if input label numbers are valid — Enable flag output port
`off` (default) | `on`

Select to enable the Flag output port.

Dependencies

To enable this parameter, set the **ROI type** parameter to `Label matrix`.

Data Types

For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Lock data type settings against change by the fixed-point tools — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Note Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

2-D Minimum | 2-D Maximum | 2-D Median

Functions

`mean`

2-D Median

2-D Median values of input array

Libraries:
Computer Vision Toolbox / Statistics

Description

The 2-D Median block computes the median value of an input array. The median value of an array is calculated by using these steps.

1. The values in the matrix are sorted in numeric order.
2. To find the median, of an array, *A*, with a total number of elements, *p*, where *p* is:
   - Odd — Median = *A*(`ceil`(*p* / 2))
   - Even — Median = (*A* (*p* / 2) + *A* ((*p* / 2) + 1)) / 2

Ports

Input

Port_1 — Input array
scalar | vector | matrix | *N*-D array

Specify the Input array as a vector, matrix, or *N*-D array.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`
Complex Number Support: Yes

Output

Port_1 — Output median values
scalar | vector | matrix | *N*-D array

The median values are returned as scalar, vector, matrix, or*N* array. The size of the output and how median is calculated depends on the setting of the **Find the median value over** parameter.

- For *M*-by-*N*,the input array, the value of the **Find the median value over** parameter determines the output form in this manner.
  - `Entire input` —The output is the median value of all the elements of the*M*-by-*N* input array as a scalar
  - `Each row` — The output is a *M*-by-1 column vector, where each element in the vector is the median value of the corresponding row in the input array.
  - `Each column` — The output is a 1-by-*N* row vector, where each element in the vector is the median value of the corresponding column in the input array.

  - `Specified dimension` — If the **Dimension** parameter is set to 1, the output is the same when you select `Each column`. If the **Dimension** parameter is set to 2, the output is the same as when you select `Each row`. If the **Dimension** parameter is set to 3, the output at each sample time is an *M*-by-*N* matrix containing the median value of each vector over the third dimension of the input
- For an *N*-D array, the value of the **Find the median value over** parameter determines the output form in this manner.
  - `Entire input` — The output is the median value of all elements of the *M*-by-*N*-by-*P* input array as scalar.
  - `Each row` — The output is a *M*-by-1-by-*P* array, where each element contains the median value of each row vector in each plane.
  - `Each column` — The output dimension is a 1-by-*N*-by-*P* array, where each element contains the median value of each column vector for each plane.
  - `Specified dimension` — The output depends on **Dimension**. If **Dimension** is set to 1, the output is the same as when you select `Each column`. If **Dimension** is set to 2, the output is the same as when you select `Each row`. If **Dimension** is set to 3, the output dimension is a *M*-by-*N* matrix containing the median value of each vector over the third dimension of the input

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Main

Sort algorithm — Algorithm to sort input array
`Quick sort` (default) | `Insertion sort`

Specify the algorithm by which to sort the input array.

- `Quick sort` — This sorting algorithm uses a recursive sort method and is faster at sorting more than 32 elements.
- `Insertion sort` — This sorting algorithm uses a non-recursive method and is faster at sorting fewer than 32 elements.

When you generate code, to avoid recursive function calls, use the `Insertion sort` algorithm.

Find the median value over — Dimension in which to compute median
`Entire input` (default) | `Each row` | `Each column` | `Specified dimension`

Specify the dimension of the input in which the block computes the median.

- `Entire input` — Computes the median over the entire input. The output value is scalar
- `Each row` — Computes the median over each row of the input. The output is column vector
- `Each column` — Computes the median over each column of the input. The output is row vector
- `Specified dimension` — Computes the median over the dimension of the input specified in the **Dimension** parameter.
  - If **Dimension** is 1, the output is the same as when you select `Each column`
  - If **Dimension** is 2, the output is the same as when you select `Each row`

Dimension — Custom dimension
1 (default) | positive scalar

Specify the dimension (one-based value) of the input array, over which the block computes the median. The value of this parameter must not exceed the number of dimensions in the input array.

Dependencies

To enable this parameter, set the **Find the median value over** parameter to `Specified dimension`.

Data Types Tab

For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Lock data type settings against change by the fixed-point tools — Option to prevent fixed-point tools from overriding data types
`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Note Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

2-D Variance | 2-D Minimum | 2-D Maximum | 2-D Mean | 2-D Standard Deviation

Functions
`median`

2-D Maximum

Compute maximum value of input or sequence of inputs

Libraries:
Computer Vision Toolbox / Statistics

Description

The 2-D Maximum block identifies the index of the largest element in an input array. The input can be a 1-D vector, 2-D matrix, or an *N-D*-array. The block can compute the maximum value along a specified dimension of the input or the entire input. The 2-D Maximum block can also track the maximum values in a sequence of inputs over a period of time.

Ports

Input

In — Input array
vector | matrix | *N-D*- array

Input array, specified as a vector, matrix, or *N-D*- array. This port is unnamed until you select the **Enable ROI processing** parameter or set the **Mode** parameter to `Running`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`
Complex Number Support: Yes

Rst — Reset port
scalar

Reset port, specified as a scalar. This port specifies the event that causes the block to reset the running maximum. The sample time of the **Rst** input must be a positive integer and a multiple of the input sample time.

Dependencies

To enable this port, set the **Mode** parameter to `Running` and set the **Reset port** parameter to `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero sample`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

ROI — Region of interest
four-element vector | *m*-by-4 matrix | *M*-by-*N* matrix

Region of interest (ROI), specified as a four-element vector, *m*-by-4 matrix, or *M*-by-*N* matrix. The input value to this port depends on the **ROI type** parameter.

Note You can use the `ROI` port only if the input is a matrix.

Dependencies

To enable this port, set the **Find the maximum value over** parameter to `Entire input` and select the **Enable ROI processing** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Label — Label matrix
matrix of nonnegative integers

Label matrix, specified as a matrix of nonnegative integers. The label matrix represents the objects in an image. The pixels labeled 0 are the background. The pixels labeled 1 make up one object; the pixels labeled 2 make up a second object; and so on. The size of the label matrix must be the same size as the 2-D input.

Dependencies

To enable this port, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Label matrix`.

Data Types: `uint8` | `uint16` | `uint32`

Label Numbers — Label values of ROIs
M-element vector

Label values of ROIs, specified as a *M*-element vector. The value of *M* can be less than or equal to the number of objects that are labeled in the label matrix.

Dependencies

To enable this port, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Label matrix`.

Data Types: `uint8` | `uint16` | `uint32`

Output

Val — Output maximum value
scalar | vector | matrix | *N-D*-array

Output maximum value, returned as a scalar, vector, matrix, or *N-D*-array. The size of the returned maximum value depends on the size of the input, and the settings for the **Find the maximum value over** parameter.

This port is unnamed if **Mode** is set to `Running`.

Compute Maximum Value of Input Array

The **Mode** parameter is set to `Value and Index` or `Value`. In this case, you can compute the maximum value along any specified dimension of the input or the entire input. The output maximum value is a:

- Scalar if the input is of any size and **Find the maximum value over** parameter is set to `Entire input`.
- Vector if the input is a matrix and the **Find the maximum value over** parameter is set to any one of `Each row`, `Each column`, and `Specified dimension`. In this case, the **Dimension** value for `Specified dimension` can be either 1 or 2.

- (*N-1*)-D array if the input is an *N*-D array and the **Find the maximum value over** parameter is set to `Specified dimension` and the **Dimension** value is *N*.
- *N*-D array with one singleton dimension if the input is an *N*-D array and the **Find the maximum value over** parameter is set to either of `Each row`, `Each column`, and `Specified dimension`.

  Example: For a 3-D input array of size *M*-by-*N*-by-*P*, the dimension of the returned output is:

  - 1-by-*N*-by-*P* if you set the **Find the maximum value over** parameter to `Entire row`.
  - *M*-by-1-by-*P* if you set the **Find the maximum value over** parameter to `Entire column`.
  - *M*-by-*N* if you set the **Find the maximum value over** parameter to `Specified dimension` and the **Dimension** value to 3.

Compute Maximum Value of Sequence of Inputs

When you set the **Mode** parameter to `Running`, the block computes the maximum value relative to each sample in the input sequence. The output is of the same size as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Idx — Indices of maximum values in the input array
scalar | vector | matrix | *N-D*-array

Indices of maximum values in the input array, returned as a scalar, vector, matrix, or *N-D*-array. The size of the returned indices depends on the size of the input, and the settings for the **Find the maximum value over** parameter.

To enable this port set the **Mode** parameter to `Value and Index` or `Index`. The indices returned at the output is a:

- Scalar if the input is a N- element vector and **Find the maximum value over** parameter is set to `Entire input`.
- Vector if the input is a matrix and the **Find the maximum value over** parameter is set to any one of `Entire input`, `Each row`, `Each column`, and `Specified dimension`. In this case, the **Dimension** value for `Specified dimension` can be either 1 or 2.
- (*N-1*)-D array if the input is a *N*-D array and the **Find the maximum value over** parameter is set to `Specified dimension` and the **Dimension** value is *N*.
- *N*-D array with one singleton dimension if the input is an *N*-D array. In this case the **Find the maximum value over** parameter is set to `Each row`, `Each column`, or `Specified dimension`. In this case, the **Dimension** value for `Specified dimension` is an integer less than *N*.

  Example: For a 3-D input array of size *M*-by-*N*-by-*P*, the dimension of the returned output is:

  - 1-by-*N*-by-*P* if you set the **Find the maximum value over** parameter to `Entire row`.
  - *M*-by-1-by-*P* if you set the **Find the maximum value over** parameter to `Entire column`.
  - *M*-by-*N* if you set the **Find the maximum value over** parameter to `Specified dimension` and the **Dimension** value to 3.

Note When a maximum value occurs more than once, the computed index corresponds to the first occurrence. For example, in the input vector `[3 2 1 2 3]`, the maximum value is 3 and the one-based index of the maximum value is `1`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Flag — Validation for ROI
0 | 1

Validation for ROI, returned as 0 or 1. The output value signifies if all of the ROIs specified at the input lie within the image bounds. The output value depends on the values of the **Output** and **ROI Type** parameters.

ROI Type	Output	Output from Flag port	Description
• `Rectangles` • `Lines`	`Individual statistics for each ROI`	0	ROI is completely outside the input image.
		1	ROI is either completely or partially inside the input image.
	`Single statistic for all ROIs`	0	ROI is completely outside the input image.
		1	ROI is either completely or partially inside the input image.
`Label matrix`	`Individual statistics for each ROI`	0	Label number is not in the label matrix.
		1	Label number is in the label matrix.
	`Single statistic for all ROIs`	0	None of the label numbers are in the label matrix.
		1	At least one of the label numbers is in the label matrix.

Note If the ROI is partially outside the image, the block computes the variance values only for the portion of the ROI that lies within the image bounds.

Dependencies

To enable this port, select the **Output flag indicating if ROI is within image bounds** parameter and set the value of **ROI type** parameter to `Rectangle`, `Lines`, or `Label Matrix`.

Parameters

Main Tab

Mode — Output mode
`Value and Index` (default) | `Value` | `Index` | `Running`

Specify the type of output to be returned by the block. Select the output mode as:

- `Value and Index` to return the maximum values and the corresponding indices in the given input.
- `Value` to return only the computed maximum values.
- `Index` to return only the indices of the maximum values in the given input.
- `Running` to return the maximum values in a sequence of inputs.

Index Base — Index origin
`One` (default) | `Zero`

Specify the index for the first element in the input array. Select the index origin as:

- `One` for one-based numbering. The range of the index values for the elements in an N-D input array is set to (1, N). For example, the index value for the first element in the matrix is set to (1,1).
- `Zero` for zero-based numbering. The range of the index value for the elements in an N-D input array is set to (0, N-1). For example, the index value for the first element in the matrix is set to (0,0).

Find the maximum value over — Dimension along which maximum is computed
`Entire input` (default) | `Each row` | `Each column` | `Specified dimension`

Specify the dimension of the input along which the block computes the maximum.

- `Entire input` — Computes maximum over the entire input.
- `Each row` — Computes maximum over each row.
- `Each column` — Computes maximum over each column.
- `Specified dimension`— Computes maximum over the dimension specified in the **Dimension** parameter.
  - If **Dimension** is 1, the output is the same as when you select `Each column`.
  - If **Dimension** is 2, the output is the same as when you select `Each row`.

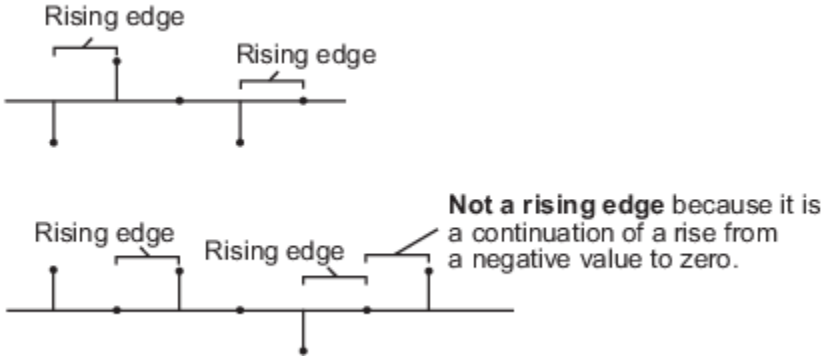
Dependencies

To enable this parameter, set the **Mode** parameter to `Value and Index`, `Value`, or `Index`.

Dimension — Custom dimension
1 (default) | scalar

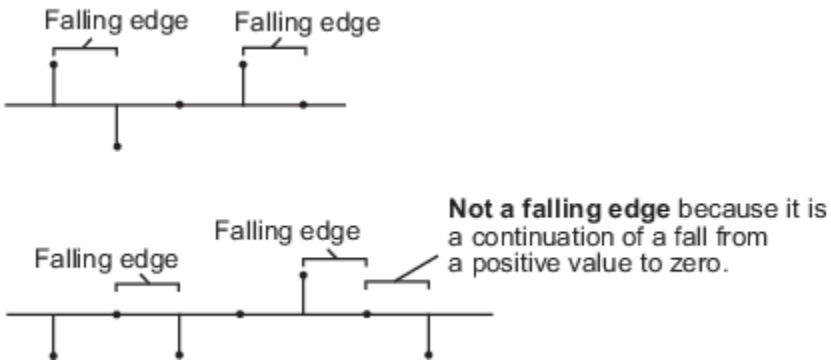
Specify the dimension of the input array over which the maximum is computed as a one-based value. The value of this parameter must be greater than 0 and less than or equal to the number of dimensions in the input array.

Dependencies



To enable this parameter, set the **Find the maximum value over** parameter to `Specified dimension`.

Reset port — Reset event
`None` (default) | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero sample`



Specify when the block detects a reset event. The block resets the running mode when a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer and a multiple of the input sample time.

Specify the reset event as:

- `None` to disable the **Rst** port.
- `Rising edge` to trigger a reset event when the **Rst** input does one of the following:
  - Rises from a negative value to either a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero

- `Falling edge` to trigger a reset event when the **Rst** input does one of the following:
  - Falls from a positive value to either a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero

- `Either edge` to trigger a reset event when the **Rst** input is a `Rising edge` or `Falling edge`.
- `Non-zero sample` to trigger a reset event at each sample time, when the **Rst** input is not zero.

Note When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset.

Dependencies

To enable this parameter, set the **Mode** parameter to `Running`.

ROI Processing

Enable ROI processing — Compute maximum value within a particular region
off (default) | on

Select to calculate maximum within a particular ROI in the image.

Note Full ROI processing is available only if you have a Computer Vision Toolbox license. If you do not have a Computer Vision Toolbox license, you can still use ROI processing, but the **ROI type** is limited to `Rectangles`.

Dependencies

To enable this parameter, set the **Find the maximum value over** parameter to `Entire input`.

ROI type — Type of ROI
`Rectangles` (default) | `Lines` | `Label matrix` | `Binary mask`

Specify the type of ROI that represents the regions in the image over which the block computes the variance. The type of ROI can be a rectangle, line, label matrix, or a binary mask.

Parameters		**Description**
ROI type	**Inputs to the ROI port**	
`Rectangles`	• Four-element row vector `[x y width height]` • *m*-by-4 matrix $\begin{bmatrix} x_1 & y_1 & width_1 & height_1 \\ x_2 & y_2 & width_2 & height_2 \\ \vdots & \vdots & \vdots & \vdots \\ x_M & y_M & width_M & height_M \end{bmatrix}$, where *m* is the number of rectangles. Each row of the matrix corresponds to a different rectangle.	• `x` and `y` are the one-based coordinates of the upper left corner of the rectangle. • `width` and `height` are the width and height, in pixels, of the rectangle. The values of `width` and `height` must be greater than 0.

`Lines`	• Four-element row vector `[x1 y1 x2 y2]` • *m*-by-4 matrix $\begin{bmatrix} x_{11} & y_{11} & x_{12} & y_{12} \\ x_{21} & y_{21} & x_{22} & y_{22} \\ \vdots & \vdots & \vdots & \vdots \\ x_{M1} & y_{M1} & x_{M2} & y_{M2} \end{bmatrix}$, where *m* is the number of lines. Each row of the matrix corresponds to a different line.	• x_1 and y_1 are the coordinates of the beginning of the line. • x_2 and y_2 are the coordinates of the end of the line.
`Label matrix`	*M*-by-*N* matrix	Matrix of the same size as the input image. The matrix contains label values that represent different objects in an image. The pixels labeled 0 are the background. The pixels labeled 1 make up one object; the pixels labeled 2 make up a second object; and so on.
`Binary mask`	*M*-by-*N* matrix	Matrix of the same size as the input image. The binary mask classifies image pixels as belonging to either the region of interest or the background. The mask pixel values of 1 indicate that the image pixel belongs to the ROI. The mask pixel values of 0 indicate that the image pixel is part of the background.

Dependencies

To enable this parameter, set the **Find the maximum value over** parameter to `Entire input` and select the **Enable ROI processing** parameter.

ROI portion to process — Portion of ROI in which to calculate maximum
`Entire ROI` (default) | `ROI perimeter`

Specify the portion of the ROI from which the block has to calculate 2-D maximum. The ROI portion is either the entire ROI or the ROI perimeter.

Dependencies

To enable this parameter, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Rectangles`.

Output — Calculate maximum for individual or entire ROI
`Individual statistics for each ROI` (default) | `Single statistic for all ROIs`

Specify whether to calculate 2-D maximum individually for each ROI or for the entire ROI.

- If you select `Individual statistics for each ROI`, the block outputs a vector of maximum values. The size of the output vector is equal to the number of ROIs.
- If you select `Single statistic for all ROIs`, the block outputs a scalar value. The scalar value represents the statistical value for all the specified ROIs.

Dependencies

To enable this parameter, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Rectangles`, `Lines`, or `Label matrix`.

Output flag indicating if ROI is within image bounds — Enable Flag port
off (default) | on

Select to expose the **Flag** port. For a description of the **Flag** port output, see “Flag” on page 1-0 .

Dependencies

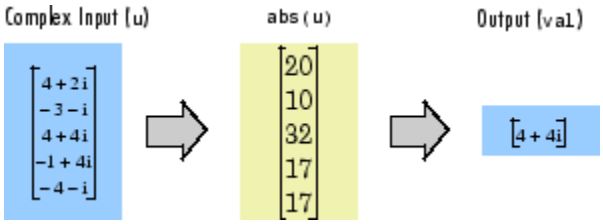
To enable this parameter, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Rectangles`, `Lines`, or `Label matrix`.

Data Types Tab

For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Lock data type settings against change by the fixed-point tools — Prevent fixed-point tools from overriding data types
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).



Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

More About

Maximum value of complex inputs

For complex inputs, the block computes the squared magnitude value for the elements in the input array. The squared magnitude value for a complex number $u = a + bi$ is computed as $a^2 + b^2$. The array element with maximum squared magnitude is the maximum value of the input array.

2-D Minimum

Find minimum values in input or sequence of inputs

Libraries:
Computer Vision Toolbox / Statistics

Description

The 2-D Minimum block identifies the value, and optionally the position, of the smallest element in the input. The input can be a vector, a matrix, or an *N*-D array. The block identifies the minimum value either along a specified dimension of the input or across the entire input. It also tracks the minimum values in a sequence of inputs over a period of time when the **Mode** parameter is set to `Running`.

Ports

Input

In — Input array
scalar | vector | matrix | *N*-D array

Input array, specified as a vector, matrix, or *N*-D array.

Dependencies

The port is named only when you either select **Enable ROI processing** parameter or set the **Mode** parameter to `Running`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`
Complex Number Support: Yes

Rst — Reset running minimum
scalar

Reset the running minimum, specified as a scalar. This port specifies the event that causes the block to reset the running minimum. The sample time of the **Rst** input must be a positive integer and a multiple of the block input sample time.

Dependencies

To enable this port, set the **Mode** parameter to `Running` and set the **Reset port** parameter to `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero sample`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

ROI — Region of interest
four-element vector | *m*-by-4 matrix | *M*-by-*N* matrix

Region of interest (ROI), specified as a four-element vector, *m*-by-4 matrix, or *M*-by-*N* matrix. This port accepts different input values depending on the setting of the **ROI type** parameter.

Note

- You can use the **ROI** port only if the input to the **In** port is a 2-D image.
- You cannot use the **ROI** port if the **Mode** parameter is set to `Running`.

Dependencies

To enable this port, set the **Find the minimum value over** parameter to `Entire input` and select the **Enable ROI processing** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Label — Label matrix
matrix of nonnegative integers

Label matrix, specified as a matrix of nonnegative integers. The label matrix represents the objects in a 2-D image. The pixels labeled `0` are the background. The pixels labeled `1` make up the first object, the pixels labeled `2` make up the second object, and so on. The size of the label matrix must be same as the size of the 2-D input image.

Dependencies

To enable this port, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Label matrix`.

Note You cannot enable the **Label** port if the **Mode** parameter is set to `Running`.

Data Types: `uint8` | `uint16` | `uint32`

Label Numbers — Label values of ROIs
M-element vector

Label values of ROI, specified as an *M*-element vector. This represents the object names for the corresponding numbers in the label matrix. *M* must be less than or equal to the number of objects in the label matrix.

Dependencies

To enable this port, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Label matrix`.

Note You cannot enable the `Label Numbers` port if the **Mode** parameter is set to **Running**.

Data Types: `uint8` | `uint16` | `uint32`

Output

Val — Minimum values of input
scalar | vector | matrix | *N*-D array

Minimum values of the input, returned as a scalar, vector, matrix, or *N*-D array. The size of this output depends on the size of the input, and the settings of the **Mode** and **Find the minimum value over** parameters.

Note This port is unnamed if the **Mode** parameter is set to `Running`. It doesn't appear if the **Mode** parameter is set to `Index`.

Compute Minimum Value of Input Array

Set the **Mode** parameter to `Value and Index` or `Value`. The block computes the minimum value along the specified dimension of the input or across the entire input. The size of the output minimum value depends on the size of the input and the setting of the **Find the Minimum value over** parameter.

- Scalar — The input is of any size, and the **Find the minimum value over** parameter is set to `Entire input`.
- Vector — The input is a matrix, and the **Find the minimum value over** parameter is set to `Each row`, `Each column`, or `Specified dimension`. If `Specified dimension` is selected, the value of the **Dimension** parameter must be either `1` or `2`.
- (*N*–*1*)-D array — The input is an *N*-D array, the **Find the minimum value over** parameter is set to `Specified dimension`, and the value of the **Dimension** parameter is *N*.
- *N*-D array with one singleton dimension — The input is an *N*-D array, and the **Find the minimum value over** parameter is set to `Each row`, `Each column`, or `Specified dimension`. If `Specified dimension` is selected, the value of the **Dimension** parameter must be an integer less than *N*.

  Example: For a 3-D input array of size *M*-by-*N*-by-*P*, the dimension of the returned output is:

  - 1-by-*N*-by-*P* if you set the **Find the minimum value over** parameter to `Entire row`.
  - *M*-by-1-by-*P* if you set the **Find the minimum value over** parameter to `Entire column`.
  - *M*-by-*N* if you set the **Find the minimum value over** parameter to `Specified dimension` and the **Dimension** parameter to `3`.

Compute Minimum Value of Sequence of Inputs

Set the **Mode** parameter to `Running`. The block finds the minimum value of all the inputs in the given sequence and compiles them into a single array. The output is of the same size as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Idx — Indices of minimum values in the input
scalar | vector | matrix | *N*-D array

Indices of the minimum values in the input array, returned as a scalar, vector, matrix, or *N*-D array.

To enable this port, set the **Mode** parameter to `Value and Index` or `Index`.The size of the output depends on the size of the input and the setting of the **Find the minimum value over** parameter.

- Scalar — The input is an *N*-element vector, and the **Find the minimum value over** parameter is set to `Entire input`.
- Vector — The input is a matrix, and the **Find the minimum value over** parameter is set to `Entire input`, `Each row`, `Each column`, or `Specified dimension`. If `Specified dimension` is selected, the value of the **Dimension** parameter must be either `1` or `2`.
- (*N*–*1*)-D array — The input is an *N*-D array, the **Find the minimum value over** parameter is set to `Specified dimension`, and the value of the **Dimension** parameter is *N*.
- *N*-D array with one singleton dimension — The input is an *N*-D array, and the **Find the minimum value over** parameter is set to `Each row`, `Each column`, or `Specified dimension`.If `Specified dimension` is selected, the value of the **Dimension** parameter must be an integer less than *N*.

  Example: For a 3-D input array of size *M*-by-*N*-by-*P*, the dimension of the returned output is:

  - 1-by-*N*-by-*P* if you set the **Find the minimum value over** parameter to `Entire row`.
  - *M*-by-1-by-*P* if you set the **Find the minimum value over** parameter to `Entire column`.
  - *M*-by-*N* if you set the **Find the minimum value over** parameter to `Specified dimension` and the **Dimension** parameter to `3`.

Note When a minimum value occurs more than once, the computed index corresponds to the first occurrence. For example, if the input vector is `[3 2 1 2 1]`, then the minimum value is `1` and the one-based index of the minimum value is `3`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Flag — ROI Validation
scalar | vector

ROI Validation, returned as a scalar or vector of logical `1`s (`true`) or `0`s (`false`). If the **ROI type** parameter is set to `Rectangles` or `Lines`, the output signifies whether or not the specified ROIs lie completely or partially within the input image. If the **ROI type** parameter is set to `Label matrix`, the output signifies whether or not the label numbers specified in the **Label Numbers** input are present in the input label matrix.

ROI type	Individual statistics for each ROI	Single statistics for all ROIs
`Rectangles`	The port returns an *m* element vector, where*m* is the number of rows in the *m*-4 matrix in the input to the **ROI** port. Each element of this vector is a `1` or `0`, indicating that the rectangular ROI is either completely or partially inside the input image (`1`) or completely outside the input image (`0`).	The port returns a scalar. The scalar is a `1` or `0`, indicating that any of the rectangles in the **ROI** input is present completely or partially inside (`1`) or completely outside (`0`) the input image.

`Lines`	The port returns a scalar. The scalar is a `1` or `0`, indicating that the input given to the **ROI** port is either completely or partially inside (`1`) the input image or completely outside (`0`) the input image.	The port returns a scalar. The scalar is a `1` or `0`, indicating that the input given to the **ROI** port is either completely or partially inside (`1`) the input image or completely outside (`0`) the input image.
`Label matrix`	The port returns an *M*-element vector, where *M* is the number of elements in the input to the **Label Numbers** port. Each element of the vector is a `1` or `0`, indicating that the associated label from the **Label Numbers** input is present in (`1`) or absent from (`0`) the Label Matrix input.	The port returns a scalar. The scalar is a `1` or `0`, indicating that any of the labels in the **Label Numbers** input are present in (`1`) or all are absent from (`0`) the Label Matrix input.

Note If the ROI is partially outside the image, the block computes the statistical values for only the portion of the ROI that lies within the image bounds.

Dependencies

To enable this port, select the **Output flag indicating if ROI is within image bounds** parameter and set the value of the **ROI type** parameter to `Rectangle`, or `Lines`, or select the **Output flag indicating if input label numbers are valid** parameter and set the value of **ROI type** parameter to`Label matrix`.

Parameters

Main

Mode — Output mode
`Value and Index` (default) | `Value` | `Index` | `Running`

Specify the output mode of the block as one of these options.

- `Value and Index` — Return both the minimum values and their corresponding indices in the given input.
- `Value` — Return only the minimum values.
- `Index` — Return only the indices of the minimum values in the given input.
- `Running` — Tracks the minimum values in a sequence of inputs.

Index Base — Index for first element
`One` (default) | `Zero`

Specify the index for the first element in the input array.

- `One` for one-based numbering. The range of index values for each dimension is 1 to *m*, where *m* is the length of that dimension. For example, the index of the first element in a matrix is (`1,1`).

- `Zero` for zero-based numbering. The range of index values for each dimension is 0 to *m*–1, where *m* is the length of that dimension. For example, the index of the first element in a matrix is (`0,0`).

Find the minimum value over — Dimension along which minimum is computed
`Entire input` (default) | `Each row` | `Each column` | `Specified dimension`

Specify the dimension of the input along which the block computes the minimum.

- `Entire input` — Computes minimum over the entire input.
- `Each row` — Computes minimum over each row.
- `Each column` — Computes minimum over each column.
- `Specified dimension`— Computes minimum over the dimension specified in the **Dimension** parameter.
  - If the **Dimension** parameter is set to `1`, the output is the same as when `Each column` is selected.
  - If the **Dimension** parameter is set to `2`, the output is the same as when `Each row` is selected.

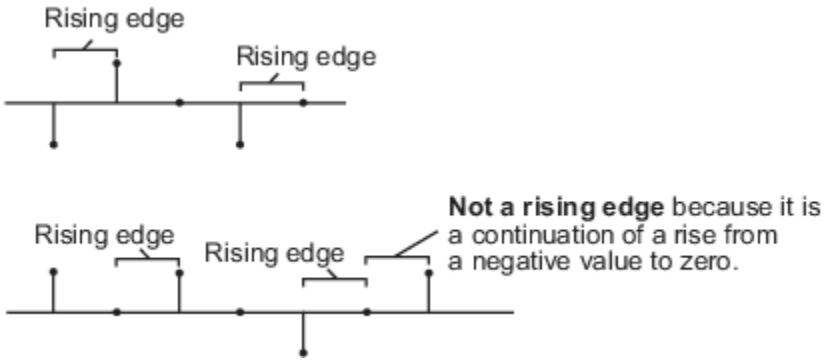
Dependencies

To enable this parameter, set the **Mode** parameter to `Value and Index`, `Value`, or `Index`.

Dimension — Custom dimension
`1` (default) | positive scalar

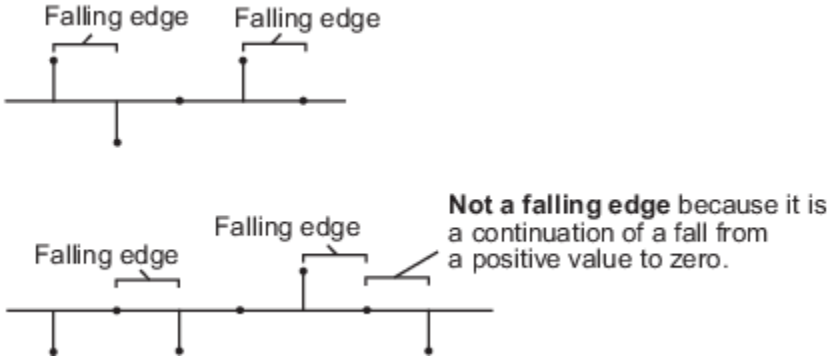
Specify the dimension of the input array over which the block computes the minimum as a one-based value. The value of this parameter must be greater than zero and less than or equal to the number of dimensions in the input array.

Dependencies



To enable this parameter, set the **Find the minimum value over** parameter to `Specified dimension`.

Reset port — Reset event
`None` (default) | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero sample`



Specifies what the block detects as a reset event. The block resets the running minimum when a reset event is detected at the **Rst** port. The reset sample time must be a positive integer and a multiple of the input sample time.

Specify the reset event as one of these options.

- `None` — Disable the **Rst** port.
- `Rising edge` — Trigger a reset event when the **Rst** input does one of the following.
  - Rises from a negative value to either a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero

- `Falling edge` — Trigger a reset event when the **Rst** input does one of the following.
  - Falls from a positive value to either a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero

- `Either edge` — Trigger a reset event when the **Rst** input is either a `Rising edge` or a `Falling edge`.
- `Non-zero sample` — Trigger a reset event at each sample time, where the **Rst** input is not zero.

Note When running simulations in Simulink multitasking mode, reset signals have a one-sample latency. In this case, when the block detects a reset event, there is a one-sample delay at the **Rst** port rate before the block applies the reset.

Dependencies

To enable this parameter, set the **Mode** parameter to `Running`.

Enable ROI processing — Compute minimum value within ROI
`off` (default) | `on`

Select to calculate the minimum within an ROI in the image.

Note Full ROI processing is available only if you have a Computer Vision Toolbox license. If you do not have a Computer Vision Toolbox license, you can still use ROI processing, but the **ROI type** parameter is limited to `Rectangles`.

Dependencies

To enable this parameter, set the **Find the minimum value over** parameter to `Entire input`.

ROI type — Format of ROI
`Rectangles` (default) | `Lines` | `Label matrix` | `Binary mask`

Specify the ROI format that represents the regions in the image over which to compute the minimum. The type of ROI can be a rectangle, line, label matrix, or a binary mask.

ROI type	Inputs to the ROI port	Description
`Rectangles`	• Four-element row vector [*x y width height*] • *m*-by-4 matrix : $\begin{bmatrix} x_1 & y_1 & width_1 & height_1 \\ x_2 & y_2 & width_2 & height_2 \\ \vdots & \vdots & \vdots & \vdots \\ x_M & y_M & width_M & height_M \end{bmatrix}$, where *m* is the number of rectangle ROIs. Each row of the matrix corresponds to a different rectangle.	• *x* and *y* are the one-based coordinates of the upper left corner of the rectangle. • *width* and *height* are the width and height, in pixels, of the rectangle. The values of *width* and *height* must be greater than zero.
`Lines`	• Four-element row vector [x_1 y_1 x_2 y_2] • *m*-by-4 matrix $\begin{bmatrix} x_{11} & y_{11} & x_{12} & y_{12} \\ x_{21} & y_{21} & x_{22} & y_{22} \\ \vdots & \vdots & \vdots & \vdots \\ x_{M1} & y_{M1} & x_{M2} & y_{M2} \end{bmatrix}$, where *m* is the number of lines. Each row of the matrix corresponds to a different line.	• x_1 and y_1 are the coordinates of the beginning of the line. • x_2 and y_2 are the coordinates of the end of the line.
`Label matrix`	*M*-by-*N* matrix	Matrix of the same size as the input image. The matrix contains label values that represent different objects in an image. The pixels labeled `0` are the background. The pixels labeled `1` make up one object, the pixels labeled `2` make up a second object, and so on.

`Binary mask`	*M*-by-*N* matrix	Matrix of the same size as the input image. The binary mask classifies image pixels as belonging to either the region of interest or the background. Binary mask values of `1` indicate that the corresponding image pixel belongs to the ROI. Binary mask values of `0` indicate that the corresponding image pixel is part of the background.

Dependencies

To enable this parameter, set the **Find the minimum value over** parameter to `Entire input` and select the **Enable ROI processing** parameter.

ROI portion to process — Portion of ROI in which to calculate minimum
`Entire ROI` (default) | `ROI perimeter`

Specify the portion of the ROI for which the block calculates the 2-D minimum.

- `Entire ROI` — The block computes the minimum value over the entire region of the rectangular ROI.
- `ROI perimeter` — The block computes the minimum value along the perimeter of the rectangular ROI.

Dependencies

To enable this parameter, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Rectangles`.

Output — Calculate individual or universal minimum for ROIs
`Individual statistics for each ROI` (default) | `Single statistic for all ROIs`

Specify whether to calculate the 2-D minimum individually for each ROI or across all ROIs.

- If you select `Individual statistics for each ROI`, the block outputs a vector of minimum values, each element representing an ROI. The size of the output vector is equal to the number of ROIs.
- If you select `Single statistic for all ROIs`, the block outputs a scalar value. The scalar value is the minimum value across all specified ROIs.

Dependencies

To enable this parameter, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Rectangles`, `Lines`, or `Label matrix`.

Output flag indicating if ROI is within image bounds — Enable Flag port
`off` (default) | `on`

Select to enable the Flag output port.

Note The name of this parameter changes to **Output flag indicating if input label numbers are valid** when the **ROI type** parameter is set to `Label matrix`.

Dependencies

To enable this parameter, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Rectangles`, or `Lines`.

Data Types

For details on the fixed-point block parameters, see "Specify Fixed-Point Attributes for Blocks" (DSP System Toolbox).

Lock data type settings against change by the fixed-point tools — Prevent fixed-point tools from overriding data types
`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in this block. For more information, see "Lock the Output Data Type Setting" (Fixed-Point Designer).

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

Blocks

2-D Mean | 2-D Variance | 2-D Maximum

2-D Standard Deviation

Compute standard deviation of input or sequence of inputs

Libraries:
Computer Vision Toolbox / Statistics

Description

The 2-D Standard Deviation block computes the standard deviation of an input array. The input can be a 1-D vector, 2-D matrix, or an *N-D*-array. The block can compute standard deviation along a specified dimension of the input or the entire input. If you select the **Running standard deviation** parameter, the block can also track the standard deviation in a sequence of inputs over a time period.

Ports

Input

In — Input array
vector | matrix | *N-D*- array

Input array, specified as a vector, matrix, or *N-D*- array. This port is unnamed until you select the **Enable ROI processing** parameter.

Data Types: `single` | `double`

Rst — Reset port
scalar

Reset port, specified as a scalar. This port specifies the event that causes the block to reset the running standard deviation. The sample time of the **Rst** input must be a positive integer and a multiple of the input sample time.

Dependencies

To enable this port, select the **Running standard deviation** parameter and set the **Reset port** parameter to `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero sample`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

ROI — Region of interest
four-element vector | *m*-by-4 matrix | *M*-by-*N* matrix

Region of interest (ROI), specified as a four-element vector, *m*-by-4 matrix, or *M*-by-*N* matrix. The input value to this port depends on the **ROI type** parameter.

Note You can use the `ROI` port only if the input is a 2-D image.

Dependencies

To enable this port, set the **Find the standard deviation value over** parameter to `Entire input` and select the **Enable ROI processing** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Label — Label matrix
matrix of nonnegative integers

Label matrix, specified as a matrix of nonnegative integers. The label matrix represents the objects in an image. The pixels labeled 0 are the background. The pixels labeled 1 make up one object; the pixels labeled 2 make up a second object; and so on. The size of the label matrix must be the same size as the 2-D input.

Dependencies

To enable this port, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Label matrix`.

Data Types: `uint8` | `uint16` | `uint32`

Label Numbers — Label values of ROIs
M-element vector

Label values of ROIs, specified as a *M*-element vector. The value of *M* can be less than or equal to the number of objects that are labeled in the label matrix.

Dependencies

To enable this port, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Label matrix`.

Data Types: `uint8` | `uint16` | `uint32`

Output

Out — Computed output standard deviation
scalar | vector | matrix | *N-D*-array

Computed output standard deviation, returned as a scalar, vector, matrix, or *N-D*-array. The size of the returned output standard deviation depends on the size of the input, and the settings for the **Running standard deviation** and **Find the standard deviation value over** parameters.

This port is unnamed until you select the **Output flag indicating if ROI is within image bounds** and the **ROI type** parameter is set to `Rectangles`, `Lines`, or `Label matrix`.

If Running standard deviation Is Cleared

You can compute standard deviation along any specified dimension of the input or the entire input. The output is a:

- Scalar if the input is of any size and the **Find the standard deviation value over** parameter is set to `Entire input`.
- Vector if the input is a matrix and the **Find the standard deviation value over** parameter is set to any one of `Each row`, `Each column`, and `Specified dimension`. In this case, the **Dimension** value for `Specified dimension` can be either 1 or 2.

- Matrix if the input is a 3-D array and the **Find the standard deviation value over** parameter is set to `Specified dimension` and the **Dimension** value is 3.
- *N-D* array if the input is an *N-D* array and the **Find the standard deviation value over** parameter is set to an option other than `Entire input`.

  If you compute standard deviation along the *N*th dimension of the input, then the returned output is an *(N-1)-D* array. In this case, the **Dimension** value for `Specified dimension` is set to *N*.

  Example: For a 3-D input array of size *M*-by-*N*-by-*P*, the dimension of the returned output is:

  - 1-by-*N*-by-*P* if you set the **Find the standard deviation value over** parameter to `Entire row`.
  - *M*-by-1-by-*P* if you set the **Find the standard deviation value over** parameter to `Entire column`.
  - *M*-by-*N* if you set the **Find the standard deviation value over** parameter to `Specified dimension` and the **Dimension** value to 3.

If Running standard deviation Is Selected

When you select the **Running standard deviation** parameter, the block computes the standard deviation of each sample in the input with respect to all previous samples. The output is of the same size as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Flag — Validation for ROI
0 | 1

Validation for ROI, returned as 0 or 1. The output value signifies if all of the ROIs specified at the input lie within the image bounds. The output value depends on the values of the **Output** and **ROI Type** parameters.

ROI Type	Output	Output from Flag port	Description
• `Rectangles` • `Lines`	`Individual statistics for each ROI`	0	ROI is completely outside the input image.
		1	ROI is either completely or partially inside the input image.
	`Single statistic for all ROIs`	0	ROI is completely outside the input image.
		1	ROI is either completely or partially inside the input image.
`Label matrix`	`Individual statistics for each ROI`	0	Label number is not in the label matrix.
		1	Label number is in the label matrix.
	`Single statistic for all ROIs`	0	None of the label numbers are in the label matrix.

		1	At least one of the label numbers is in the label matrix.

Note If the ROI is partially outside the image, the block computes the standard deviation values only for the portion of the ROI that lies within the image bounds.

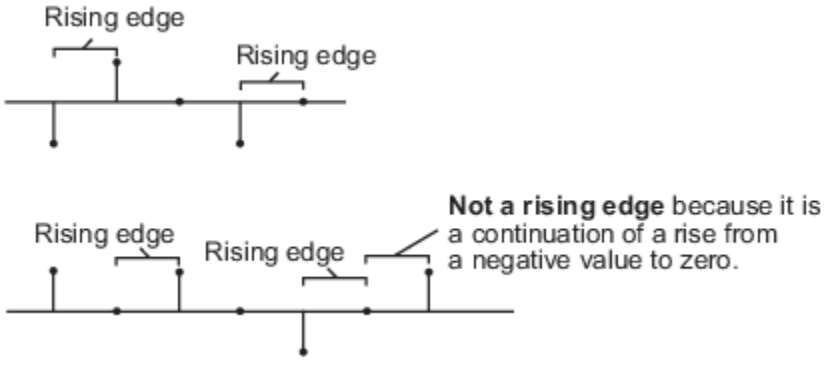
Dependencies

To enable this port, select the **Output flag indicating if ROI is within image bounds** parameter and set the value of **ROI type** parameter to `Rectangle`, `Lines`, or `Label Matrix`.

Parameters

Main Tab

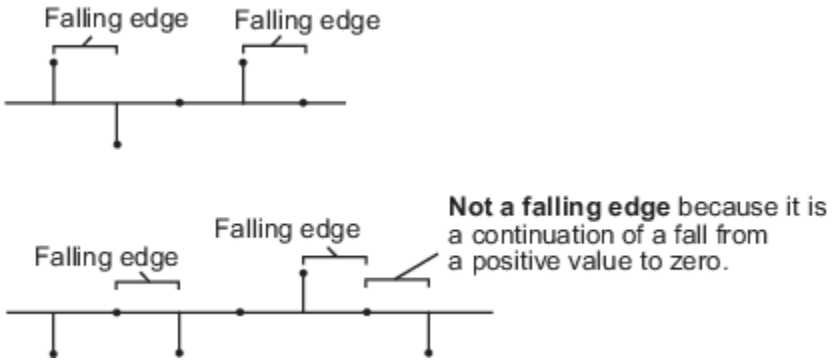
Running standard deviation — Track running standard deviation
off (default) | on



Select to track the standard deviation of successive inputs to the block. In this mode, the block treats each element as a channel.

Reset port — Reset event
`None` (default) | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero sample`

Specify when the block detects a reset event. The block resets the running standard deviation when a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer and a multiple of the input sample time.



Specify the reset event as:

- `None` to disable the **Rst** port.
- `Rising edge` to trigger a reset event when the **Rst** input does one of the following:
  - Rises from a negative value to either a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero

- `Falling edge` to trigger a reset event when the **Rst** input does one of the following:

- Falls from a positive value to either a negative value or zero
- Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero

- `Either edge` to trigger a reset event when the **Rst** input is a `Rising edge` or `Falling edge`.
- `Non-zero sample` to trigger a reset event at each sample time, when the **Rst** input is not zero.

Note When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset.

Dependencies

To enable this parameter, select the **Running standard deviation** parameter.

Find the standard deviation value over — Dimension along which standard deviation is computed
`Entire input` (default) | `Each row` | `Each column` | `Specified dimension`

Specify the dimension of the input along which the block computes the standard deviation.

- `Entire input` — Computes standard deviation over the entire input.
- `Each row` — Computes standard deviation over each row.
- `Each column` — Computes standard deviation over each column.
- `Specified dimension`— Computes standard deviation over the dimension specified in the **Dimension** parameter. By default, the **Dimension** parameter is set to 1 and the output is the same as when you select `Each column`.

Dependencies

To enable this parameter, clear the **Running standard deviation** parameter.

Dimension — Custom dimension
1 (default)

Specify the dimension of the input array over which the standard deviation is computed as a one-based value. The value of this parameter is set to 1..

Dependencies

To enable this parameter, set the **Find the standard deviation value over** parameter to `Specified dimension`.

ROI Processing

Enable ROI processing — Compute standard deviation within a particular region
off (default) | on

Select to calculate standard deviation within a particular ROI in the image.

Note Full ROI processing is available only if you have a Computer Vision Toolbox license. If you do not have a Computer Vision Toolbox license, you can still use ROI processing, but the **ROI type** is limited to `Rectangles`.

Dependencies

To enable this parameter, set the **Find the standard deviation value over** parameter to `Entire input`.

ROI type — Type of ROI
`Rectangles` (default) | `Lines` | `Label matrix` | `Binary mask`

Specify the type of ROI that represents the regions in the image over which the block computes the standard deviation. The type of ROI can be a rectangle, line, label matrix, or a binary mask.

Parameters		**Description**
ROI type	**Inputs to the ROI port**	
`Rectangles`	• Four-element row vector `[x y width height]` • *m*-by-4 matrix $\begin{bmatrix} x_1 & y_1 & width_1 & height_1 \\ x_2 & y_2 & width_2 & height_2 \\ \vdots & \vdots & \vdots & \vdots \\ x_M & y_M & width_M & height_M \end{bmatrix}$, where *m* is the number of rectangles. Each row of the matrix corresponds to a different rectangle.	• `x` and `y` are the one-based coordinates of the upper left corner of the rectangle. • `width` and `height` are the width and height, in pixels, of the rectangle. The values of `width` and `height` must be greater than 0.

`Lines`	• Four-element row vector `[x1 y1 x2 y2]` • *m*-by-4 matrix $\begin{bmatrix} x_{11} & y_{11} & x_{12} & y_{12} \\ x_{21} & y_{21} & x_{22} & y_{22} \\ \vdots & \vdots & \vdots & \vdots \\ x_{M1} & y_{M1} & x_{M2} & y_{M2} \end{bmatrix}$, where *m* is the number of lines. Each row of the matrix corresponds to a different line.	• x_1 and y_1 are the coordinates of the beginning of the line. • x_2 and y_2 are the coordinates of the end of the line.
`Label matrix`	*M*-by-*N* matrix	Matrix of the same size as the input image. The matrix contains label values that represent different objects in an image. The pixels labeled 0 are the background. The pixels labeled 1 make up one object; the pixels labeled 2 make up a second object; and so on.
`Binary mask`	*M*-by-*N* matrix	Matrix of the same size as the input image. The binary mask classifies image pixels as belonging to either the region of interest or the background. The mask pixel values of 1 indicate that the image pixel belongs to the ROI. The mask pixel values of 0 indicate that the image pixel is part of the background.

Dependencies

To enable this parameter, select the **Enable ROI processing** parameter.

ROI portion to process — Portion of ROI in which to calculate standard deviation
`Entire ROI` (default) | `ROI perimeter`

Specify the portion of the ROI from which the block has to calculate 2-D standard deviation. The ROI portion is either the entire ROI or the ROI perimeter.

Dependencies

To enable this parameter, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Rectangles`.

Output — Calculate standard deviation for individual or entire ROI
`Individual statistics for each ROI` (default) | `Single statistic for all ROIs`

Specify whether to calculate 2-D standard deviation individually for each ROI or for the entire ROI.

- If you select `Individual statistics for each ROI`, the block outputs a vector of standard deviation values. The size of the output vector is equal to the number of ROIs.
- If you select `Single statistic for all ROIs`, the block outputs a scalar value. The scalar value represents the statistical value for all the specified ROIs.

Dependencies

To enable this parameter, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Rectangles`, `Lines`, or `Label matrix`.

Output flag indicating if ROI is within image bounds — Enable Flag port
off (default) | on

Select to expose the **Flag** port. For a description of the **Flag** port output, see "Flag" on page 1-0 .

Dependencies

To enable this parameter, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Rectangles`, `Lines`, or `Label matrix`.

Data Types Tab

For details on the fixed-point block parameters, see "Specify Fixed-Point Attributes for Blocks" (DSP System Toolbox).

Lock data type settings against change by the fixed-point tools — Prevent fixed-point tools from overriding data types
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in this block. For more information, see "Lock the Output Data Type Setting" (Fixed-Point Designer).

Block Characteristics

Data Types	`double` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

2-D Mean | `var` | 2-D Variance

2-D Variance

Compute variance of input or sequence of inputs

Libraries:
Computer Vision Toolbox / Statistics

Description

The 2-D Variance block computes the unbiased variance of an input array. The input can be a 1-D vector, 2-D matrix, or an *N-D* array. The block can compute variance along a specified dimension of the input or the entire input. If you select the **Running variance** parameter, the block can also track the variance in a sequence of inputs over a time period.

Ports

Input

In — Input array
vector | matrix | array

Input array, specified as a vector, matrix, or *N-D*- array. This port is unnamed until you select the **Enable ROI processing** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Rst — Reset port
scalar

Reset port, specified as a scalar. This port specifies the event that causes the block to reset the running variance. The sample time of the **Rst** input must be a positive integer and a multiple of the input sample time.

Dependencies

To enable this port, select the **Running variance** parameter and set the **Reset port** parameter to `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero sample`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

ROI — Region of interest
vector | matrix

Region of interest (ROI), specified as a four-element vector, *m*-by-4 matrix, or *M*-by-*N* matrix. The input value to this port depends on the **ROI type** parameter.

Note You can use the `ROI` port only if the input is a 2-D image.

Dependencies

To enable this port, set the **Find the variance value over** parameter to `Entire input` and select the **Enable ROI processing** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Label — Label matrix
matrix

Label matrix, specified as a matrix of nonnegative integers. The label matrix represents the objects in an image. The pixels labeled 0 are the background. The pixels labeled 1 make up one object; the pixels labeled 2 make up a second object; and so on. The size of the label matrix must be the same size as the 2-D input.

Dependencies

To enable this port, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Label matrix`.

Data Types: `uint8` | `uint16` | `uint32`

Label Numbers — Label values of ROIs
vector

Label values of ROIs, specified as a *M*-element vector. The value of *M* can be less than or equal to the number of objects that are labeled in the label matrix.

Dependencies

To enable this port, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Label matrix`.

Data Types: `uint8` | `uint16` | `uint32`

Output

Out — Computed output variance
scalar | vector | matrix | *N-D*-array

Computed output variance, returned as a scalar, vector, matrix, or *N-D*-array. The size of the returned output variance depends on the size of the input, and the settings for the **Running variance** and **Find the variance value over** parameters.

This port is unnamed until you select the **Output flag indicating if ROI is within image bounds** and the **ROI type** parameter is set to `Rectangles`, `Lines`, or `Label matrix`.

If Running variance Is Cleared

You can compute variance along any specified dimension of the input or the entire input. The output is a:

- Scalar if the input is of any size and the **Find the variance value over** parameter is set to `Entire input`.
- Vector if the input is a matrix and the **Find the variance value over** parameter is set to any one of `Each row`, `Each column`, and `Specified dimension`. In this case, the **Dimension** value for `Specified dimension` can be either 1 or 2.

- Matrix if the input is a 3-D array and the **Find the variance value over** parameter is set to `Specified dimension` and the **Dimension** value is 3.
- *N-D* array if the input is an *N-D* array and the **Find the variance value over** parameter is set to an option other than `Entire input`.

  If you compute variance along the *N*th dimension of the input, then the returned output is an *(N-1)-D* array. In this case, the **Dimension** value for `Specified dimension` is set to *N*.

  Example: For a 3-D input array of size *M*-by-*N*-by-*P*, the dimension of the returned output is:

  - 1-by-*N*-by-*P* if you set the **Find the variance value over** parameter to `Entire row`.
  - *M*-by-1-by-*P* if you set the **Find the variance value over** parameter to `Entire column`.
  - *M*-by-*N* if you set the **Find the variance value over** parameter to `Specified dimension` and the **Dimension** value to 3.

If Running variance Is Selected

When you select the **Running variance** parameter, the block computes the variance of each sample in the input with respect to all previous samples. The output is of the same size as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Flag — Validation for ROI
`0` | `1`

Validation for ROI, returned as 0 or 1. The output value signifies if all of the ROIs specified at the input lie within the image bounds. The output value depends on the values of the **Output** and **ROI Type** parameters.

ROI Type	Output	Output from Flag port	Description
• `Rectangles` • `Lines`	`Individual statistics for each ROI`	0	ROI is completely outside the input image.
		1	ROI is either completely or partially inside the input image.
	`Single statistic for all ROIs`	0	ROI is completely outside the input image.
		1	ROI is either completely or partially inside the input image.
`Label matrix`	`Individual statistics for each ROI`	0	Label number is not in the label matrix.
		1	Label number is in the label matrix.
	`Single statistic for all ROIs`	0	None of the label numbers are in the label matrix.
		1	At least one of the label numbers is in the label matrix.

Note If the ROI is partially outside the image, the block computes the variance values only for the portion of the ROI that lies within the image bounds.

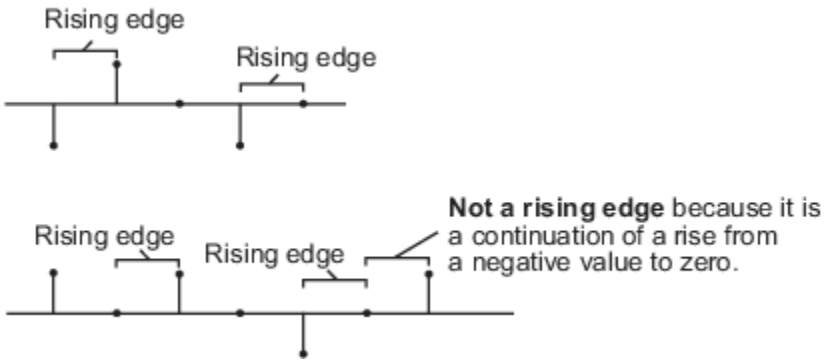
Dependencies

To enable this port, select the **Output flag indicating if ROI is within image bounds** parameter and set the value of **ROI type** parameter to `Rectangle`, `Lines`, or `Label Matrix`.

Parameters

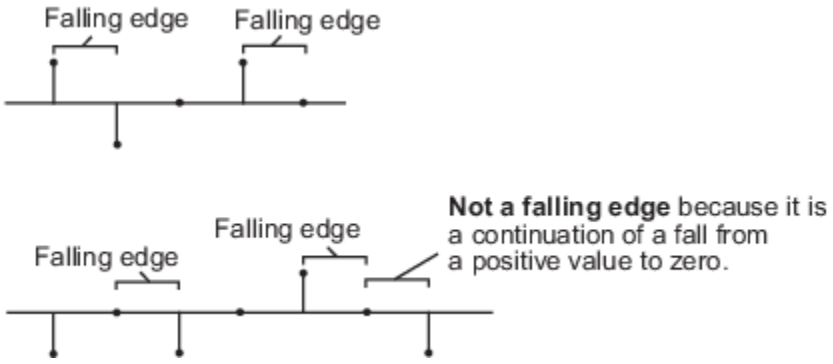
Main

Running variance — Track running variance
`off` (default) | `on`



Select to track the variance of successive inputs to the block. In this mode, the block treats each element as a channel.

Reset port — Reset event
`None` (default) | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero sample`



Specify when the block detects a reset event. The block resets the running variance when a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer and a multiple of the input sample time.

Specify the reset event as:

- `None` to disable the **Rst** port.
- `Rising edge` to trigger a reset event when the **Rst** input does one of the following:
  - Rises from a negative value to either a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero

- `Falling edge` to trigger a reset event when the **Rst** input does one of the following:
  - Falls from a positive value to either a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero

- `Either edge` to trigger a reset event when the **Rst** input is a `Rising edge` or `Falling edge`.
- `Non-zero sample` to trigger a reset event at each sample time, when the **Rst** input is not zero.

Note When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset.

Dependencies

To enable this parameter, select the **Running variance** parameter.

Find the variance value over — Dimension along which variance is computed
`Entire input` (default) | `Each row` | `Each column` | `Specified dimension`

Specify the dimension of the input along which the block computes the variance.

- `Entire input` — Computes variance over the entire input.
- `Each row` — Computes variance over each row.
- `Each column` — Computes variance over each column.
- `Specified dimension`— Computes variance over the dimension specified in the **Dimension** parameter.
  - If **Dimension** is 1, the output is the same as when you select `Each column`.
  - If **Dimension** is 2, the output is the same as when you select `Each row`.

Dependencies

To enable this parameter, clear the **Running variance** parameter.

Dimension — Custom dimension
1 (default) | scalar

Specify the dimension of the input array over which the variance is computed as a one-based value. The value of this parameter must be greater than 0 and less than or equal to the number of dimensions in the input array.

Dependencies

To enable this parameter, set the **Find the variance value over** parameter to `Specified dimension`.

ROI Processing

Enable ROI processing — Compute variance within a particular region
`off` (default) | `on`

Select to calculate variance within a particular ROI in the image.

Note Full ROI processing is available only if you have a Computer Vision Toolbox license. If you do not have a Computer Vision Toolbox license, you can still use ROI processing, but the **ROI type** is limited to `Rectangles`.

Dependencies

To enable this parameter, set the **Find the variance value over** parameter to `Entire input`.

ROI type — Type of ROI
`Rectangles` (default) | `Lines` | `Label matrix` | `Binary mask`

Specify the type of ROI that represents the regions in the image over which the block computes the variance. The type of ROI can be a rectangle, line, label matrix, or a binary mask.

Parameters		**Description**
ROI type	**Inputs to the ROI port**	
`Rectangles`	• Four-element row vector `[x y width height]` • *m*-by-4 matrix $\begin{bmatrix} x_1 & y_1 & width_1 & height_1 \\ x_2 & y_2 & width_2 & height_2 \\ \vdots & \vdots & \vdots & \vdots \\ x_M & y_M & width_M & height_M \end{bmatrix}$, where *m* is the number of rectangles. Each row of the matrix corresponds to a different rectangle.	• `x` and `y` are the one-based coordinates of the upper left corner of the rectangle. • `width` and `height` are the width and height, in pixels, of the rectangle. The values of `width` and `height` must be greater than 0.

`Lines`	• Four-element row vector `[x1 y1 x2 y2]` • *m*-by-4 matrix $\begin{bmatrix} x_{11} & y_{11} & x_{12} & y_{12} \\ x_{21} & y_{21} & x_{22} & y_{22} \\ \vdots & \vdots & \vdots & \vdots \\ x_{M1} & y_{M1} & x_{M2} & y_{M2} \end{bmatrix}$, where *m* is the number of lines. Each row of the matrix corresponds to a different line.	• x_1 and y_1 are the coordinates of the beginning of the line. • x_2 and y_2 are the coordinates of the end of the line.
`Label matrix`	*M*-by-*N* matrix	Matrix of the same size as the input image. The matrix contains label values that represent different objects in an image. The pixels labeled 0 are the background. The pixels labeled 1 make up one object; the pixels labeled 2 make up a second object; and so on.
`Binary mask`	*M*-by-*N* matrix	Matrix of the same size as the input image. The binary mask classifies image pixels as belonging to either the region of interest or the background. The mask pixel values of 1 indicate that the image pixel belongs to the ROI. The mask pixel values of 0 indicate that the image pixel is part of the background.

Dependencies

To enable this parameter, select the **Enable ROI processing** parameter.

ROI portion to process — Portion of ROI in which to calculate variance
`Entire ROI` (default) | `ROI perimeter`

Specify the portion of the ROI from which the block has to calculate 2-D variance. The ROI portion is either the entire ROI or the ROI perimeter.

Dependencies

To enable this parameter, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Rectangles`.

Output — Calculate variance for individual or entire ROI
`Individual statistics for each ROI` (default) | `Single statistic for all ROIs`

Specify whether to calculate 2-D variance individually for each ROI or for the entire ROI.

- If you select `Individual statistics for each ROI`, the block outputs a vector of variance values. The size of the output vector is equal to the number of ROIs.
- If you select `Single statistic for all ROIs`, the block outputs a scalar value. The scalar value represents the statistical value for all the specified ROIs.

Dependencies

To enable this parameter, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Rectangles`, `Lines`, or `Label matrix`.

Output flag indicating if ROI is within image bounds — Enable Flag port
`off` (default) | `on`

Select to expose the **Flag** port. For a description of the **Flag** port output, see “Flag” on page 1-0 .

Dependencies

To enable this parameter, select the **Enable ROI processing** parameter and set the **ROI type** parameter to `Rectangles`, `Lines`, or `Label matrix`.

Data Types

For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Lock data type settings against change by the fixed-point tools — Prevent fixed-point tools from overriding data types
`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`yes`
Variable-Size Signals	`yes`

More About

Variance

The variance of an input is the square of the standard deviation of the input. Variance gives a measure of deviation of the input values from its mean value.

For a purely real or imaginary input, u, of size M-by-N, the variance is:

$$y = \sigma^2 = \frac{\sum_{i=1}^{M}\sum_{j=1}^{N}\left|u_{ij}\right|^2 - \frac{\left|\sum_{i=1}^{M}\sum_{j=1}^{N}u_{ij}\right|^2}{M*N}}{M*N-1},$$

where:

- u_{ij} is the input data element at (i, j).
- M is the length of the jth column.
- N is the number of columns.

For complex inputs, the variance is:

$$\sigma^2 = \sigma_{\mathrm{Re}}{}^2 + \sigma_{\mathrm{Im}}{}^2,$$

where:

- $\sigma_{Re}{}^2$ is the variance of the real part of the complex input.
- $\sigma_{Im}{}^2$ is the variance of the imaginary part of the complex input.

Autothreshold

Convert intensity image to binary image

Libraries:
Computer Vision Toolbox / Conversions

Description

The Autothreshold block converts an intensity image to a binary image using a threshold value. This block uses Otsu's method to determine the threshold.

Ports

Input

I — Input image
matrix

Input image, specified as an *M*-by-*N* matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

BW — Output binary image
matrix

Output binary image, returned as an *M*-by-*N* matrix.

Data Types: `Boolean`

Th — Threshold value
scalar

Threshold value used to convert the intensity image to a binary image, returned as a scalar.

The block calculates the threshold value using Otsu's method. The block computes this value by splitting the histogram of the input image such that the variance of each pixel group is minimized.

Dependencies

To enable this port, select the **Output threshold** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

EMetric — Effectiveness metric value
scalar

Effectiveness metric value, returned as a scalar in the range [0, 1].

If all the pixel values of the input image are the same, the value of the effectiveness metric is `0`. If the image has two unique pixels, or if the histogram of the image is symmetric, the value of the effectiveness metric is `1`.

Dependencies

To enable this port, select the **Output effectiveness metric** parameter.

Data Types: `single` | `double`

Parameters

Main

Data Types

Main

Thresholding operator — Specify thresholding operator

`>` (default) | `<=`

Select whether the block includes pixels from the intensity image with values below the threshold or those with values equal to or greater than the threshold in the output binary image.

- `>` — For pixel values of the input image greater than the threshold, the block outputs `1` in the binary image. Otherwise, the block assigns the pixel a value of `0`.
- `<=` — For pixel values of the input image less than or equal to the threshold, the block outputs `1`. Otherwise, the block assigns the pixel a value of `0`.

Output threshold — Output threshold

`off` (default) | `on`

Select **Output threshold** to return the threshold value the block uses to convert the intensity image to a binary image. Selecting this parameter enables the **Th** output port.

Output effectiveness metric — Output effectiveness metric

`off` (default) | `on`

Select **Output effectiveness metric** to return the effectiveness metric value. Selecting this parameter enables the **EMetric** output port.

Specify data range — Specify input pixel value range

`off` (default) | `on`

Select **Specify data range** to enable specification of minimum and maximum input pixel values to use to determine the threshold. Selecting this parameter enables the **Minimum value of input**, **Maximum value of input**, and **When data range is exceeded parameters**.

Minimum value of input — Minimum input pixel value

`0` (default) | scalar

Specify the minimum value of input pixels to use to determine the threshold.

Maximum value of input — Maximum input pixel value

`255` (default) | scalar

Specify the maximum value of input pixels to use to determine the threshold.

When data range is exceeded — Operation to perform when data range is exceeded

`Ignore` (default) | `Saturate` | `Warn and saturate` | `Error`

Specify the behavior of the block when the value of an input image pixel exceeds the specified data range.

- `Ignore` — The block ignores all pixels with values outside the specified data range.
- `Saturate` — The block saturates the pixels with values below the data range to the specified minimum value, and those above the data range to the specified maximum value.
- `Warn and saturate` — The block displays a warning message in the MATLAB command window and saturates the pixel values as specified for the `Saturate` option.
- `Error` — The block displays an error message and ends the simulation.

Scale threshold — Specify scale threshold

`off` (default) | `on`

Select **Scale threshold** to enable specification of a scale factor for the thresholding operation. Selecting this parameter enables the **Threshold scaling factor** parameter.

Threshold scaling factor — Scale factor for thresholding

`1` (default) | scalar

Specify the scaling factor for the thresholding operation as a scalar. The block performs thresholding by multiplying the threshold value computed by Otsu's method by the specified scale factor.

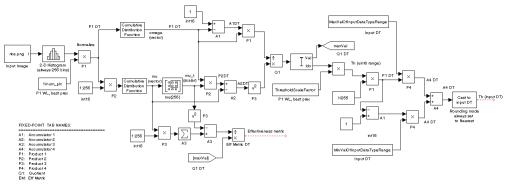
Data Types

For details on fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Lock data type settings against change by the fixed-point tools — Data type override

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).



Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

More About

Fixed-Point Data Types

This diagram shows the data types used in the Autothreshold block for fixed-point signals. You can use the default fixed-point parameters if your input has a word length less than or equal to 16. In this diagram, `DT` means data type. You can set the product, accumulator, quotient, and effectiveness metric data types in the block mask.

Blob Analysis

Statistics for labeled regions

Libraries:
Computer Vision Toolbox / Statistics

Description

The Blob Analysis block calculates statistics for labeled regions in a binary image. The block returns quantities such as the centroid, bounding box, label matrix, and blob count. The Blob Analysis block supports input and output variable-size signals. You can also use the Selector block from Simulink, to select certain blobs based on their statistics.

For information on pixel and spatial coordinate system definitions, see “Image Coordinate Systems” and “Coordinate Systems”.

Ports

Input

BW — Binary image
vector | matrix

Binary image, specified as a vector or matrix

Data Types: `Boolean`

Output

Area — Number of pixels in labeled regions
vector

Number of pixels in labeled regions, returned as a vector.

Dependencies

To enable this port, select the **Area** parameter.

Data Types: `int32`

Centroid — Centroid coordinates
M-by-2 matrix

M-by-2 matrix of *M* number of blobs.

The rows represent the coordinates of the centroid of each region, and *M* represents the number of blobs.

For example, there are two blobs where the row and column coordinates of their centroids are x_1, y_1 and x_2, y_2. The block outputs:

$$\begin{bmatrix} x_1 & y_1 \\ x_2 & y_2 \end{bmatrix}$$

at the **Centroid** port.

Dependencies

To enable this port, select the **Centroid** parameter.

Data Types: `double` | `single` | `fixed point`

BBox — Bounding box coordinates
M-by-4 matrix

Bounding box coordinates, returned as an *M*-by-4 matrix of *M* bounding boxes for blobs. Each row of the matrix defines a bounding box as a four-element vector [*x*,*y*,*width*,*height*] in pixel coordinates. The rows represent the coordinates of each bounding box, where *M* represents the number of blobs.

For example, there are two blobs, where *x* and *y* define the location of the upper-left corner of the bounding box, and *w* and *h* define the width and height of the bounding box. The block outputs

$$\begin{bmatrix} x_1 & y_1 & w_1 & h_1 \\ x_2 & y_2 & w_2 & h_2 \end{bmatrix}$$

at the **BBox** port.

Dependencies

To enable this port, select the **Bounding Box** parameter.

Parameters

Main Tab

Area — Number of pixels in labeled regions
vector

Number of pixels in labeled regions, returned as a vector.

Dependencies

To enable this port, select the **Area** parameter.

Centroid — Centroid coordinates
M-by-2 matrix

M-by-2 matrix of *M* number of blobs.

The rows represent the coordinates of the centroid of each region, and *M* represents the number of blobs.

For example, there are two blobs where the row and column coordinates of their centroids are x_1, y_1 and x_2, y_2. The block outputs:

$$\begin{bmatrix} x_1 & y_1 \\ x_2 & y_2 \end{bmatrix}$$

at the **Centroid** port.

Dependencies

To enable this port, select the **Centroid** parameter.

BBox — Bounding box coordinates
M-by-4 matrix

Bounding box coordinates, returned as an *M*-by-4 matrix of *M* bounding boxes for blobs. Each row of the matrix defines a bounding box as a four-element vector [*x*,*y*,*width*,*height*] in pixel coordinates. The rows represent the coordinates of each bounding box, where *M* represents the number of blobs.

For example, there are two blobs, where *x* and *y* define the location of the upper-left corner of the bounding box, and *w* and *h* define the width and height of the bounding box. The block outputs

$$\begin{bmatrix} x_1 & y_1 & w_1 & h_1 \\ x_2 & y_2 & w_2 & h_2 \end{bmatrix}$$

at the **BBox** port.

Dependencies

To enable this port, select the **Bounding Box** parameter.

Major axis length — Length of major axis of ellipses
off (default) | on

Enables the **Major axis length** port. Select this check box to output a vector that

- Represents the lengths of the major axes of ellipses
- Has the same normalized second central moments as the labeled regions

Minor axis length — Length of minor axis of ellipses
off (default) | on

Enables the **Minor axis length** port. Select this check box to output a vector that

- Represents the lengths of the minor axes of ellipses
- Has the same normalized second central moments as the labeled regions

Orientation — Orientation
off (default) | on

Enables the **Orientation** port.

Select this check box to output a vector that represents the angles between the major axes of the ellipses and the *x*-axis. The angle values are in radians and range between: $-\frac{\pi}{2}$ and $\frac{\pi}{2}$ inclusive.

Eccentricity — Eccentricity
off (default) | on

Enables the **Eccentricity** port. Select this check box to output a vector that represents the eccentricities of ellipses that have the same second moments as the region.

Equivalent diameter squared — Equivalent diameter squared
off (default) | on

Enables the **Equivalent diameter squared** port. Select this check box to output a vector that represents the equivalent diameters squared.

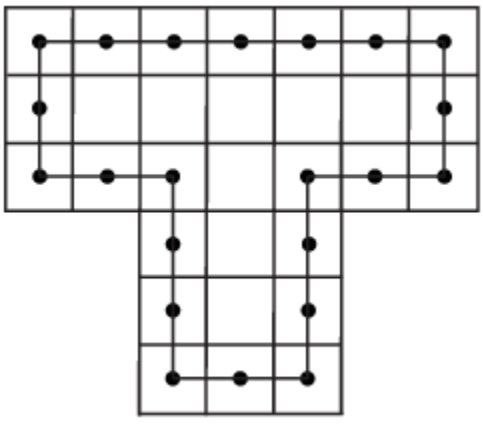
Extent — Extent
off (default) | on

Enables the **Extent** port. Select this check box to output a vector that represents the results of dividing the areas of the blobs by the area of their bounding boxes.

Perimeter — Perimeter length
off (default) | on

Enables the **Perimeter** port. Select this check box to output an *N*-by-1 vector of the perimeter lengths, in pixels, of each blob, where *N* is the number of blobs.

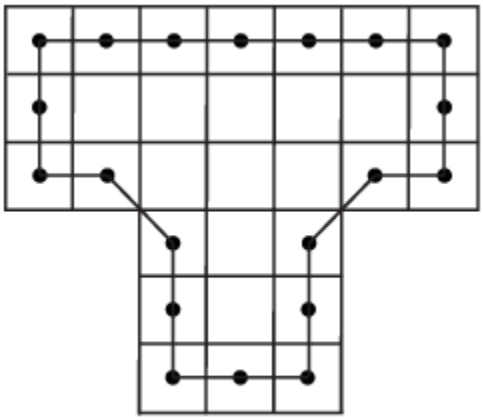
Statistics output data type — Output data type
double (default) | single | specify via Data Types tab



Specify the data type of the outputs as `double`, `single`, or `Specify via Data Types tab`.

Connectivity — Number of labeled regions
8 (default) | 4

Specify the number of labeled regions in each image.



Define which pixels connect to each other. If you want to connect pixels located on the top, bottom, left, and right, select 4. If you want to connect pixels to other pixels on the top, bottom, left, right, and diagonally, select 8. For more information about this parameter, see the Label block.

The **Connectivity** parameter also affects how the block calculates the perimeter of a blob. For example, this figure illustrates how the block calculates the perimeter when you set the **Connectivity** parameter to 4.

The block calculates the distance between the center of each pixel (marked by the black dots) and estimates the perimeter to be 22.

The next figure illustrates how the block calculates the perimeter of a blob when you set the **Connectivity** parameter to 8.

The block takes a different path around the blob and estimates the perimeter to be $18 + 2\sqrt{2}$.

Output label matrix — Output label matrix
off (default) | on

Enable the **Label** port. Select this check box to output the label matrix. The pixels equal to `0` represent the background. The pixels equal to `1` represent the first object. The pixels equal to `2` represent the second object, and so on.

Blob Properties Tab

Maximum number of blobs — Maximum number of blobs
scalar

Specify the maximum number of labeled regions in each input image. The block uses this value to preallocate vectors and matrices to ensure that they are long enough to hold the statistical values. The maximum number of blobs the block outputs depends on both the value of this parameter and the size of the input image. The number of blobs the block outputs may be limited by the input image size.

Warn if maximum number of blobs is exceeded — Warn if maximum number of blobs is exceeded
on (default) | off

Select this parameter to warn if maximum number of blobs is exceeded.

Output actual number of blobs — Number of blobs
off (default) | on

Enable the **Count** port. Select this parameter to output a scalar value that represents the actual number of connected regions in each image.

Specify minimum blob area in pixels — Minimum blob area in pixels
`0` (default) | scalar

Select this parameter to specify the minimum blob area in pixels. The blob is labeled if the number of pixels meets the minimum size specified.

Tunable: Yes

Specify maximum blob area in pixels — Maximum blob area in pixels
intmax('uint32') (default) | scalar

Select this parameter to specify the maximum blob area in pixels. The blob is labeled if the number of pixels meets the maximum size specified. The maximum allowable value is the maximum of the `uint32` data type.

Tunable: Yes

Exclude blobs touching image border — Exclude blobs touching image border
off (default) | on

Specify this parameter to exclude a labeled blob that contains at least one border pixel.

Output blob statistics as a variable size signal — Output blob statistics as a variable size signal
off (default) | on

Specify this parameter to output blob statistics as a variable-size signal.

Fill empty spaces in output — Fill empty spaces in output
off (default) | on

Specify this parameter to fill empty spaces in the statistical vectors with the values you specify in the **Fill values** parameter.

Dependencies

To enable this parameter, clear the **Output blob statistics as a variable size signal** parameter.

Fill values — Scalar used to fill empty spaces in output
-1 (default) | scalar | vector

Specify a scalar value to fill all the empty spaces in the statistical vectors. If you enter a vector, it must have the same length as the number of selected statistics. The block uses each vector element to fill a different statistics vector. If the empty spaces do not affect your computation, you can clear the **Fill empty spaces in outputs** parameter.

Dependencies

To enable this parameter, clear the **Output blob statistics as a variable size signal** parameter.

Data Types Tab

To enable option on the **Data Types** tab, in the **Main** tab, set the **Statistics output data type** parameter to `Specify via Data Types tab`. For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Block Characteristics

Data Types	`Boolean`[a] | `double`[b] | `fixed point`[b, c] | `integer`[b] | `single`[b]
Multidimensional Signals	`no`

Variable-Size Signals	`yes`

a Generated code will be restricted to MATLAB host computers when you set the FFT implementation parameter to FFTW, or when the transform length is not a power of two.
b This data type is supported at the output port(s).
c Fixed-point data types are not supported at the Major Axis, Minor Axis, Orientation, and Eccentricity output ports.

Block Matching

Estimate motion between images or video frames

Libraries:
Computer Vision Toolbox / Analysis & Enhancement

Description

The Block Matching block estimates motion between two images or two video frames by comparing blocks of pixels. The block matches the block of pixels between frames by moving the block of pixels over a search region.

Ports

Input

I/I1 — Image or video frame
scalar | vector | matrix

Image or video frame, specified as a scalar, vector, or matrix. If the Estimate motion between parameter is set to Two images, the name of this port changes to **I1**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

I2 — Image or video frame
scalar | vector | matrix

Image or video frame, specified as a scalar, vector, or matrix.

Dependencies

To enable this port, set the **Estimate motion between** parameter to `Two images`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

|V|^2 — Velocity magnitudes
scalar | vector | matrix

Velocity magnitudes, returned as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

V — Velocity components in complex form
scalar | vector | matrix

Velocity components in complex form, returned as a scalar, vector, or matrix.

Dependencies

To expose this port, set the **Velocity output** parameter to `Horizontal and vertical components in complex form`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Main Tab

Estimate motion between — Estimate motion between images or frames
`Current frame and N-th frame back` (default) | `Two images`

Specify whether to estimate the motion between two images or two video frames. Select `Two images` to estimate the motion between two images. Select `Current frame and N-th frame back` to estimate the motion between two video frames that are N frames apart.

Dependencies

Set this parameter to `Current frame and N-th frame back` to expose the **N** parameter.

N — Number of frames
1 (default) | scalar

Specify a scalar value that represents the number of frames between the reference frame and the current frame.

Dependencies

To enable this parameter, set the **Estimate motion between** parameter to `Current frame and N-th frame back`.

Search method — Block match search method
`Exhaustive` (default) | `Three-step`

Specify how the block locates the block of pixels in the current frame and the next frame that best matches the block of pixels.

- `Exhaustive` — The block selects the location of the block of pixels in the next frame by moving the block over the search region one pixel at a time. This process is computationally expensive.
- `Three-step` — The block searches for the block of pixels in the next frame that best matches the block of pixels in the current frame by using a steadily decreasing step size. The block begins with a step size approximately equal to half the maximum search range. In each step, the block compares the central point of the search region to eight search points located on the boundaries of the region and moves the central point to the search point whose values is the closest to that of the central point. The block then reduces the step size by half, and begins the process again. This option is less computationally expensive, though it might not find the optimal solution.

Block matching criteria — Block matching criteria
`Mean square error (MSE)` (default) | `Mean absolute difference (MAD)`

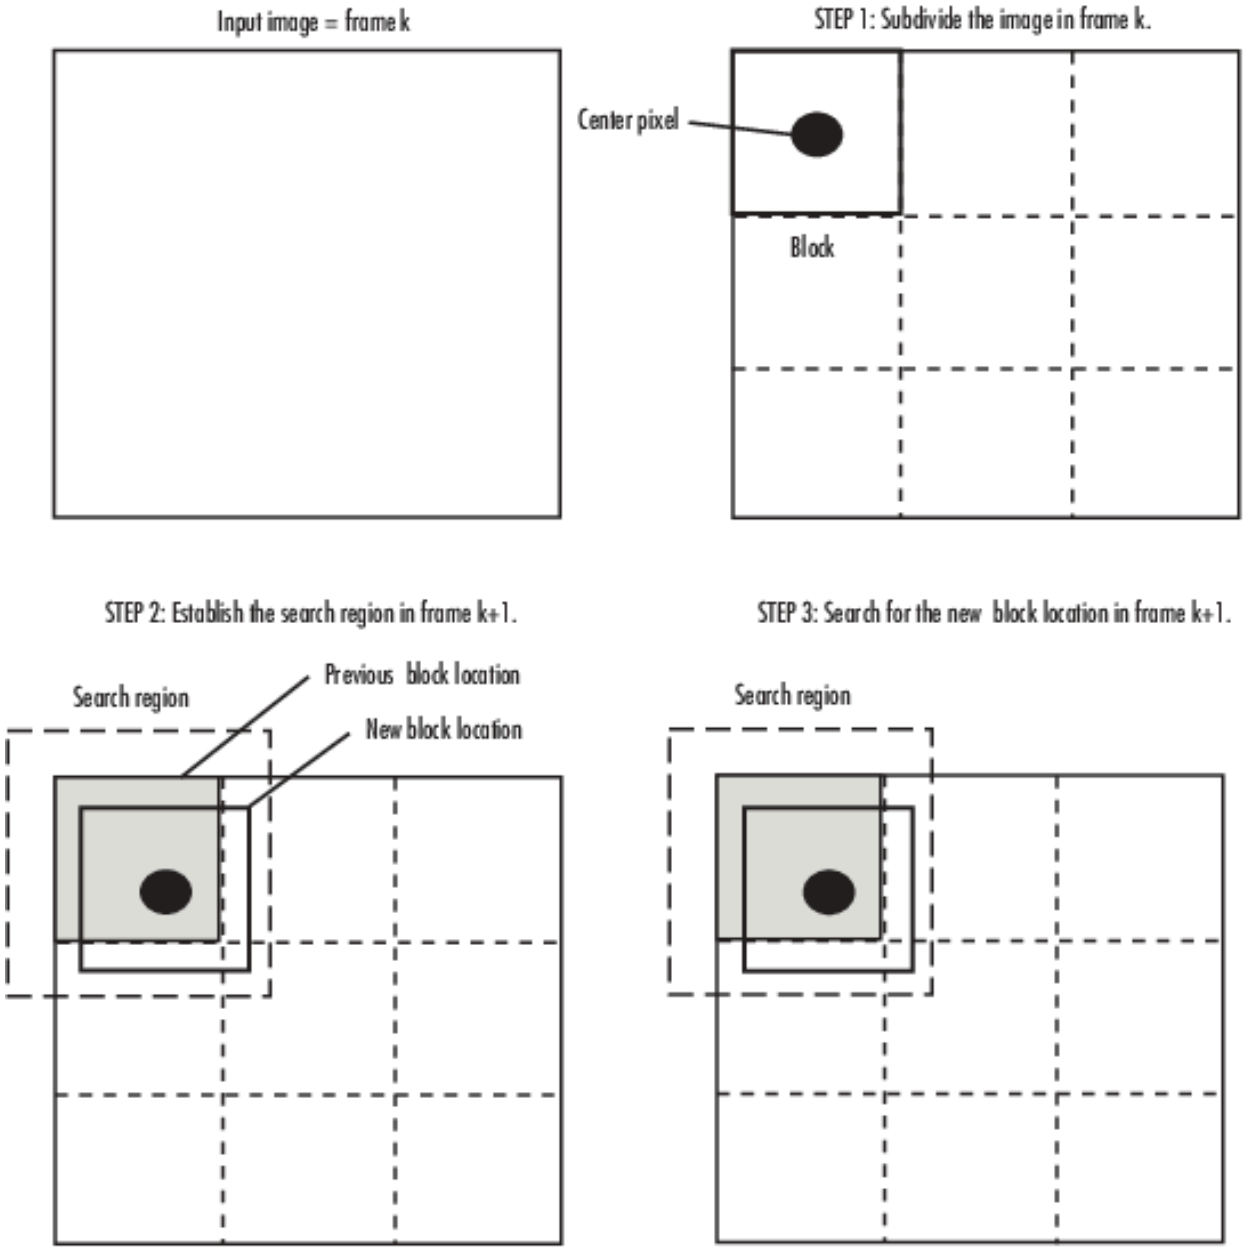
Specify how the block measures the similarity of the block of pixels in the current frame to the block of pixels in the next frame.

If you select `Mean square error (MSE)`, the block estimates the displacement of the center pixel of the block as the (d_1, d_2) values that minimize this MSE equation:

$$MSE(d_1, d_2) = \frac{1}{N_1 \times N_2} \sum_{(n_1, n_2), \in B} \sum [s(n_1, n_2, k) - s(n_1 + d_1, n_2 + d_2, k + 1)]^2$$

In the previous equation, B is an $N_1 \times N_2$ block of pixels, and $s(x,y,k)$ denotes a pixel location at (x,y) in frame k.

If you select `Mean absolute difference (MAD)`, the Block Matching block estimates the displacement of the center pixel of the block as the (d_1, d_2) values that minimize this MAD equation:



$$MAD(d_1, d_2) = \frac{1}{N_1 \times N_2} \sum_{(n_1, n_2), \in B} \sum |s(n_1, n_2, k) - s(n_1 + d_1, n_2 + d_2, k + 1)|$$

Block size [height width] — Block size
`[17 17]` (default) | two-element vector

Specify the size of the block of pixels.

Overlap size [r c] — Block overlap
`[0 0]` (default) | two-element vector

Specify the overlap (in pixels) of two subdivisions of the input image.

Maximum displacement [r c] — Maximum displacement
`[7 7]` (default) | two-element vector

Specify the maximum number of pixels any center pixel in a block of pixels might move from image to image or frame to frame. The block uses this value to determine the size of the search region.

Velocity output — Velocity output
`Magnitude-squared` (default) | `Horizontal and vertical components in complex form`

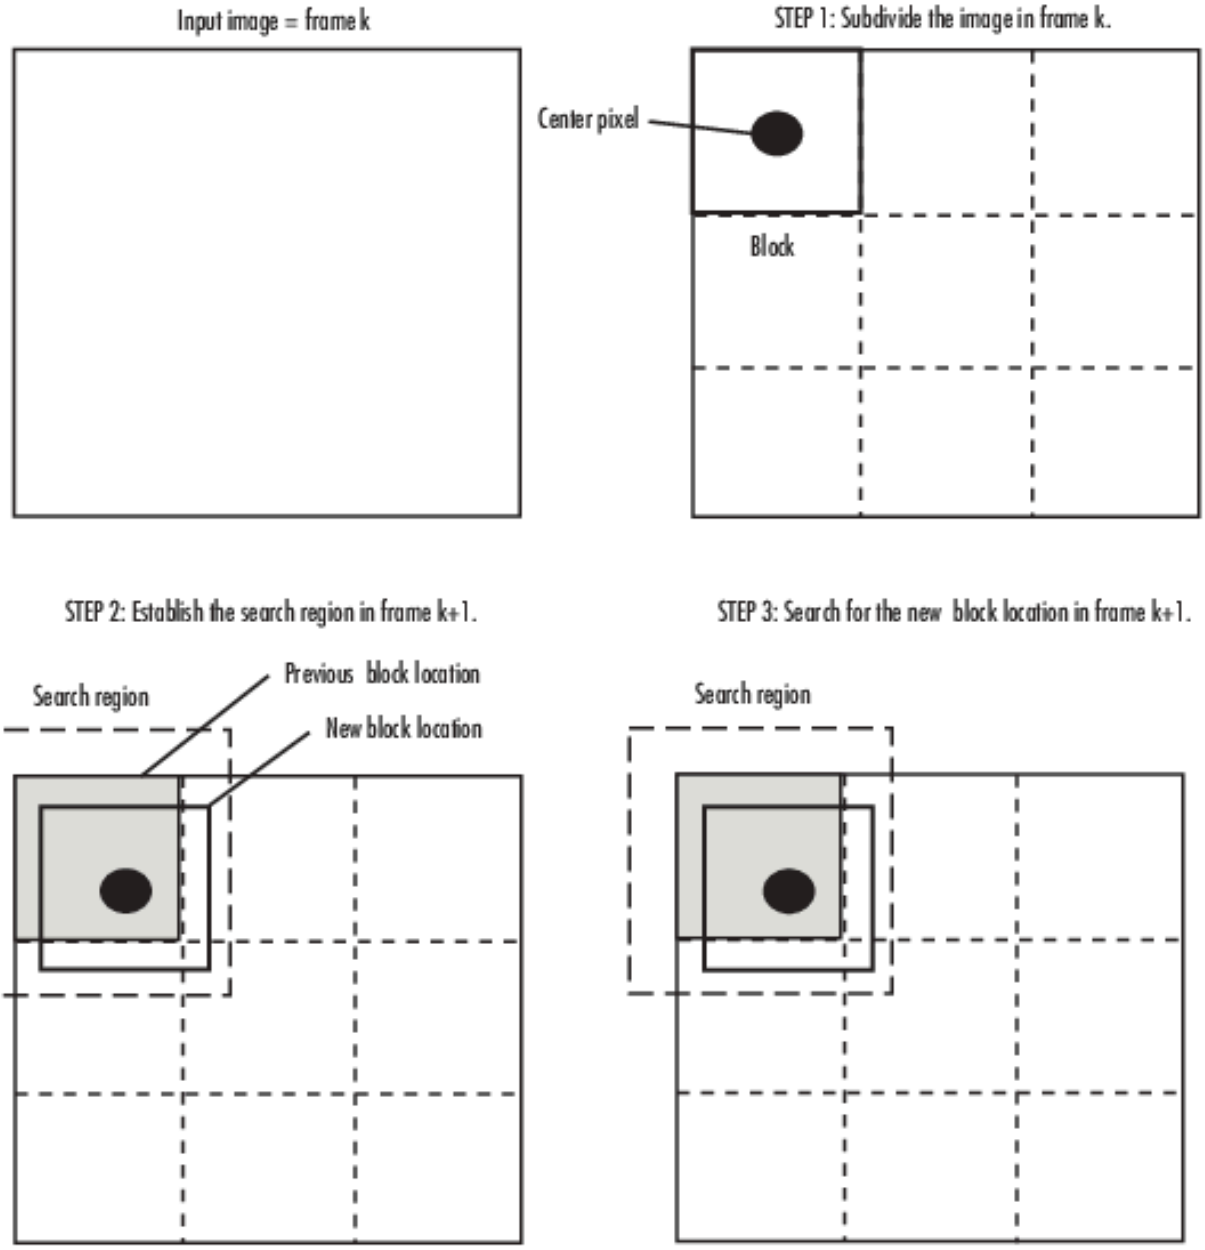
Specify the output. If you select `Magnitude-squared`, the block outputs an optical flow matrix where each element is in the form u^2+v^2. If you select `Horizontal and vertical components in complex form`, the block outputs an optical flow matrix where each element is in the form

$u + jv$. The real part of each value is the horizontal velocity component and the imaginary part of each value is the vertical velocity component.

Data Types Tab

For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Block Characteristics



Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`no`

Algorithms

Block Matching Search

Suppose the input to the block is frame k. The block performs the following steps:

1. Subdivide the frame using the values for the **Block size [height width]** and **Overlap size [r c]** parameters. For this example, **Overlap size [r c]** equals `[0 0]`.
2. For each subdivision or block in frame k+1, a search region is established based on the value of the **Maximum displacement [r c]** parameter.
3. Search for the new block location using either the `Exhaustive` or `Three-step` search method.

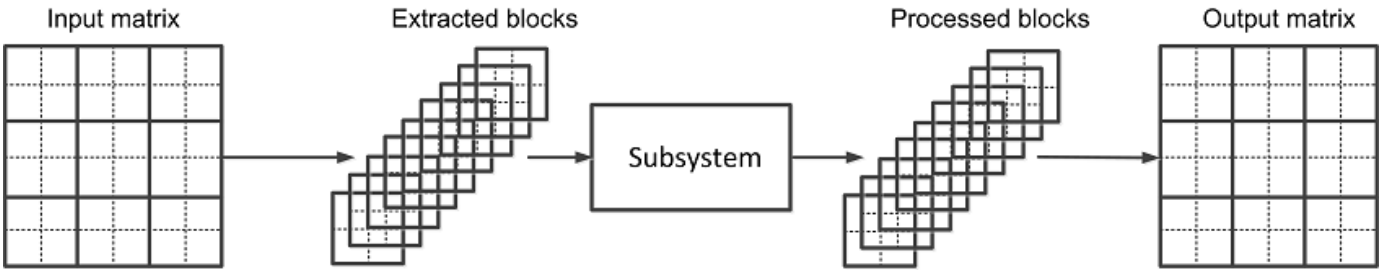
Block Processing



Repeat user-specified operation on blocks of input matrix

Libraries:
Computer Vision Toolbox / Utilities

Description

The Block Processing block extracts submatrices, or blocks , from an input matrix, passes each block to a subsystem that performs a user-specified operation. It then reassembles the processed blocks to form the output matrix. You can use this block to process an image block-wise, rather than processing the entire image at once. Matrix block processing proceeds from input matrix to extracted blocks, then the subsystem, and then recombines the processed blocks into an output matrix.

Ports

Input

I — Input signal
matrix

Input signal, specified as an *M*-by-*N* matrix. This port is unnamed unless you select the **Add port to supply subsystem parameters** parameter or set the **Number of inputs** parameter to 2 or more. If you select **Add port to supply subsystem parameters** parameter, the port name becomes **I**. If you set **Number of inputs** to a value greater than 1, *n*, then block has *n* input ports from **I** to **In**. The contents of the subsystem determines the data type of the input data.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

P — Additional input to supply subsystem parameters
scalar | vector | matrix | array

Additional input to supply subsystem parameters, specified as a scalar, vector, matrix, or array. The contents of the subsystem determines the data type of the input data.

Dependencies

To enable this port, you must select the **Add port to supply subsystem parameters** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `string`

Output

Port_1 — Output signal
matrix

Output data, returned as a matrix. The value of the **Number of outputs** determines the number of output ports. The contents of the subsystem determine the data type of the output data.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Number of inputs — Number of inputs
`1` (default) | positive scalar

Specify the number of input ports to the Block Processing block as a positive scalar.

Add port to supply subsystem parameters — Subsystem parameter input port
`off` (default) | `on`

Select this parameter to add an additional input port to the Block Processing block for supplying subsystem parameters.

Number of outputs — Number of outputs
`1` (default) | positive scalar

Specify the number of output ports on the Block Processing block as a positive scalar.

Block size — Block size
`{[8 8]}` (default) | cell array

Specify the size of each block as a cell of two-element vectors. The cell array must contain either a single cell or one cell for each input port. If the block has one input port, enter only one vector. If the block has more than one input port, you can enter one vector to use for all inputs, or you can specify an individual vector for each input. The block uses the vectors in the order you enter them.

Overlap — Block overlap
`{[0 0]}` (default) | cell array

Specify the overlap of each block as cell of two-element vectors. The cell array must contain either a single cell or one cell for each input port. If the block has one input port, enter only one vector. If the block has more than one input port, you can enter one vector to use for all inputs, or you can specify an individual vector for each input. The block uses the vectors in the order you enter them.

Traverse order — Order of block extraction
`Row-wise` (default) | `Column-wise`

Specify the traverse order with which the Block Processing block extracts submatrices from the input matrix. If you select `Row-wise`, the block extracts submatrices by moving across the rows. If you select `Column-wise`, the block extracts submatrices by moving down the columns

Subsystem

To configure the subsystem of the Block Processing block.

- Click **Open Subsystem** to open the Block Processing subsystem.
- Drag blocks into this subsystem to define the processing operations the block performs on the submatrices.

Block Characteristics

Data Types	`Boolean`[a] | `double`[a] | `fixed point`[a] | `integer`[a] | `single`[a]
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

a The blocks inside the subsystem dictate the data types supported by this block.

Bottom-hat

Perform morphological bottom-hat filtering on intensity or binary images

Libraries:
Computer Vision Toolbox / Morphological Operations

Description

The Bottom-hat block performs bottom-hat filtering on an intensity or binary image using a predefined neighborhood or structuring element. Bottom-hat filtering is the equivalent of subtracting the input image from the result of performing a morphological closing operation on the input image.

To define the structuring element that the block applies to the image, use the **Neighborhood or structuring element** parameter. Specify this element by entering a vector or matrix of `1`s and `0`s or by using the `strel` function.

This block uses two-dimensional flat structuring elements only.

Ports

Input

I — Input image
matrix

Specify an input image as a matrix of intensity values. This port is unnamed unless you set the **Neighborhood or structuring element source** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Nhood — Neighborhood values
vector | matrix

Specify neighborhood values representing a structuring element as a vector or matrix of `1`s and `0`s or by using the `strel` function.

Dependencies

To enable this port, set the **Neighborhood or structuring element source** parameter to `Input port`.

Data Types: `Boolean`

Output

Port_1 — Filtered image
matrix

The bottom-hat filtered image is returned as a matrix of intensity values. The size and data type of the filtered image are the same as those of the input image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Input image type — Type of input image

`Intensity` (default) | `Binary`

Specify the type of image as one of these options:

- `Intensity` — If the input image is an intensity image, select this option.
- `Binary` — If the input image is a binary image, select this option.

Neighborhood or structuring element source — Source of neighborhood or structuring element

`Specify via dialog` (default) | `Input port`

Specify the source of neighborhood or structuring element as one of these options:

- `Specify via dialog` — Use the **Neighborhood or structuring element** parameter to specify a neighborhood or structuring element.
- `Input port` — Use the **Nhood** input port to specify neighborhood values representing a structuring element.

Neighborhood or structuring element — Neighborhood or structuring element

`strel('octagon',15)` (default) | vector | matrix

Specify neighborhood or structuring element as a vector or matrix of `1`s and `0`s, a `strel` object or an array of `strel` objects. When you specify this value as an array of `strel` objects, the block applies each object to the entire image in turn.

If the structuring element is decomposable into smaller elements, the block executes at higher speed due to the use of a more efficient algorithm.

Dependencies

To enable this parameter, set the **Neighborhood or structuring element source** parameter, to `Specify via dialog`.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

More About

Bottom-hat Transform

Image processing tasks like background equalization, feature extraction, and image enhancement can be achieved using the bottom-hat transform. This process returns an image which contains objects that are:

- Smaller in dimension than the structuring element chosen and
- Darker than the surroundings

Chroma Resampling

Downsample or upsample chrominance components of images

Libraries:
Computer Vision Toolbox / Conversions

Description

The Chroma Resampling block resamples the chrominance components of an input image. Chroma resampling consists of these operations:

- Downsample — Reduces the bandwidth required for transmission or storage of a signal. You can prevent aliasing by applying a lowpass filter to bandlimit the input signal.
- Upsample — Expands the bandwidth of the signal. This block performs interpolation to approximate the missing chrominance values.

Ports

Input

Cb — Blue-difference chrominance component of image
matrix

Blue-difference chrominance component of the image, specified as an *M*-by-*D* matrix. *D* is half the width of the image.

Data Types: `single` | `double` | `uint8`

Cr — Red-difference chrominance component of image
matrix

Red-difference chrominance component of the image, specified as an *M*-by-*D* matrix. *D* is half the width of the image.

Data Types: `single` | `double` | `uint8`

Output

Cb — Blue-difference chrominance component of image
matrix

Blue-difference chrominance component of image, returned as an *M*-by-*P* matrix. *P* is half the width of the resampled image. If you downsample the input image, *P* is less than *D*. If you upsample the input image, *P* is greater than *D*.

Data Types: `single` | `double` | `int8` | `uint8`

Cr — Red-difference chrominance component of image
matrix

Red-difference chrominance component of image, returned as an *M*-by-*P* matrix. *P* is half the width of the resampled image. If you downsample the input image, *P* is less than *D*. If you upsample the input image, *P* is greater than *D*

Data Types: `single` | `double` | `int8` | `uint8`

Parameters

Resampling — Chrominance resampling method

`4:4:4 to 4:2:2` (default) | `4:4:4 to 4:2:0 (MPEG1)` | `4:4:4 to 4:2:0 (MPEG2)` | ...

Specify the resampling method to use to downsample or upsample the chrominance components of the image.

These options specify downsampling operations:

- `4:4:4 to 4:2:2`
- `4:4:4 to 4:2:0 (MPEG1)`
- `4:4:4 to 4:2:0 (MPEG2)`
- `4:4:4 to 4:1:1`
- `4:2:2 to 4:2:0 (MPEG1)`
- `4:2:2 to 4:2:0 (MPEG2)`

These options specify upsampling operations:

- `4:2:2 to 4:4:4`
- `4:2:0 (MPEG1) to 4:2:2`
- `4:2:0 (MPEG1) to 4:4:4`
- `4:2:0 (MPEG2) to 4:2:2`
- `4:2:0 (MPEG2) to 4:4:4`
- `4:1:1 to 4:4:4`

For more information, see “Chrominance Resampling Formats” on page 1-126.

Antialiasing filter — Chroma downsampling antialiasing filter

`Default` (default) | `User-defined` | `None`

Specify the lowpass filter that the block uses to prevent aliasing.

- `Default` — The block uses a built-in lowpass filter.
- `User-defined` — Specify custom filter coefficients for the block. Depending on the value of the Resampling parameter, this option enables the **Horizontal filter coefficients** parameter, the **Vertical filter coefficients** parameter, or both.
- `None` — The block does not filter the input signal.

Dependencies

To enable this parameter, set the **Resampling** parameter to one of these options:

- `4:4:4 to 4:2:2`
- `4:4:4 to 4:2:0 (MPEG1)`
- `4:4:4 to 4:2:0 (MPEG2)`
- `4:4:4 to 4:1:1`
- `4:2:2 to 4:2:0 (MPEG1)`
- `4:2:2 to 4:2:0 (MPEG2)`

.

Horizontal filter coefficients — Coefficients for horizontal lowpass filter

`[0.2 0.6 0.2]` (default) | row vector

Specify the horizontal filter coefficients as a vector of even number of elements to apply to your input signal.

Dependencies

To enable this parameter, you must:

- Set the **Resampling** parameter to one of these options:
  - `4:4:4 to 4:2:2`
  - `4:4:4 to 4:2:0 (MPEG1)`
  - `4:4:4 to 4:2:0 (MPEG2)`
  - `4:4:4 to 4:1:1`
- Set the **Antialiasing filter** parameter to `User-defined`.

Vertical filter coefficients — Coefficients for vertical lowpass filter

`[0.5 0.5]` (default) | row vector

Specify the filter coefficients as a vector of odd number of elements to apply to your input signal.

Dependencies

To enable this parameter, you must:

- Set the **Resampling** parameter to one of these options:
  - `4:4:4 to 4:2:0 (MPEG1)`
  - `4:4:4 to 4:2:0 (MPEG2)`
  - `4:2:2 to 4:2:0 (MPEG1)`
  - `4:2:2 to 4:2:0 (MPEG2)`
- Set the **Antialiasing filter** parameter to `User-defined`.

Interpolation — Chrominance upsampling interpolation method

`linear` (default) | `pixel replication`

Specify whether the block uses linear interpolation or pixel replication interpolation to approximate the missing chrominance values when upsampling an image.

- `linear` — The block uses linear interpolation to calculate the missing values.
- `pixel replication` — The block replicates the chrominance values of the neighboring pixels to assign values to the additional pixels in the upsampled image.

Dependencies

To enable this parameter, set the **Resampling** parameter to one of these options:

- `4:2:2 to 4:4:4`
- `4:2:0 (MPEG1) to 4:2:2`
- `4:2:0 (MPEG1) to 4:4:4`
- `4:2:0 (MPEG2) to 4:2:2`
- `4:2:0 (MPEG2) to 4:4:4`
- `4:1:1 to 4:4:4`

.

Input image is transposed (data order is row major) — Read data row-wise

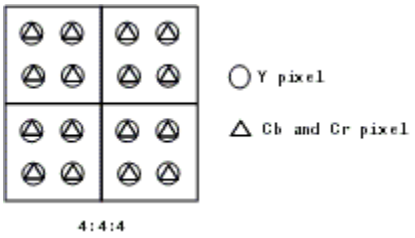
`off` (default) | `on`

Enable this parameter to read data elements row-wise.

Block Characteristics

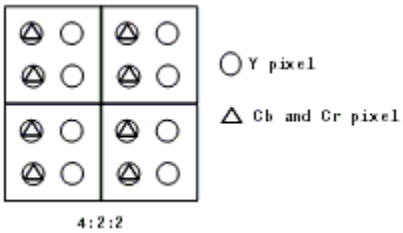
Data Types	`double` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

Algorithms



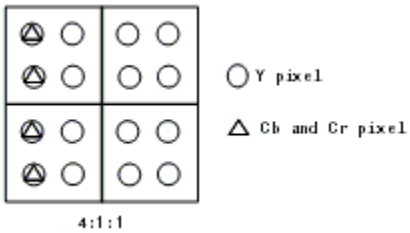
Chrominance Resampling Formats

Chrominance resampling format is represented as a three-part ratio J:a:b (for example, 4:2:2). The three-parts are represented as:

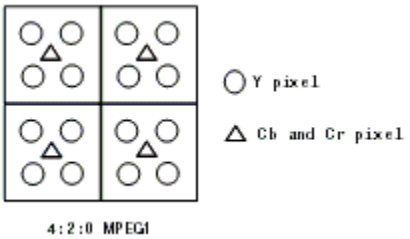


- J — Horizontal sampling reference
- a — Number of chrominance samples (Cr, Cb) in the first row of J pixels.
- b — Number of chrominance samples (Cr, Cb) in the second row of J pixels

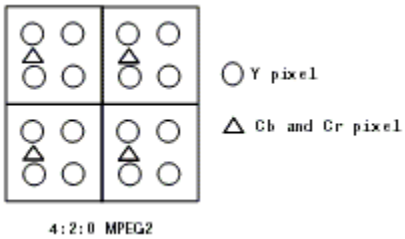
The Chroma Resampling block supports these formats:



- Chrominance resampling format 4:4:4



- Chrominance resampling format 4:2:2



- Chrominance resampling format 4:1:1

- Chrominance resampling format 4:2:0 (MPEG1)

- Chrominance resampling format 4:2:0 (MPEG2)

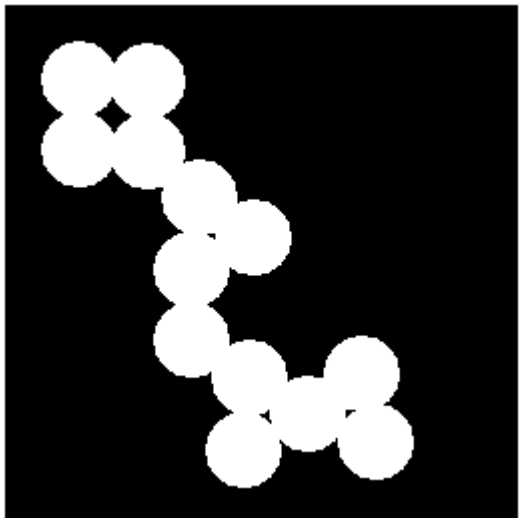
Closing

Perform morphological closing on binary or intensity images



Libraries:
Computer Vision Toolbox / Morphological Operations

Description

The Closing block performs a dilation operation followed by an erosion operation on an intensity or binary image using a predefined neighborhood or structuring element.

To define the structuring element that the block applies to the image, use the **Neighborhood or structuring element** parameter. Specify this element by entering a vector or matrix of `1`s and `0`s or by using the `strel` function.

Below are an input image and the output image after the closing operation, respectively.

This block uses two-dimensional flat structuring elements only.

Ports

Input

I — Input image
matrix

Specify an input image as a matrix of intensity values. This port is unnamed unless you set the **Neighborhood or structuring element source** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Nhood — Neighborhood values
vector | matrix

Specify neighborhood values representing a structuring element as a vector or matrix of `1`s and `0`s or by using the `strel` function.

Dependencies

To enable this port, set the **Neighborhood or structuring element source** parameter to `Input port`.

Data Types: `Boolean`

Output

Port_1 — Closed image
matrix

The closed image is returned as a matrix of intensity values. The size and data type of the closed image are the same as those of the input image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Neighborhood or structuring element source — Source of neighborhood or structuring element

`Specify via dialog` (default) | `Input port`

Specify the source of neighborhood or structuring element as one of these options:

- `Specify via dialog` — Use the **Neighborhood or structuring element** parameter to specify a neighborhood or structuring element.
- `Input port` — Use the **Nhood** input port to specify neighborhood values representing a structuring element.

Neighborhood or structuring element — Neighborhood or structuring element

`strel('line',5,45)` (default) | vector | matrix

Specify neighborhood or structuring element as a vector or matrix of `1`s and `0`s, a `strel` object or an array of `strel` objects. When you specify this value as an array of `strel` objects, the block applies each object to the entire image in turn.

If the structuring element is decomposable into smaller elements, the block executes at higher speed due to the use of a more efficient algorithm.

Dependencies

To enable this parameter, set the **Neighborhood or structuring element source** parameter, to `Specify via dialog`.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

More About

Closing Operation

Closing smoothes the contour of an object in an image by

- Fusing narrow breaks and long thin gulfs
- Eliminating small holes and
- Filling gaps in the contour

Color Space Conversion

Convert color space of image

Libraries:
Computer Vision Toolbox / Conversions

Description

The Color Space Conversion block converts color information between color spaces. Use the **Conversion** parameter to specify the color spaces you are converting between.

Ports

Input

Port_1 — Input image
array

Input image, specified as an *M*-by-*N*-by-*C* array, where *C* is the number of color channels in the input image.

Data Types: `single` | `double` | `uint8`

R' — Red color component of image
matrix

Red color component of image, specified as an *M*-by-*N* matrix.

Note Inputs to the **R'**, **G'**, and **B'** ports must have the same dimensions and data type as one another.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to one of these options:

- `R'G'B' to Y'CbCr`
- `R'G'B' to intensity`
- `R'G'B' to HSV`
- `sR'G'B' to XYZ`
- `sR'G'B' to L*a*b*`

Data Types: `single` | `double` | `uint8`

G' — Green color component of image
matrix

Green color component of image, specified as an *M*-by-*N* matrix.

Note Inputs to the **R'**, **G'**, and **B'** ports must have the same dimensions and data type as one another.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to one of these options:

- `R'G'B' to Y'CbCr`
- `R'G'B' to intensity`
- `R'G'B' to HSV`
- `sR'G'B' to XYZ`
- `sR'G'B' to L*a*b*`

Data Types: `single` | `double` | `uint8`

B' — Blue color component of image
matrix

Blue color component of image, specified as an *M*-by-*N* matrix.

Note Inputs to the **R'**, **G'**, and **B'** ports must have the same dimensions and data type as one another.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to one of these options:

- `R'G'B' to Y'CbCr`
- `R'G'B' to intensity`
- `R'G'B' to HSV`
- `sR'G'B' to XYZ`
- `sR'G'B' to L*a*b*`

Data Types: `single` | `double` | `uint8`

Y' — Luma component of image
matrix

Luma component of image, specified as an *M*-by-*N* matrix.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `Y'CbCr to R'G'B'`.

Data Types: `single` | `double` | `uint8`

Cb — Blue-difference chroma component of image
matrix

Blue-difference chroma component of image, specified as an *M*-by-*D* matrix, where *D* is half the width of the image.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `Y'CbCr to R'G'B'`.

Data Types: `single` | `double` | `uint8`

Cr — Red-difference chroma component of image
matrix

Red-difference chroma component of image, specified as an *M*-by-*D* matrix, where *D* is half the width of the image.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `Y'CbCr to R'G'B'`.

Data Types: `single` | `double` | `uint8`

H — Hue component of image
matrix

Hue component of image, specified as an *M*-by-*N* matrix.

Note Inputs to the **H**, **S**, and **V** ports must have the same dimensions and data type as one another.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `HSV to R'G'B'`.

Data Types: `single` | `double`

S — Saturation component of image
matrix

Saturation component of image, specified as an *M*-by-*N* matrix.

Note Inputs to the **H**, **S**, and **V** ports must have the same dimensions and data type as one another.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `HSV to R'G'B'`.

Data Types: `single` | `double`

V — Brightness component of image
matrix

Brightness component of image, specified as an *M*-by-*N* matrix.

Note Inputs to the **H**, **S**, and **V** ports must have the same dimensions and data type as one another.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `HSV to R'G'B'`.

Data Types: `single` | `double`

X — X component of image
matrix

X component of image, specified as an *M*-by-*N* matrix.

Note Inputs to the **X**, **Y**, and **Z** ports must have the same dimensions and data type as one another.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `XYZ to sR'G'B'`.

Data Types: `single` | `double`

Y — Y component of image
matrix

Y component of image, specified as an *M*-by-*N* matrix.

Note Inputs to the **X**, **Y**, and **Z** ports must have the same dimensions and data type as one another.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `XYZ to sR'G'B'`.

Data Types: `single` | `double`

Z — Z component of image
matrix

Z component of image, specified as an *M*-by-*N* matrix.

Note Inputs to the **X**, **Y**, and **Z** ports must have the same dimensions and data type as one another.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `XYZ to sR'G'B'`.

Data Types: `single` | `double`

L* — Lightness component of image
matrix

Lightness component of image, specified as an *M*-by-*N* matrix.

Note Inputs to the **L***, **a***, and **b*** ports must have the same dimensions and data type as one another.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `L*a*b* to sR'G'B'`.

Data Types: `single` | `double`

a* — Red-green component of image
M-by-*N* matrix

Red-green component of image, specified as an *M*-by-*N* matrix.

Note Inputs to the **L***, **a***, and **b*** ports must have the same dimensions and data type as one another.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `L*a*b* to sR'G'B'`.

Data Types: `single` | `double`

b* — Yellow-blue component of image
M-by-*N* matrix

Yellow-blue component of image, specified as an *M*-by-*N* matrix.

Note Inputs to the **L***, **a***, and **b*** ports must have the same dimensions and data type as one another.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `L*a*b* to sR'G'B'`.

Data Types: `single` | `double`

Output

Port_1 — Output image
array

Output image, returned as an *M*-by-*N*-by-*P* array, where *P* is the number of color channels in the output image. For Y'CbCr output, the value range for the Y component differs from those of the Cb and Cr components.

- If the input is `uint8`, then Y'CbCr is `uint8`. `Y'` is in the range `[16, 235]`, and `Cb` and `Cr` are in the range `[16, 240]`.
- If the input is `double`, then `Y'CbCr` is `double`. `Y'` is in the range `[16/255, 235/255]`, and `Cb` and `Cr` are in the range `[16/255, 240/255]`.

Data Types: `single` | `double` | `int8` | `uint8`

R' — Red color component of image
matrix

Red color component of image, returned as an *M*-by-*N* matrix.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to one of these options:

- `Y'CbCr to R'G'B'`
- `HSV to R'G'B'`
- `XYZ to sR'G'B'`
- `L*a*b* to sR'G'B'`

.

Data Types: `single` | `double` | `int8` | `uint8`

G' — Green color component of image
matrix

Green color component of image, returned as an *M*-by-*N* matrix.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to one of these options:

- `Y'CbCr to R'G'B'`
- `HSV to R'G'B'`
- `XYZ to sR'G'B'`
- `L*a*b* to sR'G'B'`

Data Types: `single` | `double` | `int8` | `uint8`

B' — Blue color component of image
matrix

Blue color component of image, returned as an *M*-by-*N* matrix.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to one of these options:

- `Y'CbCr to R'G'B'`
- `HSV to R'G'B'`
- `XYZ to sR'G'B'`
- `L*a*b* to sR'G'B'`

.

Data Types: `single` | `double` | `int8` | `uint8`

Y' — Luma component of image
matrix

Luma component of image, returned as an *M*-by-*N* matrix.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `R'G'B' to Y'CbCr`.

Data Types: `single` | `double` | `int8` | `uint8`

Cb — Blue-difference chroma component of image
matrix

Blue-difference chroma component of image, returned as an *M*-by-*N* matrix.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `R'G'B' to Y'CbCr`.

Data Types: `single` | `double` | `int8` | `uint8`

Cr — Red-difference chroma component of image
matrix

Red-difference chroma component of image, returned as an *M*-by-*N* matrix.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `R'G'B' to Y'CbCr`.

Data Types: `single` | `double` | `int8` | `uint8`

I' — Intensity image
matrix

Intensity image, returned as an *M*-by-*N* matrix.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `R'G'B' to intensity`.

Data Types: `single` | `double` | `int8` | `uint8`

H — Hue component of image
matrix

Hue component of image, returned as an *M*-by-*N* matrix.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `R'G'B' to HSV`.

Data Types: `single` | `double`

S — Saturation component of image
matrix

Saturation component of image, returned as an *M*-by-*N* matrix.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `R'G'B' to HSV`.

Data Types: `single` | `double`

V — Brightness component of image
matrix

Brightness component of image, returned as an *M*-by-*N* matrix.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `R'G'B' to HSV`.

Data Types: `single` | `double`

X — X component of image
matrix

X component of image, returned as an *M*-by-*N* matrix.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `sR'G'B' to XYZ`.

Data Types: `single` | `double`

Y — Y component of image
matrix

Y component of image, returned as an *M*-by-*N* matrix.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `sR'G'B' to XYZ`.

Data Types: `single` | `double`

Z — Z component of image
matrix

Z component of image, returned as an *M*-by-*N* matrix.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `sR'G'B' to XYZ`.

Data Types: `single` | `double`

L* — Lightness component of image
matrix

Lightness component of image, returned as an *M*-by-*N* matrix.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `sR'G'B' to L*a*b*`.

Data Types: `single` | `double`

a* — Red-green component of image
matrix

Red-green component of image, returned as an *M*-by-*N* matrix.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `sR'G'B' to L*a*b*`.

Data Types: `single` | `double`

b* — Yellow-blue component of image
matrix

Yellow-blue component of image, returned as an *M*-by-*N* matrix.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals` and set the **Conversion** parameter to `sR'G'B' to L*a*b*`.

Data Types: `single` | `double`

Parameters

Conversion — Color space conversion

`R'G'B' to Y'CbCr` (default) | `Y'CbCr to R'G'B'` | `R'G'B' to intensity` | ...

Specify which color space to convert the image from and to using these options:

- `R'G'B' to Y'CbCr`
- `Y'CbCr to R'G'B'`
- `R'G'B' to intensity`
- `B'G'R' to intensity`
- `B'G'R' to R'G'B'`
- `R'G'B' to B'G'R'`
- `R'G'B' to HSV`
- `HSV to R'G'B'`
- `sR'G'B' to XYZ`
- `XYZ to sR'G'B'`
- `sR'G'B' to L*a*b*`
- `L*a*b* to sR'G'B'`

Note The prime notation indicates that the signal is gamma corrected.

Use conversion specified by — Color conversion standard

`Rec. 601 (SDTV)` (default) | `Rec. 709 (HDTV)`

Specify the color conversion standard for converting the image between the R'G'B' and Y'CbCr color spaces as either `Rec. 601 (SDTV)` or `Rec. 709 (HDTV)`.

Dependencies

To enable this parameter, set the **Conversion** parameter to `R'G'B' to Y'CbCr` or `Y'CbCr to R'G'B'`.

Scanning standard — Scanning standard

`1125/60/2:1` (default) | `1250/50/2:1`

Specify the scanning standard for converting the image between the R'G'B' and Y'CbCr color spaces as either `1125/60/2:1` or `1250/50/2:1`.

Dependencies

To enable this parameter, set the **Conversion** parameter to `R'G'B' to Y'CbCr` or `Y'CbCr to R'G'B'` and set the **Use conversion specified by** parameter to `Rec. 709 (HDTV)`.

White point — White point

`D50` (default) | `D55` | `D65`

Specify the reference white point for converting the image between the sR'G'B' and L*a*b* color spaces as `D50`, `D55`, or `D65`.

Dependencies

To enable this parameter, set the **Conversion** parameter to `sR'G'B' to L*a*b*` or `L*a*b* to sR'G'B'`.

Image signal — Image signal input

`One multidimensional signal` (default) | `Separate color signals`

Specify whether to combine the color channels of the image into one signal or input and output them individually.

- `One multidimensional signal` — The block accepts all color channels of the input image as a multidimensional array to a single input port, and outputs the converted image as a single matrix or array from a single output port.
- `Separate color signals` — The block accepts each color channel of the input image to a separate input port, and outputs each color channel of the converted image from a separate output port.

Block Characteristics

Data Types	`Boolean` | `double` | `integer` | `single` | `image`
Multidimensional Signals	`yes`
Variable-Size Signals	`yes`

Algorithms

Conversion Between R'G'B' and Y'CbCr Color Spaces

These equations define R'G'B' to Y'CbCr conversion and Y'CbCr to R'G'B' conversion, respectively:

$$\begin{bmatrix} Y' \\ Cb \\ Cr \end{bmatrix} = \begin{bmatrix} 16 \\ 128 \\ 128 \end{bmatrix} + A \times \begin{bmatrix} R' \\ G' \\ B' \end{bmatrix}$$

$$\begin{bmatrix} R' \\ G' \\ B' \end{bmatrix} = B \times \left(\begin{bmatrix} Y' \\ Cb \\ Cr \end{bmatrix} - \begin{bmatrix} 16 \\ 128 \\ 128 \end{bmatrix} \right)$$

The values in matrices `A` and `B` are based on your choices for the **Use conversion specified by** and **Scanning standard** parameters.

Matrix	Use conversion specified by = Rec. 601 (SDTV)	Use conversion specified by = Rec. 709 (HDTV)	
		Scanning standard = 1125/60/2:1	Scanning standard = 1250/50/2:1
A	$\begin{bmatrix} 0.25678824 & 0.50412941 & 0.09790588 \\ -0.1482229 & -0.29099279 & 0.43921569 \\ 0.43921569 & -0.36778831 & -0.07142737 \end{bmatrix}$	$\begin{bmatrix} 0.18258588 & 0.61423059 & 0.06200706 \\ -0.10064373 & -0.33857195 & 0.43921569 \\ 0.43921569 & -0.39894216 & -0.04027352 \end{bmatrix}$	$\begin{bmatrix} 0.25678824 & 0.50412941 & 0.09790588 \\ -0.1482229 & -0.29099279 & 0.43921569 \\ 0.43921569 & -0.36778831 & -0.07142737 \end{bmatrix}$

Matrix	Use conversion specified by = Rec. 601 (SDTV)	Use conversion specified by = Rec. 709 (HDTV)	
		Scanning standard = 1125/60/2:1	Scanning standard = 1250/50/2:1
B	$\begin{bmatrix} 1.1643836 & 0 & 1.5960268 \\ 1.1643836 & -0.39176229 & -0.81296765 \\ 1.1643836 & 2.0172321 & 0 \end{bmatrix}$	$\begin{bmatrix} 1.16438356 & 0 & 1.79274107 \\ 1.16438356 & -0.21324861 & -0.53290933 \\ 1.16438356 & 2.11240179 & 0 \end{bmatrix}$	$\begin{bmatrix} 1.1643836 & 0 & 1.5960268 \\ 1.1643836 & -0.39176229 & -0.81296765 \\ 1.1643836 & 2.0172321 & 0 \end{bmatrix}$

Conversion from R'G'B' to Intensity

This equation defines conversion from the R'G'B' color space to an intensity image:

$$\text{intensity} = [0.299\ \ 0.587\ \ 0.114]\begin{bmatrix} R' \\ G' \\ B' \end{bmatrix}$$

Conversion from B'G'R' to Intensity

This equation defines conversion from the B'G'R' color space to an intensity image:

$$\text{intensity} = [0.114\ \ 0.587\ \ 0.2999]\begin{bmatrix} B' \\ G' \\ R' \end{bmatrix}$$

Conversion Between R'G'B' and HSV Color Spaces

In the equations defining the R'G'B' to HSV conversion, MAX and MIN are the highest and lowest component values, respectively, of a given R'G'B' triplet. H, S, and V vary from 0 to 1.

$$H = \begin{cases} \left(\frac{G' - B'}{MAX - MIN}\right)/6, & \text{if } R' = MAX \\ \left(2 + \frac{B' - R'}{MAX - MIN}\right)/6, & \text{if } G' = MAX \\ \left(4 + \frac{R' - G'}{MAX - MIN}\right)/6, & \text{if } B' = MAX \end{cases}$$

$$S = \frac{MAX - MIN}{MAX}$$

$$V = MAX$$

This equation defines the HSV to R'G'B' conversion, where M is the highest value among R_{tmp}, G_{tmp} and B_{tmp}:

$H_i = \lfloor 6H \rfloor$

$f = 6H - H_i$

$p = 1 - S$

$q = 1 - (f * S)$

$t = 1 - S(1 - f)$

if $H_\text{i} = 0,\ R_\text{tmp} = 1,\ G_\text{tmp} = t,\ B_\text{tmp} = p$

if $H_\text{i} = 1,\ R_\text{tmp} = q,\ G_\text{tmp} = 1,\ B_\text{tmp} = p$

if $H_\text{i} = 2,\ R_\text{tmp} = p,\ G_\text{tmp} = 1,\ B_\text{tmp} = t$

if $H_\text{i} = 3,\ R_\text{tmp} = p,\ G_\text{tmp} = q,\ B_\text{tmp} = 1$

if $H_\text{i} = 4,\ R_\text{tmp} = t,\ G_\text{tmp} = p,\ B_\text{tmp} = 1$

if $H_\text{i} = 5,\ R_\text{tmp} = 1,\ G_\text{tmp} = p,\ B_\text{tmp} = q$

$u = V/M$

$R' = u * R_\text{tmp}$

$G' = u * G_\text{tmp}$

$B' = u * B_\text{tmp}$

Conversion Between sR'G'B' and XYZ Color Spaces

The sR'G'B' to XYZ conversion is a two-step process. First, the block converts the gamma-corrected sR'G'B' values to linear sRGB values using these equations:

If R'_sRGB, G'_sRGB, and B'_sRGB are each less than or equal to 0.03928, then:

$R_\text{sRGB} = R'_\text{sRGB}/12.92$

$G_\text{sRGB} = G'_\text{sRGB}/12.92$

$B_\text{sRGB} = B'_\text{sRGB}/12.92$

Otherwise:

$$R_\text{sRGB} = \left[(R'_\text{sRGB} + 0.055) \Big/ 1.055 \right]^{2.4}$$

$$G_\text{sRGB} = \left[(G'_\text{sRGB} + 0.055) \Big/ 1.055 \right]^{2.4}$$

$$B_\text{sRGB} = \left[(B'_\text{sRGB} + 0.055) \Big/ 1.055 \right]^{2.4}$$

Then, the block converts the sRGB values to XYZ values using this equation:

$$\begin{bmatrix} X \\ Y \\ Z \end{bmatrix} = \begin{bmatrix} 0.41239079926596 & 0.35758433938388 & 0.18048078840183 \\ 0.21263900587151 & 0.71516867876776 & 0.07219231536073 \\ 0.01933081871559 & 0.11919477979463 & 0.95053215224966 \end{bmatrix} \times \begin{bmatrix} R_{sRGB} \\ G_{sRGB} \\ B_{sRGB} \end{bmatrix}$$

The XYZ to sR'G'B' conversion is also a two-step process. First, the block converts the XYZ values to linear sRGB values using this equation:

$$\begin{bmatrix} R_{sRGB} \\ G_{sRGB} \\ B_{sRGB} \end{bmatrix} = \begin{bmatrix} 0.41239079926596 & 0.35758433938388 & 0.18048078840183 \\ 0.21263900587151 & 0.71516867876776 & 0.07219231536073 \\ 0.01933081871559 & 0.11919477979463 & 0.95053215224966 \end{bmatrix}^{-1} \times \begin{bmatrix} X \\ Y \\ Z \end{bmatrix}$$

Then the block applies gamma correction, using these equations, to obtain the sR'G'B' values:

If R_{sRGB}, G_{sRGB} and B_{sRGB} are each less than or equal to 0.00304, then:

$$R'_{\text{sRGB}} = 12.92R_{\text{sRGB}}$$
$$G'_{\text{sRGB}} = 12.92G_{\text{sRGB}}$$
$$B'_{\text{sRGB}} = 12.92B_{\text{sRGB}}$$

Otherwise:

$$R'_{\text{sRGB}} = 1.055R_{\text{sRGB}}^{(1.0/2.4)} - 0.055$$
$$G'_{\text{sRGB}} = 1.055G_{\text{sRGB}}^{(1.0/2.4)} - 0.055$$
$$B'_{\text{sRGB}} = 1.055B_{\text{sRGB}}^{(1.0/2.4)} - 0.055$$

Note Computer Vision Toolbox uses a D65 white point, which is specified in Recommendation ITU-R BT.709, for this conversion. In contrast, the Image Processing Toolbox™ conversion is based on ICC profiles, and it uses a D65 to D50 Bradford adaptation transformation to the D50 white point. If you are using these two products and comparing results, you must account for this difference.

Conversion Between sR'G'B' and L*a*b* Color Spaces

The Color Space Conversion block converts sR'G'B' values to L*a*b* values in two steps. First, it converts sR'G'B' to XYZ values using the equations described in “Conversion Between sR'G'B' and XYZ Color Spaces” on page 1-145. Then, it uses these equations to transform the XYZ values to L*a*b* values. Here, X_n, Y_n, and Z_n are the tristimulus values of the reference white point you specify using the **White point** parameter:

If Y/Y_{n} is greater than 0.008856, then:

$$L^* = 116(Y/Y_{\text{n}})^{1/3} - 16$$

Otherwise:

$$L^* = 903.3Y/Y_{\text{n}}$$

$$a^* = 500(f(X/X_{\text{n}}) - f(Y/Y_{\text{n}}))$$
$$b^* = 200(f(Y/Y_{\text{n}}) - f(Z/Z_{\text{n}})),$$

If t is greater than 0.008856, then:

$$f(t) = t^{1/3}$$

Otherwise:

$$f(t) = 7.787t + 16/166$$

The block converts L*a*b* values to sR'G'B' values in two steps, as well. First, the block transforms the L*a*b* values to XYZ values using these equations:

If Y/Y_n is greater than 0.008856, then:

$$X = X_n(P + a^*/500)^3$$

$$Y = Y_n P^3$$

$$Z = Z_n(P - b^*/200)^3,$$

where:

$$P = (L^* + 16)/116$$

Otherwise:

$$X = {X_n((P + {a}/{500}) - 0.138)}/{7.787}$$

$$Y = {Y_n(P - 0.138)}/{7.787}$$

$$Z = Z_n\left(\left(P - {b}/{200}\right) - 0.138\right)(7.787)$$

Then it converts XYZ to sR'G'B' values using the equations described in “Conversion Between sR'G'B' and XYZ Color Spaces” on page 1-145.

Compositing

Combine two images or apply mask to image

Libraries:
Computer Vision Toolbox / Text & Graphics

Description

The Compositing block combines two images, overlays one image over another, or highlights selected pixels in an image. When combining two images, the block uses this equation, in which the output image O is a linear combination of the two images I_1 and I_2:

$$O(i, j) = (1 - X) * I_1(i, j) + X * I_2(i, j) .$$

The opacity factor X scales each pixel before combining the images, where $0 \le X \le 1$.

When overlaying one image over another image, or highlighting selected pixels in an input image, the block uses a binary mask to specify which pixels to overwrite or highlight.

Note This block supports binary, intensity, and color images.

Ports

Input

Image1 — Input image one
matrix | array

Input image one, specified as an M-by-N matrix or M-by-N-by-P array. If the input is a M-by-N-by-P array, P is the number of color channels in the image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Image2 — Input image two
matrix | array

Input image two, specified as an M-by-N matrix or M-by-N-by-P array. If the input is a M-by-N-by-P array, P is the number of color channels in the image.

Dependencies

To enable this port, set the **Operation** parameter to `Blend` or `Binary mask`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Mask — Binary mask
scalar | matrix

Binary mask, specified as a scalar or matrix. This mask determines which pixels of **Image1** the block overwrites with the pixel values of **Image2** or highlights, depending on the value of the **Operation** parameter.

- `Binary mask` — The block overwrites the pixel values of **Image1**, indicated by the mask, with the corresponding pixel values of **Image2**. You can specify **Mask** as a scalar `0` or `1`, which the block uses for all pixels of **Image2**, or as binary matrix of same size as **Image2**.
- `Highlight selected pixels` — The block highlights the pixels of **Image1** indicated by the mask.

Dependencies

To enable this port:

- If overwriting pixel values in one image with pixel values in another image, set the **Operation** parameter to `Binary mask` and the **Mask source** parameter to `Input port`.
- If highlighting selected pixels in an image, set the **Operation** parameter to `Highlight selected pixels`.

Data Types: `single` | `double` | `Boolean`

Factor — Opacity factor
scalar | matrix

Opacity factor, specified as a scalar or matrix. If specified as a scalar, the value is the scale of combination for each pixel of **Image2** with each corresponding pixel of **Image1**. If specified as a matrix, its dimensions must match the dimensions of **Image2**. Each opacity factor must be in the range [0, 1].

Dependencies

To enable this port, set the **Operation** parameter to `Blend` and the **Opacity factor(s) source** parameter to `Input port`.

Data Types: `single` | `double`

Location — Location index
vector

Location index, specified as a two-element vector. The first element represents the row and the second represents the column position of the upper-left corner of **Image2**, relative to the upper-left corner of **Image1**. If the location of the upper-left corner of **Image2** is such that any of its pixels would render outside the bounds of **Image1**, the block clips **Image2** at the final row or column or **Image1**, instead.

Note When the **Image1** input has a fixed-point or boolean data type, the **Location** input must have a built-in integer data type.

Dependencies

To enable this port, set the **Location source** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Output

Port_1 — Output image
matrix

Output image, returned as an *M*-by-*N* matrix or *M*-by-*N*-by-*P* array. If the output is an *M*-by-*N*-by-*P* array, *P* is the number of color channels in the image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Parameters

Main

Operation — Specify operation

`Blend` (default) | `Binary mask` | `Highlight selected pixels`

Select the image operation for the block to perform.

- `Blend` — Linearly combines the pixel values of **Image1** with the pixel values of **Image2**, with the specified opacity factor.
- `Binary mask` — Overwrites the pixel values of **Image1** with the values of **Image2** specified by the binary mask.
- `Highlight selected pixels` — Highlights the pixels of **Image1** indicated by the binary mask. The highlight operation assign the highest intensity or color values to the pixels of **Image1** corresponding to the pixels with logic 1 of the binary mask.

Opacity factor(s) source — Source of opacity factor

`Specify via dialog` (default) | `Input port`

Specify the source of the opacity factor. If you set this parameter to `Input port`, it enables the **Factor** input port.

Dependencies

To enable this parameter, set the **Operation** parameter to `Blend`.

Opacity factor(s) — Opacity factor

`0.75` (default) | scalar | matrix

Defines the scale of combination for each pixel of **Image2** with each corresponding pixel of **Image1**. When you specify the opacity factor as matrix, its dimensions must match the dimensions of **Image2**. If you specify it as a scalar, the block uses that value as the opacity factor for all pixels of **Image2**. The opacity factor must be in the range [0, 1].

Dependencies

To enable this parameter, set the **Operation** parameter to `Blend` and the **Opacity factor(s) source** parameter to `Specify via dialog`.

Location source — Source of overlay location

`Specify via dialog` (default) | `Input port`

Select the source of the overlay location. If you set this parameter to `Input port`, it enables the **Location** input port.

Location [x y] — Overlay location index

`[1 1]` (default) | two-element vector

Specify the row and column position of the upper-left corner of **Image2**, relative to the upper-left corner of **Image1**, as a two-element vector. If the location of the upper-left corner of **Image2** is such that any of its pixels would render outside the bounds of **Image1**, the block clips **Image2** at the final row or column or **Image1**, instead.

Dependencies

To enable this parameter, set the **Location source** parameter to `Specify via dialog`.

Mask source — Source of mask

`Specify via dialog` (default) | `Input port`

Select the source of the binary mask. If you set this parameter to `Input port`, it enables the **Mask** input port.

Dependencies

To enable this parameter, set the **Operation** parameter to `Binary mask`.

Mask — Binary mask

`0` (default) | `1` | matrix

Binary mask, specified as a scalar or matrix, defines which pixels of **Image1** the block overwrites with the corresponding pixel values of **Image2** or highlights. You specify `0` or `1`, which the block uses for all pixels in **Image2**, or a binary matrix of the same size of as **Image2**.

Dependencies

To enable this parameter, set the **Operation** parameter to `Binary mask` and the **Mask source** parameter to `Specify via dialog`.

Data Types

For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Block Characteristics

Contrast Adjustment

Adjust image contrast using linear scaling

Libraries:
Computer Vision Toolbox / Analysis & Enhancement

Description

The Contrast Adjustment block adjusts the contrast of an image by linearly scaling the pixel values between specified upper and lower limits. Pixel values that are above or below the specified range are saturated to the upper or lower limit value, respectively. For more information, see “Adjust Contrast of Image” on page 1-157.

Ports

Input

I — Input image
matrix | array

Input image, specified as an *M*-by-*N* matrix or an *M*-by-*N*-by-*C* array, where *C* is the number of color channels in the input image.

Data Types: `single` | `double` | `int8` | `int16` | `uint8` | `uint16` | `Boolean` | `fixed point`

Output

Port_1 — Output image
matrix | array

Output image, returned as an *M*-by-*N* matrix or an *M*-by-*N*-by-*C* array, where *C* is the number of color channels.

Data Types: `single` | `double` | `int8` | `int16` | `uint8` | `uint16` | `Boolean` | `fixed point`

Parameters

Main

Adjust pixel values from — Input pixel value range definition
`Full input data range [min max]` (default) | `User-defined range` | `Range determined by saturating outlier pixels`

Specify how the block determines the pixel value range of the input image as one of these options:

- `Full input data range [min max]` — Range set to the minimum and maximum pixel values in the input image.

- `User-defined range` — Select this value to enable a **Range [low high]** parameter. Specify the **Range [low high]** parameter as a two-element vector of nonnegative values, in which the first element is the lower limit of the input pixel value range and the second element is the upper limit of the input pixel value range.
- `Range determined by saturating outlier pixels` — Range specified by saturating the outlier pixels. The block determines the range based on the **Percentage of pixels to saturate [low high]**, **Specify number of histogram bins (used to calculate the range when outliers are eliminated)**, and **Number of histogram bins** parameters. For more information, see “Determine Contrast Adjustment Range by Saturating Outlier Pixels” on page 1-158.

Range [low high] — Input pixel value range
`[0 255]` (default) | two-element vector of nonnegative numbers

Specify the input pixel value range as a two-element vector of nonnegative numbers. The first and second elements of the vector specify the lower and upper limit of the input pixel value range, respectively.

Dependencies

To enable this parameter, set the **Adjust pixel values from** parameter to `User-defined`.

Percentage of pixels to saturate [low high] — Maximum percentages of pixels to saturate
`[1 1]` (default) | two-element vector of nonnegative numbers

Specify the maximum percentages of pixels to saturate as a two-element vector of nonnegative numbers. Each element must be in the range 0 to 100. The block calculates the lower limit of the input pixel value range such that the percentage of pixels in the input image with values less than the lower limit is at most the value of the first element. Similarly, the block calculates the upper limit of the input pixel value range such that the percentage of pixels in the input image with values greater than the upper limit is at most the value of the second element.

Dependencies

To enable this parameter, set the **Adjust pixel values from** parameter to `Range determined by saturating outlier pixels`.

Specify number of histogram bins (used to calculate the range when outliers are eliminated) — Custom number of histogram bins
`on` (default) | `off`

Select this parameter to enable the **Number of histogram bins** parameter, which enables you to specify a custom number of histogram bins for the block to use to calculate the input pixel value range after outliers are eliminated.

Dependencies

To enable this parameter, set the **Adjust pixel values from** parameter to `Range determined by saturating outlier pixels`.

Number of histogram bins — Number of histogram bins
`256` (default) | positive integer

Specify the number of histogram bins to use to calculate the range for scaling the input pixel values.

Dependencies

To enable this parameter, set the **Adjust pixel values from** parameter to `Range determined by saturating outlier pixels`, and select the **Specify number of histogram bins (used to calculate the range when outliers are eliminated)** parameter.

Adjust pixel values to — Output pixel value range definition
`Full data type range` (default) | `User-defined range`

Specify how the block determines the pixel value range of the output image as one of these options:

- `Full data type range` — Specifies the output range of pixel values as from the minimum to the maximum value of the input data type.
- `User-defined range` — Select this value to enable a **Range [low high]** parameter. Specify the **Range [low high]** parameter as a two-element vector of nonnegative values, in which the first element is the lower limit of the output pixel value range and the second element is the upper limit of the output pixel value range.

Range [low high] — Output pixel value range
`[0 255]` (default) | two-element vector of nonnegative numbers

Specify the output pixel value range as a two-element vector of nonnegative numbers. The first and second elements of the vector specify the lower and upper limit of the output pixel value range, respectively.

Dependencies

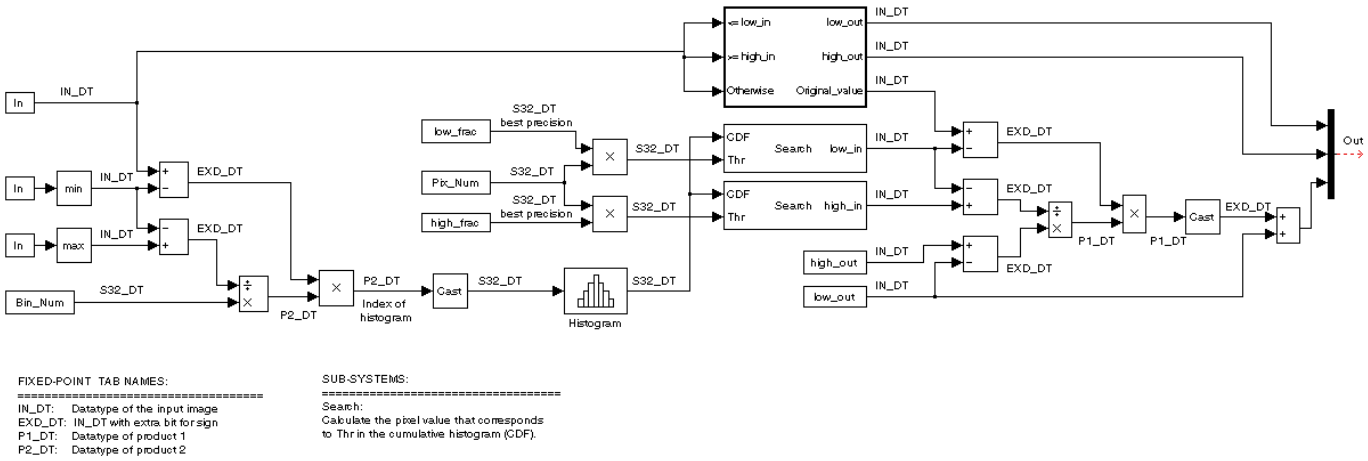
To enable this parameter, set the **Adjust pixel values to** parameter to `User-defined range`.

Data Types

For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Lock data type settings against change by the fixed-point tools — Data type override

`off` (default) | `on`



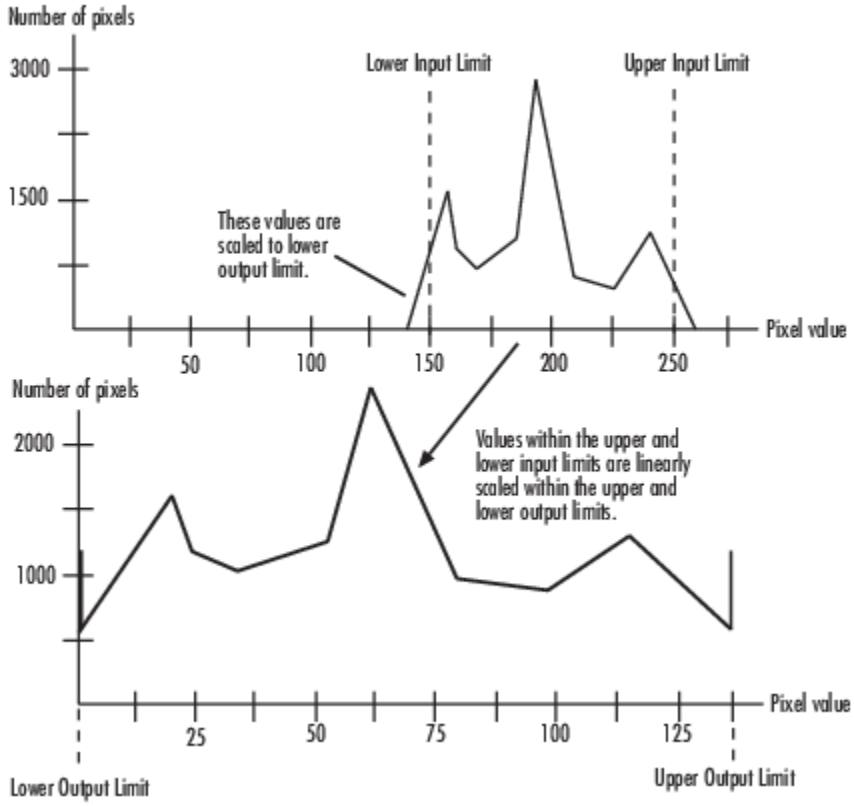
Select this parameter to prevent the fixed-point tools from overriding the data types you specify in this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

More About

The following diagram shows the data types used in the Contrast Adjustment block for fixed-point signals:



Algorithms

Adjust Contrast of Image

The contrast adjustment operation is defined by this equation.

$$O_i = \left\{ \begin{array}{c} l_{\text{out}},\ I_i \le l_{\text{in}} \\ l_{\text{out}} + (I_i - l_{\text{in}})\dfrac{h_{\text{out}} - l_{\text{out}}}{h_{\text{in}} - l_{\text{in}}},\ l_{\text{in}} < I_i < h_{\text{in}} \\ h_{\text{out}},\ I_i \ge h_{\text{in}} \end{array} \right\},$$

where I_i and O_i are the input and output image pixels, the input pixel value range is [l_{in} h_{in}] and the output pixel value range is [l_{out} h_{out}].

Determine Contrast Adjustment Range by Saturating Outlier Pixels

When you set the **Adjust pixel values from** parameter to `Range determined by saturating outlier pixels`, the block determines the input pixel value range using these steps.

1. Finds the minimum input pixel value *min_in* and maximum input pixel value *max_in*.
2. Scales the pixel values in the range [*min_in*, *max_in*] to [0, *num_bins*–1], where *num_bins* is the number of histogram bins specified by the **Number of histogram bins** parameter. Then, the block calculates the histogram of the scaled input. For more information on image histograms, see the 2-D Histogram block.
3. Determines the lower input pixel value limit such that the percentage of pixels in the input image with values less than the lower limit is at most the value of the first element of the **Percentage of pixels to saturate [low high]** parameter. Similarly, find the upper input pixel value limit such that the percentage of pixels in the input image with values greater than the upper limit is at most the value of the second element of the parameter.

Corner Detection

Calculate corner metric matrix and find corners in images

Libraries:
Computer Vision Toolbox / Analysis & Enhancement

Description

The Corner Detection block finds corners in an image by using the Harris corner detection (by Harris and Stephens), minimum eigenvalue (by Shi and Tomasi), or local intensity comparison (based on the *Accelerated Segment Test, (FAST)* method by Rosten and Drummond) method. The block finds the corners in the image based on the pixels that have the largest corner metric values.

Ports

Input

I — Input image
matrix of intensity values

Input image, specified as a matrix of intensity values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Loc — Corner locations
M-by-2 matrix

Corner locations, returned as an *M*-by-2 matrix of [*x y*] coordinates. *M* represents the number of corners and is less than or equal to the **Maximum number of corners** parameter.

Dependencies

To enable this port, set the **Output** parameter to one of these:

- `Corner location`
- `Corner location and metric matrix`

Data Types: `uint32`

Count — Number of detected corners
scalar

Number of detected corners, returned as a scalar.

Dependencies

To enable this port, set these block parameters:

- **Output**: `Corner location` | `Corner location and metric matrix`
- **Output variable size signal**: `off`

Data Types: `uint32`

Metric — Corner metric values
matrix

Corner metric values, returned as a matrix of intensity values. The returned matrix is the same size as the input image.

Dependencies

To enable this port, set the **Output** parameter to one of these:

- `Corner location and metric matrix`
- `Metric matrix`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Main

Method — Corner detection method
`Harris corner detection (Harris & Stephens)` (default) | `Minimum eigenvalue (Shi & Tomasi)` | `Local intensity comparison (Rosten & Drummond)`

Specify the corner detection method as `Harris corner detection (Harris & Stephens)`, `Minimum eigenvalue (Shi & Tomasi)`, or `Local intensity comparison (Rosten & Drummond)`.

To get the most accurate results, use `Minimum eigenvalue (Shi & Tomasi)`. For the fastest computation, use `Local intensity comparison (Rosten & Drummond)`. For a balance between accuracy and computation speed, use `Harris corner detection (Harris & Stephens)`. For more information on each method, see the “Algorithms” on page 1-166 section.

Sensitivity factor (0<k<0.25) — Sensitivity factor
0.04 (default) | scalar

Specify the sensitivity factor, k. As k decreases, the likelihood that the algorithm can detect sharp corners increases.

Tunable: Yes

Dependencies

To enable this parameter, set the **Method** parameter to `Harris corner detection (Harris & Stephens)`.

Coefficients for separable smoothing filter — Filter coefficients
fspecial('gaussian', [1 5], 1.5) (default) | vector

Specify a vector of filter coefficients for the smoothing filter.

Dependencies

To enable this parameter, set the **Method** parameter to one of these:

- `Harris corner detection (Harris & Stephens)`
- `Minimum eigenvalue (Shi & Tomasi)`

Intensity comparison threshold — Intensity threshold
0.1 (default) | scalar

Specify the intensity threshold value used to find valid surrounding pixels.

Tunable: Yes

Dependencies

To enable this parameter, set the **Method** parameter to `Local intensity comparison (Rosten & Drummond)`.

Maximum angle to be considered a corner (in degrees) — Maximum corner angle
157.5 (default) | scalar

Specify the maximum corner angle.

Tunable: Yes

Dependencies

- To enable this parameter, set the **Method** parameter to `Local intensity comparison (Rosten & Drummond)`.
- This parameter is tunable for simulation only.

Output — Block output
`Corner location` (default) | `Corner location and metric matrix` | `Metric matrix`

Specify the block output as `Corner location`, `Corner location and metric matrix`, and `Metric matrix`.

Set this parameter to `Corner location` or `Corner location and metric matrix` to expose the **Maximum number of corners**, **Minimum metric value that indicates a corner**, and **Neighborhood size (suppress region around detected corners)** parameters.

Maximum number of corners — Maximum number of corners
200 (default) | integer

Specify the maximum number of corners you want the block to find.

Dependencies

To enable this parameter, set the **Output** parameter to one of these:

- `Corner location`
- `Corner location and metric matrix`

Minimum metric value that indicates a corner — Minimum corner metric
0.0005 (default) | scalar

Specify the minimum corner metric value.

Tunable: Yes

Dependencies

To enable this parameter, set the **Output** parameter to one of these:

- `Corner location`
- `Corner location and metric matrix`

Neighborhood size — Neighborhood size
[11 11] (default) | 2-element vector

Specify the neighborhood size as a two-element vector of positive odd integers, [*row*, *column*]. The block uses this parameter to suppress the region around a valid corner point with the largest corner metric value.

Dependencies

To enable this parameter, set the **Output** parameter to one of these:

- `Corner location`
- `Corner location and metric matrix`

Output variable size signal — Variable size signal
`on` (default) | `off`

Select this parameter to output a variable size signal.

Dependencies

To enable this parameter, set the **Output** parameter to one of these:

- `Corner location`
- `Corner location and metric matrix`

Data Types

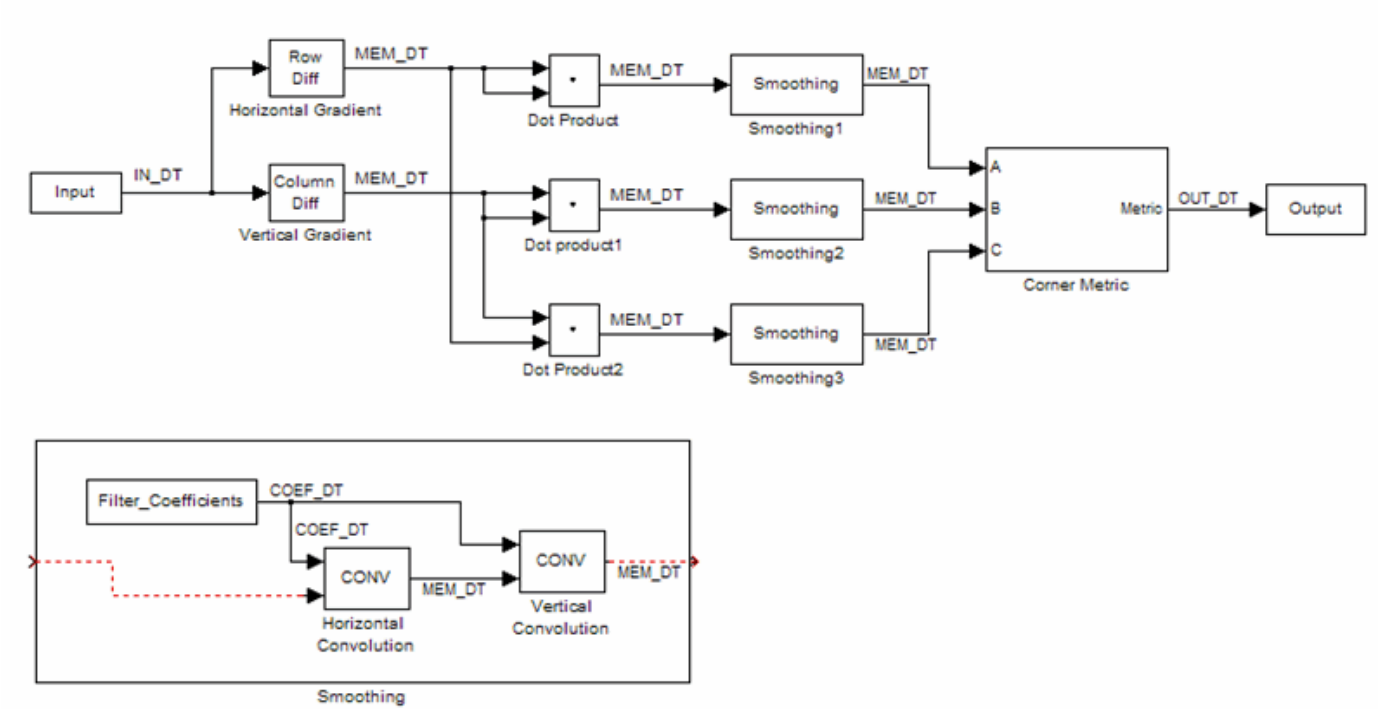
For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Lock data type settings against change by the fixed-point tools — Data type override

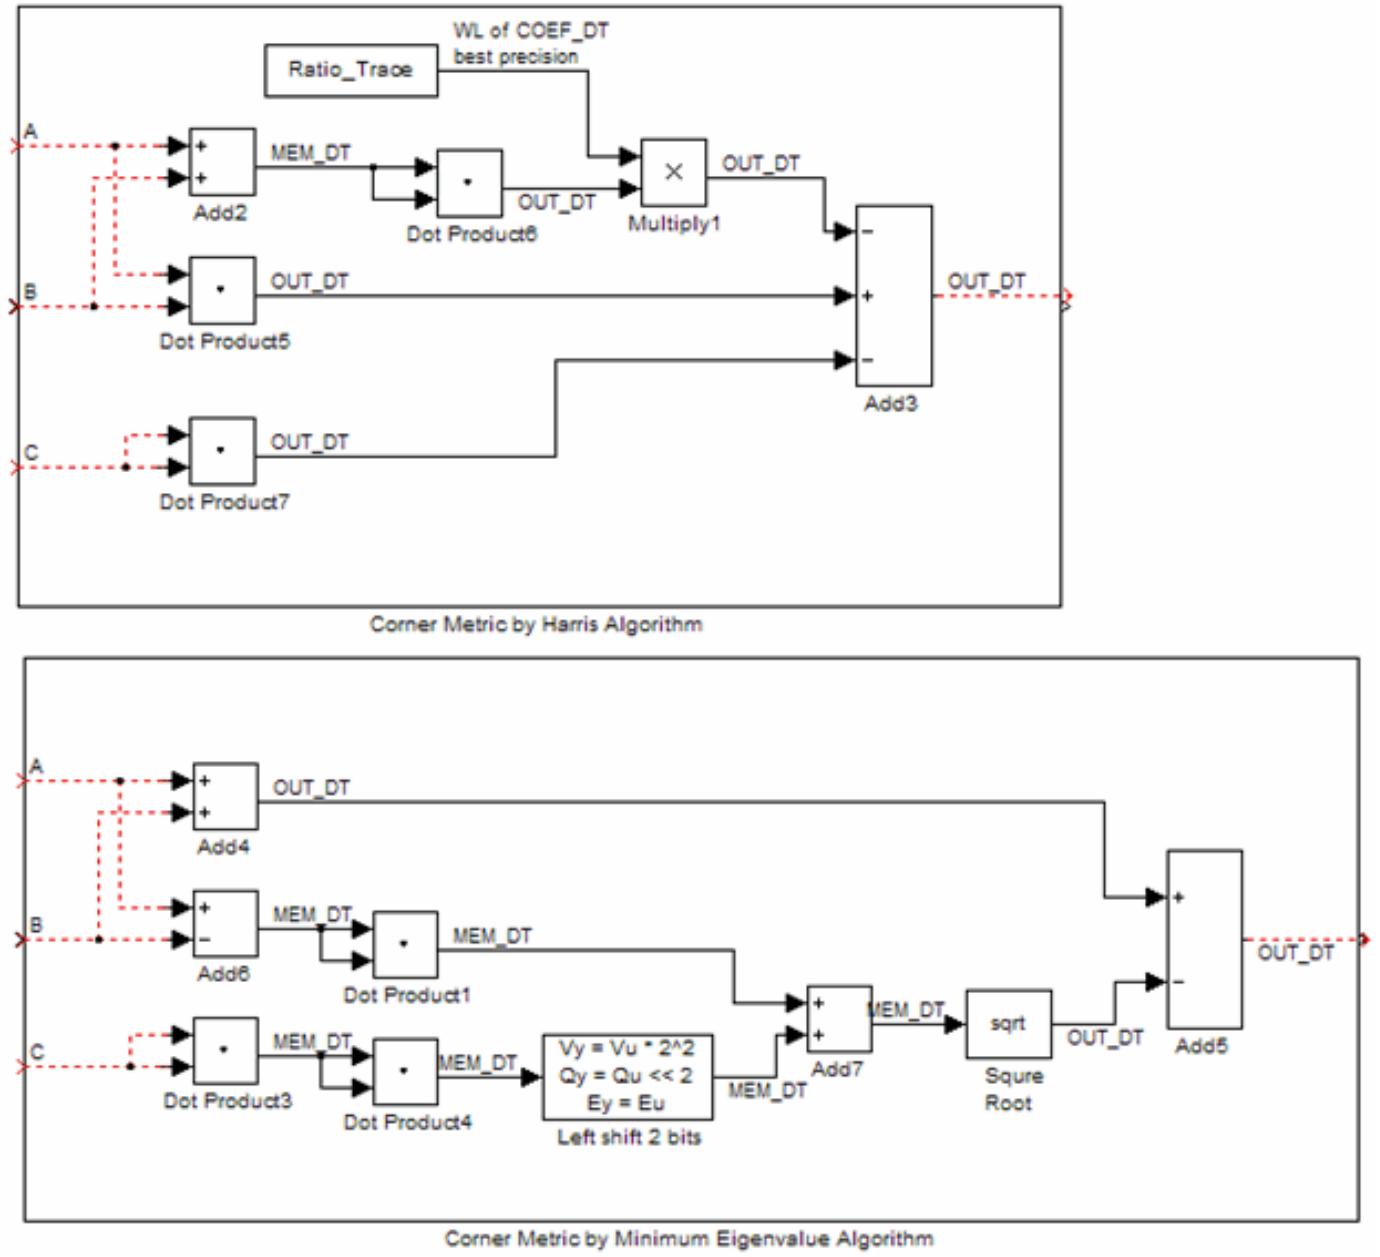
`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Block Characteristics



Data Types	`Boolean`[a] | `double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`



Variable-Size Signals	yes

a This data type is not supported for the Local Intensity Comparison method.

More About

These diagrams show the data types used in the Corner Detection block for fixed-point signals. These diagrams apply to the Harris corner detection and minimum eigenvalue methods only.

The following table summarizes the variables used in the previous diagrams.

Variable Name	Definition
IN_DT	Input data type
MEM_DT	Memory data type
OUT_DT	Metric output data type
COEF_DT	Coefficients data type

Algorithms

Determine final corner values

To determine the final corner values, the block follows this process:

1. Find the pixel with the largest corner metric value.
2. Verify that the metric value is greater than or equal to the value you specified for the **Minimum metric value that indicates a corner** parameter.
3. Suppress the region around the corner value by the size defined in the **Neighborhood size (suppress region around detected corners)** parameter.

The block repeats this process until it finds all the corners in the image or it finds the number of corners you specified in the **Maximum number of corners** parameter.

The corner metric values computed by the `Minimum eigenvalue` and `Local intensity comparison` methods are always nonnegative. The corner metric values computed by the `Harris corner detection` method can be negative.

Minimum Eigenvalue Method

The method is more computationally expensive than the Harris corner detection algorithm because it directly calculates the eigenvalues of the sum of the squared difference matrix, M.

The sum of the squared difference matrix, M, is defined as follows:

$$M = \begin{bmatrix} A & C \\ C & B \end{bmatrix}$$

The previous equation is based on the following values:

$$A = (I_x)^2 \otimes w$$

$$B = (I_y)^2 \otimes w$$

$$C = (I_x I_y)^2 \otimes w$$

where I_x and I_y are the gradients of the input image, I, in the x and y direction. The $\otimes$ symbol denotes a convolution operation.

Use the **Coefficients for separable smoothing filter** parameter to define a vector of filter coefficients. The block multiplies this vector of coefficients by its transpose to create a matrix of filter coefficients, w.

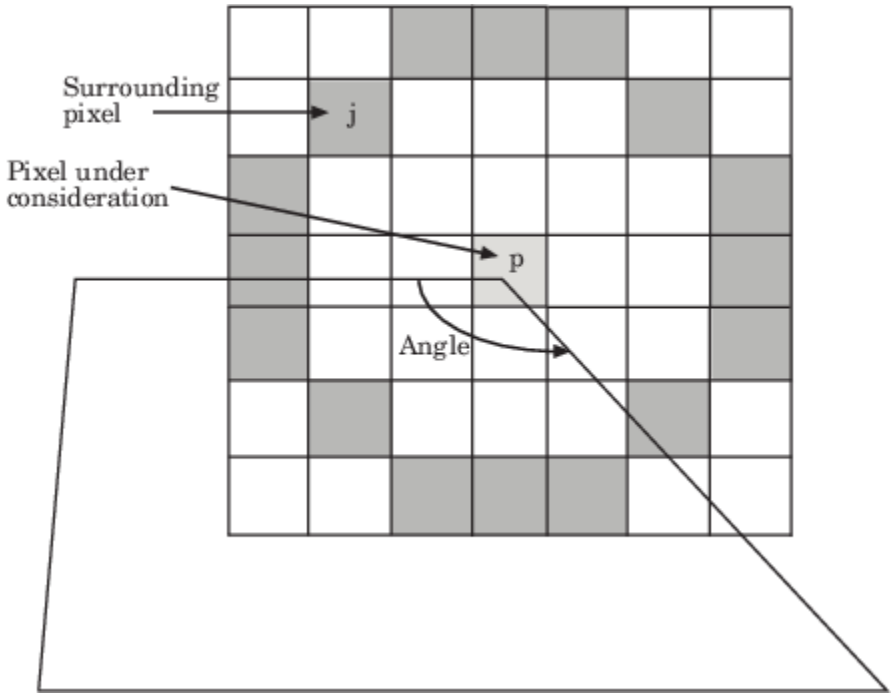
The block calculates the smaller eigenvalue of the sum of the squared difference matrix. This minimum eigenvalue corresponds to the corner metric matrix.

Harris Corner Method

The Harris corner detection method avoids the explicit computation of the eigenvalues of the sum of squared differences matrix by solving for the corner metric matrix, R:

$$R = AB - C^2 - k(A + B)^2$$

See the Minimum Eigenvalue Method section for the definitions of A, B, and C.



The variable *k* corresponds to the sensitivity factor. You can specify its value using the **Sensitivity factor (0<k<0.25)** parameter. As *k* decreases, the likelihood that the algorithm can detect sharp corners increases.

Use the **Coefficients for separable smoothing filter** parameter to define a vector of filter coefficients. The block multiplies this vector of coefficients by its transpose to create a matrix of filter coefficients, *w*.

Local Intensity Method

The method determines that a pixel is a possible corner if it has either, *N* contiguous valid bright surrounding pixels, or *N* contiguous dark surrounding pixels.

Suppose that *p* is the pixel under consideration and *j* is one of the pixels surrounding *p*. The locations of the other surrounding pixels are denoted by the shaded areas in the following figure. The shaded areas in this figure denote the locations of other surrounding pixels.

I_p and I_j are the intensities of pixels *p* and *j*, respectively. Pixel *j* is a valid bright surrounding pixel if $I_j - I_p \geq T$. Similarly, pixel *j* is a valid dark surrounding pixel if $I_p - I_j \geq T$. In these equations, *T* is the value you specified for the **Intensity comparison threshold** parameter.

The block repeats this process to determine whether the block has *N* contiguous valid surrounding pixels. The value of *N* is related to the value you specify for the **Maximum angle to be considered a corner (in degrees)** parameter, as shown in this table.

Number of Valid Surrounding Pixels and Angle

Number of Valid Surrounding Pixels	Angle (degrees)
15	22.5
14	45
13	67.5
12	90
11	112.5
10	135
9	157.5

After the block determines that a pixel is a possible corner, it computes its corner metric using the following equation:

$$R = \max\left(\sum_{j:I_j \geq I_p + T} \left|I_p - I_j\right| - T, \sum_{j:I_j \leq I_p - T} \left|I_p - I_j\right| - T\right)$$

Deinterlacing

Remove interlacing effect

Libraries:
Computer Vision Toolbox / Analysis & Enhancement

Description

The `Deinterlacing` block removes the motion artifact known as the interlacing effect from an interlaced image or a video. An interlaced image or video frame comprises of top field and bottom field that has slightly different capture times. The odd numbered lines in an interlaced image constitute the top field and the even numbered lines constitute the bottom field.

When you display an interlaced image, the temporal difference between the top and bottom fields causes a visible artifact where the alternate lines in the interlaced image appear displaced.

This artifact is known as the interlacing effect and can be corrected through deinterlacing techniques. You can use the `Deinterlacing` block to convert an interlaced video into a deinterlaced video by using one of these methods:

- Line repetition
- Linear interpolation
- Vertical temporal median filtering

You can use this block to deinterlace both intensity and color images.

Ports

Input

Port_1 — Interlaced input
numeric matrix | 3-D numeric array | image | video

Interlaced input, specified as a numeric matrix, 3-D numeric array, image, or video.

To input an interlaced image, read the image file by using the Image From File or Image From Workspace block. The image can also be a video frame. To input an interlaced video, read the video file by using the From Multimedia File or Video From Workspace block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Port_1 — Deinterlaced output
numeric matrix | 3-D numeric array | image | video

Deinterlaced output, returned as a numeric matrix, 3-D numeric array, image, or video. The output is of same size and datatype as that of the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Main Tab

Method — Deinterlacing method

`Line repetition` (default) | `Linear interpolation` | `Vertical temporal median filtering`

Use this parameter to specify the method for deinterlacing the input data.

- If you set the **Method** parameter value to `Line repetition`, the values in the bottom field of the interlaced image or video frame are replaced with the values in the preceding top field.

Line Repetition

Original Interlaced Video

	Top Field			Bottom Field			
Row 1	A	B	C	Row 1			
Row 2				Row 2	D	E	F
Row 3	G	H	I	Row 3			
Row 4				Row 4	J	K	L
Row 5	M	N	O	Row 5			
Row 6				Row 6	P	Q	R

	Block Input			Block Output - Deinterlaced Video			
Row 1	A	B	C	Row 1	A	B	C
Row 2	D	E	F	Row 2	A	B	C
Row 3	G	H	I	Row 3	G	H	I
Row 4	J	K	L	Row 4	G	H	I
Row 5	M	N	O	Row 5	M	N	O
Row 6	P	Q	R	Row 6	M	N	O

- If you set the **Method** parameter value to `Line interpolation`, the values in a bottom field are computed as the average of the values in the two neighboring top fields.

Linear Interpolation

Original Interlaced Video

Top Field				Bottom Field			
Row 1	A	B	C	Row 1			
Row 2				Row 2	D	E	F
Row 3	G	H	I	Row 3

Row 5	M	N	O	Row 5	M	N	O
Row 6	P	Q	R	Row 6	M	N	O

- If you set the **Method** parameter value to `Vertical temporal median filtering`, the values in a bottom field are computed as the median of the values in the bottom field and its two neighboring top fields.

Vertical Temporal Median Filtering

Original Interlaced Video

	Top Field				Bottom Field		
Row 1	A	B	C	Row 1			
Row 2				Row 2	D	E	F
Row 3	G	H	I	Row 3			
Row 4				Row 4	J	K	L
Row 5	M	N	O	Row 5			
Row 6				Row 6	P	Q	R

Block Input				Block Output - Deinterlaced Video			
Row 1	A	B	C	Row 1	A	B	C
Row 2	D	E	F	Row 2	median([A,D,G])	median([B,E,H])	median([C,F,I])
Row 3	G	H	I	Row 3	G	H	I
Row 4	J	K	L	Row 4	median([G,J,M])	median([H,K,N])	median([I,L,O])
Row 5	M	N	O	Row 5	M	N	O
Row 6	P	Q	R	Row 6	M	N	O

Input image is transposed (data order is row major) — Specify data order

off (default) | on

You can use this parameter to specify if the interlaced input is stored in row major order. When you select this parameter, the block assumes that the input buffer contains contiguous data elements of an array that are arranged sequentially row by row. Otherwise, the blocks assumes that the buffer stores data in the column major order such that the elements are arranged sequentially column by column.

Use this parameter only when

- You are developing algorithms to run on an embedded target that uses the row-major format.
- You want to limit the additional processing required to take the transpose of signals at the interfaces of the row-major and column-major systems.

When you select this check box, the first two dimensions of the Deinterlacing block's input are swapped.

Data Types Tab

To enable options on the **Data Types** tab, set the **Method** parameter in the **Main** tab to `Linear interpolation`.

Fixed-point operational parameters

Rounding mode — Rounding mode for calculating fixed-point value

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specifies the rounding mode for the block to use when the specified data type and scaling cannot exactly represent the result of a fixed-point calculation.

See “Rounding Modes” for more information on the available options.

Saturate on integer overflow — Specify overflow mode
on (default) | off

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation.

For details on saturate and wrap, see “Overflow Handling” for fixed-point operations.

Fixed-point data types

Accumulator — Accumulator data type

`Binary point scaling` (default) | `Same as input`

Use this parameter to specify the data type and scaling of the accumulator (sum).

- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits. The default value for word length is set to 12 and fraction length is set to 3. The data type format is same as that of the input data format, signed or unsigned.
- When you select `Same as input`, the word length and the fractional length of the accumulator match those of the input.

Output — Data type for output
`Same as input` (default) | `Binary point scaling`

Use this parameter to specify the data type and scaling of the output data.

- When you select `Same as input`, the word length and the fractional length of the accumulator match those of the input.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits. The default value for word length is set to 8 and fraction length is set to 0. The data type format is same as that of the input data type format, signed or unsigned.

Lock data type settings against change by the fixed-point tools — Data type override
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask. For more information, see `fxptdlg`, a reference page on the Fixed-Point Tool.

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`

Demosaic

Demosaic Bayer format images

Libraries:
Computer Vision Toolbox / Conversions

Description

The Demosaic block takes images in Bayer format and outputs RGB images. The block performs this operation using a gradient-corrected linear interpolation algorithm or a bilinear interpolation algorithm. This figure illustrates a 4-by-4 image in Bayer format with each pixel labeled R, G, or B.

B	G	B	G
G	R	G	R
B	G	B	G
G	R	G	R

Ports

Input

I — Image to demosaic
matrix

Image to demosaic, specified as a 2-D numeric matrix. The size requirements for the matrix depend on the value of the **Interpolation algorithm** parameter.

- If the value of **Interpolation algorithm** is `Bilinear`, the matrix must have three or more rows and three or more columns.
- If the value of **Interpolation algorithm** is `Gradient-corrected linear`, the matrix must have five or more rows and five or more columns.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

R — Red color channel of processed image
matrix

Red color channel of processed image, returned as a 2-D numeric matrix of the same size and data type as **I**.

Dependencies

To enable this port, set the **Output image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

G — Green color channel of processed image
matrix

Green color channel of processed image, returned as a 2-D numeric matrix of the same size and data type as **I**.

Dependencies

To enable this port, set the **Output image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

B — Blue color channel of processed image
matrix

Blue color channel of processed image, returned as a 2-D numeric matrix of the same size and data type as **I**.

Dependencies

To enable this port, set the **Output image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Image — Multidimensional processed image
matrix

Multidimensional processed image, returned as a 3-D numeric matrix of the same data type as **I**. If the input image **I** has the dimensions *M*-by-*N*, then **Image** has the dimensions *M*-by-*N*-by-*P*, where *P* is the number of color channels.

Dependencies

To enable this port, specify the **Output image signal** parameter as `One multidimensional signal`.

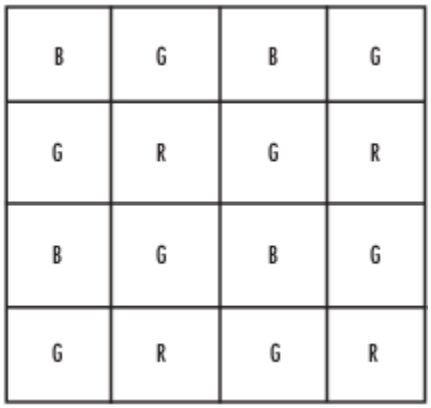
Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Main

Interpolation algorithm — Interpolation algorithm

`Bilinear` (default) | `Gradient-corrected linear`



Specify the algorithm the block uses to calculate the missing color information. If you select `Bilinear`, the block spatially averages the values of the neighboring pixels of a missing color value to calculate its color information.

If you select `Gradient-corrected linear`, the block uses a Weiner approach to minimize the mean-squared error in the interpolation. This method performs well on the edges of objects in the image. Both methods use symmetric padding at the image boundaries. For more information, see the Image Pad block reference page.

Sensor alignment — R,G,B pixel alignment

`RGGB` (default) | `GRBG` | `GBRG` | `BGGR`

Specify the alignment of the input image. Select the sequence of R, G, and B pixels that correspond to the 2-by-2 block of pixels in the top-left corner of the image. Specify the sequence in left-to-right, top-to-bottom order. For example, for this image, you would select `BGGR`.

Output image signal — Dimensions of output image

`One multidimensional signal` (default) | `Separate color signals`

Specify how to output the RGB image. Given an *M*-by-*N* input image, this parameter affects the output of this block in these ways.

- `One multidimensional image` — The block has a single port, Image, that outputs an *M*-by-*N*-by-*P* RGB image, where *P* is the number of color channels.
- `Separate color signals` — The block has three ports, R, G, and B, that each output one *M*-by-*N* color channel of the RGB image.

Data Types

For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Lock data type settings against change by the fixed-point tools — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`

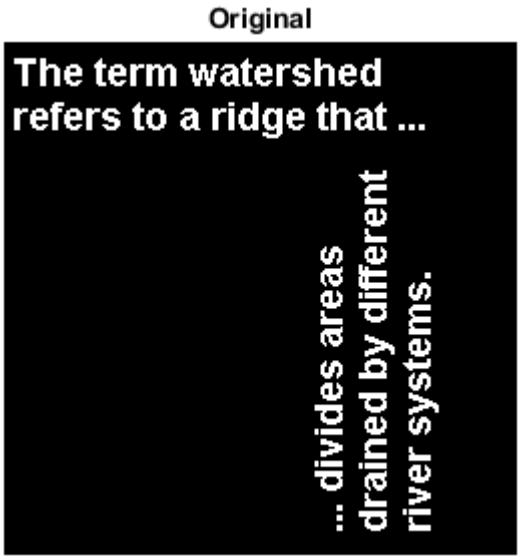
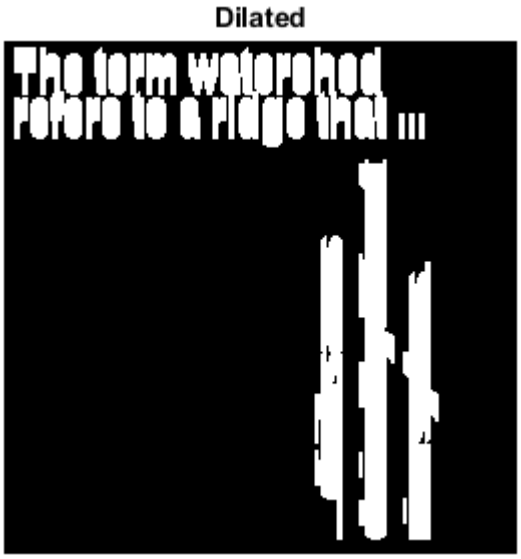
Dilation

Dilate binary or intensity image by finding local maxima





Libraries:
Computer Vision Toolbox / Morphological Operations

Description

The Dilation block performs morphological dilation on an intensity or binary image and outputs the dilated image.

To define the structuring element that the block applies to the image, use the **Neighborhood or structuring element** parameter.

This block uses two-dimensional flat structuring elements only.

Ports

Input

I — Input image
matrix

Specify an input image as a matrix of intensity values. This port is unnamed unless you set the **Neighborhood or structuring element source** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Nhood — Neighborhood values
vector | matrix

Specify neighborhood values representing a structuring element as a vector or matrix of `1`s and `0`s or by using the `strel` function.

Dependencies

To enable this port, set the **Neighborhood or structuring element source** parameter to `Input port`.

Data Types: `Boolean`

Output

Port_1 — Dilated image
matrix

The block returns the dilated image as a matrix of intensity values. The size and data type of the output image are the same as those of the input image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Neighborhood or structuring element source — Source of neighborhood or structuring element

`Specify via dialog` (default) | `Input port`

Specify the source of the neighborhood or structuring element as one of these options:

- `Specify via dialog` — Use the **Neighborhood or structuring element** parameter to specify a neighborhood or structuring element.
- `Input port` — Use the **Nhood** input port to specify neighborhood values representing a structuring element.

Neighborhood or structuring element — Neighborhood or structuring element

`[1 1; 1 1]` (default) | vector | matrix

Specify a neighborhood or structuring element as a vector or matrix of `1`s and `0`s, a `strel` object, or an array of `strel` objects. When you specify an array of `strel` objects, the block applies each object to the entire image sequentially.

If the structuring element is decomposable into smaller elements, the block uses a more efficient algorithm that can execute more quickly.

Dependencies

To enable this parameter, set the **Neighborhood or structuring element source** parameter, to `Specify via dialog`.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

More About

Dilation and Structuring Element

Performing dilation on an image includes:

- Increasing the size of the object by expanding the image pixels and adding pixels to the boundary of the object.
- Filling small holes and broken areas
- Connecting areas separated by a space smaller than the structuring element

The direction and extent of the growth of an object in an image depends on the shape of the structuring element. Each structuring element has an origin.

- If the structuring element is symmetrical, the origin coincides with its centroid.
- If the structuring element is asymmetrical, the pixel in the structuring element that is close to its centroid and is in the top-left direction is considered as the origin.

The Dilation block rotates the structuring element about this origin and places the origin over each pixel of the image object. The block creates the dilated image from the local maxima values at each pixel.

Binary Dilation

The binary dilation of A by B, denoted as $A \oplus B$, is defined as the set operation:

$$A \oplus B = \left\{ z \middle| \left(\widehat{B} \right)_z \cap A \neq \varnothing \right\},$$

where $\widehat{B}$ is the reflection of the structuring element B. Note that some applications use a definition of dilation in which the structuring element is not reflected.

Grayscale Dilation

In the general form of grayscale dilation, the structuring element has a specified height. The grayscale dilation of $A(x, y)$ by $B(x, y)$ is defined as:

$$(A \oplus B)(x, y) = \max\{A(x - x', y - y') + B(x', y') | (x', y') \in D_B\},$$

where D_B is the domain of the structuring element B and $A(x, y)$ is assumed to be $-\infty$ outside the domain of the image. To create a structuring element with nonzero height values, use the syntax `strel(nhood,height)`, where `height` specifies the height values and `nhood` corresponds to the structuring element domain D_B.

Grayscale dilation is often performed with a flat structuring element ($B(x,y) = 0$). Grayscale dilation using such a structuring element is equivalent to a local-maximum operator:

$$(A \oplus B)(x, y) = \max\{A(x - x', y - y') | (x', y') \in D_B\}.$$

All of the `strel` syntaxes except for `strel(nhood,height)`, `strel("arbitrary",nhood,height)`, and `strel("ball",...)` produce flat structuring elements.

Draw Markers

Draw markers on image

Libraries:
Computer Vision Toolbox / Text & Graphics

Description

The Draw Markers block draws markers on an image or video frame by overwriting pixel values in the input image. This embeds the markers in the output image. The block supports five types of markers: `Circle`, `X-mark`, `Plus`, `Star`, and `Square`.

The block uses Bresenham's circle drawing algorithm to draw circles and Bresenham's line drawing algorithm to draw all other markers.

Ports

Input

Image — Input Image
matrix | array

Specify the input image as either an *M*-by-*N* matrix of intensity values or an *M*-by-*N*-by-*P* array of color values with *P* color planes.

Dependencies

To enable this port, set the **Image signal** parameter to `One multidimensional signal`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

R — Red color component of image
matrix

Specify the red color component of the input RGB image as an *M*-by-*N* matrix. The **R**, **G**, and **B** ports must have the same dimensions and data type.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

G — Green color component of image
matrix

Specify the green color component of the input RGB image as an *M*-by-*N* matrix. The **R**, **G**, and **B** ports must have the same dimensions and data type.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

B — Blue color component of image
matrix

Specify the blue color component of the input RGB image as an *M*-by-*N* matrix. The **R**, **G**, and **B** ports must have the same dimensions and data type.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Pts — Marker coordinates
vector | matrix

Specify the coordinates of markers as one of these options:

- Single marker — Two-element vector that specifies the *x*- and *y*- coordinates for the center of the marker.
- Multiple markers — *K*-by-2 matrix. *K* is the number of markers. Each row of the matrix specifies the *x*- and *y*- coordinates for the center of a marker.

Note The block does not support single-precision or double-precision floating-point data types for this parameter unless the input image is also floating point.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Clr — Marker color
scalar | vector | matrix

Specify the color values for the markers. Use this table to determine the type of value to input at this port.

Type of Input Image	Same Color for All Markers	Different Color for Each Marker
Intensity image	scalar value	*K*-element vector. *K* is the number of markers.
Color image	*P*-element vector. *P* is the number of color planes.	*K*-by-*P* matrix. *P* is the number of color planes and *K* is the number of markers.

Dependencies

To enable this port, use one of these options:

- The **Marker shape** parameter is set to `X-mark`, `Plus`, or `Star`, or the **Filled** parameter is cleared — Set the **Border color source** parameter to `Input port`.
- The **Marker shape** parameter is set to `Circle` or `Square` and the **Filled** parameter is selected — Set the **Fill color source** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

ROI — Region of interest
vector

Specify a rectangular region of interest (ROI) as a four-element vector of form [*x y width height*]. The *x* and *y* elements are the coordinates of the top-left corner of the ROI.

Dependencies

To enable this port, set the **Draw markers in** parameter to `Specify region of interest via port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Output

Port_1 — Output image
matrix | array

Output image, returned as an *M*-by-*N* matrix of intensity values or an *M*-by-*N*-by-*P* array of color values. *P* is the number of color planes in the output image. The output image has the same size and data type as the input image.

Dependencies

To enable this port, set the **Image signal** parameter to `One multidimensional signal`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

R — Red color component of output image
matrix

Red color component of the output RGB image, returned as an *M*-by-*N* matrix. The red color component of the output image has the same dimensions and data type as the red color component of the input image.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

G — Green color component of output image
matrix

Green color component of the output RGB image, returned as an *M*-by-*N* matrix. The green color component of the output image has the same dimensions and data type as the green color component of the input image.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

B — Blue color component of output image
matrix

Blue color component of the output RGB image, returned as an *M*-by-*N* matrix. The blue color component of the output image has the same dimensions and data type as the blue color component of the input image.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Main

Marker shape — Shape of marker

`Circle` (default) | `X-mark` | `Plus` | `Star` | `Square`

Specify the shape of the marker to draw. You can render the `Circle` and`Square` markers as outlines or as filled shapes.

Marker size — Size of marker

3 (default) | positive integer

Specify the size of the marker as a positive integer, *M*, that defines a square area, with sides of length 2*M*+1, into which the marker fits.

Filled — Filled marker

`off` (default) | `on`

Select this parameter to fill the marker with the specified intensity value or color.

Dependencies

To enable this parameter, set the **Marker shape** parameter to `Circle` or `Square`.

Border color source — Color source of marker border
`Specify via dialog` (default) | `Input port`

Specify the source of the color for the border of the marker as one of these options:

- `Specify via dialog` — Use the **Border color** parameter to specify a color for the border of the marker.
- `Input port` — Use the **Clr** input port to specify a color for the border of the marker.

Dependencies

To enable this parameter, clear the **Filled** parameter or set the **Marker shape** parameter to `X-mark`, `Plus`, or `Star`.

Border color — Color value of marker
`Black` (default) | `White` | `User-specified value`

Specify the color value for the border of the marker as `Black`, `White`, or `User-specified value`.

Dependencies

To enable this parameter, clear the **Filled** parameter and set the **Border color source** parameter to `Specify via dialog`.

Fill color source — Color source of filled marker
`Specify via dialog` (default) | `Input port`

Specify the source of the color with which to fill the marker as one of these options:

- `Specify via dialog` — Use the **Fill color** parameter to specify a color with which to fill the marker.
- `Input port` — Use the **Clr** input port to specify a color with which to fill the marker.

Dependencies

To enable this parameter, set the **Marker shape** parameter to `Circle` or `Square` and select the **Filled** parameter.

Fill color — Color value of filled marker
`Black` (default) | `White` | `User-specified value`

Specify the color value with which to fill the marker as `Black`, `White`, or `User-specified value`.

Dependencies

To enable this parameter, set the **Marker shape** parameter to `Circle` or `Square`, select the **Filled** parameter, and set the **Fill color source** parameter to `Specify via dialog`.

Opacity factor (between 0 and 1) — Opacity factor

`0.6` (default) | scalar in range [`0`, `1`] | *K*-element vector

Specify the opacity factor for the marker in the range [`0`, `1`], where `0` is completely transparent and `1` is completely opaque. Specify this parameter as one of these options:

- Scalar — Apply the specified opacity factor to all markers.
- *K*-element Vector — Apply a different opacity factor to each marker. *K* is the number of markers.

Dependencies

To enable this parameter, set the **Marker shape** parameter to `Circle` or `Square` and select the **Filled** parameter.

Color value(s) — User-specified color values

`[200 255 100]` (default) | scalar | *P*-element vector | *K*-by-*P* matrix

Specify the color values for the markers. Use this table to determine the type of value to enter for this parameter.

Type of Input Image	Same Color for All Markers	Different Color for Each Marker
Intensity image	scalar value	*K*-element vector. *K* is the number of markers.
Color image	*P*-element vector. *P* is the number of color planes.	*K*-by-*P* matrix. *P* is the number of color planes and *K* is the number of markers.

Dependencies

To enable this parameter, use one of these options:

- The **Marker shape** parameter is set to `X-mark`, `Plus`, or `Star`, or the **Filled** parameter is cleared — Set the **Border color source** parameter to `Specify via dialog` and the **Border color** parameter to `User-specified value`.
- The **Marker shape** parameter is set to `Circle` or `Square` and the **Filled** parameter is selected — Set the **Fill color source** parameter to `Specify via dialog` and the **Fill color** parameter to `User-specified value`.

Draw Markers in — Area for markers

`Entire image` (default) | `Specify region of interest via port`

Specify where to draw the markers. By default, you can draw markers in the entire image. To specify markers within a rectangular ROI, set this parameter to `Specify region of interest via port`, and specify a four-element vector of the form [*x y width height*] to the **ROI** input port.

Use antialiasing — Smoothing algorithm

`off` (default) | `on`

Select this parameter to perform a smoothing algorithm on the `Circle`, `X-mark`, or `Star` marker shapes.

Dependencies

To enable this parameter, set the **Marker shape** parameter to `Circle`, `X-mark`, or `Star`.

Image signal — Port configuration for RGB image

`One multidimensional signal` (default) | `Separate color signals`

Specify how to input and output an RGB color image.

- `One multidimensional signal` — The block accepts input using only the **Image** port and returns the output using only the **Port_1** port.
- `Separate color signals` — The block accepts and returns the color image using three separate color channels, divided across the **R**, **G**, and **B** input and output ports.

Data Types

For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Block Characteristics

Draw Shapes

Draw rectangles, lines, polygons, or circles on images

Libraries:
Computer Vision Toolbox / Text & Graphics

Description

The Draw Shapes block draws rectangles, lines, polygons, or circles on images by overwriting the pixel values. As a result, the shapes are drawn on the output image. The block uses Bresenham's line drawing algorithm to draw lines, polygons, and rectangles and Bresenham's circle drawing algorithm to draw circles. The output signal is of the same size and data type as the input signal fed to the **Image**, **R**, **G**, and **B** ports.

You can set the shape fill or border color via the input port or by manually entering the values using the parameters. Use the color parameters to specify the appearance of the rectangles, lines, polygons, or circles.

Ports

Input

Image — Input image or video stream
M-by-*N* matrix of intensity values | *M*-by-*N*-by-*3* array of color values

Input image, specified as either an *M*-by-*N* matrix of intensity values or an *M*-by-*N*-by-*3* matrix of color values with *3* color planes.

When the input is a video stream, the block processes it frame by frame.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

R — Red color channel of the image or video frame
M-by-*N* matrix

Red color channel of the image or video frame, specified as an *M*-by-*N* matrix. The **R**, **G**, and **B** ports must have the same dimensions and data type.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

G — Green color channel of the image or video frame
M-by-*N* matrix

Green color channel of the input image or video frame, specified as an *M*-by-*N* matrix. The **R**, **G**, and **B** ports must have the same dimensions and data type.

Dependencies

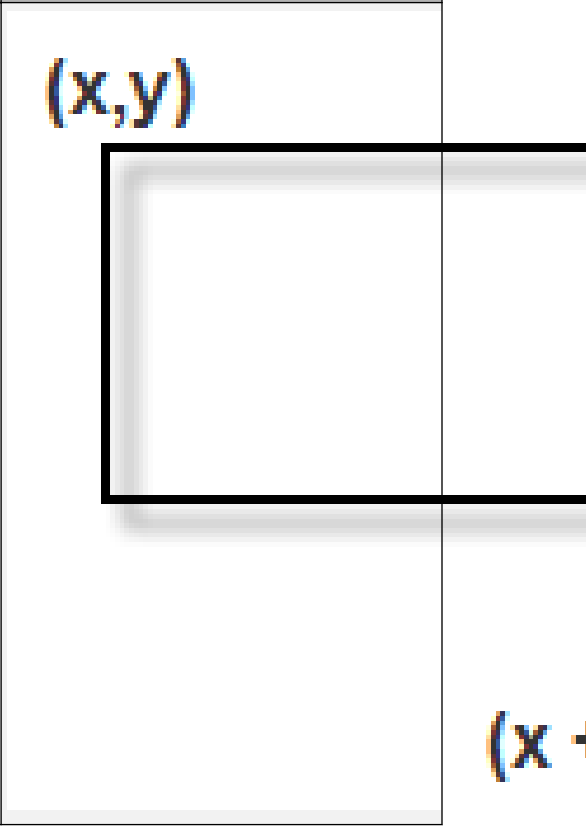
To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

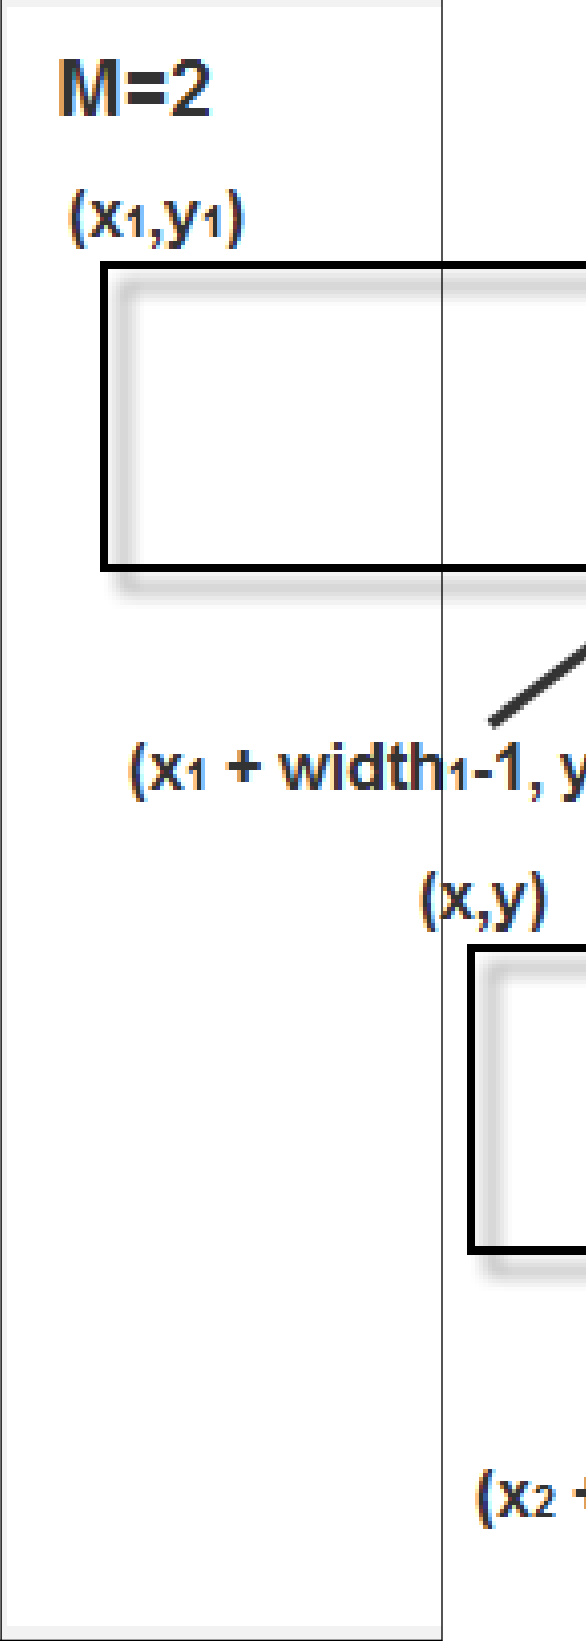
B — Blue color channel of the image or video frame
M-by-*N* matrix

Blue color channel of the input image or video frame, specified as an *M*-by-*N* matrix. The **R**, **G**, and **B** ports must have the same dimensions and data type.

Dependencies

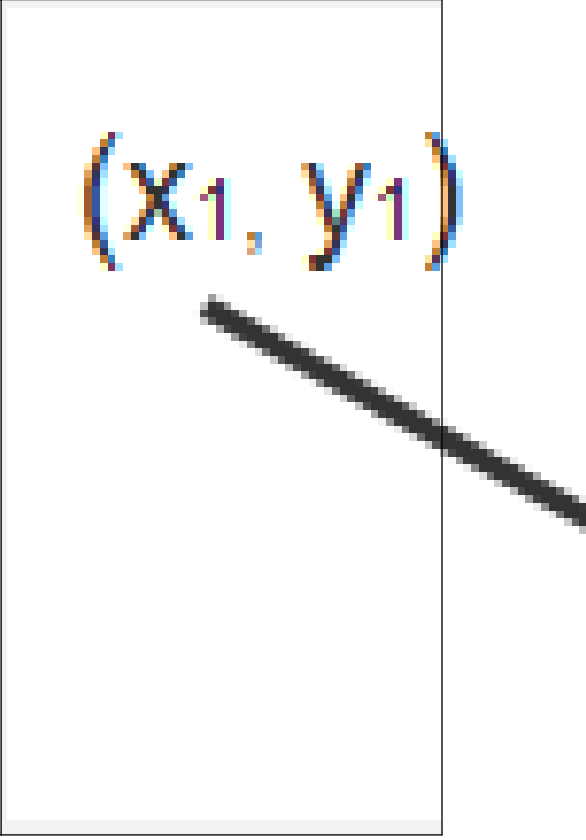


To enable this port, set the **Image signal** parameter to `Separate color signals`.

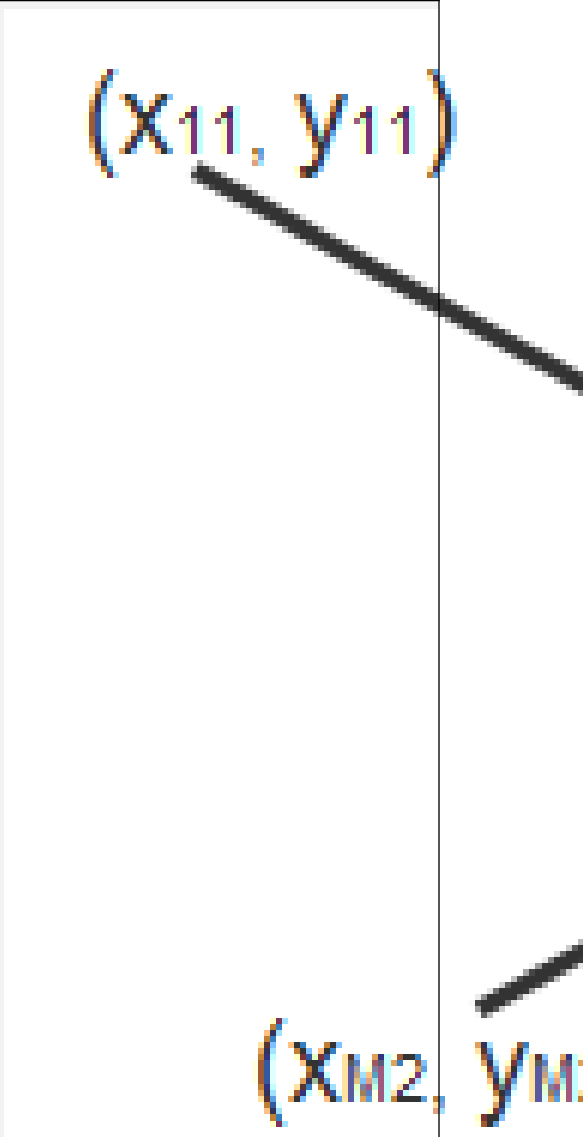


Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

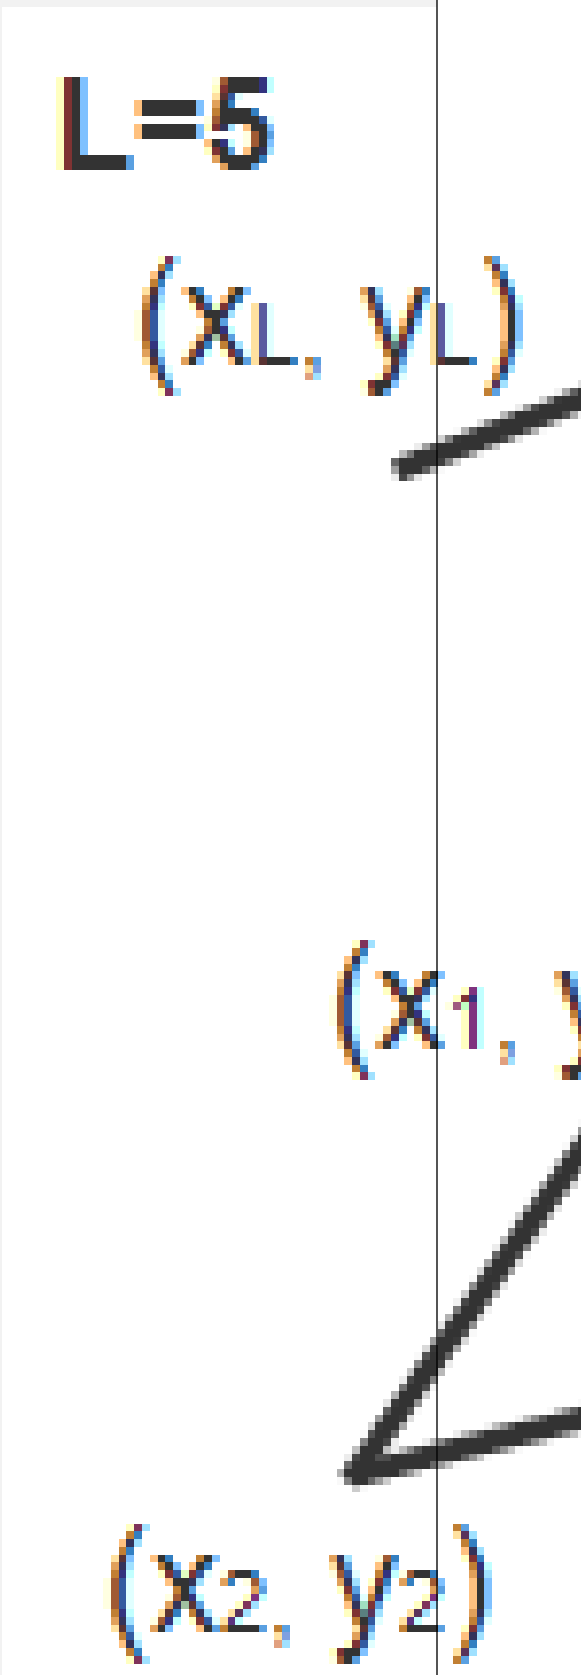
Pts — Shape coordinates
M-by-3 matrix | *M*-by-4 matrix | *M*-by-2*L* matrix



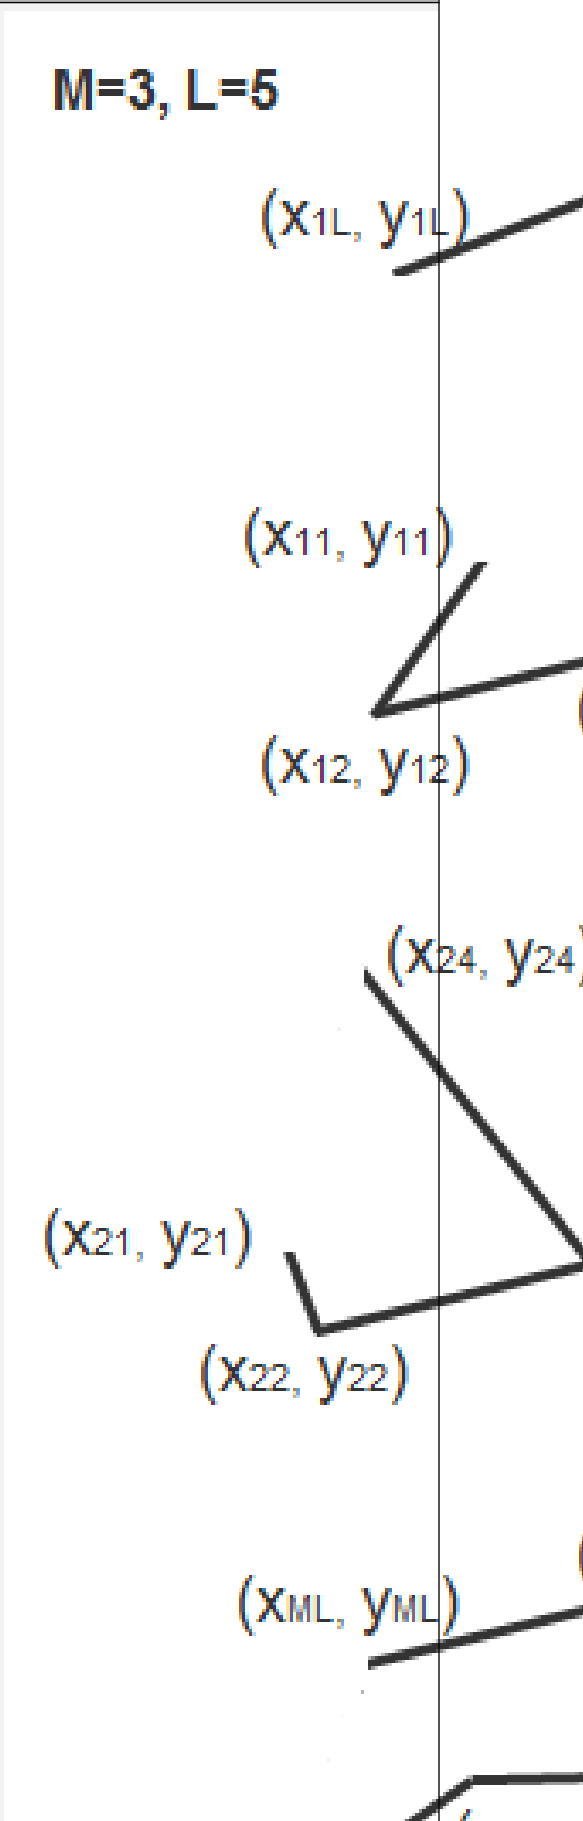
Coordinates of the input shapes to be drawn on the input. The format of the points depends on the type of shape you specify with the **Shape** parameter.



- `Rectangles` — *M*-by-4 matrix of the form [*x y width height*]. *M* is the number of rectangles.

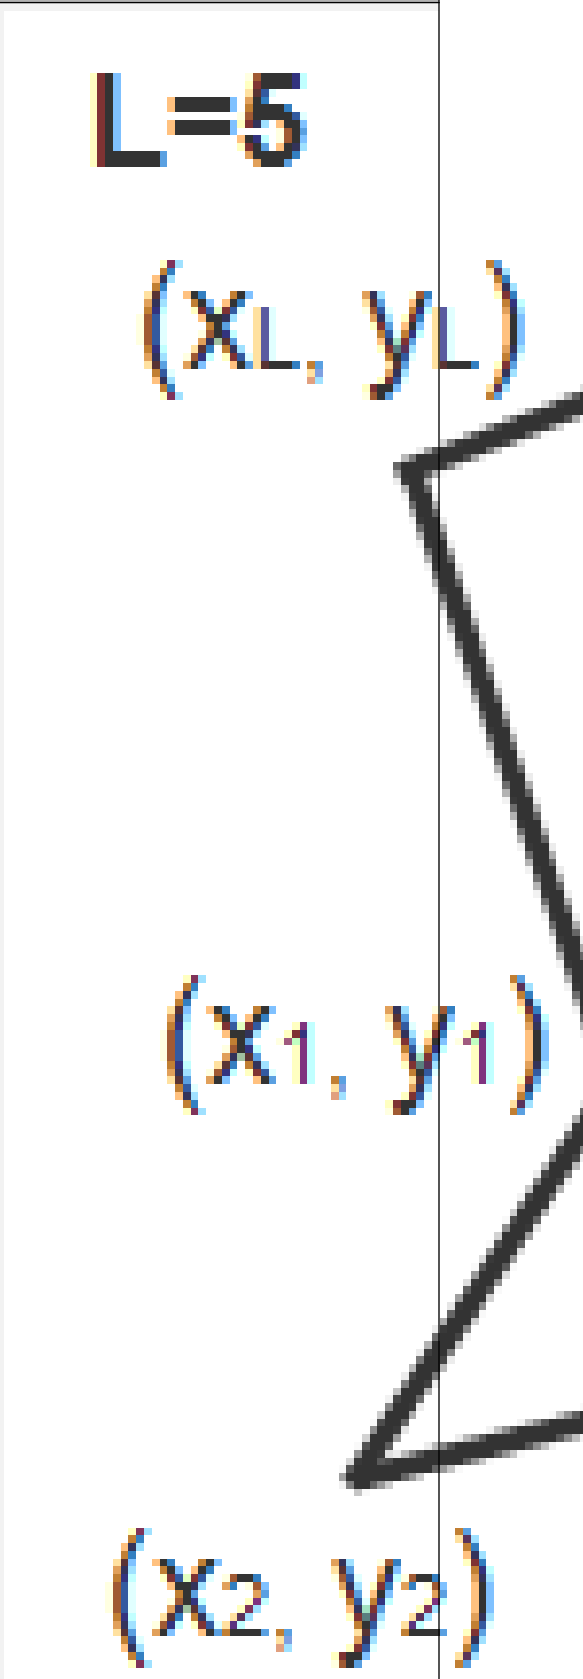


Shape	Input to the Pts Port	Drawn Shape
Single Rectangle	Four-element row vector in the format `[x y width height]`, where: • `x` and `y` are the coordinates of the upper-left corner of the rectangle. • `width` and `height` parameters are the width and height of the rectangle, in pixels. The values of `width` and `height` must be greater than 0.	

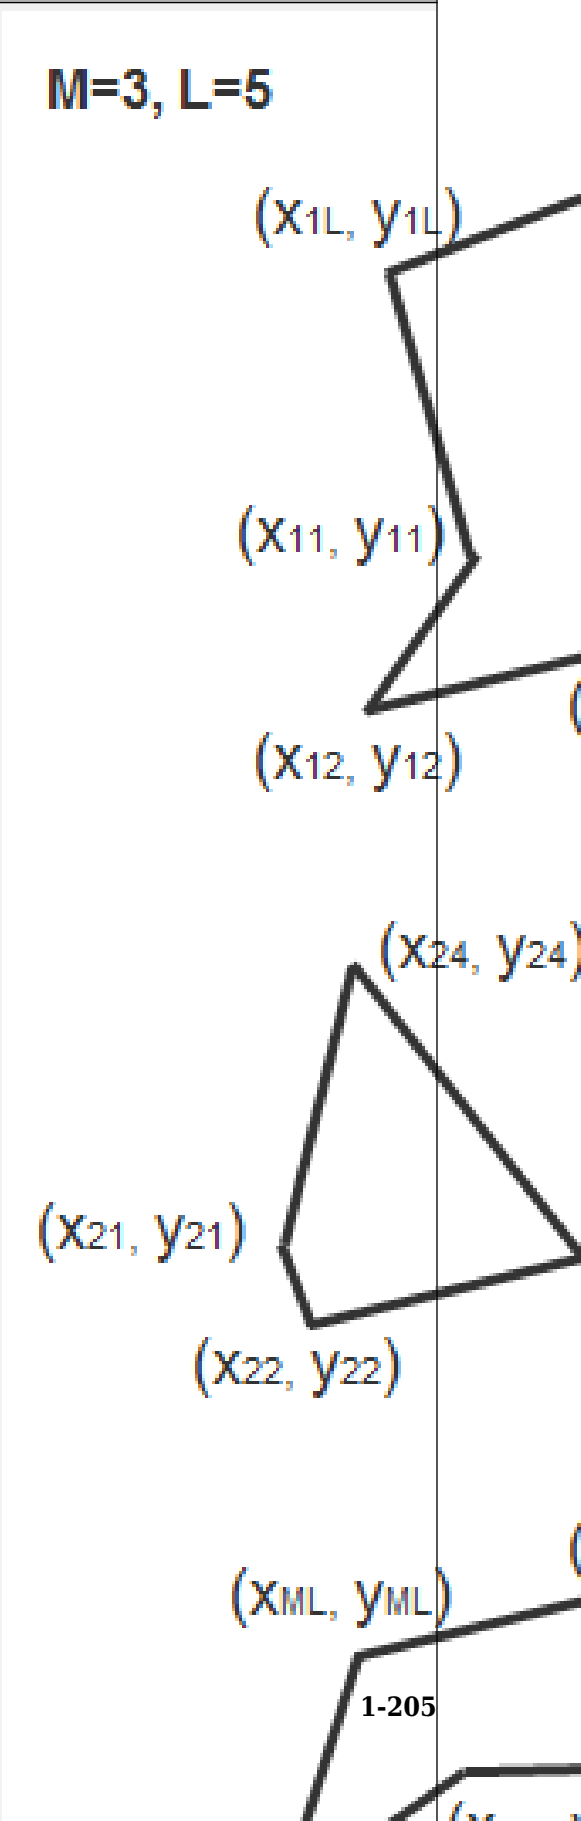


Shape	Input to the Pts Port	Drawn Shape
M Rectangles	*M*-by-4 matrix in the format $\begin{bmatrix} x_1 & y_1 & width_1 & height_1 \\ x_2 & y_2 & width_2 & height_2 \\ \vdots & \vdots & \vdots & \vdots \\ x_M & y_M & width_M & height_M \end{bmatrix}$,where each row of the matrix corresponds to a different rectangle and is of the same form as the vector for a single rectangle.	

- `Lines` — M-by-$2L$ matrix of the form $[x_1, y_1, x_2, y_2,\ldots,x_L, y_L]$. M is the number of polylines.

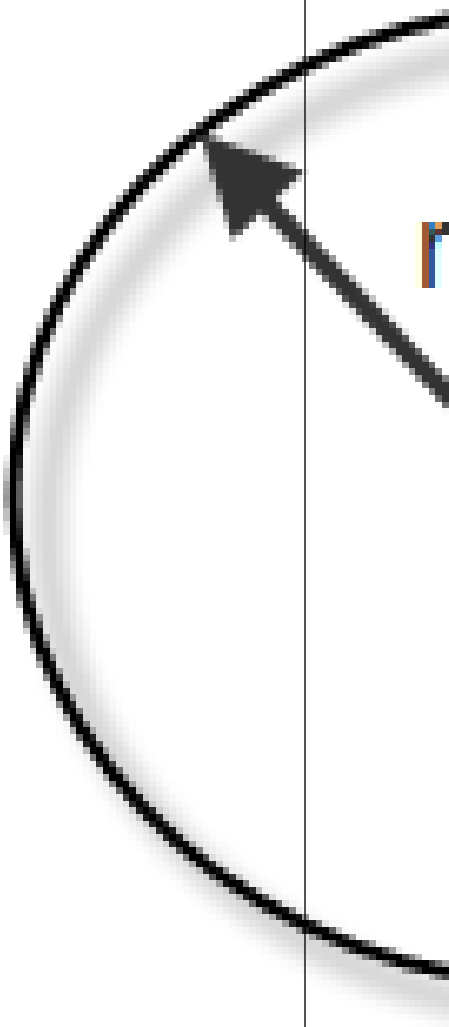


Shape	Input to the Pts Port	Drawn Shape
Single Line	Four-element row vector in the format `[x1 y1 x2 y2]`, where: • x_1 and y_1 are the coordinates of the beginning of the line. • x_2 and y_2 are the coordinates of the end of the line.	



Shape	Input to the Pts Port	Drawn Shape
M Lines	*M*-by-4 matrix in the format $\begin{bmatrix} x_{11} & y_{11} & x_{12} & y_{12} \\ x_{21} & y_{21} & x_{22} & y_{22} \\ \vdots & \vdots & \vdots & \vdots \\ x_{M1} & y_{M1} & x_{M2} & y_{M2} \end{bmatrix}$,where each row of the matrix corresponds to a different line and is of the same form as the vector for a single line.	

Shape	Input to the Pts Port	Drawn Shape
Single Polyline with (L-1) Segments	Vector of size $2L$, where L is the number of vertices, in the format, `[`x_1`, `y_1`, `x_2`, `y_2`, ..., `x_L`, `y_L`]`, where • x_1 and y_1 are the coordinates of the beginning of the first line segment. • x_2 and y_2 are the coordinates of the end of the first line segment and the beginning of the second line segment. • x_L and y_L are the coordinates of the end of the $(L\text{-}1)^{th}$ line segment. The polyline always contains (L-1) number of segments because the first and last vertex points do not connect. The block produces an error message when the number of columns is less than two or not a multiple of two.	



Shape	Input to the Pts Port	Drawn Shape
M Polylines with (*L*-1) Segments	*M*-by-*2L* matrix in the format $\begin{bmatrix} x_{11} & y_{11} & x_{12} & y_{12} & \cdots & x_{1L} & y_{1L} \\ x_{21} & y_{21} & x_{22} & y_{22} & \cdots & x_{2L} & y_{2L} \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ x_{M1} & y_{M1} & x_{M2} & y_{M2} & \cdots & x_{ML} & y_{ML} \end{bmatrix}$, where each row of the matrix corresponds to a different polyline and is of the same form as the vector for a single polyline. When one of the polylines contains less than (*L*–1) number of segments, fill the matrix by repeating the coordinates of the last vertex. The block produces an error message if the number of columns is less than two or not a multiple of two.	

- `Polygons` — M-by-$2L$ matrix of the form $[x_1, y_1, x_2, y_2,...,x_L, y_L]$. M is the number of polygons. The points are specified in consecutive order to form a polygon.

Shape	Input to the Pts Port	Drawn Shape
Single Polygon with L line segments	Row vector of size $2L$, where L is the number of vertices, in the format `[x1 y1 x2 y2 ... xL yL]`, where: • x_1 and y_1 are the coordinates of the beginning of the first line segment. • x_2 and y_2 are the coordinates of the end of the first line segment and the beginning of the second line segment. • x_L and y_L are the coordinates of the end of the $(L\text{-}1)^{th}$ line segment and the beginning of the L^{th} line segment. The block connects `[x1 y1]` to `[xL yL]` to complete the polygon. The block produces an error if the number of columns is less than two or not a multiple of two.	

Shape	Input to the Pts Port	Drawn Shape
M Polygons with the largest number of line segments in any line being *L*	*M*-by-2*L* matrix in the format $\begin{bmatrix} x_{11} & y_{11} & x_{12} & y_{12} & \cdots & x_{1L} & y_{1L} \\ x_{21} & y_{21} & x_{22} & y_{22} & \cdots & x_{2L} & y_{2L} \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ x_{M1} & y_{M1} & x_{M2} & y_{M2} & \cdots & x_{ML} & y_{ML} \end{bmatrix}$, where each row of the matrix corresponds to a different polygon and is of the same form as the vector for a single polygon. When one of the polygons contains less than *L* number of segments, fill the matrix by repeating the coordinates of the last vertex. The block produces an error message if the number of columns is less than two or not a multiple of two.	

- `Circles` — *M*-by-3 matrix of the form [*x y radius*]. *M* is the number of circles.

Shape	Input to the Pts Port	Drawn Shape
Single Circle	Three-element row vector in the format `[x y radius]`, where: • `x` and `y` are coordinates for the center of the circle. • `radius` is the radius of the circle, which must be greater than 0.	

Shape	Input to the Pts Port	Drawn Shape
M Circles	*M-by-3* matrix in the format $\begin{bmatrix} xctr_1 & yctr_1 & radius_1 \\ xctr_2 & yctr_2 & radius_2 \\ \vdots & \vdots & \vdots \\ xctr_M & yctr_M & radius_M \end{bmatrix}$, where each row of the matrix corresponds to a different circle and is of the same form as the vector for a single circle.	

Dependencies

- Double-precision floating point is only supported if the input to the **Image** or **R**, **G**, and **B** ports is floating point.
- Single-precision floating point is only supported if the input to the **Image** or **R**, **G**, and **B** ports is floating point.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

ROI — Region of interest
4-element vector

Region of interest, specified as a four-element vector of the form [*x y width height*]. The region defines a rectangular area to draw shapes. The first two elements represent the one-based coordinates of the upper-left corner of the area. The remaining two elements represent the width and height of the area.

Dependencies

To enable this port, set the **Draw shapes in** parameter to `Specify region of interest via port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Clr — Color of shape
3-element vector | *M*-by-*3* matrix

Color of the shape, specified as either a *3*-element vector or an *M*-by-*3* matrix. *M* is the number of shapes and three denotes the number of color planes. You can specify different color for each of the *M* shapes, or specify one color for all shapes.

Dependencies

To enable this port, set the **Border color source** or **Fill color source** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Output

Port_1 — Output image
M-by-*N* matrix of intensity values | *M*-by-*N*-by-*3* array of color values

Output image, returned as an *M*-by-*N* matrix or *M*-by-*N*-by-*3* array. The output image is of the same dimension as the input image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Main Tab

Shape — Shape to draw
`Rectangles` (default) | `Lines` | `Polygons` | `Circles`

One or more shapes to draw on the image, specified as one of the following:

- `Rectangles` — Draw one or more rectangles on the input image or the video frame using the specified shape coordinates.
- `Lines` — Draw one or more lines on the input image or the video frame using the specified shape coordinates.
- `Polygons` — Draw one or more polygons on the input image or the video frame using the specified shape coordinates.
- `Circles` — Draw one or more circles on the input image or the video frame using the specified shape coordinates.

Fill shapes — Fill shapes with color
off (default) | on

Select **Fill shapes** to enable the color parameters to fill shapes.

Note If you are generating the code and selecting the **Fill shapes** check box, the word length of the block input(s) cannot exceed 16 bits.

Line width — Line width for the shapes
1 (default) | positive scalar

Specify the line width for the shapes to be drawn, as a positive scalar.

Fill color source — Input source to specify fill color
`Specify via dialog` (default) | `Input port`

Specify the input source for the fill color value. Select **Fill color source** as one of the following:

- `Specify via dialog` — To specify the color value by using **Fill color** parameter.
- `Input port` — To specify the color value by using **Clr** port.

Dependencies

To enable this parameter, select **Fill shapes**.

Fill color — Color to fill the shapes
`Black` (default) | `White` | `User-specified value`

Specify the shape fill color as either `Black`, `White` or `User-specified value`. The `User-specified value` can be scalar or a 3-element vector. Use a scalar to specify an intensity value and 3-element vector to specify RGB color value.

Color Value(s) for Filling One Shape or Multiple Shapes with the Same Color	Color Value(s) for Filling Multiple Shapes with Unique Colors
Scalar intensity value	*R*-element vector, where *R* is the number of shapes.
3-element RGB vector	*R*-by-*3* matrix, where *3* is the number of color planes and *R* is the number of shapes.

For each value in the **Color Value(s)** parameter, enter a number between the minimum and maximum values that can be represented by the data type of the input image. If you enter a value outside this range, the block produces an error message.

Dependencies

To enable this parameter, select the **Fill shapes** parameter.

Border color source — Input source to specify border color
`Specify via dialog` (default) | `Input port`

Specify the input source for the border color value. Select **Border color source** as one of the following:

- `Specify via dialog` — To specify the color value by using **Border color** parameter.
- `Input port` — To specify the color value by using **Clr** port.

Border color — Outline color of the shape
`Black` (default) | `White` | `User-specified value`

Specify the border color of shape as either `Black`, `White` or `User-specified value`. The `User-specified value` can be scalar or a 3-element vector. Use a scalar to specify an intensity value and 3-element vector to specify RGB color value.

Color Value(s) for Drawing One Shape or Multiple Shapes with the Same Color	Color Value(s) for Drawing Multiple Shapes with Unique Colors
Scalar intensity value	*R*-element vector, where *R* is the number of shapes.
3-element RGB vector	*R*-by-*3* matrix, where three is the number of color planes and *R* is the number of shapes.

For each value in the **Color Value(s)** parameter, enter a number between the minimum and maximum values that can be represented by the data type of the input image. If you enter a value outside this range, the block produces an error message.

Color value(s) — Color value to draw the border or fill the shape
scalar | 3-element vector

Specify color value to draw the border or fill the shape as a scalar or 3-element vector. Use a scalar to specify intensity value and a 3-element vector for RGB color value.

Tunable: Yes

Dependencies

To enable this parameter set the **Border color** or **Fill color** parameter to `User-specified value`.

Opacity factor (between 0 and 1) — Opacity of the color
value in the range [0,1] | *R*-element vector

Specify the opacity of the color as a positive value in the range [0, 1]. `0` is transparent and `1` is opaque.

Opacity Factor value for Filling One Shape or Multiple Shapes with the Same Color	Opacity Factor value for Filling Multiple Shapes with Unique Colors
Scalar intensity value	*R*-element vector where *R* is the number of shapes

Dependencies

To enable this parameter, select the **Fill shapes** parameter.

Use antialiasing — Smoothing algorithm
off | on

Performs smoothing on the line, polygon, or circle.

Dependencies

- To enable this parameter, set the **Shape** parameter to either `Lines`, `Polygons`, or `Circles`.

Draw shapes in — Region to draw the shape
`Entire image` (default) | `Specify region of interest via port`

Specify the extent of the region to draw the specified shape. Select the value as one of the following:

- `Entire image` — To draw the shape on the entire image.
- `Specify region of interest via port` — To draw the shape within an ROI specified by the input **ROI** port.

Image signal — Number of input ports for the image signal
`One multidimensional signal` (default) | `Separate color signals`

Specify the number of input ports to use for specifying the input image. Select the value as one of the following:

- `One multidimensional signal` — To specify intensity or color image using a single port. The block enables the **Image** port for a *M*-by-*N*-by-*3* color image, or a *M*-by-*N* intensity image.
- `Separate color signals` — To specify red, green, and, blue color planes of the input color image. The block enables the **R**,**G**, and, **B** input ports. Each port accepts the *M*-by-*N* plane of an RGB color image.

Data Types Tab

Edge Detection

Find edges of objects in images using Sobel, Prewitt, Roberts, or Canny method

Libraries:
Computer Vision Toolbox / Analysis & Enhancement

Description

The Edge Detection block finds edges of objects in an input image. The block supports four methods: Sobel, Prewitt, Roberts, and Canny. The first three methods find the edges by approximating the gradient magnitude of the image. The block convolves the input matrix with the Sobel, Prewitt, or Roberts kernel respectively, and outputs the resulting gradient components of the image. Additionally, the block outputs a binary image of the edge detections by thresholding the gradient magnitude.

The Canny method computes the gradient of input image using the derivative of the Gaussian filter. It then finds edges by looking for the local maxima of the gradient. This method uses two thresholds to detect the strong and weak edges. The weak edges are part of the output only if they are connected to strong edges. The block outputs a binary image of the edge detections for this method.

Ports

Input

I — Input image
matrix

Input image, specified as a matrix of intensity values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Note The Canny method does not support 8-bit, 16-bit, or 32-bit signed fixed-point integers or 8-bit, 16-bit, or 32-bit unsigned integers.

Th — Threshold
scalar | vector

Specify a threshold as a scalar or a two-element vector to detect edges from the gradient. The data type of this value must match the input image data type. For the Canny edge detection method, the threshold must be a two-element vector in the range [0 1]. For the other methods, the threshold is a scalar.

Dependencies

To enable this port:

- Set the **Method** parameter to `Canny`. Alternatively, set the **Method** parameter to `Sobel`, `Prewitt`, or `Roberts`, and also set the **Output type** parameter to `Binary image` or `Binary image and gradient components`.
- Select the **User-defined threshold**.
- Set the **Threshold source** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Note The Canny method does not support 8-bit, 16-bit, or 32-bit signed fixed-point integers or 8-bit, 16-bit, or 32-bit unsigned integers.

Output

Edge — Edge detections
matrix

Edge detections, returned as a binary image. The pixels with the value of `1` represent the edge pixels.

Dependencies

This port is always enabled when you set the **Method** parameter to `Canny`. To enable this port for the `Sobel`, `Prewitt`, or `Roberts` methods, set the **Output type** parameter to `Binary image` or `Binary image and gradient components`.

Data Types: `Boolean`

Gv — Gradient responses to vertical edges
matrix

Matrix of gradient responses to the vertical edges.

Dependencies

To enable this port, set these parameters:

- **Method** — `Sobel` or `Prewitt`
- **Output type** — `Gradient components` or `Binary image and gradient components`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Gh — Gradient responses to horizontal edges
matrix

Matrix of gradient responses to the horizontal edges.

Dependencies

To enable this port, set these parameters:

- **Method** — `Sobel` or `Prewitt`
- **Output type** — `Gradient components` or `Binary image and gradient components`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

G45 — Gradient responses to edges at 45 degrees
matrix

Matrix of gradient responses to edges at 45 degrees.

Dependencies

To enable this port, set these parameters:

- **Method** — `Roberts`
- **Output type** — `Gradient components` or `Binary image and gradient components`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

G135 — Gradient responses to edges at 135 degrees
matrix

Matrix of gradient responses to edges at 135 degrees.

Dependencies

To enable this port, set these parameters:

- **Method** — `Roberts`
- **Output type** — `Gradient components` or `Binary image and gradient components`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Main

Method — Edge detection method
`Sobel` (default) | `Prewitt` | `Roberts` | `Canny`

Specify a method to detect edges in the input image. You can choose from `Sobel`, `Prewitt`, `Roberts` or `Canny`.

Output Type — Output image type
`Binary image` (default) | `Gradient components` | `Binary image and gradient components`

Specify the type of output image from one of these options:

- `Binary image` — The block outputs a Boolean matrix at the **Edge** port. The elements of the matrix labeled `1` represent the edge pixels.
- `Gradient components` — The block outputs the gradient components. For the `Sobel` and `Prewitt` methods, the gradient components correspond to the horizontal and vertical edge responses at the **Gh** and **Gv** ports respectively. For the `Roberts` method the gradient components correspond to 45 degree and 135 degree edge responses at the **G45** and **G135** ports respectively.

- `Binary image and gradient components` — The block outputs both the binary image and the gradient components of the image

Dependencies

To enable this parameter, set the **Method** parameter to `Sobel`, `Prewitt`, or `Roberts`.

User-defined threshold — User-defined threshold
off (default) | on

Specify a desired threshold value via dialog box or the **Th** port.

Dependencies

This parameter is always enabled when you set the **Method** parameter to `Canny`. To enable this parameter for the `Sobel`, `Prewitt`, or `Roberts` methods, set the **Output type** parameter to `Binary image` or `Binary image and gradient components`.

Threshold source — Threshold source
`Input port` (default) | `Specify via dialog`

Select the source to enter the threshold value from one of these options:

- `Input port` — Specify a threshold value using the **Th** port. The data type of this value must match the input image data type.
- `Specify via dialog` — Enter the desired threshold value in the dialog box.

Dependencies

To enable this parameter:

- Set the **Method** parameter to `Canny`. Alternatively set the **Method** parameter to `Sobel`, `Prewitt`, or `Roberts`, and also set the **Output type** parameter to `Binary image` or `Binary image and gradient components`.
- Select the **User-defined threshold**.

Threshold — Threshold
20 (default) | scalar

Specify the threshold value that is within the range of your input data. This threshold applies to Sobel, Prewitt, and Roberts edge detection methods.

Dependencies

To enable this parameter, set these block parameters:

- **Method** — `Sobel`, `Prewitt`, or `Roberts`
- **Output type** — `Binary image` or `Binary image and gradient components`
- **User-defined threshold** — `On`.
- **Threshold source** — `Specify via dialog`

Threshold, [Low High] — Threshold for Canny edge detection
[0.25 0.60] (default) | vector

Specify the threshold for the Canny edge detection as a two-element vector in the range [0 1]. The elements of the vector specifies the low and high threshold values for the weak and strong edges respectively.

Dependencies

To enable this parameter, set these block parameters:

- **Method** — `Canny`
- **User-defined threshold** — `On`.
- **Threshold source** — `Specify via dialog`

Threshold scale factor:(used to automatically calculate threshold value) — Threshold scale factor
4 (default) | scalar

Specify the threshold scale factor to automatically calculate threshold value. The block computes the automatic threshold using the mean of the gradient magnitude squared image and multiplies the value of this parameter with the automatic threshold value to determine a new threshold value.

Dependencies

To enable this parameter, set these block parameters:

- **Method** — `Sobel`, `Prewitt`, or `Roberts`
- **Output type** — `Binary image` or `Binary image and gradient components`
- **User-defined threshold** — `Off`

Edge Thinning — Edge thinning
`off` (default) | `on`

Select this parameter to reduce the thickness of the edges in your output images. This option requires additional processing time and memory resources.

Tip This block is most efficient in terms of memory usage and processing time when you clear the **Edge thinning** check box and use the **Threshold** parameter to specify a threshold value.

Dependencies

To enable this parameter, set these block parameters:

- **Method** — `Sobel`, `Prewitt`, or `Roberts`
- **Output type** — `Binary image` or `Binary image and gradient components`

Approximate percentage of weak edge and nonedge pixels (used to automatically calculate threshold values) — Approximate percentage of weak edge and nonedge pixels
70 (default) | scalar

Specify the approximate percentage of weak edge and nonedge image pixels. The block computes the automatic threshold values using this value.

Dependencies

To enable this parameter, set these block parameters:

- **Method** — `Canny`
- **User-defined threshold** — `Off`

Standard deviation of Gaussian filter — Standard deviation of Gaussian filter
1 (default) | scalar

Specify the standard deviation of Gaussian filter used for Canny edge detection algorithm.

Dependencies

To enable this parameter, set the **Method** parameter to `Canny`.

Data Types

For information about the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`

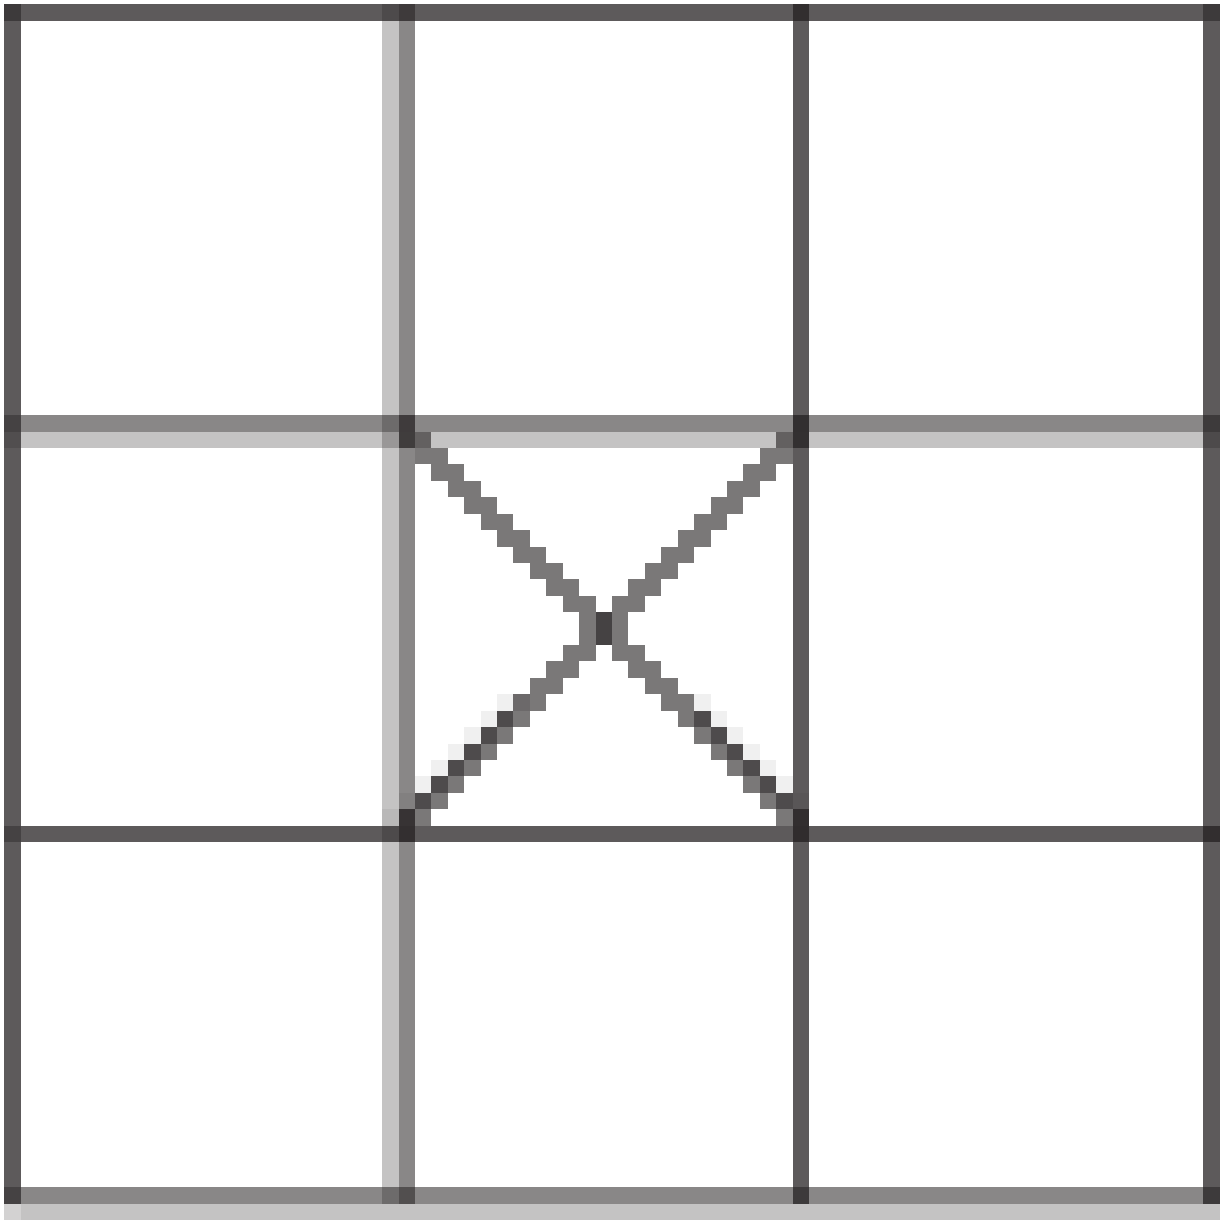
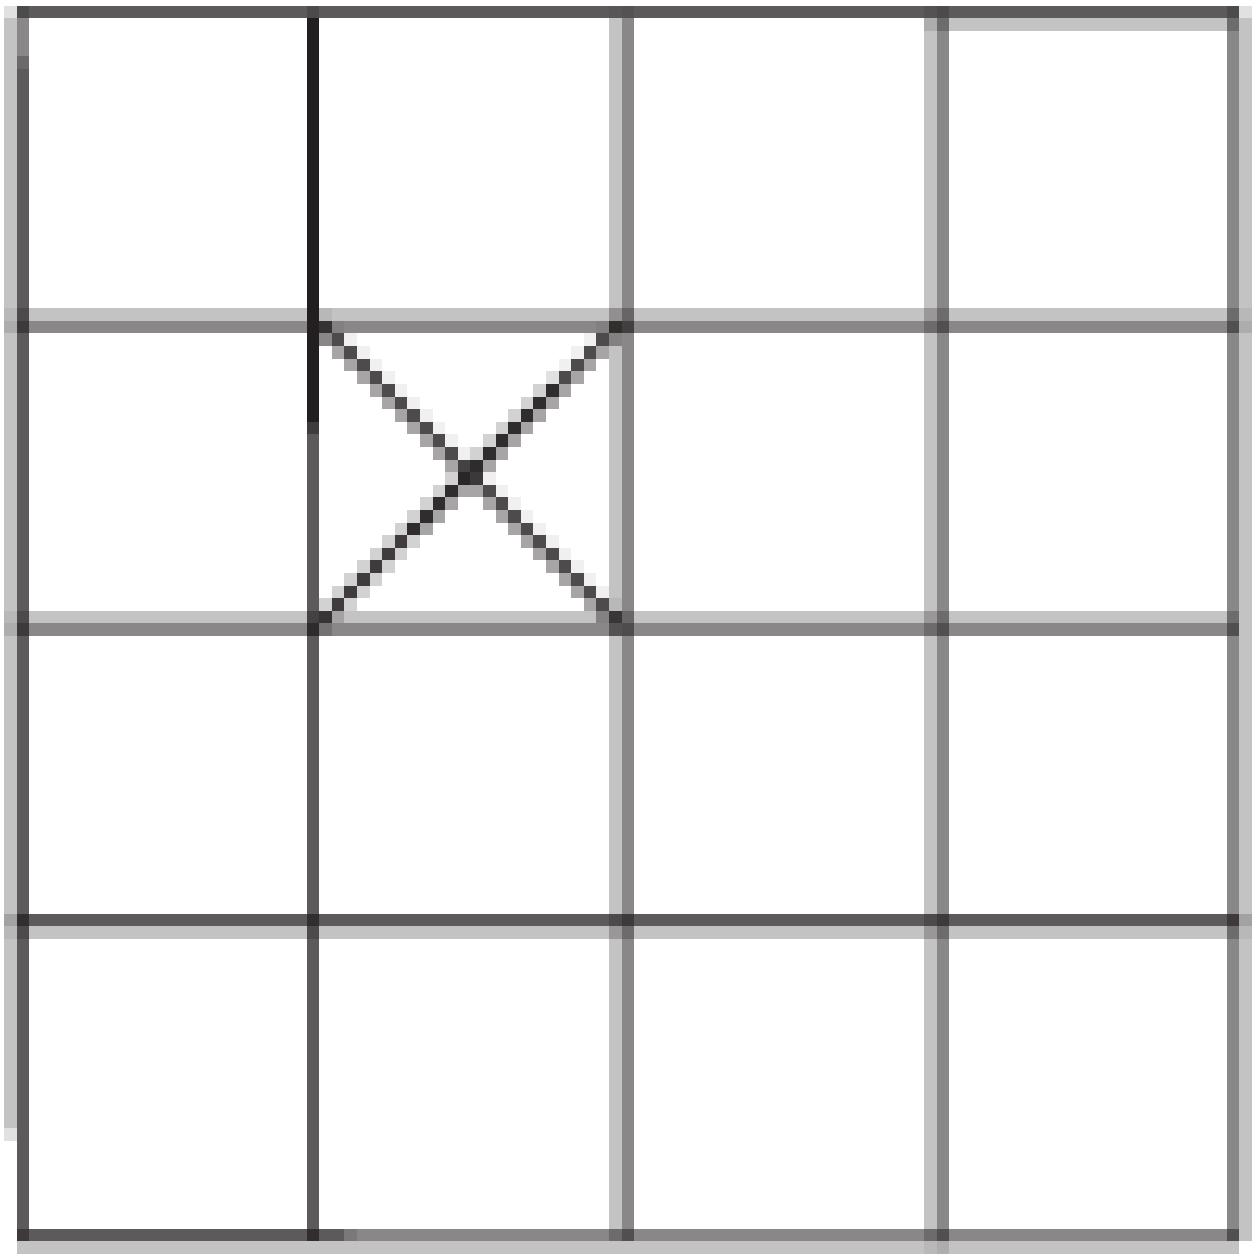
Erosion



Find local minima in binary or intensity image



Libraries:
Computer Vision Toolbox / Morphological Operations

Description

The Erosion block slides a neighborhood or structuring element over an image, finds the local minima, and creates an output matrix from these minimum values. If the neighborhood or structuring element has a center element, the block places the minima there, as shown in this figure.

If the neighborhood or structuring element does not have an exact center, the block has a bias toward the upper-left of the central elements and places the minima there, as shown in this figure.

This block uses flat structuring elements only.

Ports

Input

I — Input image
matrix

Specify an input image as a matrix of binary or intensity values. This port is unnamed until you set the **Neighborhood or structuring element source** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Nhood — Neighborhood values
vector | matrix

Specify neighborhood values, representing a structuring element, as a vector or matrix of `1`s and `0`s.

Dependencies

To enable this port, set the **Neighborhood or structuring element source** parameter to `Input port`.

Data Types: `Boolean`

Output

Port_1 — Eroded image
matrix

Eroded image, returned as a matrix. The size and data type of the output image are the same as those of the input image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Neighborhood or structuring element source — Source of neighborhood or structuring element

`Specify via dialog` (default) | `Input port`

Specify the source of the neighborhood or structuring element as one of these options:

- `Specify via dialog` — Use the **Neighborhood or structuring element** parameter to specify a neighborhood or structuring element.
- `Input port` — Use the **Nhood** input port to specify neighborhood values representing a structuring element.

Neighborhood or structuring element — Neighborhood or structuring element

`strel('square',4)` (default)

Specify the neighborhood or structuring element as a vector or matrix of `1`s and `0`s, a `strel` object, or an array of `strel` objects. When you specify an array of `strel` objects, the block applies each object to the entire image in sequence.

If the structuring element is decomposable into smaller elements, the block execution speed improves due to the more efficient algorithm.

Dependencies

To enable this parameter, set the **Neighborhood or structuring element source** parameter to `Specify via dialog`.

Block Characteristics

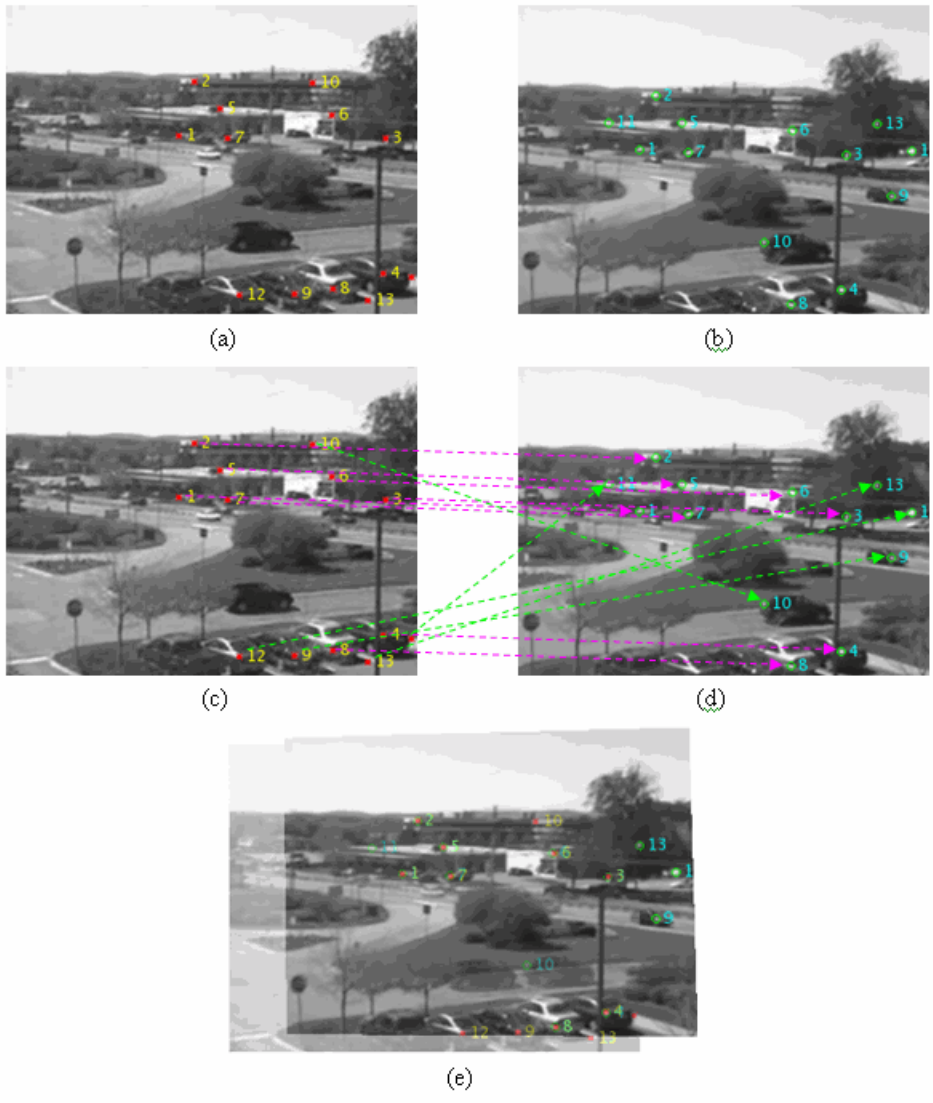
Estimate Geometric Transformation

Estimate geometric transformation from matching point pairs

Libraries:
Computer Vision Toolbox / Geometric Transformations



Description

Use the Estimate Geometric Transformation block to find the transformation matrix which maps the greatest number of point pairs between two images. A point pair refers to a point in the input image and its related point on the image created using the transformation matrix. You can select to use the RANdom SAmple Consensus (RANSAC) or the Least Median Squares algorithm to exclude outliers and to calculate the transformation matrix. You can also use all input points to calculate the transformation matrix.

Examples

Calculate transformation matrix from largest group of point pairs

1. Examples of input data and application of the Estimate Geometric Transformation block appear in the following figures. Figures (a) and (b) show the point pairs. The points are denoted by stars or circles, and the numbers following them show how they are paired. Some point pairs can be mapped by the same transformation matrix. Other point pairs require a different transformation matrix. One matrix exists that maps the largest number of point pairs, the block calculates and returns this matrix. The block finds the point pairs in the largest group and uses them to calculate the transformation matrix. The point pairs connected by the magenta lines are the largest group.
2. The transformation matrix can then be used to stitch the images as shown in Figure (e).

Ports

Input

Pts1 — Point coordinates
M-by-2 matrix

Point coordinates, specified as an *M*-by-2 matrix of one-based [*x* *y*] point coordinates, where *M* represents the number of points.

The block outputs the same data type for the transformation matrix as the **Pts1** and **Pts2** image points.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Pts2 — Point coordinates
M-by-2 matrix

Point coordinates, specified as an *M*-by-2 matrix of one-based [*x* *y*] point coordinates, where *M* represents the number of points.

The block outputs the same data type for the transformation matrix as the **Pts1** and **Pts2** image points.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Num — Number of valid points
scalar

Number of valid points to find in **Pts1** and **Pts2**, specified as a scalar. This port appears when you enable the **Allow variable-size signal input** parameter.

Data Types: `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Output

TForm — Transformation
3-by-2 matrix | 3-by-3 matrix

Transformation, returned as either a 3-by-2 or a 3-by-3 matrix. The block outputs the same data type for the transformation matrix as the **Pts1** and **Pts2** image points.

Dependencies

- When **Pts1** and **Pts2** are single or double, the output transformation matrix will also have single or double data type.
- When **Pts1** and **Pts2** images are built-in integers, the option is available to set the transformation matrix data type to either `Single` or `Double`.

Data Types: `single` | `double`

Inlier — Points used
M-by-1 vector

Points used to calculate `TForm`, returned as an *M*-by-1 vector.

Dependencies

- The **Inlier** port appears when you enable the **Output Boolean signal indicating which point pairs are inliers** parameter.

Data Types: `Boolean`

Parameters

Transformation type — Transformation type
`Affine` (default) | `Nonreflective similarity` | `Projective`

Specify the transformation type as either `Nonreflective similarity`, `Affine`, or `Projective`. See “Transformations” on page 1-231 for a more detailed discussion.

Dependencies

You can set additional parameters depending on the transformation type:

- For `Projective` transformation, you can specify a scalar algebraic distance threshold for determining inliers.
- For `Affine` or `Nonreflective similarity` transformation, you can specify the distance threshold for determining inliers in pixels.

Find and exclude outliers — Find and exclude outliers
on (default) | off

Enable to find and exclude outliers from the input points and use only the inlier points to calculate the transformation matrix. When you turn this parameter off, all input points are used to calculate the transformation matrix.

Method — Method to find outliers
`RANdom SAmple Consensus (RANSAC)` (default) | `Least Median of Squares`

Select the method to find outliers as either `RANdom SAmple Consensus (RANSAC)` or `Least Median of Squares` See “RANSAC and Least Median Squares Algorithms” on page 1-230 for a more detailed discussion.

Dependencies

This parameter appears when you enable the **Find and exclude outliers** check box.

Algebraic distance threshold for determining inliers — Algebraic distance threshold for determining inliers
1.5 (default) | scalar

Specify a scalar threshold value for determining inliers. The threshold controls the upper limit used to find the algebraic distance in the RANSAC algorithm.

Dependencies

This parameter appears when you set the **Method** parameter to `Random Sample Consensus (RANSAC)` and the **Transformation type** parameter to `Projective`.

Distance threshold for determining inliers (in pixels) — Distance threshold for determining inliers (in pixels)
`1.5` (default) | scalar

Specify the upper limit distance a point can differ from the projection location of its corresponding point.

Dependencies

This parameter appears when you set the **Method** parameter to `Random Sample Consensus (RANSAC)` and you set the value of the **Transformation type** parameter to `Nonreflective similarity` or `Affine`.

Determine number of random samplings using — Determine number of random samplings using
`Specified value` (default) | `Desired confidence`

Select `Specified value` to enter a positive integer value for the number of random samplings. Select `Desired confidence` to set the number of random samplings as a percentage and a maximum number.

Dependencies

This parameter appears when you select the **Find and exclude outliers** check box, and you set the value of the **Method** parameter to `Random Sample Consensus (RANSAC)`.

Number of random samplings — Number of random samplings
`500` (default) | scalar

Specify the number of random samplings for the algorithm to perform.

Dependencies

This parameter appears when you set the value of the **Determine number of random samplings using** parameter to `Specified value`.

Desired confidence (in %) — Desired confidence (in %)
`99` (default) | scalar

Specify a percent desired confidence by entering a number between `0` and `100`. The value represents the probability of the algorithm to find the largest group of points that can be mapped by a transformation matrix.

Dependencies

This parameter appears when you set the **Determine number of random samplings using** parameter to `Desired confidence`.

Maximum number of random samplings — Maximum number of random samplings
`1000` (default) | integer

Specify an integer number for the maximum number of random samplings.

Dependencies

This parameter appears when you set the **Method** parameter to `Random Sample Consensus (RANSAC)` and you set the value of the **Determine number of random samplings using** parameter to `Desired confidence`.

Stop sampling earlier when a specified percentage of point pairs are determined to be inlier — Stop sampling
off (default) | on

Enable this parameter to stop random sampling when a percentage of input points have been found as inliers.

Dependencies

This parameter appears when you set the **Method** parameter to `Random Sample Consensus (RANSAC)`.

Perform additional iterative refinement of the transformation matrix — Perform additional iterative refinement
off (default) | on

Specify whether to perform refinement on the transformation matrix.

Dependencies

This parameter appears when you select **Find and exclude outliers** check box.

Output Boolean signal indicating which point pairs are inliers — Output Boolean signal
off (default) | on

Enable this parameter to output the inlier point pairs that were used to calculate the transformation matrix.

Dependencies

- This parameter appears when you select the **Find and exclude outliers** check box.
- The block will not use this parameter with signed or double, data type points.

When Pts1 and Pts2 are built-in integers, set transformation matrix date type to — Set transformation matrix date type
`Single` (default) | `Double`

Specify transformation matrix data type as `Single` or `Double` when the input points are built-in integers.

Dependencies

The block will not use this parameter with signed or double, data type points.

Allow variable-sized signal input — Allow variable-sized signal input
on (default) | off

Enable this parameter to allow variable-sized signal input.

Dependencies

Block Characteristics

Data Types	`double` | `integer`[a] | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

a Generated code will be restricted to MATLAB host computers when you set the FFT implementation parameter to FFTW, or when the transform length is not a power of two.

Troubleshooting

The success of estimating the correct geometric transformation depends heavily on the quality of the input point pairs. If you chose the RANSAC or LMS algorithm, the block will randomly select point pairs to compute the transformation matrix and will use the transformation that best fits the input points. There is a chance that all of the randomly selected point pairs may contain outliers despite repeated samplings. In this case, the output transformation matrix, `TForm`, is invalid, indicated by a matrix of zeros.

To improve your results, try the following:
Increase the percentage of inliers in the input points.

Increase the number for random samplings.
For the RANSAC method, increase the desired confidence.
For the LMS method, make sure the input points have 50% or more inliers.
Use features appropriate for the image contents
Be aware that repeated patterns, for example, windows in office building, will cause false matches when you match the features. This increases the number of outliers.
Do not use this function if the images have significant parallax. You can use the `estimateFundamentalMatrix` function instead.
Choose the minimum transformation for your problem.
If a projective transformation produces the error message, "A portion of the input image was transformed to the location at infinity. Only transformation matrices that do not transform any part of the image to infinity are supported.", it is usually caused by a transformation matrix and an image that would result in an output distortion that does not fit physical reality. If the matrix was an output of the Estimate Geometric Transformation block, then most likely it could not find enough inliers.

Algorithms

RANSAC and Least Median Squares Algorithms

The *RANSAC* algorithm relies on a distance threshold. A pair of points, p_i^a(image a, Pts1) and p_i^b (image b, Pts2) is an inlier only when the distance between p_i^b and the projection of p_i^abased on the transformation matrix falls within the specified threshold. The distance metric used in the RANSAC algorithm is as follows:

$$d = \sum_{i=1}^{Num} \min(D(p_i^b, \psi(p_i^a{:}H)), t)$$

The Least Median Squares algorithm assumes at least 50% of the point pairs can be mapped by a transformation matrix. The algorithm does not need to explicitly specify the distance threshold. Instead, it uses the median distance between all input point pairs. The distance metric used in the Least Median of Squares algorithm is as follows:

$$d = median(D(p_1^b, \psi(p_1^a{:}H)), D(p_2^b, \psi(p_2^a{:}H)), \ldots, D(p_{Num}^b, \psi(p_N^a{:}H)))$$

For both equations:

p_i^a is a point in image a (`Pts1`)

p_i^b is a point in image b (`Pts2`)

$\psi(p_i^a{:}H)$ is the projection of a point on image a based on transformation matrix H

$D(p_i^b, p_j^b)$ is the distance between two point pairs on image b

t is the threshold

$Num$is the number of points

The smaller the distance metric, the better the transformation matrix and therefore the more accurate the projection image.

Transformations

The Estimate Geometric Transformation block supports `Nonreflective similarity`, `Affine`, and `Projective` transformation types, which are described in this section.

Nonreflective similarity transformation supports translation, rotation, and isotropic scaling. It has four degrees of freedom and requires two pairs of points.

The transformation matrix is: $H = \begin{bmatrix} h_1 & -h_2 \\ h_2 & h_1 \\ h_3 & h_4 \end{bmatrix}$

The projection of a point $[x\ y]$ by $H$is: $[\widehat{x}\ \widehat{y}] = [x\ y\ 1]H$

affine transformation supports anisotropic scaling in addition to all transformations that the nonreflective similarity transformation supports. It has six degrees of freedom that can be determined from three pairs of noncollinear points.

The transformation matrix is: $H = \begin{bmatrix} h_1 & h_4 \\ h_2 & h_5 \\ h_3 & h_6 \end{bmatrix}$

The projection of a point $[x\ y]$ by $H$is: $[\widehat{x}\ \widehat{y}] = [x\ y\ 1]H$

Projective transformation supports tilting in addition to all transformations that the affine transformation supports.

The transformation matrix is : $h = \begin{bmatrix} h_1 & h_4 & h_7 \\ h_2 & h_5 & h_8 \\ h_3 & h_6 & h_9 \end{bmatrix}$

The projection of a point $[x\ y]$ by $H$is represented by homogeneous coordinates as:
$[\widehat{u}\ \widehat{v}\ \widehat{w}] = [x\ y\ 1]H$

Distance Measurement

For computational simplicity and efficiency, this block uses algebraic distance. The algebraic distance for a pair of points, $\begin{bmatrix} x^a & y^a \end{bmatrix}^T$ on image a, and $\begin{bmatrix} x^b & y^b \end{bmatrix}$ on image b , according to transformation H,is defined as follows;

For projective transformation:

$D(p_i^b, \psi(p_i^a : H)) = ((\widehat{u}^a - \widehat{w}^a x^b)^2 + (\widehat{v}^a - \widehat{w}^a y^b)^2)^{\frac{1}{2}}$, where $\begin{bmatrix} \widehat{u}^a & \widehat{v}^a & \widehat{w}^a \end{bmatrix} = \begin{bmatrix} x^a & y^a & 1 \end{bmatrix} H$

For Nonreflective similarity or affine transformation: $D(p_i^b, \psi(p_i^a : H)) = ((\widehat{x}^a - x^b)^2 + (\widehat{y}^a - \widehat{y}^b)^2)^{\frac{1}{2}}$,

where $\begin{bmatrix} \widehat{x}^a & \widehat{y}^a \end{bmatrix} = \begin{bmatrix} x^a & y^a & 1 \end{bmatrix} H$

Algorithm

The block performs a comparison and repeats it K number of times between successive transformation matrices. If you select the **Find and exclude outliers** option, the RANSAC and Least Median Squares (LMS) algorithms become available. These algorithms calculate and compare a distance metric. The transformation matrix that produces the smaller distance metric becomes the new transformation matrix that the next comparison uses. A final transformation matrix is resolved when either:

- K number of random samplings is performed
- The RANSAC algorithm, when enough number of inlier point pairs can be mapped, (dynamically updating K)

The Estimate Geometric Transformation algorithm follows these steps:

1. A transformation matrix H is initialized to zeros
2. Set `count = 0` (Randomly sampling).
3. While `count < K` , where `K` is total number of random samplings to perform, perform the following;

   a. Increment the count; `count = count + 1`.
   b. Randomly select pair of points from images a and b, (2 pairs for Nonreflective similarity, 3 pairs for affine, or 4 pairs for projective).
   c. Calculate a transformation matrix H, from the selected points.
   d. If Hhas a distance metric less than that of H, then replace H with H.

      (Optional for RANSAC algorithm only)

      i. Update `K` dynamically.
      ii. Exit out of sampling loop if enough number of point pairs can be mapped by H.
4. Use all point pairs in images a and b that can be mapped by H to calculate a refined transformation matrix H
5. Iterative Refinement, (Optional for RANSAC and LMS algorithms)

   a. Denote all point pairs that can be mapped by H as inliers.
   b. Use inlier point pairs to calculate a transformation matrix H.
   c. If Hhas a distance metric less than that of H, then replace H with H, otherwise exit the loop.

Number of Random Samplings

The number of random samplings can be specified by the user for the RANSAC and Least Median Squares algorithms. You can use an additional option with the RANSAC algorithm, which calculates this number based on an accuracy requirement. The **Desired Confidence** level drives the accuracy.

The calculated number of random samplings, K used with the RANSAC algorithm, is as follows:

$$K = \frac{\log(1-p)}{\log(1-q^s)}$$

where

- p is the probability of independent point pairs belonging to the largest group that can be mapped by the same transformation. The probability is dynamically calculated based on the number of inliers found versus the total number of points. As the probability increases, the number of samplings, K, decreases.
- q is the probability of finding the largest group that can be mapped by the same transformation.
- s is equal to the value 2, 3, or 4 for Nonreflective similarity, affine, and projective transformation, respectively.

Iterative Refinement of Transformation Matrix

The transformation matrix calculated from all inliers can be used to calculate a refined transformation matrix. The refined transformation matrix is then used to find a new set of inliers. This procedure can be repeated until the transformation matrix cannot be further improved. This iterative refinement is optional.

Find Local Maxima

Find local maxima in matrices

Libraries:
Computer Vision Toolbox / Statistics

Description

The Find Local Maxima block finds the local maxima in a given input matrix. The block finds the local maxima of values within a region specified by the neighborhood size. The block compares the values in the search region to a user-specified threshold and identifies a value that is greater than or equal to the threshold as the local maximum. After finding the local maximum, the block sets all the matrix values in the neighborhood, including the maximum value, to zero. This step ensures that subsequent searches do not include this maximum. The process repeats until the block either finds all valid maxima or the specified number of local maxima.

The threshold and the neighborhood size must be chosen such that the block detects only the true local maxima and eliminates false peaks.

The input to this block can also be a Hough matrix generated from the Hough Transform block. The Find Local Maxima block outputs the one-based [*x* *y*] coordinates of the detected local maxima. The data sent to all input ports must be the same data type.

Ports

Input

I — Input
M-by-*N* matrix

Input, specified as the *M*-by-*N* matrix in which you want to detect the local maxima. If the input is a Hough matrix output from the Hough Transform block, select the **Input is Hough matrix spanning full theta range** parameter that renames this port as **Hough**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Th — Threshold for detecting local maxima
scalar

Threshold for the detecting local maxima, specified as a scalar.

Dependencies

To enable this port, set the **Source of threshold value** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

Idx — Coordinates of local maxima
P-by-2 matrix

Coordinates of the local maxima, returned as a *P*-by-2 matrix of one-based [*x y*] coordinates. *P* represents the number of local maxima.

Data Types: `single` | `double` | `uint8` | `uint16` | `uint32`

Count — Number of local maxima
scalar

Number of local maxima, returned as a scalar.

Dependencies

To enable this port, clear the check box for the **Output variable size signal** parameter.

Data Types: `single` | `double` | `uint8` | `uint16` | `uint32`

Parameters

Maximum number of local maxima — Maximum number of local maxima to detect

2 (default) | positive integer

Specify the maximum number of local maxima to detect in the input matrix. The value must be a positive integer greater than 0.

Neighborhood size — Size of neighborhood region

[5 7] (default) | two-element vector

Specify the size of the neighborhood region as a two-element vector in the form `[r c]`. The vector specifies the window size *r*×*c*, within which the block determines the local maxima. The window size must be greater than or equal to 1×1.

Source of threshold value — Source to enter the threshold value

`Specify via dialog` (default) | `Input port`

Specify the source for entering the threshold value. When you select the `Input port`, the block enables the **Th** port. When you select the `Specify via dialog`, the block enables the **Threshold** parameter.

Threshold — Threshold for detecting local maxima

10 (default) | scalar

Specify a scalar value that represents the threshold for detecting the local maxima.

Dependencies

To enable this parameter, set the **Source of threshold value** parameter to `Specify via dialog`.

Input is Hough matrix spanning full theta range — Whether input is a Hough matrix

off (default) | on

Select the parameter, if the input to this block is the Hough matrix output from the Hough Transform block. The Find Local Maxima block assumes that the input is a Hough matrix that is antisymmetric about the rho axis, with values of theta from -pi/2 to pi/2 radians. As a result, if the local maximum is near the boundary and its neighborhood region is outside the Hough matrix, the block detects only one local maximum. The block ignores the corresponding antisymmetric maximum.

Index output data type — Data type for coordinates of local maximums
`uint32` (default) | `double` | `single` | `uint8` | `uint16`

Specify the data type for the coordinates of local maximums returned at the output port **Idx**.

Output variable size signal — Support input signals of varying length
on (default) | off

Specify if the model supports input signals of varying length.

Count output data type — Data type for number of local maximums
`uint32` (default) | `double` | `single` | `uint8` | `uint16`

Specify the data type for the number of local maximums returned at the output port **Count**.

Dependencies

To enable this parameter, clear the **Output variable size signal** parameter.

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

Frame Rate Display

Calculate and display video frame rate

Libraries:
Computer Vision Toolbox / Sinks

Description

The Frame Rate Display block calculates and displays the average update rate of an input signal. For an input video signal, this block displays the video frame rate of the simulation. The calculated rate is in relation to the wall clock time. For example, if the model is updating the input signal 30 times for every second, this block displays `30` on the block mask.

This block supports images and video frames as input. Inputs can contain intensity or color values.

Ports

Input

Port_1 — Input data
matrix | array

Input data, specified as an *M*-by-*N* matrix, *M*-by-*N*-by-*T* array, or *M*-by-*N*-by-*C*-by-*T* array. *T* is the number of frames in a video or image sequence, and *C* is the number of color channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Update rate — Frequency of updates

`10` (default) | positive scalar

Specify this parameter to control how often the block updates the display. The block displays the average update rate across the specified number of video frames. For example, if this parameter is set to `10`, the Frame Rate Display block calculates the elapsed time to pass `10` video frames to the block, divides the elapsed time by `10`, and displays the average video frame rate.

Note If the input port of Frame Rate Display block is not connected to a signal, the block displays the base (fastest) rate of the Simulink model.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

Blocks

To Multimedia File | To Video Display | Video To Workspace | Video Viewer

From Multimedia File

Read video frames and audio samples from multimedia file

Libraries:
Computer Vision Toolbox / Sources

Description

The From Multimedia File block reads video frames, audio samples, or both from a multimedia file. The block imports data from a file, of a supported file format, into a Simulink model. For more information about supported file formats, see “Supported Platforms and File Formats” on page 1-246.

This block enables you to read WMA or WMV streams from your system or over a network connection. Similarly, the To Multimedia File block enables you to write WMA or WMV streams to your system or over a network connection. If your system does not have the codec necessary to support a file format, you must re-encode files of that format into a file format supported by the Computer Vision Toolbox.

If you have a Simulink Coder™ license, you can generate code from a model containing this block. To run a generated executable file, you may need to add precompiled shared library files to your system path. For more information, see “Simulink Shared Library Dependencies” and “Accelerating Simulink Models”.

Note This block supports code generation for a host computer that has file I/O available. You cannot use this block with Simulink Desktop Real-Time™ software because that product does not support file I/O.

Ports

Output

Image — Color image or video frame
array

Color image or video frame, returned as an *M*-by-*N*-by-*P* array. *M* and *N* are the number of rows and columns in each image. *P* is the number of color channels in each image.

Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.
- Set the **Output color format** parameter to RGB and **Image signal** parameter to `One multidimensional signal`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Simulink.ImageType`

I — Grayscale image or video frame
matrix

Grayscale image or video frame, returned as an *M*-by-*N* matrix. *M* and *N* are the number of rows and columns in the grayscale image.

Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.
- Set the **Output color format** parameter to `Intensity`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

R — Red color component of image or video frame
matrix

Red color component of the image or video frame, returned as an *M*-by-*N* matrix. *M* and *N* are the number of rows and columns in the image.

Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.
- Set the **Output color format** parameter to RGB and **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

G — Green color component of image or video frame
matrix

Green color component of the image or video frame, returned as an *M*-by-*N* matrix. *M* and *N* are the number of rows and columns in the image.

Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.
- Set the **Output color format** parameter to RGB and **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

B — Blue color component of image or video frame
matrix

Blue color component of the image or video frame, returned as an *M*-by-*N* matrix. *M* and *N* are the number of rows and columns in the image.

Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.
- Set the **Output color format** parameter to `RGB` and **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Y — Luma component of image or video frame
matrix

Luma component of the image or video frame, returned as an *M*-by-*N* matrix. *M* and *N* are the number of rows and columns in the image.

Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.
- Set the **Output color format** parameter to `YCbCr 4:2:2`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Cb — Blue-difference chrominance component of image or video frame
matrix

Blue-difference chrominance component of the image or video frame, returned as an *M*-by-*N*/2 matrix. *M* and *N* are the number of rows and columns in the input image.

Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.
- Set the **Output color format** parameter to `YCbCr 4:2:2`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Cr — Red-difference chrominance component of image or video frame
matrix

Red-difference chrominance component of the image or video frame, returned as an *M*-by-*N*/2 matrix. *M* and *N* are the number of rows and columns in each input image.

Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.
- Set the **Output color format** parameter to `YCbCr 4:2:2`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Audio — Audio signal
vector | matrix

Audio signal, returned as an *M*-element vector or an *M*-by-*N* matrix. *M* is the number of samples in each channel and *N* is the number of channels.

Dependencies

To enable this port, set the **File name** parameter to the name of a multimedia file that contains audio data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Audio only` or `Video and audio`.

Data Types: `single` | `double` | `int16` | `uint8`

EOF — End-of-file indicator
scalar

End-of-file indicator, returned as a logical scalar for each video frame or audio sample. The end-of-file indicator is `1` when the block outputs the final video frame or audio sample from the file, and is `0` otherwise.

Dependencies

To enable this port, select the **Output end-of-file indicator** parameter.

Data Types: `Boolean`

Parameters

Main

File name — Name of multimedia file

`vipmen.avi` (default) | character vector

Specify the name of the multimedia file for the block to read. If the file is not located on your MATLAB path, select **Browse** and navigate to the file, or specify the full file path.

On Microsoft® Windows® platforms, this parameter supports URLs that point to Microsoft Media Server (MMS) streams.

Inherit sample time from file — Inherit sample time from file

`on` (default) | `off`

Specify whether the block inherits the sample time from the multimedia file or uses a specified sample time. When you select this parameter, the block inherits the sample time from the input multimedia file.

Tip Select this parameter when you do not know the intended sample rate of the multimedia file.

Desired sample time — Block sample time

`1/30` (default) | real positive scalar

Specify a sample time for the block.

Dependencies

To enable this parameter, clear the **Inherit sample time from file** parameter.

Number of times to play file — Number of times to play multimedia file

`inf` (default) | real positive integer

Specify the number of times to play the input multimedia file. The default value of `inf` specifies that the block repeats playing the multimedia file until the simulation stop time.

Output end-of-file indicator — End-of-file indicator

`off` (default) | `on`

Select this parameter to enable the **EOF** port, which indicates whether the output frame or sample is the final video frame or audio sample in the multimedia file.

Multimedia outputs — Type of media

`Video only` (default) | `Audio only` | `Video and audio`

Specify the type of media to read from a file containing both video and audio data.

Dependencies

To enable this parameter, set the **File name** parameter to the name of a multimedia file that contains both audio and video data.

Output color format — Color format of video

`RGB` (default) | `Intensity` | `YCbCr 4:2:2`

Specify the output color format of the input video data. The block supports the `RGB`, `Intensity`, and `YCbCr 4:2:2` color formats.

Dependencies

To enable this parameter, set the **File name** parameter to the name of a multimedia file that contains video data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.

Image signal — Output port configuration for RGB video

`One multidimensional signal` (default) | `Separate color signals` | `Simulink image signal`

Specify how the block outputs an RGB color video. If you select `One multidimensional signal`, the block outputs the video data using only the **Image** port. If you select `Separate color signals`, the block outputs the video data using three separate color channels, divided across the **R**, **G**, and **B** ports. If you select `Simulink image signal`, the block outputs a video in `Simulink.ImageType` datatype.

Dependencies

To enable this parameter:

- Set the **File name** parameter to the name of a multimedia file that contains video data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.
- Set the **Output color format** parameter to RGB.

Read range — Range of audio samples

`[1 Inf]` (default) | two-element row vector

Specify the range of audio samples to read from the input file as a two-element row vector of the form `[StartSample EndSample]`. `StartSample` is the first sample the block reads from the audio file, and `EndSample` is the final sample the block reads from the audio file. `StartSample` must be greater than or equal to `1`. `EndSample` must be greater than `StartSample`.

Dependencies

To enable this parameter, set the **File name** parameter to the name of a multimedia file that contains audio data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Audio only`.

Samples per audio channel — Samples per audio channel

`1024` (default) | real positive integer

Specify the number of samples per audio channel.

Dependencies

To enable this parameter, set the **File name** parameter to the name of a multimedia file that contains audio data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Audio only`.

Data Types

Video output data type — Video output data type

`single` (default) | `double` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `Inherit from file`

Specify the data type for the output video frames.

Dependencies

To enable this parameter, set the **File name** parameter to the name of a multimedia file that contains video data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.

Audio output data type — Audio output data type

`int16` (default) | `double` | `single` | `uint8`

Specify the data type for the output audio samples.

Dependencies

To enable this parameter, set the **File name** parameter to the name of a multimedia file that contains audio data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Audio only` or `Video and audio`.

Block Characteristics

Data Types	`double` | `integer`[a] | `single`
Direct Feedthrough	`no`
Multidimensional Signals	`no`
Variable-Size Signals	`no`
Zero-Crossing Detection	`no`

a Supports 16- and 32-bit signed and 8-bit unsigned integers.

More About

Supported Platforms and File Formats

Which supported file formats are available to you depends on the codecs installed on your system.

Platform	Supported File Formats
All Platforms	AVI (`.avi`) Motion JPEG 2000 (`.mj2`)
Microsoft Windows	**Image**: JPEG(`.jpg`) Bitmap (`.bmp`)
	Video: MPEG (`.mpeg`) MPEG-2 (`.mp2`) MPEG-1 (`.mpg`) MPEG-4, including H.264 encoded video (`.mp4`, `.m4v`) Windows Media Video (`.wmv`, `.asf`, `.asx`) Any format supported by Microsoft DirectShow® 9.0 or higher.

Platform	Supported File Formats
	Audio: WAVE (`.wav`) Windows Media Audio File (`.wma`) Audio Interchange File Format (`.aif`, `.aiff`) Compressed Audio Interchange File Format (`.aifc`) MP3 (`.mp3`) Sun Audio (`.au`) Apple (`.snd`)
macOS	**Video**: MPEG-4, including H.264 encoded video (`.mp4`, `.m4v`) Apple QuickTime Movie (`.mov`) Any format supported by QuickTime®.
	Audio: Uncompressed AVI (`.avi`)
Linux®	Any format supported by your installed plug-ins for GStreamer 0.1 or higher, including Ogg Theora (`.ogg`).

Sample Time Calculations Used for Video and Audio Files

The sample rate that the block uses depends on the audio and video sample rate. While the block operates at a single rate in Simulink, the underlying audio and video streams can produce different rates. In some cases, the block makes a small adjustment to the video rate when the block outputs both audio and video.

Sample time = $\frac{ceil(AudioSampleRate/FPS)}{AudioSampleRate}$. *AudioSampleRate* is the sample rate for audio data, and *FPS* is the video frame rate.

When the audio sample time, $\frac{AudioSampleRate}{FPS}$, is not an integer,, the equation cannot reduce to $\frac{1}{FPS}$.

To prevent synchronization problems, when the audio stream leads the video stream by more than $\frac{1}{FPS}$, the block drops the corresponding video frame.

In summary, the block outputs one video frame at each Simulink time step. To calculate the number of audio samples to output at each time step, the block divides the audio sample rate by the video frame rate. If the audio sample rate does not divide evenly by the number of video frames per second (FPS), the block rounds the number of audio samples up to the nearest whole number. If necessary, the block periodically drops a video frame to maintain synchronization for large files.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- Host computer only. Excludes Simulink Desktop Real-Time code generation.
- The executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed ZIP file. Using this ZIP file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed.

Data Types: `Simulink.ImageType`

Output

Port_1 — Output signal
matrix

Output signal from the From Simulink Image block. The output is a matrix or an array, depending on the format of the input.

- *M*-by-*N* matrix — The input is a `Grayscale` image. *M* and *N* are the height and width of the image, in pixels.
- *M*-by-*N*-by-*C* matrix — The input is an RGB or BGR image. *M* and *N* are the height and width of the image, in pixels. *C* is the number of color channels.

Data Types: `integer` | `single` | `double` | `Boolean`

Parameters

Output dimensions — Dimensions of block output signal
`[480 640 3]` (default)

Specify the dimensions of the output image signal. The expression must be a three-element numeric row vector of form: `[Rows Columns Channels]`.

Programmatic Use

Block Parameter: `ImageSize`
Type: character vector
Value: character vector

Default: `[480 640 3]`

Block Characteristics

Data Types	`double` | `single` | `integer` | `Boolean` | `image`
Direct Feedthrough	`yes`
Multidimensional Signals	`yes`
Variable-Size Signals	`no`
Zero-Crossing Detection	`no`

Version History

Introduced in R2022a

Gamma Correction

Apply or remove gamma correction to or from image or video stream

Libraries:
Computer Vision Toolbox / Conversions

Description

The Gamma Correction block applies or removes gamma correction to or from an image or video stream.

Ports

Input

I — Input image
matrix | array

Input image, specified as an *M*-by-*N* matrix or an *M*-by-*N*-by-*C* array, where *C* is the number of color channels in the input image.

Dependencies

To enable this port, set the **Operation** parameter to `Gamma`.

Data Types: `single` | `double` | `int8` | `int16` | `uint8` | `uint16` | `Boolean` | `fixed point`

I' — Gamma-corrected input image
matrix | array

Gamma-corrected input image, specified as an *M*-by-*N* matrix or an *M*-by-*N*-by-*C* array, where *C* is the number of color channels in the input image.

Dependencies

To enable this port, set the **Operation** parameter to `De-gamma`.

Data Types: `single` | `double` | `int8` | `int16` | `uint8` | `uint16` | `Boolean` | `fixed point`

Output

I' — Gamma-corrected output image
matrix | array

Gamma-corrected output image, returned as an *M*-by-*N* matrix or an *M*-by-*N*-by-*C* array, where *C* is the number of color channels.

Dependencies

To enable this port, set the **Operation** parameter to `Gamma`.

Data Types: `single` | `double` | `int8` | `int16` | `uint8` | `uint16` | `Boolean` | `fixed point`

I — Gamma-removed output image
matrix | array

Gamma-removed output image, returned as an *M*-by-*N* matrix or an *M*-by-*N*-by-*C* array, where *C* is the number of color channels.

Dependencies

To enable this port, set the **Operation** parameter to `De-gamma`.

Data Types: `single` | `double` | `int8` | `int16` | `uint8` | `uint16` | `Boolean` | `fixed point`

Parameters

Operation — Block operation

`Gamma` (default) | `De-gamma`

Specify the gamma operation the block performs.

- `Gamma` — Apply gamma correction to the input image.
- `De-gamma` — Remove gamma correction from the input image.

Gamma — Gamma value

`2.2` (default) | scalar

Specify the gamma as a value greater than or equal to 1. A value less than 1 encodes luminance values in image and a value greater than 1 decodes luminance values in image, represented as gamma compression and gamma expansion respectively.

Linear segment — Linear segment

`on` (default) | `off`

Select this parameter to define the gamma curve as a linear segment near the origin. For more information, see “Gamma Correction Method” on page 1-253.

Break point — Break point value

`0.018` (default) | scalar

Specify a scalar break point value, which indicates the *I*-axis value at the end of the gamma curve linear segment. For more information, see “Gamma Correction Method” on page 1-253.

Dependencies

To enable this parameter, select the **Linear segment** parameter.

Block Characteristics

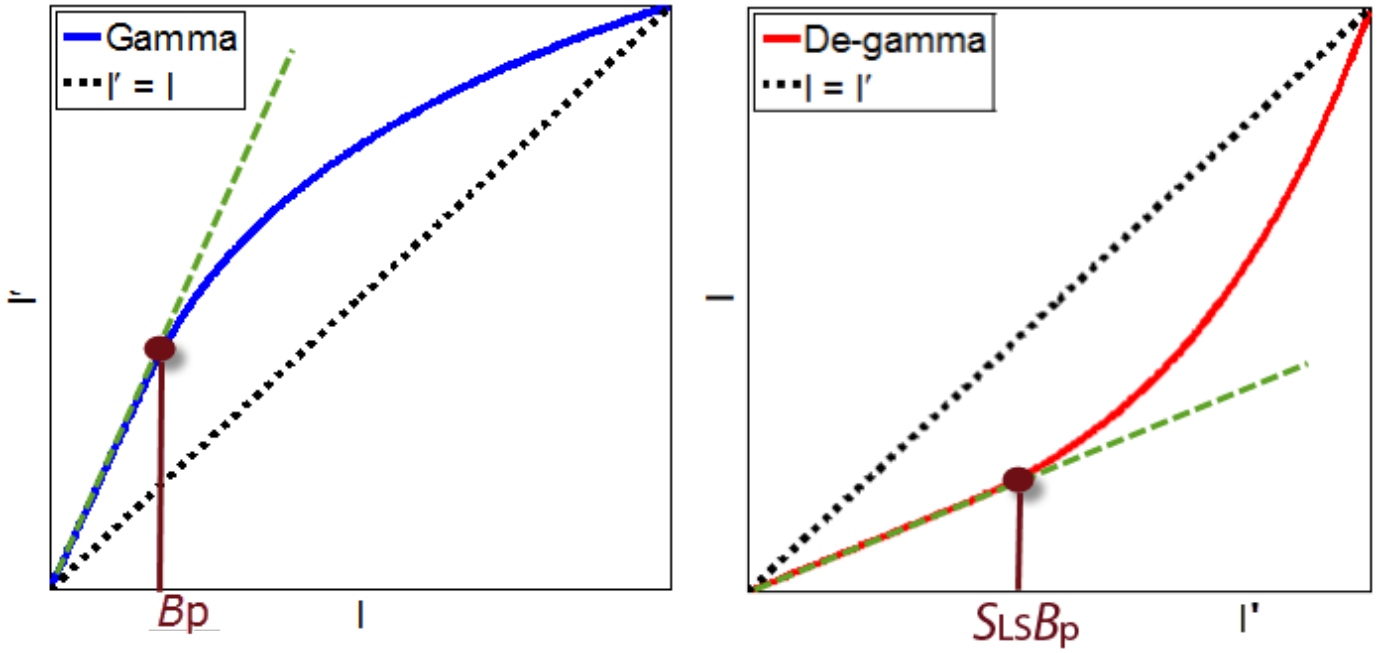
Data Types	`double` | `fixed point`[a] | `integer`[a] | `single`
Multidimensional Signals	`yes`
Variable-Size Signals	`yes`

a Supports word lengths less than or equal to 16 bits.

Algorithms

Gamma Correction Method

For input signals normalized between 0 and 1, gamma correction is defined by these equations. For integers and fixed-point data types, these equations are generalized by applying scaling and offset values specific to each data type.



$$S_{LS} = \frac{1}{\frac{\gamma}{B_p^{(1/\gamma - 1)}} - \gamma B_p + B_p}$$

$$F_S = \frac{\gamma S_{LS}}{\left(\frac{1}{\gamma}-1\right) B_p}$$

$$C_O = F_S B_p^{\frac{1}{\gamma}} - S_{LS} B_p$$

$$I' = \begin{cases} S_{LS} I, & I \le B_p \\ F_S I^{\frac{1}{\gamma}} - C_O, & I > B_p \end{cases}$$

S_{LS} is the slope of the straight line segment. B_P is the break point of the straight line segment, which corresponds to the **Break point** parameter. F_S is the slope-matching factor, which matches the slope of the linear segment to the slope of the power function segment. C_O is the segment offset, which ensures that the linear segment and the power function segments connect. This figure shows the slope of the straight line segment S_{LS} and break point of the straight line segment B_P for gamma and de-gamma operations.

By linearizing the input normalized signal, the block removes gamma correction as defined by this equation.

$$I = \begin{cases} \dfrac{I'}{S_{LS}}, & I' \le S_{LS}B_p \\ \left(\dfrac{I' + C_O}{F_S}\right)^{\gamma}, & I' > S_{LS}B_p \end{cases}$$

Typical gamma values range from 1 to 3. Most LCD monitor gamma values range from 1.8 to 2.2. Check with the manufacturer of your hardware to obtain its gamma value. This table shows the gamma function parameters for different standards.

Standard	Slope	Break Point	Gamma
CIE L*	9.033	0.008856	3
Recommendation ITU-R BT.709-3, Parameter Values for the HDTV Standards for Production and International Programme Exchange	4.5	0.018	20/9
sRGB	12.92	0.00304	2.4

Gaussian Pyramid

Perform Gaussian pyramid decomposition

Libraries:
Computer Vision Toolbox / Transforms

Description

The Gaussian Pyramid block computes Gaussian pyramid reduction or expansion to resize an image. The image reduction process involves lowpass filtering and then downsampling the image pixels. The image expansion process involves upsampling and then lowpass filtering the image pixels. You can also use this block to build a Laplacian pyramid.

Ports

Input

I — Input image
scalar | vector | matrix | array

Input image, specified as a scalar, a vector, an *M*-by-*N* matrix, or an *M*-by-*N*-by-*C* array. *C* is the number of color channels in the input image. To specify this input as a scalar or vector, you must set the **Operation** parameter to `Expand`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

Port_1 — Output image
scalar | vector | matrix | array

Output image, returned as a scalar, a vector, a matrix, or an array. The dimensions of the output image are determined by the **Operation**and **Pyramid level** parameter values. For this port to return a scalar or vector, you must set the **Operation** parameter to `Reduce`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Operation — Select operation

`Reduce` (default) | `Expand`

Select the Gaussian pyramid operation as one of these methods:

- `Reduce` — The block applies a lowpass filter and then downsamples the input image.
- `Expand` — The block upsamples and then applies a lowpass filter to the input image.

Pyramid level — Image scaling factor

`1` (default) | positive integer

Specify the factor of 2 by which to upsample or downsample each dimension of the image.

For an *M*-by-*N* input image, if you set the **Operation** parameter to `Reduce` and the **Pyramid level** to `1`, the dimensions of the output image are `ceil(M/2)`-by-`ceil(N/2)`.

For an *M*-by-*N* input image, if you set the **Operation** parameter to `Expand`, the dimensions of the output image are $[(M-1)2^l+1]$-by-$[(N-1)2^l+1]$, where the **Pyramid level** parameter l must be a positive integer.

Coefficient source — Lowpass filter coefficient source

`Default separable filter [1/4-a/2 1/4 a 1/4 1/4-a/2]` (default) | `Specify via dialog`

Specify the lowpass filter coefficient source as `Default separable filter [1/4-a/2 1/4 a 1/4 1/4-a/2]` or `Specify via dialog`.

Coefficients for separable filter — Separable filter coefficient

`[0.0625 0.25 0.375 0.25 0.0625]` (default) | vector

Specify the separable filter coefficients as a vector.

Hidden coefficients — Hidden separable filter coefficients

`[1/4-0.375/2 1/4 0.375 1/4 1/4-0.375/2]` (default) | vector

Specify the hidden separable filter coefficients as a vector.

Histogram Equalization

Enhance contrast of images using histogram equalization

Libraries:
Computer Vision Toolbox / Analysis & Enhancement

Description

The Histogram Equalization block enhances the contrast of images. The block transforms the intensity values in an image so that the histogram of the output image approximately matches a specified histogram. By default, the block transforms the input image so that the histogram of the output image is nearly flat.

Ports

Input

I — Input image
matrix

Input image, specified as a matrix of intensity values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Hist — Target histogram
vector of integers

Target histogram for the output image, specified as a vector of integers. Each element of the vector represents the desired count value for the corresponding bin. You must normalize the input vector such that the sum of all the bin counts equals the number of pixels in the input image.

When the data type of the input image is `single` or `double`, the **Hist** port input must be the same data type.

Dependencies

To enable this port, set these block parameters:

- **Target histogram**: `User-defined`
- **Histogram source**: `Input port`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Output

Port_1 — Output image
matrix

Output image, returned as a matrix of intensity values. The data type of the output image is the same as the data type of the input image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Target histogram — Type of desired histogram

`Uniform` (default) | `User-defined`

Specify the desired histogram type.

- `Uniform` — The block transforms the input image so that the histogram of the output image is approximately flat.
- `User-defined` — The block transforms the input image so that the histogram of the output image approximately matches the specified histogram.

Number of bins — Number of bins of target histogram

`64` (default) | integer greater than one

Specify the number of bins for the target histogram. The block spaces the bins equally.

Dependencies

To enable this parameter, set the **Target histogram** parameter to `Uniform`.

Histogram source — Source of target histogram

`Specify via dialog` (default) | `Input port`

Specify the source of the target histogram as either `Specify via dialog` or `Input port`.

- `Specify via dialog` — Use the **Histogram** parameter to specify a vector of integer values representing the desired counts of the equally spaced bins of the target histogram.
- `Input port` — Use the **Hist** input port to specify the target histogram.

Dependencies

To enable this parameter, set the **Target histogram** parameter to `User-defined`.

Note Normalize the input vector, specified using the selected **Histogram source**, such that the sum of all the bin counts equals the number of pixels in the input image. The block does not display an error if you do not normalize the vector.

Histogram — Bin counts of target histogram

`ones(1,64)` (default) | vector of integers

Specify the count for each bin of the target histogram. The sum of the bin counts must equal the number of pixels in the input image.

Dependencies

To enable this parameter, set these block parameters:

- **Target histogram**: `User-defined`
- **Histogram source**: `Specify via dialog`

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`no`

Hough Lines

Find Cartesian coordinates of lines described by rho and theta pairs

Libraries:
Computer Vision Toolbox / Transforms

Description

The Hough Lines block finds the points of intersection between the boundary lines of a reference image and a line specified as a rho-theta pair. The block outputs Cartesian coordinates for the points of intersection. The boundary lines indicate the left and right vertical boundaries and the top and bottom horizontal boundaries of the reference image.

If the line specified by a rho-theta pair does not intersect two border lines in the reference image, the block outputs the values, `[0 0 0 0]` for that line. This output value enables the next block in your model to ignore the outputs for that line, as the Hough Lines block generally precedes a block that draws a point or shape at each output intersection.

Ports

Input

Theta — Theta value
scalar | vector

Theta value, specified as a scalar or *M*-element vector. *M* is the number of specified lines. Each element represents the rotation angle of the corresponding line in radians.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

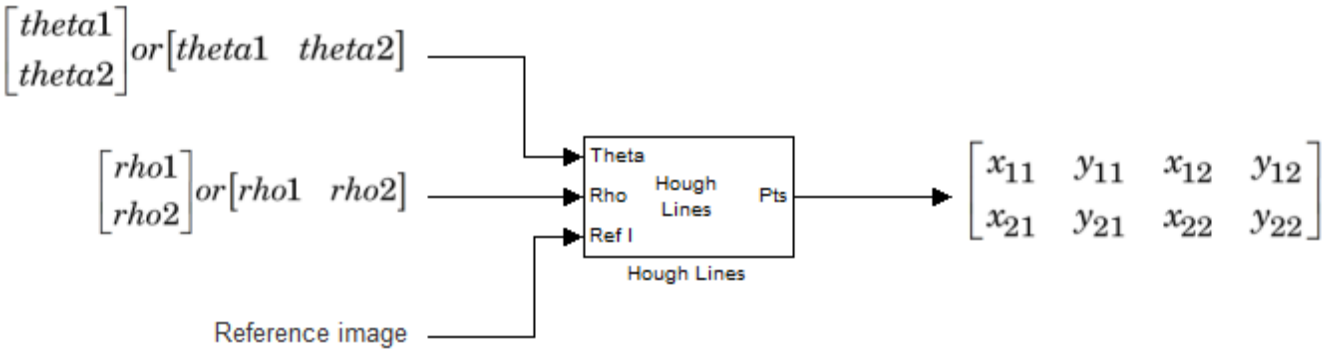
Rho — Rho value
scalar | vector

Rho value, specified as a scalar or *M*-element vector. *M* is the number of specified lines. Each element that represents the distance of the corresponding line from the top-left coordinate origin of the image at the angle specified by the corresponding element of **Theta**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Ref I — Reference image
matrix

Reference image, specified as an *M*-by-*N* matrix.



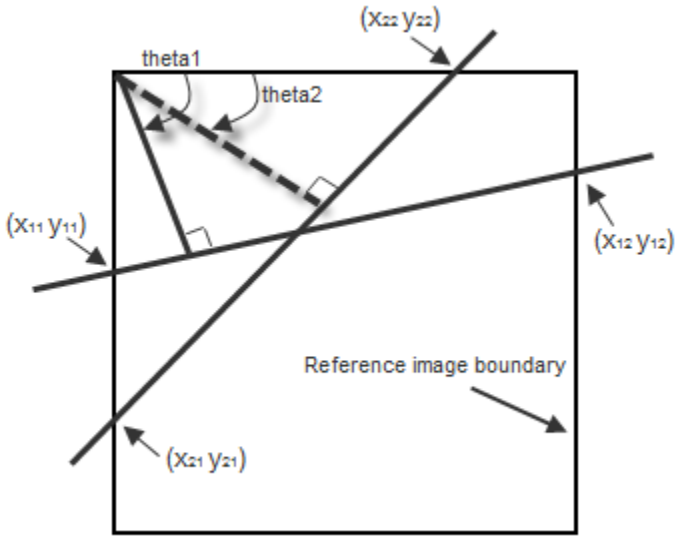
Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

Pts — Intersection points
matrix

Intersection points, returned as an *M*-by-4 matrix of coordinate values, where *M* is the number of input lines.

For example, consider a Hough Lines block with two-element vectors as the theta and rho inputs, describing two lines.



The block outputs a 2-by-4 matrix, in which each row consists of two *xy*-pairs of coordinates that describe the points at which the corresponding line intersects with the boundary lines of the reference image.

$[x_{11}\ y_{11}\ x_{12}\ y_{12};$

$x_{21}\ y_{21}\ x_{22}\ y_{22}]$

This figure shows the line described by the first rho-theta pair intersecting the boundaries of the reference image at $[x_{11}\ y_{11}\ x_{12}\ y_{12}]$ and the line described by the second pair intersecting the boundaries at $[x_{21}\ y_{21}\ x_{22}\ y_{22}]$.

Data Types: `int32`

Parameters

Sine value computation method — Sine value computation method

`Table lookup` (default) | `Trigonometric function`

You can specify one of these options.

- `Table lookup` — Before the simulation starts, the block computes and stores the trigonometric values required to calculate the intersections of the lines. In this case, the block requires additional memory.
- `Trigonometric function` — The block computes the sine and cosine values required to calculate the intersections of the lines during the simulation.

Theta resolution (radians) — Theta resolution

`pi/180` (default) | positive scalar

Specify the spacing of the theta-axis. Value must be greater than 0 and less than `pi/2`.

Dependencies

To enable this parameter, set the **Sine value computation method** parameter to `Table lookup`.

Block Characteristics

Data Types	`Boolean`[a] | `double` | `fixed point`[b, c] | `integer`[d] | `single`
Multidimensional Signals	`no`

Variable-Size Signals	yes

a This data type is only supported at the input port Ref1.
b Generated code will be restricted to MATLAB host computers when you set the FFT implementation parameter to FFTW, or when the transform length is not a power of two.
c Input ports Theta and Rho support signed fixed-point data types with word lengths less than or equal to 32, while Ref1 supports signed and unsigned fixed-point data types.
d The output port supports 32-bit signed integers only. Input ports Theta and Rho support signed integers, while Ref1 supports signed and unsigned integers.

Blocks

Find Local Maxima | Hough Transform

Hough Transform

Find lines in images

Libraries:
Computer Vision Toolbox / Transforms

Description

Use the Hough Transform block to find straight lines in an image. The block outputs the Hough space matrix and, optionally, the *rho*-axis and *theta*-axis vectors. Peak values in the matrix represent potential straight lines in the input image. You can use the output of the Hough Transform block to find straight lines in the image by using the Hough Lines block. Alternatively, you can use a custom algorithm to identify potential straight lines by locating peaks in the Hough space matrix.

Ports

Input

BW — Binary image
matrix

Binary image, specified as a matrix of `Boolean` values.

Data Types: `Boolean`

Output

Hough — Parameter space matrix
matrix

Parameter space matrix, returned as a numeric matrix. The values in the parameter space matrix are in the (*rho*, *theta*) space.

Data Types: `single` | `double` | `fixed point`

Theta — Theta values
vector

Theta values, returned as a numeric vector. Each element represents the rotation angle of the corresponding line, in radians.

Dependencies

To enable this port, you must select the **Output theta and rho values** parameter.

Data Types: `single` | `double` | `fixed point`

Rho — Rho values
vector

Rho values, returned as a numeric vector. Each element represents the distance of the corresponding line from the top-left point of the image.

Dependencies

To enable this port, you must select the **Output theta and rho values** parameter.

Data Types: `single` | `double` | `fixed point`

Parameters

Main

Theta resolution (radians) — Theta resolution

`pi/180` (default) | positive scalar

Specify the spacing of the Hough transform bins along the *theta*-axis. This value must be less than `pi/2`.

Rho resolution (pixels) — Rho resolution

`1` (default) | positive scalar

Specify the spacing of the Hough transform bins along the *rho*-axis.

Output theta and rho values — Enable Theta and Rho output ports

`off` (default) | `on`

Select this parameter to enable the **Theta** and **Rho** output ports. The block outputs the *theta*-axis and *rho*-axis vectors, respectively, at these ports.

Output data type — Output data type

`double` (default) | `single` | `Specify via Fixed-point tab`

Specify the data type of your output signal. If you select `double` or `single`, all the outputs are of the specified data type. If you select `Specify via Fixed-point tab`, you can specify the word length of each output in the **Data Types** tab.

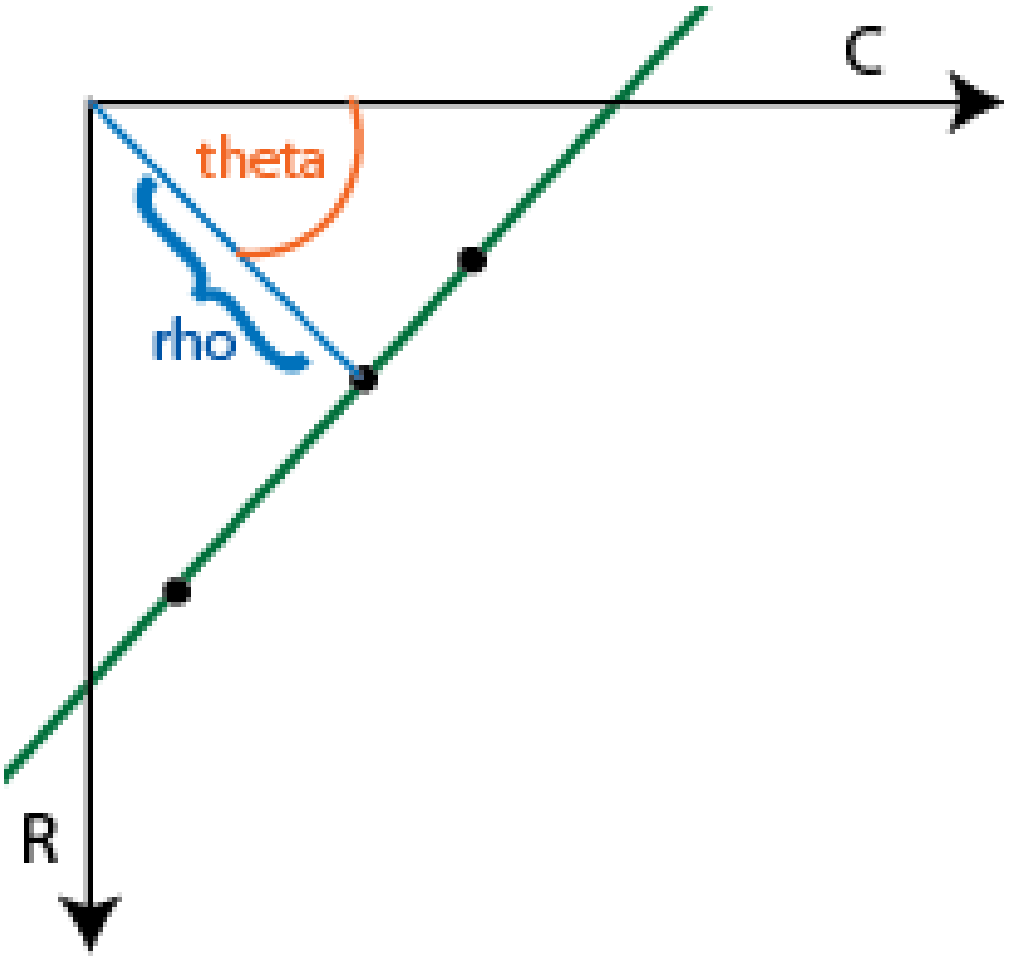
Data Types

For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Lock data type settings against change by the fixed-point tools — Prevent fixed-point tools from overriding data types
`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Block Characteristics



Data Types	`Boolean` | `double`[a] | `fixed point` | `integer` | `single`[a]
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

a This data type is supported at the output port(s).

Algorithms

The Hough Transform block implements the Standard Hough Transform (SHT). The SHT uses the parametric representation of a line:

$$rho = x * \cos(theta) + y * \sin(theta)$$

The block uses the upper-left corner pixel of the image as the origin, assigning it the *xy*-value of (0, 0).

The *rho* value indicates the perpendicular distance from the origin to the Hough line.

The *theta* value indicates the angle of inclination of the normal line from the *x*-axis. The range of *theta* is $-\frac{\pi}{2} \le \theta < +\frac{\pi}{2}$, with a step-size determined by the **Theta resolution (radians)** parameter. The SHT measures the angle of the line clockwise, with respect to the positive *x*-axis.

The Hough Transform block creates an accumulator matrix. The (*rho, theta*) pair represent the location of a cell in the accumulator matrix. Every valid (logical `true`) pixel of the input binary image represented by (*row, col*) produces a rho value for all theta values. The block quantizes the rho values to the nearest number in the rho vector. The rho vector depends on the size of the input image and the user-specified rho resolution. The block increments a counter (initially set to zero) in those accumulator array cells represented by the (*rho, theta*) pairs found for each pixel. This process validates that the point (*row, col*) is on the line defined by (*rho, theta*). The block repeats this process for each logical `true` pixel in the image. The Hough Transform block outputs the resulting accumulator matrix.

Image Attributes

Output attributes of Simulink image signal

Libraries:
Computer Vision Toolbox / Utilities

Description

The Image Attributes block outputs attributes of Simulink image signal as numeric data. Use Image Attributes block to:

- Display image attributes for debugging purposes.
- Use image attributes in control or data flow of an image processing algorithm.

Ports

Input

Port_1 — Input signal
`Simulink.ImageType`

Input signal to the Image Attributes block. The input is a Simulink image data type.

Data Types: `Simulink.ImageType`

Output

rows — Number of rows in image data
scalar

Number of rows in the image data, returned as a positive integer.

Data Types: `uint32`

columns — Number of columns in image data
scalar

Number of columns in the image data, returned as a positive integer.

Data Types: `uint32`

channels — Number of color channels or samples for each pixel in array
scalar

Number of color channels or samples for each pixel in the array, returned as 1, 3, or 4. The number of channels correspond to the number of color channels in the color format of the image data. These are the values of `Channels` for the supported color formats:

Color Format	Channels
Grayscale	1
RGB	3
BGR	3
BGRA	4

Data Types: uint32

class — Data type of underlying image data
string

Data type of the underlying image data, returned as one of these values:

- 'uint8'
- 'int8'
- 'uint16'
- 'int16'
- 'uint32'
- 'int32'
- 'single'
- 'double'
- 'boolean'

Data Types: string

color — Color format of underlying image data
string

Color format of the underlying image data, returned as 'RGB', 'Grayscale', 'BGR', or 'BGRA'. The color format determines what each color channel of a pixel in the image represents.

Data Types: string

layout — Array layout of image data
string

Memory arrangement of the matrix data in the image, returned as 'ColumnMajor' or 'RowMajor'.

Data Types: string

Block Characteristics

Data Types	integer | string | image

Image Complement

Compute the complement of pixel values in binary or intensity images

Libraries:
Computer Vision Toolbox / Conversions

Description

The Image Complement block computes the complement of a binary or intensity image.

For binary images, the block replaces pixel values equal to `0` with `1` and pixel values equal to `1` with `0`. In the output image, black and white are reversed. For intensity images, the block subtracts each pixel value from the maximum value that can be represented by the input data type and outputs the difference. In the output image, dark areas become lighter and light areas become darker.

For example, suppose the input pixel values are given by $x(i)$ and the output pixel values are given by $y(i)$. If the data type of the input is boolean, double or single, the block outputs $y(i) = 1.0-x(i)$. If the input is an 8-bit unsigned integer, the block outputs $y(i) = 255-x(i)$.

Ports

Input

Port_1 — Input image
matrix

Specify an input image as a matrix of intensity values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean`

Output

Port_1 — Output image
matrix

The complement of the binary or intensity input image is returned as a matrix of intensity values. The size and data type of the output image are the same as those of the input image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean`

Image Data Type Conversion

Convert and scale input image to specified output data type

Libraries:
Computer Vision Toolbox / Conversions

Description

The Image Data Type Conversion block converts the data type of the input image to the specified data type and scales the pixel values to the dynamic range of the output data. To convert between data types without scaling, use the Data Type Conversion block.

The behavior of the block changes depending on the input and output data types of the image.

- When converting between floating-point data types, the block casts the input values into the output data type and clips values below or above the range of the output data type to `0` or `1`, respectively.
- When converting to the `Boolean` data type, the block maps `0` values to `0` (`false`) and all other values to `1` (`true`).
- Between all other data types, the block casts and scales the input data type values into the dynamic range of the output data type. For double- and single-precision floating-point data types, the dynamic range is between `0` and `1`. For fixed-point data types, the dynamic range is between the minimum and maximum pixel values of that data type.

Ports

Input

I — Input image
matrix | array

Input image, specified as an *M*-by-*N* matrix or an *M*-by-*N*-by-*C* array, where *C* is the number of color channels in the input image.

Data Types: `single` | `double` | `int8` | `int16` | `uint8` | `uint16` | `Boolean` | `fixed point`

Output

Port_1 — Output image
matrix | array

Output image, returned as an *M*-by-*N* matrix or an *M*-by-*N*-by-*C* array, where *C* is the number of color channels in the output image.

Data Types: `single` | `double` | `int8` | `int16` | `uint8` | `uint16` | `Boolean` | `fixed point`

Parameters

Output data type — Output data type

`double` (default) | `single` | `int8` | `uint8` | `int16` | `uint16` | `boolean` | `Fixed-point` | `Inherit via back propagation`

Specifies the data type of your output signal.

Signed — Signed output

`on` (default) | `off`

Specifies the fixed-point data type of your output signal as signed.

Dependencies

To enable this parameter, set the **Output data type** parameter to `Fixed-point`.

Word length — Word length

`16` (default) | scalar

Specifies the word length of your fixed-point output.

Dependencies

To enable this parameter, set the **Output data type** parameter to `Fixed-point`.

Fraction length — Fraction length

`0` (default) | scalar

Specifies the fraction length of your fixed-point output.

Dependencies

To enable this parameter, set the **Output data type** parameter to `Fixed-point`.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point`[a] | `integer`[a] | `single`
Multidimensional Signals	`yes`
Variable-Size Signals	`yes`

a Supports word lengths less than or equal to 16 bits.

Version History

Image To Matrix

Converts Simulink image data to matrix data

Libraries:
Computer Vision Toolbox OpenCV Interface for Simulink

Description

The Image To Matrix block converts Simulink image data to matrix data.

Ports

Input

Port_1 — Input signal
`Simulink.ImageType`

Input signal to the Image To Matrix block. The input is a Simulink image data type.

Data Types: `Simulink.ImageType`

Output

Port_1 — Output signal
matrix

Output signal from the Image To Matrix block. The output is a matrix or an array, depending on the format of the input.

- *M*-by-*N* matrix — The input is a `Grayscale` image. *M* and *N* are the height and width of the image, in pixels.
- *M*-by-*N*-by-*C* matrix — The input is an RGB or BGR image. *M* and *N* are the height and width of the image, in pixels. *C* is the number of color channels.

Data Types: `uint8` | `uint16` | `int8` | `int16` | `single` | `double`

Parameters

Rows — Number of rows in image data
`'480'` (default) | positive integer

Specify the number of rows in the image data as a positive integer.

Programmatic Use
Block Parameter: Rows
Type: `double`
Value: positive integer

Default: `'480'`

Columns — Number of columns in image data
`'640'` (default) | positive integer

Specify the number of columns in the image data as a positive integer.

Programmatic Use
Block Parameter: `Columns`
Type: `double`
Value: positive integer
Default: `'640'`

Channels — Number of color channels or samples for each pixel
3 (default) | 1

Specify the number of color channels or samples for each pixel in the array as 1 or 3. The number of channels must correspond to the number of color channels in the color format of the image data. These are the values of **Channels** for the supported color formats:

Color Format	Channels
`Grayscale`	1
`RGB`	3
`BGR`	3

Programmatic Use
Block Parameter: `Channels`
Type: `double`
Value: positive integer
Default: `'3'`

Block Characteristics

Data Types	`double` | `single` | `uint8` | `uint16` | `int8` | `int16` | `int32` | `image`
Direct Feedthrough	`Yes`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`

Version History

Introduced in R2021b

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using Simulink® Coder™.

Supports C++ code generation.

Matrix To Image | From Simulink Image

Topics

“Install and Use Computer Vision Toolbox Interface for OpenCV in Simulink”

Image From File

Read image from file location

Libraries:
Computer Vision Toolbox / Sources

Description

The Image From File block reads an image from a specified file location and imports it to the Simulink workspace. The input file can contain a binary image, grayscale image, or color image.

Ports

Output

Image — Output image
matrix | 3-D array

Output image, returned as a matrix or 3-D array. If the image read is a binary or grayscale image, the output is an *M*-by-*N* matrix. If the image read is a color image, the output is an *M*-by-*N*-by-3 array.

Dependencies

To enable this port, set the **Image signal** parameter to `One multidimensional signal`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

R — Red color component of image
matrix

Red color component of the image, returned as an *M*-by-*N* matrix. The block returns this output if the input is a color image. If the **Image signal** parameter is set to Separate color signals and the input image is grayscale, the block returns only this port.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

G — Green color component of image
matrix

Green color component of the image, returned as an *M*-by-*N* matrix. The block returns this output only if the input is a color image.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

B — Blue color component of image
matrix

Blue color component of the image, returned as an *M*-by-*N* matrix. The block returns this output only if the input is a color image.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

File name — Input image
`peppers.png` (default) | file name

Specify the name of the file that contains the image to read. If the file is not on the MATLAB path, click **Browse** and navigate to the file. For the list of supported file formats, see the `imread` function reference page in the MATLAB documentation.

Note The **File name** parameter supports URL paths.

Sample time — Sample time for block execution
`inf` (default) | `Positive scalar` | `Vector`

Specify the sample time for block execution. Vector length must be 2 which represents [Period, Offset] values where offset should be less than period and non-negative. Given the default value of inf, the block outputs a matrix for grayscale and binary. For an input grayscale or color image, the output is a 3-D or 4-D array, respectively.

The value of the added dimension is equal to floor((T_{sim}/T_s)+1).

T_{sim} is the simulation time and T_s is the sample time, for block execution. For example, if the input image is a 256-by-256 matrix, the simulation time is 10 sec, and the sample time is set to 0.5 sec, then the output is a 256-by-256-by-21 array.

Image signal — Signal returned by block
`One multidimensional signal` (default) | `Separate color signals`

Specify how the block returns the image read from the file.

- `One multidimensional signal`— The block has one output port, which returns the entire image.
- `Separate color signals` — The block has three output ports, one for each color channel, which returns the individual color channels of the image.

Output port labels — Output port labels
`R|G|B` (default) | port names

Specify the labels for the output ports. Each label can be any value. Use vertical bar character, |, as a delimiter between the names of all the output ports.

Dependencies

To enable this parameter, set the **Image signal** parameter to `Separate color signals`.

Data type

Output data type — Data type of output image
inherit from input image (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | boolean | fixed-point | user-defined | inherit via back propagation

Specify the data type of the output image. If the input image data type,differs from the selected value of the **Output data type** parameter, the block scales the pixel values, adds an offset to the pixel values so that they are in the dynamic range of the new data type, or both. Double- and single-precision floating-point pixel values must be in the range [0 1].

Signed — Signed fixed-point data type
`on` (default) | `off`

Select this parameter if the input image data type is signed fixed-point.

Dependencies

To enable this parameter, set the **Output data type** parameter to `Fixed-point`.

Word length — Bits in fixed-point data type
16 (default) | positive scalar

Specify the word length, in bits, of the fixed-point output data type. The value should be less than 32.

Dependencies

To enable this parameter, set the **Output data type** parameter to `Fixed-point`.

Set fraction length in output to — Scaling factor of fixed-point data type
`User-defined` (default) | `Best precision`

Specify the scaling factor of the fixed-point output as one of these options.

- `Best precision`— The output scales automatically such that the output signal has the best possible precision.
- Choose `User-defined`— Specify the output scaling in the **Fraction length** parameter.

Dependencies

To enable this parameter, set the **Output data type** parameter to `Fixed-point`.

Fractional length — Fractional bits
15 (default) | scalar

Specify the number of bits to the right of the decimal point.

Dependencies

To enable this port ,set the **Output data type** parameter to `Fixed-point`, and set the **Set fraction length in output** parameter to `User-defined`.

User-defined data type — User-defined fixed-point data type
`uint(8)` (default) | `User-defined fixed-point data type`

Specify any built-in or fixed-point data type. You can specify fixed-point data types using the `fixdt` function.

Dependencies

To enable this parameter, set the **Output data type** parameter to `User-defined`.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`no`

Version History

Introduced before R2006a

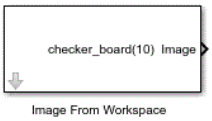
Blocks



From Multimedia File | Image From Workspace | To Video Display | Video From Workspace | Video Viewer

Functions

`im2double` | `im2uint8` | `imread`

Image From Workspace

Import image from MATLAB workspace

Libraries:
Computer Vision Toolbox / Sources

Description

The Image From Workspace block imports an image from a matrix, 3-D array, MATLAB function, or variable stored in the MATLAB workspace, to the Simulink workspace.

Ports

Output

Image — Output image
matrix | 3-D array

Output image, returned as a matrix or 3-D array. If the imported image is binary or grayscale image, the output is a matrix of size *M*-by-*N*. If the imported image is a color image, the output is a 3-D array of size *M*-by-*N*-by-3.

Dependencies

To enable this port ,set the **Image signal** parameter to `One multidimensional signal`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

R — Red color component of image
matrix

Red color component of the image, returned as an *M*-by-*N* matrix. The block returns this output if the input is a color image. If the **Image signal** parameter is set to `Separate color signals` and the input image is binary or grayscale, the block returns only this port

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

G — Green color component of image
matrix

Green color component of the image, returned as an *M*-by-*N* matrix. The block returns this output only if the input is a color image.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

B — Blue color component of image
matrix

Blue color component of the image, returned as an *M*-by-*N* matrix. The block returns this output only if the input is a color image.

Dependencies

To enable this port ,set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Main

Value — Image to be imported
`rand(100,100,3)` (default) | vector | matrix | 3-D array | `MATLAB workspace variable` | `MATLAB function`

Specify the image as a vector, matrix, 3-D array, function, or MATLAB workspace variable. The value parameter can be:

- Vector — The value given to the **Value** parameter can be a row vector or column vector
- 3-D numeric array — The value given to the **Value** parameter can be 3-D array, which is generated using MATLAB functions
- MATLAB workspace variable — The value given to the **Value** parameter can be a variable name, which is MATLAB workspace variable
- MATLAB function — The value given to the **Value** parameter can be a MATLAB function with specified input arguments to generate a numeric array

Sample time — Sample time for block execution
`inf` (default) | `positive scalar` | `Vector`

This parameter specifies the sample time for block execution. Vector length must be 2 which represents [Period, Offset] values where offset should be less than period and non-negative. Given the default value of inf, the block outputs a matrix for grayscale and binary. The output is 3-D or 4-D, if the input image is a gray scale or color image respectively.

The value of the added dimension is equal to $floor((T_{sim}/T_s)+1)$

T_{sim} is the simulation time and T_s is the sample time, for block execution. For example, if the input image is a 256-by-256 matrix, the simulation time is 10 sec and the sample time is set to 0.5 sec, then the output is a 256-by-256-by-21 array.

Image signal — Signal returned by block
`One multidimensional signal` (default) | `Separate color signals`

Specify how the block returns the image read from the MATLAB workspace.

- `One multidimensional signal`— The block has one output port, **Image**, that returns the entire image.
- `Separate color signals` — The block has an output port for each color channel. Each port returns a single color channel of the image.

Output port labels — Output port labels
`R|G|B` (default) | port names

Specify labels for the output ports. Each label can be any value. Use the vertical bar character, |, as a delimiter to name all the output ports.

Dependencies

To enable this parameter, set the **Image signal** parameter to `Separate color signals`.

Data type

Output data type — Data type of the output image
`Inherit from Value` (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `boolean` | `Fixed-point` | `User-defined` | `Inherit via back propagation` | ...

Specify the data type of the output image. If the data type of the imported image, specified in the **Value** parameter, differs from the value of the **Output data type** parameter, the block scales the pixel values, adds an offset to the pixel values so that they are in the dynamic range of the new data type, or does both. Double- and single-precision floating-point pixel values must be in the range of [0, 1].

Signed — Signed fixed-point data type
`on` (default) | `off`

Select this parameter if the input image data type is signed fixed-point.

Dependencies

To enable this parameter, set the **Output data type** parameter to `Fixed-point`.

Word length — Bits in fixed-point data type
16 (default) | positive scalar

Specify the word length, in bits, of the fixed-point output data type. The value should be less than 32.

Dependencies

To enable this parameter, set the **Output data type** parameter to `Fixed-point`.

Set fraction length in output to — Scaling factor of the fixed-point
`User-defined` (default) | `Best precision`

Specify the scaling factor of the fixed-point output by either of the following two methods:

- `Best precision`— The output scaling automatically such that the output signal has the best possible precision.
- `User-defined` — The output scaling in the **Fraction length** parameter.

Dependencies

To enable this parameter, set the **Output data type** parameter to `Fixed-point`.

Fractional length — Fractional bits
15 (default) | `scalar`

Specify the number of bits to the right of the decimal point.

Dependencies

To enable this parameter, set the **Output data type** parameter to `Fixed-point`, and set the **Set fraction length in output** parameter to `User-defined`.

User-defined data type — User-defined fixed-point data type
`sfix(16)` (default) | `user-defined fixed-point data type`

Specify any built-in or fixed-point data type. You can specify fixed-point data types using the `fixdt` function.

Dependencies

To enable this parameter, set the **Output data type** parameter to `User-defined`.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`no`

Version History

Image Pad

Pad image by adding rows, columns, or both

Libraries:
Computer Vision Toolbox / Utilities

Description

The Image Pad block expands the dimensions of an image by padding its rows, columns, or both.

Ports

Input

I — Input image
matrix | array

Input image, specified as an *M*-by-*N* matrix or an *M*-by-*N*-by-*P* array, where *P* is the number of color planes in the input image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

PVal — Pad value
scalar

Pad value, specified as a scalar. The block uses this value for each element of the rows or columns added to the input image.

Dependencies

To enable this port, set the **Method** parameter to `Constant` and the **Pad value source** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Output

Port_1 — Output image
matrix | array

Output image, returned as a padded matrix or an array. The dimensions of the output image are specified by the **Specify** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Method — Padding method

`Constant` (default) | `Replicate` | `Symmetric` | `Circular`

Pad the image using one of these methods:

- `Constant` — Pad the image with a constant value. See “Pad with Constant Value” on page 1-295.
- `Replicate` — Pad the image by repeating the border values of the input image. See “Pad by Repeating Border Values” on page 1-296.
- `Symmetric` — Pad the image using a mirror image of the input data. See “Pad with Mirror Image” on page 1-297.
- `Circular` — Pad the image using a circular repetition of the elements in the input image. See “Pad Using Circular Repetition of Elements” on page 1-298.

Pad value source — Source of constant pad value

`Specify via dialog` (default) | `Input port`

Specify the padding source as `Specify via dialog` or `Input port`.

- `Specify via dialog` — Specify a pad value using the **Pad Value** parameter.
- `Input port` — Specify a pad value using the **PVal** input port.

Dependencies

To enable this parameter, set the **Method** parameter to `Constant`.

Pad value — Pad value

`0` (default) | scalar

Specify a scalar value with which to pad the image.

Dependencies

To enable this parameter, set the **Method** parameter to `Constant` and the **Pad value source** parameter to `Specify via dialog`.

Specify — Padding size specification format

`Pad size` (default) | `Output size`

Select how to specify the size of the image padding from these two options:

- `Pad size` — Specify the number of columns and rows with which to pad the image, using the **Number of added columns** and **Number of added rows** parameters, respectively.
- `Output size` — Specify the size of the padded output image using a combination of the **Output row mode**, **Number of output rows**, **Output column mode**, and **Number of output columns** parameters.

Add columns to — Column padding location

`Left` (default) | `Right` | `Both left and right` | `No padding`

Select which sides of the input image to pad with additional columns:

- `Left` — Add columns to the left side of the input image.
- `Right` — Add columns to the right side of the input image.
- `Both left and right` — Add columns to both the left and right sides of the input image.
- `No padding` — Do not add columns to the input image.

Output column mode — Output column sizing method

`User-specified` (default) | `Next power of two`

Specify the number of columns in the output image using one of these options:

- `User-specified` — Specify the number of columns in the output image using the **Number of output columns** parameter.
- `Next power of two` — Add columns to the input image until the total number of columns is a power of two.

Dependencies

To enable this parameter, set the **Specify** parameter to `Output size`.

Number of output columns — Number of columns in output image

`10` (default) | positive integer

Specify the number of columns in the output image as a positive integer M. If the value of this parameter is less than the number of columns in the input image, then the output image contains only the last M columns of the input image.

Dependencies

To enable this parameter, set the **Specify** parameter to `Output size` and the **Output column mode** parameter to `User-specified`.

Number of added columns — Number of columns added to input image

2 (default) | positive integer | two-element vector of positive integers

Specify how many columns to add to the input signal. The behavior of this parameter changes depending on whether you are padding only one side or both sides of the image.

Add columns to	Number of added columns	Description
`Left`	P	Add P columns to the left side of the input image.
`Right`	Q	Add Q columns to the right side of the input image.
`Both left and right`	$[P\ Q]$	Add P columns to the left side and Q columns to the right side of the input image.

Dependencies

To enable this parameter, set the **Specify** parameter to `Pad size` and the **Add columns** to parameter to `Left`, `Right`, or `Both left and right`.

Add rows to — Row padding location

`Top` (default) | `Bottom` | `Both top and bottom` | `No padding`

Select which sides of the input image to pad with additional rows:

- `Top` — Add rows to the top of the input image.
- `Bottom` — Add rows to the bottom of the input image.
- `Both top and bottom` — Add rows to both the top and bottom of the input image.
- `No padding` — Do not add rows to the input image.

Output row mode — Output row sizing method

`User-specified` (default) | `Next power of two`

Specify the number of rows in the output image using one of these options:

- `User-specified` — Specify the number of rows in the output image using the **Number of output rows** parameter.
- `Next power of two` — Add rows to the input image until the total number of rows is a power of two.

Dependencies

To enable this parameter, set the **Specify** parameter to `Output size`.

Number of output rows — Number of rows in output image

`12` (default) | positive integer

Specify the number of rows in the output image as a positive integer *N*. If the value of this parameter is less than the number of rows in the input image, then the output image contains only the last *N* rows of the input image.

Dependencies

To enable this parameter, set the **Specify** parameter to `Output size` and the **Output row mode** parameter to `User-specified`.

Number of added rows — Number of rows added to input image

`[2 3]` (default) | positive integer | two-element vector of positive integers

Specify how many rows to add to the input signal. The behavior of this parameter changes depending on whether you are padding only one side or both sides of the image.

Add rows to	Number of added rows	Description
`Top`	*R*	Add *R* rows to the top of the input image.
`Bottom`	*S*	Add *S* rows to the bottom of the input image.
`Both top and bottom`	[*R S*]	Add *R* rows to the top and *S* rows to the bottom of the input image.

Dependencies

To enable this parameter, set the **Specify** parameter to `Pad size` and the **Add rows** to parameter to `Top`, `Bottom`, or `Both top and bottom`.

Action when truncation occurs — Action when input signal is truncated

`None` (default) | `Warning` | `Error`

You can specify how the block behaves when the input signal is truncated as one of these options:

- `None` — Does not notify you when the signal is truncated.
- `Warning` — Displays a warning message in the MATLAB command window when the input signal is truncated.
- `Error` — Displays an error dialog box and terminates the simulation when the input signal is truncated.

Dependencies

To enable this parameter, set the **Specify** parameter to `Output size`.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`no`

More About

Pad with Constant Value

When padding an image with a constant value, every element of the rows and columns the Image Pad block adds to the input image is a specified scalar value.

If you want to pad each of your input signal with three initial values equal to `0`, and this is how your input signal is defined:

$$\begin{bmatrix} a_{00} & a_{01} & a_{02} \\ a_{10} & a_{11} & a_{12} \\ a_{20} & a_{21} & a_{22} \end{bmatrix}.$$

Specify these parameters for the Image Pad block:

- **Method** — `Constant`
- **Pad value source** — `Specify via dialog`
- **Pad value** — `0`
- **Specify** — `Output size`
- **Add columns to** — `Left`
- **Output column mode** — `User-specified`
- **Number of output columns** — `6`
- **Add rows to** — `No padding`

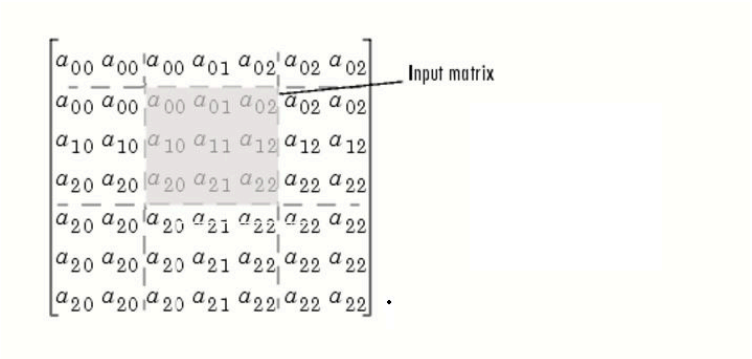
The Image Pad block outputs this signal:

$$\begin{bmatrix} 0 & 0 & 0 & a_{00} & a_{01} & a_{02} \\ 0 & 0 & 0 & a_{10} & a_{11} & a_{12} \\ 0 & 0 & 0 & a_{20} & a_{21} & a_{22} \end{bmatrix}.$$

Pad by Repeating Border Values

When padding an image with the **Method** parameter set to `Replicate`, the Image Pad block replicates border values of the input signal across all directions.

If you want to pad your input signal with its border values and this is how your input signal is defined:



$$\begin{bmatrix} a_{00} & a_{01} & a_{02} \\ a_{10} & a_{11} & a_{12} \\ a_{20} & a_{21} & a_{22} \end{bmatrix}.$$

Specify these parameters for the Image Pad block:

- **Method** — `Replicate`
- **Specify** — `Pad size`
- **Add columns to** — `Both left and right`
- **Number of added columns** — `2`

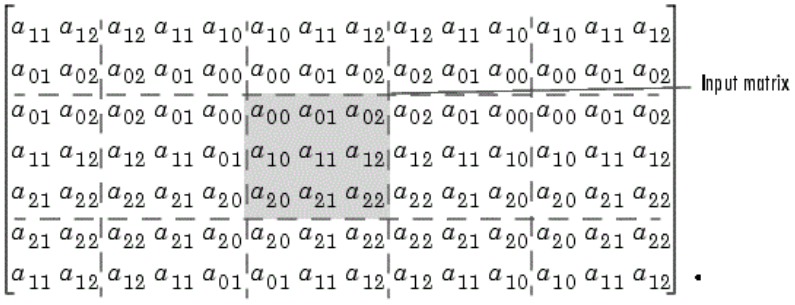
- **Add rows to** — `Both top and bottom`
- **Number of added rows** = `[1 3]`

The Image Pad block outputs this signal:

The border values of the input signal are replicated on the top, bottom, left, and right of the input signal, so that the output is a 7-by-7 matrix. The values in the corners of this output matrix are determined by replicating the border values of the matrices on the top, bottom, left, and right sides of the original input signal.

Pad with Mirror Image

When padding an image with the **Method** parameter set to `Symmetric`, the Image Pad block flips the original input matrix and each matrix it creates, to populate across all directions of the input signal.



If you want to pad your input signal using its mirror image and this is how your input signal is defined:

$$\begin{bmatrix} a_{00} & a_{01} & a_{02} \\ a_{10} & a_{11} & a_{12} \\ a_{20} & a_{21} & a_{22} \end{bmatrix}.$$

Specify these parameters for the Image Pad block:

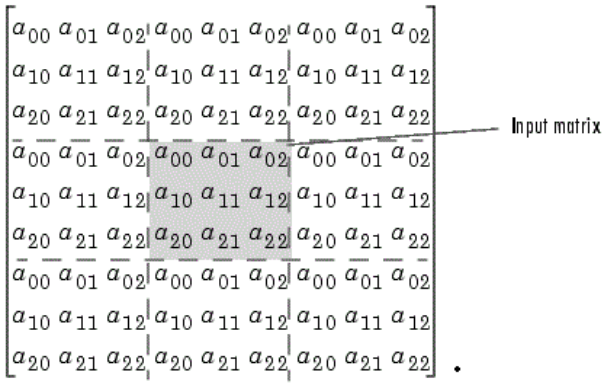
- **Method** — `Symmetric`
- **Specify** — `Pad size`
- **Add columns to** — `Both left and right`
- **Number of added columns** — `[5 6]`
- **Add rows to** — `Both top and bottom`
- **Number of added rows** — `2`

The Image Pad block outputs this signal:

The block flips the original input matrix and each matrix it creates about their top, bottom, left, and right sides to populate the 7-by-13 output signal. For example, the block flips the input matrix about its right side to create the matrix directly to its right, but flips that second matrix about its bottom to create the matrix below it.

Pad Using Circular Repetition of Elements

When padding an image with the **Method** parameter set to `Circular`, the Image Pad block repeats the values of the input signal in a circular pattern across all directions.



If you want to pad your input signal using a circular repetition of its values and this is how your input signal is defined:

$$\begin{bmatrix} a_{00} & a_{01} & a_{02} \\ a_{10} & a_{11} & a_{12} \\ a_{20} & a_{21} & a_{22} \end{bmatrix}.$$

Specify these parameters for the Image Pad block:

- **Method** — `Circular`
- **Specify** — `Output size`
- **Add columns to** — `Both left and right`
- **Number of output columns** — `9`
- **Add rows to** — `Both top and bottom`
- **Number of output rows** — `9`

The Image Pad block outputs this signal:

The block repeats the values of the input signal in a circular pattern to populate the 9-by-9 output matrix.

Version History

Introduced in R2007a

Insert Text

Draw text on images or video frames

Libraries:
Computer Vision Toolbox / Text & Graphics

Description

The Insert Text block draws formatted text on an input image or video stream. The block produces stylized text bitmaps using the open-source font engine Free Type 2.3.5 library. For more information about the library, see The FreeType Project website.

Note This block supports only ASCII characters.

This block enables you to insert:

- A single instance of text
- Multiple instances of the same text
- Multiple instances of text, with different text at each location

Ports

Input

Image — Input image
matrix | array

Input image or video, specified as an *M*-by-*N* matrix, *M*-by-*N*-by-*T* array, *M*-by-*N*-by-*C* array, or *M*-by-*N*-by-*C*-by-*T* array. *T* is the number of frames in a video or image sequence, and *C* is the number of color channels.

Dependencies

To enable this port, set the **Image signal** parameter to `One multidimensional signal`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

R — Red color component of input image
matrix | array

Red color component of the input image or video, specified as an *M*-by-*N* matrix or *M*-by-*N*-by-*T* array, where *T* is the number of frames in the input video.

Note Inputs to the **R**, **G**, and **B** ports must have the same dimensions and data type.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

G — Green color component of input image
matrix | array

Green color component of the input image or video, specified as an *M*-by-*N* matrix or *M*-by-*N*-by-*T* array, where *T* is the number of frames in the input video.

Note Inputs to the **R**, **G**, and **B** ports must have the same dimensions and data type.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

B — Blue color component of input image
matrix | array

Blue color component of the input image or video, specified as an *M*-by-*N* matrix or *M*-by-*N*-by-*T* array, where *T* is the number of frames in the input video.

Note Inputs to the **R**, **G**, and **B** ports must have the same dimensions and data type.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Select — Select the display text
positive integer

Select the display text, specified as a positive integer.

Select a display text from the cell array using this port, when the input to the **Text** parameter is a cell array of character vectors. For example, the value to the **Select** port must be in the range `[1, S]`, when the **Text** parameter is a cell array of *S* character vectors.

Dependencies

To enable this port, specify the **Text** parameter as a cell array of character vectors.

Data Types: `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Color — Text color value
scalar | vector | matrix

Text color value, specified as a scalar, a vector or a matrix. Use this table to determine the type of input value to this port.

Input Image	Same Color for All Text	Different Color for Each Character Vector
Intensity image	scalar value	*S*-element vector. *S* is the number of character vectors in the cell array specified to **Text** parameter.
Color image	three-element vector	*S*-by-3 matrix. *S* is the number of character vectors in the cell array specified to **Text** parameter.

The data type of the input image determines the range of color values. For example, a color value for a floating-point input image data type is in the range `[0, 1]`. For an input image with a `uint8` data type, the value is in the range `[0, 255]`.

Note The input to this port must be of the same data type as the input image.

Dependencies

To enable this port, set the **Color value source** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Location — Location index
vector | matrix

Location index, specified as a two-element vector of the form `[x y]` or an *S*-by-2 matrix. `[x y]` specify the coordinates of the input image to display the text. Specify it as an *S*-by-2 matrix, to display *S* character vectors at different locations in the image.

Dependencies

To enable this port, set the **Location source** parameter to `Input port`.

Data Types: `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Opacity — Opacity factor
scalar | vector

Opacity factor, specified as a scalar or an *S*-element vector.

- Scalar — Specify same opacity value to all the display text.
- *S*-element vector — Specify different opacity values to *S* character vectors specified in the **Text** parameter.

Specify opacity values in the range `[0, 1]`.

Note The input to the **Image**, **R**, **G**, **B**, and **Color** ports must be of the same data type as the input to this port.

Dependencies

To enable this port, set the **Opacity source** parameter to `Input port`.

Data Types: `single` | `double`

Variables — Text variable values

scalar | vector

Text variable values, specified as a scalar or a vector. The block replaces the format specifiers such as `%d`, `%f`, or `%s` in the **Text** parameter, with the elements specified by the **Variables** port.

Use the **Variables** port to display S character vectors or numerical values simultaneously, at S locations of the input image or video frame. The input to this port depends on the type of format specifier specified to the **Text** parameter.

Display Text	Data Type	Format Specifier	Input to the Variables Port
Character vectors	`uint8`	`'%s', '%c'`	`['Text1' 0 'Text2' 0 .... 0 'Text`S`']`
Integers	`uint8`, `uint16`, `uint32`, `int8`, `int16`, `int32`	`'%d', '%i', '%o', '%x', '%X'`	$[x_1\ x_2\ x_3 \ldots\ x_S]$
Floating point numbers	`single`, `double`	`'%f', '%e', '%E', '%g', '%G'`	$[x_1\ x_2\ x_3 \ldots\ x_S]$

For more information on format specifiers, see `sprintf`.

Dependencies

To enable this port, enter ANSI C `printf`-style format specifiers, such as `'%d'`, `'%f'`, or `'%s'` in the **Text** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Output

Port_1 — Output image

matrix | array

Output image or video, returned as an M-by-N matrix, M-by-N-by-T array, M-by-N-by-C array, or M-by-N-by-C-by-T array. T is the number of frames in a video or image sequence, and C is the number of color channels.

Dependencies

To enable this port, set the **Image signal** parameter to `One multidimensional signal`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

R — Red color component of output image

matrix | array

Red color component of the output image or video, returned as an M-by-N matrix or M-by-N-by-T array, where T is the number of frames in the output video.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

G — Green color component of output image
matrix | array

Green color component of the output image or video, returned as an *M*-by-*N* matrix or *M*-by-*N*-by-*T* array, where *T* is the number of frames in the output video.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

B — Blue color component of output image
matrix | array

Blue color component of the output image or video, returned as an *M*-by-*N* matrix or *M*-by-*N*-by-*T* array, where *T* is the number of frames in the output video.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Parameters

Main

Text — Text to insert

`'Text'` (default) | character vector | cell array of character vectors

Specify the text to insert into the image, as a character vector or a cell array of character vectors. You can display either a single text or multiple texts simultaneously, using the **Text** parameter.

- Single text — You can specify **Text** parameter as either a character vector or a cell array of *S* character vectors. If you specify a cell array, select one-out-of-*S* character vectors from the cell array, by using the **Select** input port.
- Multiple texts simultaneously — You can specify ANSI C `printf`-style format specifiers in the **Text** parameter. You can then specify the texts by using the **Variable** input port. Supported format specifiers include `%d`, `%i`, `%u`, `%o`, `%x`, `%X`, `%c`, `%s`, `%f`, `%e`, `%E`, `%g`, and `%G`. For more information on format specifiers, see `sprintf`.

Use this table to determine the type of input value to the **Text** parameter.

Display	Input toText parameter	Status of Select port	Status of Variables port
A character vector	Single character vector such as `'Text'`	`Disabled`	`Disabled`

Display	Input toText parameter	Status of Select port	Status of Variables port
One-out-of-*S* character vectors	Cell array of *S* character vectors such as `{'Text1', 'Text2',...., 'TextS'}`	`Enabled`	`Disabled`
S character vectors	Format specifier such as `'%s'`	`Disabled`	`Enabled`

Color value source — Source of text color

`Specify via dialog` (default) | `Input port`

Select the text color source as either `Specify via dialog` or `Input port`. You can specify this parameter as `Specify via dialog` to specify insert text colors using the **Color value** parameter. You can specify this parameter as `Input port` to specify text colors by using the **Color** input port.

Color value — Text color value

`[0 0 0]` (default) | scalar | vector | matrix

Text color value specified as a scalar, a vector, or a matrix. Use this table to determine the type of input value to this port.

Input Image	Same Color for All Text	Different Color for Each Character Vector
Intensity image	scalar value	*S*-element vector. *S* is the number of character vectors in the cell array specified to the **Text** parameter.
Color image	three-element vector	*S*-by-*3* matrix. *S* is the number of character vectors in the cell array specified to the **Text** parameter.

The data type of the input image determines the range of color values. For example, a color value for a floating-point input image data type is in the range [`0`, `1`]. For an input image with a `uint8` data type, the value is in the range [`0`, `255`].

Dependencies

To enable this parameter, set the **Color value source** parameter to `Specify via dialog`.

Location source — Source of location indices

`Specify via dialog` (default) | `Input port`

Specify the source of location coordinates of the display text as one these options:

- `Specify via dialog` — Use the **Location [x y]** parameter to specify location coordinates of the display text.

- `Input port` — Use the **Location** input port to specify location coordinates of the display text.

Location [x y] — Text location index

`[1,1]` (default) | vector | matrix

Text location index, specified as a two-element vector `[x y]` or an *S*-by-2 matrix. `[x y]` specify the coordinates of the input image to display the text. Specify the value as an *S*-by-2 matrix, to display *S* character vectors at different locations in the image.

Dependencies

To enable this parameter, set the **Location source** parameter to `Specify via dialog`.

Opacity source — Source of opacity factor

`Specify via dialog` (default) | `Input port`

Specify opacity factor source as one of these options:

- `Specify via dialog` — Use the **Opacity** parameter to specify opacity factor.
- `Input port` — Use the **Opacity** input port to specify opacity factor.

Opacity — Opacity factor

`1` (default) | scalar | vector

Opacity factor, specified as a scalar or an *S*-element vector.

- Scalar — Specify same opacity value to the display text.
- *S*-element vector — Specify different opacity values to *S* character vectors specified to the **Text** parameter

Specify opacity value in the range `[0, 1]`.

Dependencies

To enable this parameter, set the **Opacity source** parameter to `Specify via dialog`.

Image signal — Input and output signal format

`One multidimensional signal` (default) | `Separate color signals`

Specify the format of the input and output images of the block using these options:

- `One multidimensional signal` — The block enables a single input port and single output port.
- `Separate color signals` — The block enables R, G, and B input and output signal ports for the respective color channels of the image.

Input image is transposed (data order is row major) — Mirror text and text location

`off` (default) | `on`

Enable this parameter to mirror the text string and reverse its location in the image from `[x y]` to `[y x]`.

Font

Font face — Font of text

`Roboto-Regular` (default) | `Agency FB` | `Agency FB Bold` | `Algerian` | `Ariel` | `Arial Black` | `Arial Bold` | `Arial Bold Italic` | ...

Specify the font of the inserted text. The block populates this list with the fonts installed on your system. On Windows, the block searches the system registry for font files. On UNIX, the block searches the font path of the X Server for font files.

Font size (points) — Font size

12 (default) | positive scalar

Specify the font size of the inserted text.

Anti-aliased — Smooth text edges

`on` (default) | `off`

Enable this parameter to smooth the edges of the inserted text. The smoothing process is computationally expensive.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point`[a] | `integer` | `single`
Multidimensional Signals	`yes`
Variable-Size Signals	`yes`

a Supports word lengths less than or equal to 32 bits.

Version History

Introduced in R2013a

R2026a: Default value of Font face changed to `Roboto-Regular`
Behavior changed in R2026a

Starting in R2026a, the default value of the **Font face** parameter is `Roboto-Regular`. In previous releases, the default value was `LucidaSansRegular`.

Extended Capabilities

Draw Shapes | Draw Markers

Label

Label connected components in binary image

Libraries:
Computer Vision Toolbox / Morphological Operations

Description

The Label block finds and labels the connected components or objects in a 2-D binary image. The block ignores the background pixels in the input image and searches for connected components within remaining pixels. The block then labels all the pixels of each connected component with a unique number and computes the number of labeled objects.

Ports

Input

BW — Input binary image
vector | matrix

The input image must be a vector or matrix of binary values, each element representing a pixel of the image. The block categorizes pixels with a value of `0` as background pixels, searching for connected components within pixels with a value of `1`.

Data Types: `Boolean`

Output

Label — Labeled objects
vector | matrix

Labeled objects in the input image, returned as a vector or matrix of nonnegative integers. The elements of the output vector or matrix labeled `0` represent the background, the elements labeled `1` represent the first object, the elements labeled `2` represent the second object, and so on. The size of this output matches the size of the **BW** input.

Dependencies

To enable this port, set the **Output** parameter to either `Label matrix` or `Label matrix and number of labels`.

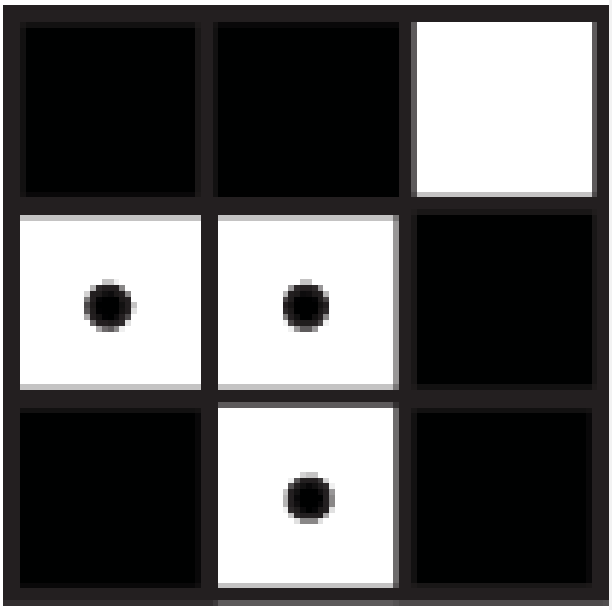
Data Types: `uint8` | `uint16` | `uint32`

Count — Number of labeled objects
scalar

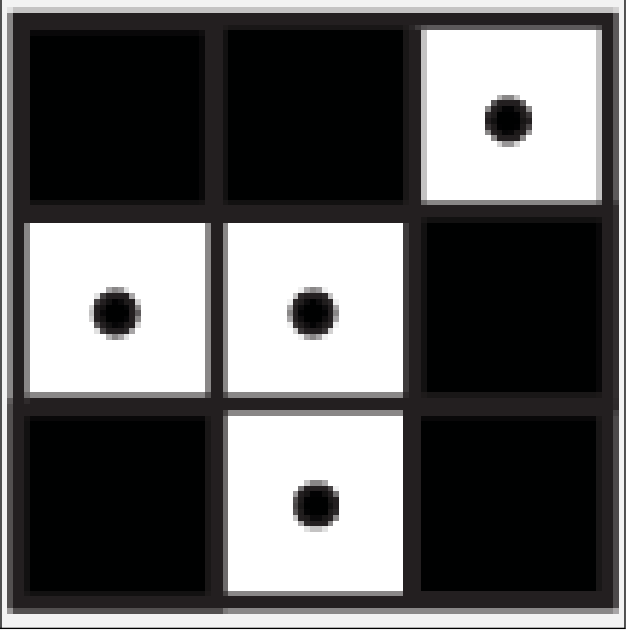
Number of labeled objects, returned as a scalar.

Dependencies

To enable this port, set the **Output** parameter to either `Number of labels` or `Label matrix and number of labels`.



Data Types: `uint8` | `uint16` | `uint32`



Parameters

Connectivity — Type of pixel connectivity

8 (default) | 4

Specify how the block defines which pixels are connected to each other. If you want to connect adjacent pixels in only the horizontal and vertical directions, select `4`. If you want to connect adjacent pixels in the horizontal, vertical, and diagonal directions, select `8`. These figures show how the block defines a connected component for 4-connected and 8-connected pixels. The block considers the white pixels marked by black circles to be connected to each other.

Type of Connectivity	Connected Pixels
4-connected pixels	

Type of Connectivity	Connected Pixels
8-connected pixels	

Output — Block output

`Label matrix and number of labels` (default) | `Label matrix` | `Number of labels`

Specify the block output as one of these options:

- `Label matrix` — The block outputs the labeled objects at the **Label** port.
- `Number of labels` — The block outputs the number of labeled objects at the **Count** port.
- `Label matrix and number of labels` — The block outputs both the labeled objects and number of labeled objects to the **Label** and **Count** ports, respectively.

Output data type — Data type of output

`Automatic` (default) | `uint8` | `uint16` | `uint32`

Specify the data type of the outputs at the **Label** and **Count** ports. When you specify this parameter as `Automatic`, the block calculates the maximum number of objects that can fit inside the image based on the image size and the specified connectivity. Using this calculation, it chooses the output data type with the minimum value that guarantees unique region labels.

If label exceeds data type size, mark remaining regions using — Overflow mode of output labels

`maximum value of the output data type` (default) | `zero`

Use this parameter to specify the behavior of the block when the block finds more objects than the maximum possible value the output data type can represent. The block labels the remaining objects with the value determined by one of these options:

- `maximum value of the output data type` — The block labels the remaining objects with the maximum value of the output data type.

- `zero` — The block labels the remaining objects with `0`.

Dependencies

To enable this parameter, set the **Output data type** parameter to either `uint8` or `uint16`.

Block Characteristics

Data Types	`Boolean` | `integer`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

Version History

Introduced before R2006a

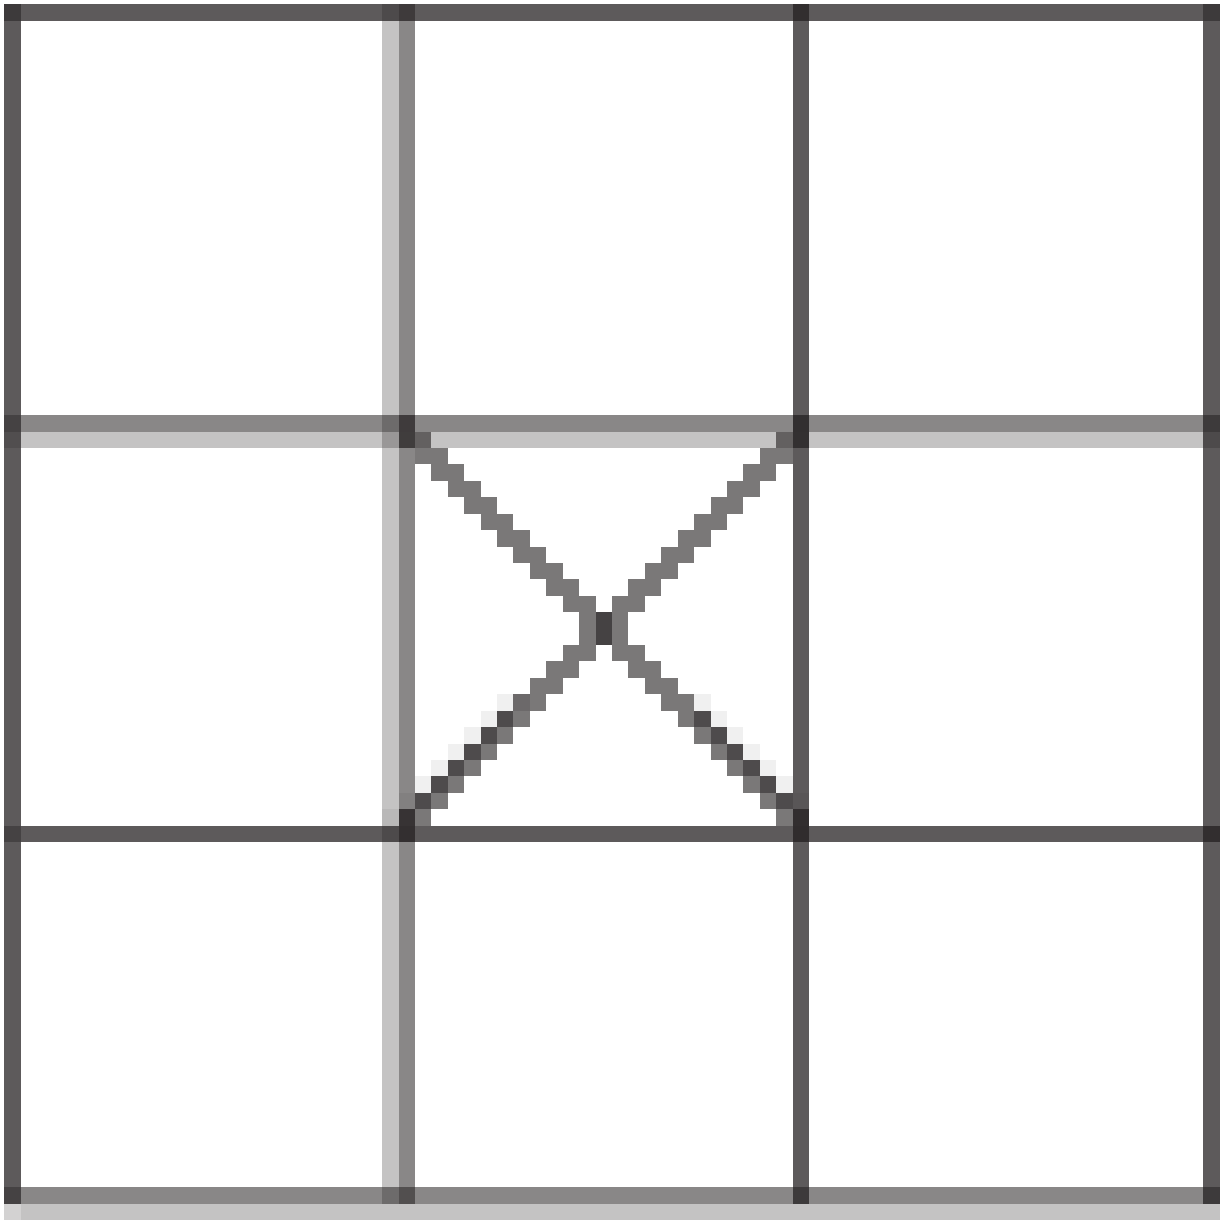
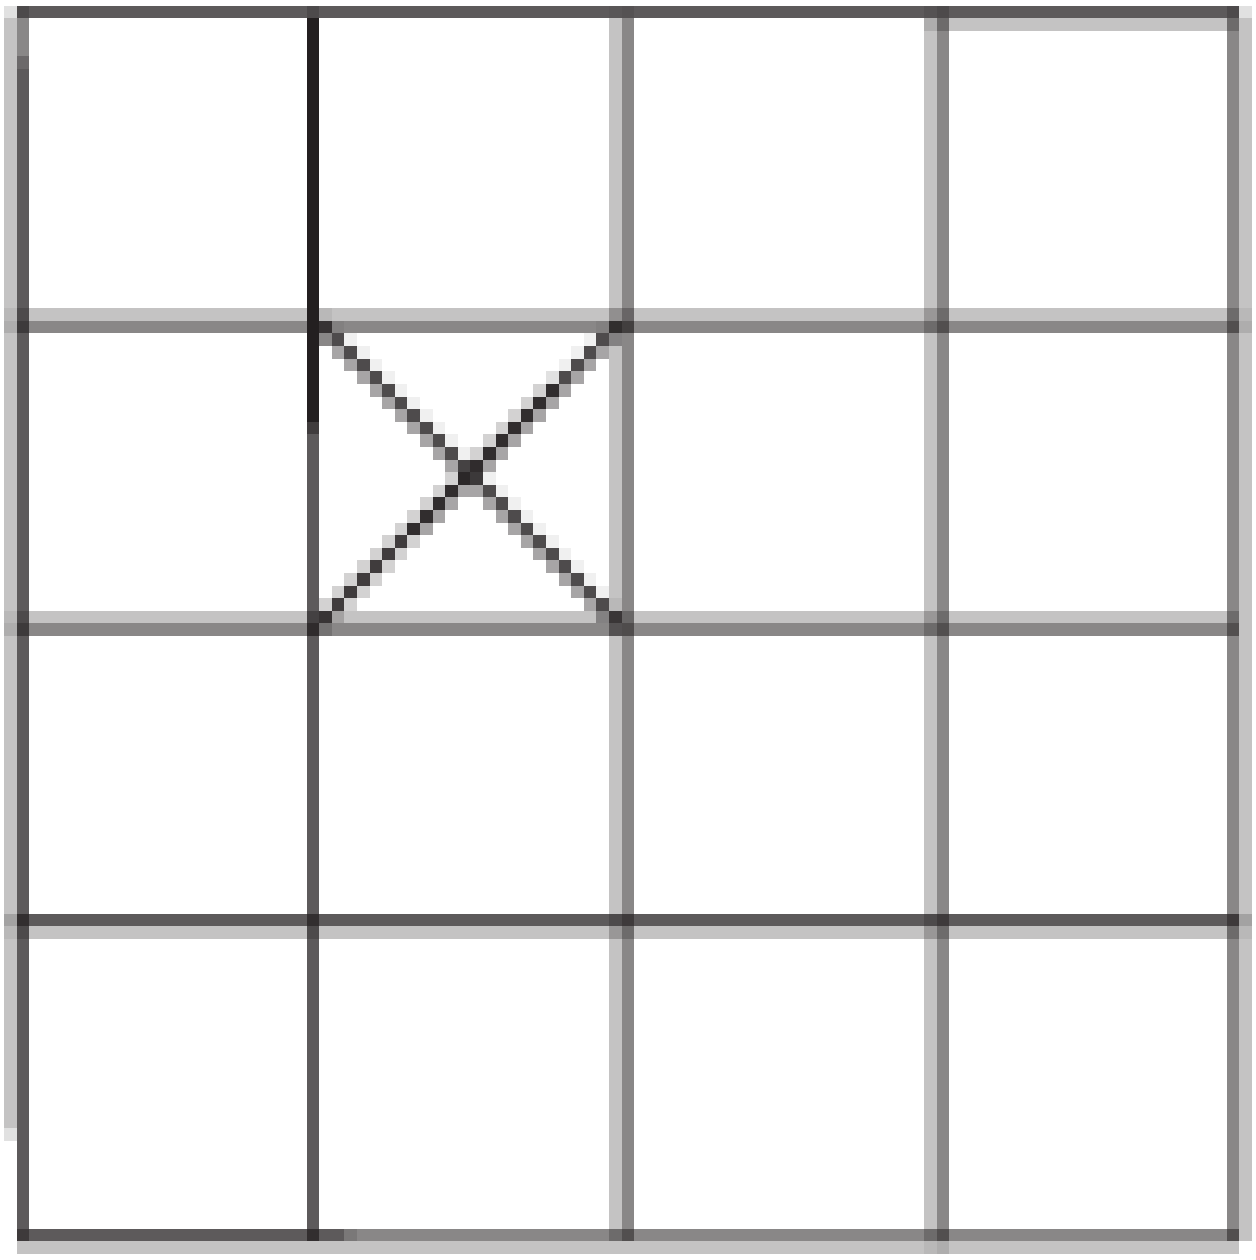
Median Filter



Perform 2-D median filtering



Libraries:
Computer Vision Toolbox / Analysis & Enhancement
Computer Vision Toolbox / Filtering

Description

The Median Filter block applies a median filter to each pixel of an input image. For each *M*-by-*N* neighborhood, the filter replaces the central value with the median value of the neighborhood. If the neighborhood has a center element, the block replaces the center pixel with the median value, as shown in this figure.

If the neighborhood does not have an exact center, then the block has a bias toward the upper-left corner of the neighborhood. In this figure, the median value has been placed in the top-left pixel of the four pixels that meet at the center of the neighborhood.

The block pads the edges of the input image for filtering. This causes the pixels within *M/2* pixels of the sides and *N/2* pixels of the top or bottom of the image to appear distorted.

The median value is less sensitive than the mean to extreme values. Thus, Median Filter is effective for removing salt-and-pepper noise from an image without significantly reducing the sharpness of the image.

Ports

Input

I — Input image
matrix

Input image, specified as an *M*-by-*N* matrix.

Data Types: `single` | `double` | `int8` | `int16` | `uint8` | `uint16` | `Boolean` | `fixed point`

PVal — Pad value
scalar

Pad value, specified as a scalar. The block uses this value for each element of the rows or columns added to the input image.

Dependencies

To enable this port:

- Set the **Output size** parameter to `Same as input port I`.
- Set the **Padding options** parameter to `Constant`.
- Set the **Pad value source** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Output

Port_1 — Output image
matrix

Output image, returned as a matrix. The dimensions of the median-filtered output image are specified by the **Output size** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Neighborhood size — Neighborhood window size

`[3 3]` (default) | positive integer | two-element vector of positive integers

Specify the window size of the neighborhood over which the block computes the median. If specified as a scalar, this value creates a square neighborhood with the specified number of rows and columns. If specified as a vector, the first element is the number of rows in the neighborhood, and the second element is the number of columns in the neighborhood.

Output size — Output sizing method

`Same as input port I` (default) | `Valid`

Specify the output sizing method as one of these options.

- `Same as input port I` — The block computes the neighborhood median for the entire image, using padding to compute the boundary pixels. The output image has the same dimensions as the input image. Selecting this option enables the **Padding options** parameter.
- `Valid` — The block computes the median where the neighborhood fits within the input image without padding. For an input image of size *M*-by-*N* and neighborhood of size *X*-by-*Y*, the output image has the dimensions (`M`–`X`+1)-by-(`N`–`Y`+1).

Padding options — Padding method

`Symmetric` (default) | `Constant` | `Replicate` | `Circular`

Pad the image using one of these methods:

- `Constant` — Pad image with a constant value. Selecting this option enables the **Pad value source** parameter. For more information, see “Pad with Constant Value” on page 1-295.
- `Replicate` — Pad the image by repeating the border values of the input image. For more information, see “Pad by Repeating Border Values” on page 1-296.
- `Symmetric` — Pad the image using a mirror image of the input data. For more information, see “Pad with Mirror Image” on page 1-297
- `Circular` — Pad the image using a circular repetition of the elements in the input image. For more information, see “Pad Using Circular Repetition of Elements” on page 1-298.

Dependencies

To enable this parameter, set the **Output size** parameter to `Same as input port I`.

Pad value source — Source of constant padding value

`Specify via dialog` (default) | `Input port`

Specify the padding source as `Specify via dialog` or `Input port`.

- `Specify via dialog` — Specify a padding value using the **Pad value** parameter.
- `Input port` — Specify a padding value using the **PVal** input port.

Dependencies

To enable this parameter, set the **Output size** parameter to `Same as input port I`, and set the **Padding options** parameter to `Constant`.

Pad value — Pad value

`0` (default) | scalar

Specify a scalar value with which to pad the image.

Dependencies

To enable this port:

- Set the **Output size** parameter to `Same as input port I`.
- Set the **Padding options** parameter to `Constant`.
- Set the **Pad value source** parameter to `Specify via dialog`.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

Matrix To Image

Converts matrix data to Simulink image data

Libraries:
Computer Vision Toolbox OpenCV Interface for Simulink

Description

The Matrix To Image block converts matrix data to Simulink image data.

Ports

Input

Port_1 — Input signal
matrix

Input signal to the Matrix To Image block. The input is a numerical matrix.

Data Types: `uint8` | `uint16` | `int8` | `int16` | `single` | `double`

Output

Port_1 — Output signal
`Simulink.ImageType`

Output signal from the Matrix To Image block. The output is an image in `Simulink.ImageType` data type.

Data Types: `Simulink.ImageType`

Parameters

Rows — Number of rows in image data
`'480'` (default) | positive integer

Specify the number of rows in the image data as a positive integer.

Programmatic Use

Block Parameter: Rows
Type: `double`
Value: positive integer
Default: `'480'`

Columns — Number of columns in image data
`'640'` (default) | positive integer

Specify the number of columns in the image data as a positive integer.

Programmatic Use

Block Parameter: `Columns`
Type: `double`
Value: positive integer
Default: `'640'`

Channels — Number of color channels or samples for each pixel in the array
3 (default) | 1

Specify the number of color channels or samples for each pixel in the array as 1 or 3. The number of channels must correspond to the number of color channels in the color format of the image data. These are the values of **Channels** for the supported color formats:

Channels	Color Format
1	Grayscale
3	RGB
3	BGR

Programmatic Use

Block Parameter: `Columns`
Type: character vector
Value: positive integer
Default: `'3'`

Underlying Datatype — Data type of underlying image data
`'uint8'` (default) | `'int8'` | `'uint16'` | `'int16'` | `'uint32'` | `'int32'` | `'single'` | `'double'` | `'logical'`

Specify the data type of the underlying image data as one of these options:

- `'uint8'`
- `'int8'`
- `'uint16'`
- `'int16'`
- `'uint32'`
- `'int32'`
- `'single'`
- `'double'`
- `'logical'`

Programmatic Use

Block Parameter: `ClassUnderlying`
Type: character vector
Value: `'uint8'` | `'int8'` | `'uint16'` | `'int16'` | `'uint32'` | `'int32'` | `'single'` | `'double'` | `'logical'`
Default: `'uint8'`

Array Layout — Memory arrangement of matrix data in image
`'Column-major'` (default) | `'Row-major'`

Specify the memory arrangement of the matrix data in the image as `Column-major` or `Row-major`.

Programmatic Use
Block Parameter: `Layout`
Type: character vector
Value: `'Column-major'` | `'Row-major'`
Default: `'Column-major'`

Color Format — Color format of pixels in underlying image data
`'RGB'` (default) | `'Grayscale'` | `'BGR'`

Specify what each color channel of a pixel represents in the underlying image data as `Grayscale`, RGB, or BGR.

Programmatic Use
Block Parameter: `ColorFormat`
Type: character vector
Value: `'Grayscale'` | `'RGB'` | `'BGR'`
Default: `'RGB'`

Block Characteristics

Data Types	`double` | `single` | `uint8` | `uint16` | `int8` | `int16` | `int32` | `image`
Direct Feedthrough	`Yes`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`

Version History

Introduced in R2021b

Deep Learning Object Detector

Detect objects using trained deep learning object detector

Libraries:
Computer Vision Toolbox / Analysis & Enhancement

Description

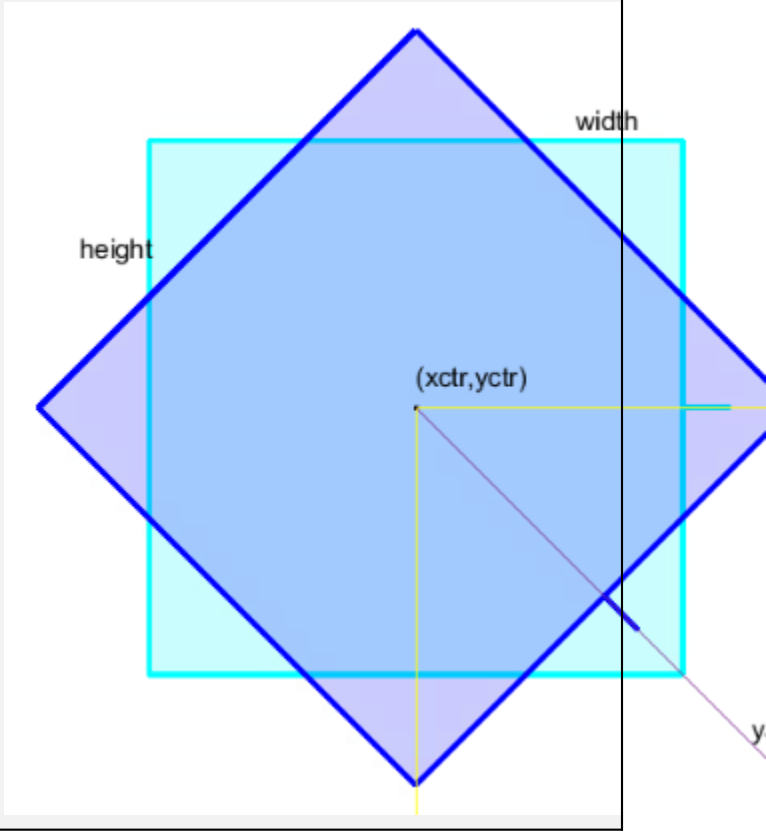
The Deep Learning Object Detector block predicts bounding boxes, class labels, and scores for the input image by using the trained object detector specified through the block parameter. This block allows loading of a pretrained object detector into the Simulink model from a MAT file or from a MATLAB function. This block provides a graphical interface for using the detector objects in Simulink. To enable some parameters of the Deep Learning Object Detector block you must choose an object detector that supports those parameters. For example, using a `yolov2ObjectDetector` object with this block enables you to select parameters similar to the name-value arguments of the associated `detect` object function.

Ports

Input

Image — Image data
array

An *H*-by-*W*-by-*C* numeric array, where *H*, *W*, and *C* are the height, width, and number of channels of the image, respectively. Only one image per time step is allowed as input.



Output

Bboxes — Locations of objects detected
matrix

Locations of the objects detected within the input image, returned as an *M*-by-4 or an *M*-by-5 matrix. *M* is the number of bounding boxes detected in the image. You can put an upper bound to the size *M* by specifying the **Maximum Number of Detections** parameter.

The table describes the format of bounding boxes.

Bounding Box	*Description*
Axis-aligned rectangle	Defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and y specify the upper-left corner of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis. • *h* specifies the height of the rectangle, which is its length along the *y*-axis.

Bounding Box	*Description*
Rotated rectangle	Defined in spatial coordinates as an *M*-by-5 numeric matrix with rows of the form [*xctr yctr w h yaw*], where: • *M* is the number of rotated rectangles. • *xctr* and *yctr* specify the center of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis before rotation. • *h* specifies the height of the rectangle, which is its length along the *y*-axis before rotation. • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the bounding box. 

For more information, see “Datastores for Deep Learning” (Deep Learning Toolbox).

Labels — Labels for bounding boxes
vector

Labels for the bounding boxes, returned as an *M*-by-1 enumerated vector. *M* is the number of bounding boxes detected in the image.

Scores — Detection scores
vector

Detection confidence scores for each label, returned as an *M*-by-1 vector. *M* is the number of bounding boxes detected in the image. A higher score indicates higher confidence in the detection.

Parameters

Detector — Source for trained detector object
`Detector from MAT file` (default) | `Detector from MATLAB function`

Select the source for the detector object from these options:

- `Detector from MAT file` — Import a detector object from a MAT file. For example, select a MAT file containing a `yolov2ObjectDetector` object.
- `Detector from MATLAB function` — Import a detector object from a MATLAB function. For example, specify the function `vehicleDetectorYOLOv2`, which returns a trained `yolov2ObjectDetector` object.

The imported detector must be one of these supported objects:

- `rcnnObjectDetector`
- `fastRCNNObjectDetector`
- `fasterRCNNObjectDetector`
- `rtmdetObjectDetector`
- `ssdObjectDetector`
- `yolov2ObjectDetector`
- `yolov3ObjectDetector`
- `yolov4ObjectDetector`
- `yoloxObjectDetector`

Programmatic Use
Block Parameter: `Detector`
Type: character vector, string
Values: `Detector from MAT file' | 'Detector from MATLAB function'`
Default: `Detector from MAT file'`

File path — MAT file containing detector object
`untitled.mat` (default) | MAT file name

This parameter specifies the name of the MAT file that contains the detector object to load. If the file is not on the MATLAB path, use the **Browse** button to locate the file.

Dependencies

To enable this parameter, set the **Detector** parameter to `Detector from MAT file`.

Programmatic Use
Block Parameter: `DetectorFilePath`
Type: character vector, string
Values: MAT file path or name

Default: `'untitled.mat'`

Simulate using — Specify type of simulation to run
`Auto mode` (default) | `Interpreted execution` | `Code generation`

- `Auto mode` –– This option automatically selects the simulation mode based on the model configuration and code generation compatibility. It uses `Code generation` whenever code generation is supported and switches to `Interpreted execution` when the model is incompatible for code generation.
- `Interpreted execution` –– Simulate model using the MATLAB interpreter. This option shortens startup time but has a slower simulation speed than `Code generation`. In this mode, you can debug the source code of the block.
- `Code generation` –– Simulate model using generated code.

  The first time you simulate a model that contains a Deep Learning Object Detector block, the software generates binary code or C/C++ MATLAB executable (MEX) code from the block and integrates this code with the model. The Deep Learning Object Detector block uses the same infrastructure as MATLAB Coder, which you use to generate C/C++ code from MATLAB code outside of Simulink. The generated code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time, but the speed of the subsequent simulations is comparable to `Interpreted execution`.

If your Simulink model is set up to simulate in Normal mode and if you use Deep Learning Object Detector block via code generation, individual Deep Learning Object Detector blocks can take advantage of acceleration via code generation. If the Simulink model is set up to simulate in accelerator mode or any of the other target modes, Deep Learning Object Detector block's **Simulate using** parameter does not have any effect. However, there is one exception, if the model is set up to simulate in accelerator mode and you use Deep Learning Object Detector block with interpreted execution mode, the block will run in interpreted execution mode.

Programmatic Use
Block Parameter: `SimulateUsing`
Type: character vector, string
Values: `"Auto mode"` | `"Interpreted execution"` | `"Code generation"`
Default: `"Auto mode"`

MATLAB function — MATLAB function name
`untitled` (default) | MATLAB function name

This parameter specifies the name of the MATLAB function that returns a trained object detector. For example, specify the function `vehicleDetectorYOLOv2`, which returns a trained `yolov2ObjectDetector` object, or specify a custom function.

Dependencies

To enable this parameter, set the **Detector** parameter to `Detector from MATLAB function`.

Programmatic Use
Block Parameter: `DetectorFunction`
Type: character vector, string
Values: MATLAB function name
Default: `'untitled'`

Region of interest — Search region of interest
vector of the form [*x y width height*]

Specify the search region of interest as vector of the form [*x y width height*]. The vector specifies the upper-left corner and size of a region in pixels.

Dependencies

To enable this parameter, select the **Specify region of interest** parameter.

Programmatic Use
Block Parameter: `ROI`
Type: character vector, string
Values: character vector specified as `'[x y width height]'`
Default: `'[1 1 100 100]'`

Detection threshold — Detection threshold
scalar in the range [0, 1]

Specify the detection threshold as scalar in the range [0, 1]. Detections that have scores lower than this threshold value are removed. To reduce false positives, increase this value.

Dependencies

To enable this parameter, you must use a detector that supports the **Detection threshold** parameter. For example, use a `yolov2ObjectDetector` object.

Programmatic Use
Block Parameter: `Threshold`
Type: character vector, string
Values: scalar
Default: `'0.5'`

Number of Strongest Regions — Maximum number of strongest region proposals
`2000` (default) | positive integer

Specify the maximum number of strongest region proposals as an integer. Reduce this value to speed up processing at the cost of detection accuracy. To use all region proposals, specify this parameter as `Inf`.

Dependencies

To enable this parameter, use a detector that supports the **Number of Strongest Regions** parameter. For example, use an `rcnnObjectDetector` object.

Programmatic Use
Block Parameter: `NumStrongestRegions`
Type: character vector, string
Values: integer
Default: `'2000'`

Maximum Region Size — Maximum region size
vector of the form [*height width*]

Specify the maximum region size as a vector of the form [*height width*]. Units are in pixels. The maximum region size defines the size of the largest region containing the object. For example, [`50 50`] sets the size of the largest region containing the object to `50`-by-`50` pixels. To reduce computation time, set this value to the known maximum region size for the objects that can be detected in the input test images.

Dependencies

To enable this parameter

- Select the **Specify maximum region size** parameter.
- Use a detector that supports the **Maximum Region Size** parameter. For example, use a `yolov2ObjectDetector` object.

Programmatic Use

Block Parameter: `MaxSize`
Type: character vector, string
Values: character vector specified as `'[height width]'`
Default: `'[50 50]'`

Minimum Region Size — Minimum region size
vector of the form [*height width*]

Specify the minimum region size as a vector of the form [*height width*]. Units are in pixels. The minimum region size defines the size of the smallest region containing the object. For example, `[1 1]` sets the size of the smallest region containing the object to 1-by-1 pixels.

Dependencies

To enable this parameter

- Select the **Specify minimum region size** parameter.
- Use a detector that supports the **Minimum Region Size** parameter. For example, use a `yolov2ObjectDetector` object.

Programmatic Use

Block Parameter: `MinSize`
Type: character vector, string
Values: character vector specified as `'[height width]'`
Default: `'[1 1]'`

Maximum Number of Detections — Maximum number of detections
`500` (default) | positive integer

Specify the maximum number of detections as a positive integer. This value is the upper bound for the number of detections and must be greater than or equal to 2.

Programmatic Use

Block Parameter: `MaxDetections`
Type: character vector, string
Values: integer
Default: `'500'`

Version History

Introduced in R2021b

R2024b: Support to RTMDet object detector

Starting in R2024b, `Deep Learning Object Detector` block supports Real-Time Model for object Detection (RTMDet). You can import a pretrained RTMDet object detector object, `rtmdetObjectDetector` to perform object detection.

R2024b: Support for YOLOX object detector

Starting in R2024b, `Deep Learning Object Detector` block supports You Only Look Once X (YOLOX) object detection. You can import a pretrained YOLOX object detector object, `yoloxObjectDetector` to perform object detection.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- The **Language** parameter in the **Configuration Parameters > Code Generation** general category must be set to `C++`.
- For a list of networks and layers supported for code generation, see "Networks and Layers Supported for Code Generation" (MATLAB Coder).
- To generate code for the Math Kernel Library for Deep Neural Networks (MKL-DNN) target library with YOLOv3, YOLOv4, or RTMDet as the object detectors, set the `MaxStackSize` and `TLCOptions` model parameters to a higher value. For example, you can set the `MaxStackSize` and `TLCOptions` parameter values to '`inf`' using the following syntax.

```
>> set_param(modelName,'MaxStackSize','inf')
>> set_param(modelName,'TLCOptions','-aMaxStackVariableSize=inf')
```

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- The **Language** parameter in the **Configuration Parameters > Code Generation** general category must be set to `C++`.
- For a list of networks and layers supported for CUDA® code generation, see "Supported Networks, Layers, and Classes" (GPU Coder).

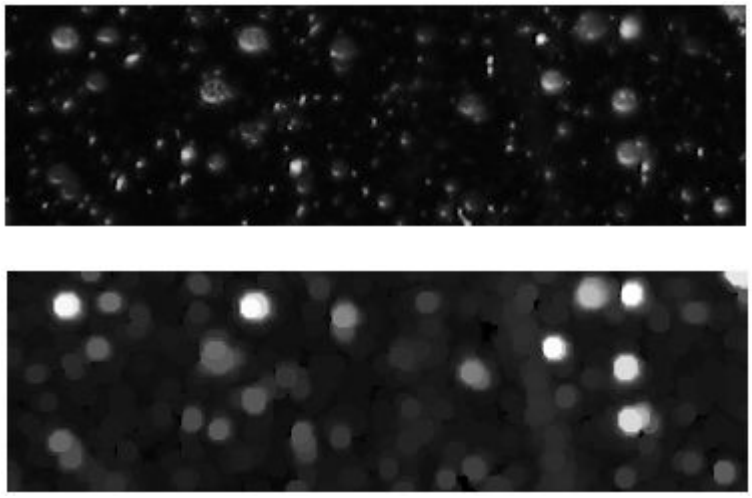
Blocks

Classify (Deep Learning Toolbox) | Predict (Deep Learning Toolbox)

Opening

Perform morphological opening on binary or intensity images



Libraries:
Computer Vision Toolbox / Morphological Operations

Description

The Opening block performs an erosion operation followed by a dilation operation on an intensity or binary image using a predefined neighborhood or structuring element.

To define the structuring element that the block applies to the image, use the **Neighborhood or structuring element** parameter. Specify this element by entering a vector or matrix of `1`s and `0`s or by using the `strel` function.

Below are an input image and the output image after the opening operation, respectively.

This block uses two-dimensional flat structuring elements only.

Ports

Input

I — Input image
matrix

Specify an input image as a matrix of intensity values. This port is unnamed unless you set the **Neighborhood or structuring element source** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Nhood — Neighborhood values
vector | matrix

Specify neighborhood values representing a structuring element as a vector or matrix of `1`s and `0`s or by using the `strel` function.

Dependencies

To enable this port, set the **Neighborhood or structuring element source** parameter to `Input port`.

Data Types: `Boolean`

Output

Port_1 — Opened image
matrix

The opened image is returned as a matrix of intensity values. The size and data type of the opened image are the same as those of the input image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Neighborhood or structuring element source — Source of neighborhood or structuring element

`Specify via dialog` (default) | `Input port`

Specify the source of neighborhood or structuring element as one of these options:

- `Specify via dialog` — Use the **Neighborhood or structuring element** parameter to specify a neighborhood or structuring element.
- `Input port` — Use the **Nhood** input port to specify neighborhood values representing a structuring element.

Neighborhood or structuring element — Neighborhood or structuring element

`strel('disk',5)` (default) | vector | matrix

Specify neighborhood or structuring element as a vector or matrix of `1`s and `0`s, a `strel` object or an array of `strel` objects. When you specify this value as an array of `strel` objects, the block applies each object to the entire image in turn.

If the structuring element is decomposable into smaller elements, the block executes at higher speed due to the use of a more efficient algorithm.

Dependencies

To enable this parameter, set the **Neighborhood or structuring element source** parameter, to `Specify via dialog`.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

More About

Opening Operation

Opening smoothes the contour of an object in an image by

- Breaking narrow isthmuses and
- Eliminating thin protrusions

Optical Flow

Estimate object velocities

Libraries:
Computer Vision Toolbox / Analysis & Enhancement

Description

The Optical Flow block estimates the direction and speed of object motion between two images or between one video frame to another frame using either the Horn-Schunck or the Lucas-Kanade method.

Ports

Input

I/I1 — Image or video frame
scalar | vector | matrix

Image or video frame, specified as a scalar, vector, or matrix. If the **Compute optical flow between** parameter is set to `Two images`, the name of this port changes to **I1**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

I2 — Image
scalar | vector | matrix

Image or video frame, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

|V|^2 — Velocity magnitudes
scalar | vector | matrix

Velocity magnitudes, returned as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

V — Velocity components in complex form
scalar | vector | matrix

Velocity components in complex form, specified as a scalar, vector, or matrix.

Dependencies

To enable this port, set the **Velocity output** parameter to `Horizontal and vertical components in complex form`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Main Tab

Method — Optical flow calculation method
`Horn-Schunck` (default) | `Lucas-Kanade`

Select the method to use to calculate the optical flow. Options include `Horn-Schunck` or `Lucas-Kanade`.

Compute optical flow between — Compute optical flow
`Current frame and N-th frame back` (default) | `Two images`

Select how to compute the optical flow. Select `Two images` to compute the optical flow between two images. Select `Current frame and N-th frame back` to compute the optical flow between two video frames that are N frames apart.

Dependencies

To enable this parameter, set the:

- **Method** parameter to `Horn-Schunck`
- **Method** parameter to `Lucas-Kanade` and the **Temporal gradient filter** to `Difference filter [-1 1]`

N — Number of frames
1 (default) | scalar

Enter a scalar value that represents the number of frames between the reference frame and the current frame.

Dependencies

To enable this parameter, set the **Compute optical flow between** parameter to `Current frame and N-th frame back`.

Smoothness factor — Smoothness factor
1 (default) | positive scalar

Specify the smoothness factor. Enter a large positive scalar value for high relative motion between the two images or video frames. Enter a small positive scalar value for low relative motion.

Dependencies

To enable this parameter, set the **Method** parameter to `Horn-Schunck`.

Stop iterative solution — Stop iterative solution
`When maximum number of iterations is reached` (default) | `When velocity difference falls below threshold` | `Whichever comes first`

Specify the method to control when the block's iterative solution process stops. If you want the process to stop when the velocity difference is below a certain threshold value, select `When velocity difference falls below threshold`. If you want the process to stop after a certain number of iterations, choose `When maximum number of iterations is reached`. You can also select `Whichever comes first`.

Dependencies

To enable this parameter, set the **Method** parameter to `Horn-Schunck`.

Maximum number of iterations — Maximum number of iterations
`10` (default) | scalar

Specify the maximum number of iterations for the block to perform.

Dependencies

To enable this parameter, set the **Method** parameter to `Horn-Schunck` and the **Stop iterative solution** parameter to `When maximum number of iterations is reached` or `Whichever comes first`.

Velocity output — Optical flow output
`Magnitude-squared` (default) | `Horizontal and vertical components in complex form`

Specify how to output an optical flow. If you select `Magnitude-squared`, the block outputs an optical flow matrix where each element is in the form $u^2 + v^2$. If you select `Horizontal and vertical components in complex form`, the block outputs the optical flow matrix where each element is in the form $u + jv$.

Temporal gradient filter — Filter used for temporal gradient
`Difference filter [-1 1]` (default) | `Derivative of Gaussian`

Specify whether the block solves for u and v using a difference filter or a derivative of a Gaussian filter.

Dependencies

To enable this parameter, set the **Method** parameter to `Lucas-Kanade`.

Number of input frames to buffer — Number of input frames to buffer for smoothing
`3` (default) | scalar

Specify the number of input frames to buffer for smoothing. Use this parameter for temporal filter characteristics such as the standard deviation and number of filter coefficients.

Dependencies

To enable this parameter, set the **Temporal gradient filter** parameter to `Derivative of Gaussian`.

Standard deviation for image smoothing filter — Standard deviation for image smoothing filter
`1.5` (default) | scalar

Specify the standard deviation for the image smoothing filter.

Dependencies

To enable this parameter, set the **Temporal gradient filter** parameter to `Derivative of Gaussian`.

Standard deviation for gradient smoothing filter — Standard deviation for gradient smoothing filter
`1` (default) | scalar

Specify the standard deviation for the gradient smoothing filter.

Dependencies

To enable this parameter, set the **Temporal gradient filter** parameter to `Derivative of Gaussian`.

Discard normal flow estimates when constraint equation is ill-conditioned — Discard normal flow estimates
off (default) | on

Select this parameter to set the motion vector to zero when the optical flow constraint equation is ill-conditioned.

Dependencies

To enable this parameter, set the **Temporal gradient filter** parameter to `Derivative of Gaussian`.

Output image corresponding to motion vectors (accounts for block delay) — Output image corresponding to motion vectors
off (default) | on

Select this parameter to output the image that corresponds to the motion vector outputted by the block.

Dependencies

To enable this parameter, set the **Temporal gradient filter** parameter to `Derivative of Gaussian`.

Threshold for noise reduction — Threshold for noise reduction
`0.0039` (default) | scalar

Specify a scalar value that determines the motion threshold between each image or video frame. The higher the number, the less small movements impact the optical flow calculation.

Dependencies

To enable this parameter, set the **Method** parameter to `Lucas-Kanade`.

Data Types Tab

For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Block Characteristics

Data Types	`double` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`no`

Algorithms

Optical Flow Equation

To compute the optical flow between two images, you must solve this optical flow constraint equation:

$$I_x u + I_y v + I_t = 0$$

.

- I_x, I_y, and I_t are the spatiotemporal image brightness derivatives.
- u is the horizontal optical flow.
- v is the vertical optical flow.

Horn-Schunck Method

By assuming that the optical flow is smooth across the entire image, the Horn-Schunck method estimates a velocity field, $[u\ v]^T$, that minimizes this equation:

$$E = \iint (I_x u + I_y v + I_t)^2 dx dy + \alpha \iint \left\{ \left(\frac{\partial u}{\partial x}\right)^2 + \left(\frac{\partial u}{\partial y}\right)^2 + \left(\frac{\partial v}{\partial x}\right)^2 + \left(\frac{\partial v}{\partial y}\right)^2 \right\} dx dy$$

.

In this equation, $\frac{\partial u}{\partial x}$ and $\frac{\partial u}{\partial y}$ are the spatial derivatives of the optical velocity component, u, and α scales the global smoothness term. The Horn-Schunck method minimizes the previous equation to obtain the velocity field, $[u\ v]$, for each pixel in the image. This method is given by the following equations:

$$u_{x,y}^{k+1} = \bar{u}_{x,y}^{k} - \frac{I_x [I_x \bar{u}^k_{x,y} + I_y \bar{v}^k_{x,y} + I_t]}{\alpha^2 + I_x^2 + I_y^2}$$

$$v_{x,y}^{k+1} = \bar{v}_{x,y}^{k} - \frac{I_y [I_x \bar{u}^k_{x,y} + I_y \bar{v}^k_{x,y} + I_t]}{\alpha^2 + I_x^2 + I_y^2}$$

.

In these equations, $\left[u_{x,y}^k\ v_{x,y}^k\right]$ is the velocity estimate for the pixel at (x,y), and $\left[\bar{u}_{x,y}^k\ \bar{v}_{x,y}^k\right]$ is the neighborhood average of $\left[u_{x,y}^k\ v_{x,y}^k\right]$. For $k = 0$, the initial velocity is 0.

To solve u and v using the Horn-Schunck method:

1. Compute I_x and I_y by using the Sobel convolution kernel, $[-1\ -2\ -1;\ 0\ 0\ 0;\ 1\ 2\ 1]$, and its transposed form for each pixel in the first image.
2. Compute I_t between images 1 and 2 using the $[-1\ 1]$ kernel.
3. Assume the previous velocity to be 0, and compute the average velocity for each pixel using $[0\ 1\ 0;\ 1\ 0\ 1;\ 0\ 1\ 0]$ as a convolution kernel.
4. Iteratively solve for u and v.

Lucas-Kanade Method

To solve the optical flow constraint equation for u and v, the Lucas-Kanade method divides the original image into smaller sections and assumes a constant velocity in each section. Then it performs a weighted, least-square fit of the optical flow constraint equation to a constant model for $[u\ v]^T$ in each section Ω. The method achieves this fit by minimizing this equation:

$$\sum_{x \in \Omega} W^2[I_x u + I_y v + I_t]^2$$

W is a window function that emphasizes the constraints at the center of each section. The solution to the minimization problem is

$$\begin{bmatrix} \sum W^2 I_x^2 & \sum W^2 I_x I_y \\ \sum W^2 I_y I_x & \sum W^2 I_y^2 \end{bmatrix} \begin{bmatrix} u \\ v \end{bmatrix} = -\begin{bmatrix} \sum W^2 I_x I_t \\ \sum W^2 I_y I_t \end{bmatrix}$$

.

Lucas-Kanade Difference Filter

When you set the **Temporal gradient filter** to `Difference filter [-1 1]`, u and v are solved as follows:

1. Compute I_x and I_y using the kernel $[-1\ 8\ 0\ -8\ 1]/12$ and its transposed form.

   If you are working with fixed-point data types, the kernel values are signed fixed-point values with a word length equal to 16 and a fraction length equal to 15.
2. Compute I_t between images 1 and 2 by using the $[-1\ 1]$ kernel.
3. Smooth the gradient components, I_x, I_y, and I_t, by using a separable and isotropic 5-by-5 element kernel whose effective 1-D coefficients are $[1\ 4\ 6\ 4\ 1]/16$. If you are working with fixed-point data types, the kernel values are unsigned fixed-point values with a word length equal to 8 and a fraction length equal to 7.
4. Solve the 2-by-2 linear equations for each pixel using the following method:

   - If $A = \begin{bmatrix} a & b \\ b & c \end{bmatrix} = \begin{bmatrix} \sum W^2 I_x^2 & \sum W^2 I_x I_y \\ \sum W^2 I_y I_x & \sum W^2 I_y^2 \end{bmatrix}$

     then the eigenvalues of A are $\lambda_i = \frac{a+c}{2} \pm \frac{\sqrt{4b^2 + (a-c)^2}}{2}; i = 1, 2$

     In the fixed-point diagrams, $P = \frac{a+c}{2}, Q = \frac{\sqrt{4b^2 + (a-c)^2}}{2}$

- The eigenvalues are compared to the threshold, τ, that corresponds to the value you enter for the threshold for noise reduction. The results fall into one of the following cases.

  Case 1: $\lambda_1 \geq \tau$ and $\lambda_2 \geq \tau$

  A is nonsingular, and the system of equations is solved using Cramer's rule.

  Case 2: $\lambda_1 \geq \tau$ and $\lambda_2 < \tau$

  A is singular (noninvertible), and the gradient flow is normalized to calculate u and v.

  Case 3: $\lambda_1 < \tau$ and $\lambda_2 < \tau$

  The optical flow, u and v, is 0.

Derivative of Gaussian

If you set the temporal gradient filter to `Derivative of Gaussian`, u and v are solved using these steps.

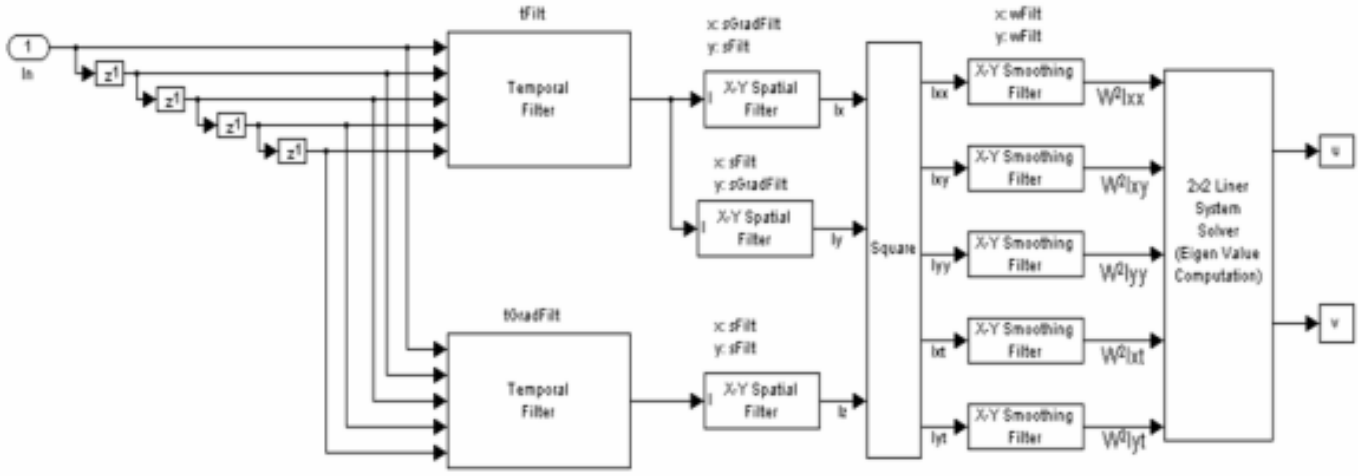
1. Compute I_x and I_y.
   a. Use a Gaussian filter to perform temporal filtering. Specify the temporal filter characteristics, such as the standard deviation and number of filter coefficients, by using the **Number of frames to buffer for temporal smoothing** parameter.
   b. Use a Gaussian filter and the derivative of a Gaussian filter to smooth the image by using spatial filtering. Specify the standard deviation and length of the image smoothing filter by using the **Standard deviation for image smoothing filter** parameter.
2. Compute I_t between images 1 and 2.
   a. Use the derivative of a Gaussian filter to perform temporal filtering. Specify the temporal filter characteristics, such as the standard deviation and number of filter coefficients, by using the **Number of frames to buffer for temporal smoothing** parameter.
   b. Use the filter described in step 1b to perform spatial filtering on the output of the temporal filter.
3. Smooth the gradient components, I_x, I_y, and I_t, by using a gradient smoothing filter. Use the **Standard deviation for gradient smoothing filter** parameter to specify the standard deviation and the number of filter coefficients for the gradient smoothing filter.
4. Solve the 2-by-2 linear equations for each pixel using this method:

   - If $A = \begin{bmatrix} a & b \\ b & c \end{bmatrix} = \begin{bmatrix} \sum W^2 I_x^2 & \sum W^2 I_x I_y \\ \sum W^2 I_y I_x & \sum W^2 I_y^2 \end{bmatrix}$

     then the eigenvalues of A are $\lambda_i = \frac{a+c}{2} \pm \frac{\sqrt{4b^2 + (a-c)^2}}{2}; i = 1, 2$

   - When the block finds the eigenvalues, it compares them to the threshold, τ, that corresponds to the value you enter for the **Threshold for noise reduction** parameter. The results fall into one of the following cases.

     Case 1: $\lambda_1 \geq \tau$ and $\lambda_2 \geq \tau$



A is nonsingular, so the block solves the system of equations by using Cramer's rule.

Case 2: $\lambda_1 \geq \tau$ and $\lambda_2 < \tau$

A is singular (noninvertible), so the block normalizes the gradient flow to calculate u and v.

Case 3: $\lambda_1 < \tau$ and $\lambda_2 < \tau$

the optical flow, u and v, is 0.

tFilt = Coefficients of Gaussian Filter
tGradFilt = Coefficients of the Derivative of a Gaussian Filter

PSNR

Compute peak signal-to-noise ratio (PSNR) between images

Libraries:
Computer Vision Toolbox / Statistics

Description

The PSNR block computes the peak signal-to-noise ratio, in decibels, between two images. This ratio is used as a quality measurement between the original and a compressed image. The higher the PSNR, the better the quality of the compressed, or reconstructed image.

The mean-square error (MSE) and the peak signal-to-noise ratio (PSNR) are used to compare image compression quality. The MSE represents the cumulative squared error between the compressed and the original image, whereas PSNR represents a measure of the peak error. The lower the value of MSE, the lower the error.

To compute the PSNR, the block first calculates the mean-squared error using the following equation:

$$MSE = \frac{\sum_{M,N} [I_1(m,n) - I_2(m,n)]^2}{M*N}$$

In the previous equation, M and N are the number of rows and columns in the input images. Then the block computes the PSNR using the following equation:

$$PSNR = 10\log_{10}\left(\frac{R^2}{MSE}\right)$$

In the previous equation, R is the maximum fluctuation in the input image data type. For example, if the input image has a double-precision floating-point data type, then R is 1. If it has an 8-bit unsigned integer data type, R is 255, etc.

Computing PSNR for Color Images

Different approaches exist for computing the PSNR of a color image. Because the human eye is most sensitive to luma information, you can compute the PSNR for color images by converting the image to a color space that separates the intensity (luma) channel, such as YCbCr. The Y (luma), in YCbCr represents a weighted average of R, G, and B. G is given the most weight, again because the human eye perceives it most easily. Compute the PSNR only on the luma channel.

Ports

Input

I1 — Input image
scalar | vector | matrix

Input image, specified as scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

I2 — Input image
scalar | vector | matrix

Input image, specified as scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Output

Output — Output
scalar

Peak signal-to-noise ratio between images, returned as a scalar.

Dependencies

If the input is a fixed-point or integer data type, the block output is double-precision floating point. Otherwise, the block input and output are the same data type.

Data Types: `double`

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Rotate

Rotate image by specified angle

Libraries:
Computer Vision Toolbox / Geometric Transformations

Description

Use the Rotate block to rotate a grayscale or color image by an angle specified in radians.

Ports

Input

Image — Image to rotate
matrix | array

Image to rotate, specified as a 2-D numeric matrix for a grayscale image or 3-D numeric array for a color image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Angle — Rotation angle
scalar

Rotation angle, specified as a numeric scalar, in radians.

If the input to the **Image** port is of data type `single`, `double`, or `fixed point`, then the input to the **Angle** port must be of the same data type.

If the input to the **Image** port is of a signed or unsigned integer data type, then the input to the **Angle** port must be of a signed integer data type.

Dependencies

To enable this port, set the **Rotation angle source** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Output

Output — Rotated image
matrix | array

Rotated image, returned as 2-D numeric matrix if the input image is a grayscale image and a 3-D numeric array if the input image is a color image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Main

Output size — Size of rotated image

`Expanded to fit rotated input image` (default) | `Same as input image`

Specify the size of the rotated image as one of these options.

- `Expanded to fit rotated input image`- The block outputs a matrix or array expanded to contain all values.
- `Same as input image`- The block outputs a matrix or array the same size as the input image, which contains the middle part of the rotated image. This can result in the block cropping the edges of the rotated image.

Use the **Background fill value** parameter to specify the color or intensity value of pixels outside the rotated image.

Rotation angle source — Rotation angle source

`Specify via dialog` (default) | `Input port`

Specify the source of the rotation angle as one of these options.

- `Specify via dialog` - Specify the rotation angle using the **Angle (radians)** parameter.
- `Input port` - Specify the rotation angle using the **Angle** port. The block uses the input to this port as the rotation angle at each time step.

Angle (radians) — Rotation angle

`pi/6` (default) | numeric scalar

Specify the rotation angle in radians.

When the rotation angle is a multiple of `pi/2`, the block uses a more efficient algorithm. If the specified value for the **Angle (radians)** parameter is within `1e-5` radians of a multiple of `pi/2`, the block rounds the angle value to that multiple of `pi/2` before performing the rotation.

Dependencies

To enable this parameter, set the **Rotation angle source** parameter to `Specify via dialog`.

Maximum angle (enter pi radians to accommodate all positive and negative angles) — Maximum angle of rotation

`pi` (default) | nonnegative scalar less than or equal to `pi`

Specify the maximum angle by which to rotate the input image as a scalar value in the range [`0`, `pi`], in radians. The block determines which angle, between `0` and the specified maximum angle, requires the largest output size and sets the dimensions of the output port accordingly.

Dependencies

To enable this parameter, specify these parameter values.

- **Output size** — `Expanded to fit rotated input image`
- **Rotation angle source** — `Input port`

Display rotated image in — Position of output image

`Top-left corner` (default) | `Center`

Specify the position of the rotated image in the output image. If you select `Top-left corner`, the block positions the rotated image so that it has corners in contact with the top and left sides of the output image. If you select `Center`, the output image displays the rotated image at its center.

Dependencies

To enable this parameter, set the **Rotation angle source** parameter to `Input port`.

Sine value computation method — Sine value computation method

`Table lookup` (default) | `Trigonometric function`

Specify the sine value computation method. If you select `Trigonometric function`, the block computes the sine and cosine values required to calculate the rotation of the image during the simulation.

If you select `Table lookup`, the block computes and stores the trigonometric values required to calculate the rotation of the image before the simulation starts. For this method, the block requires extra memory.

Background fill value — Background fill value

numeric scalar | three-element numeric vector

Specify a value for the pixels that are outside the image.

If the input image is grayscale, the value of **Background fill value** must be a numeric scalar. The default value is `0` for grayscale images. If the input image is a color image, the value of **Background fill value** must be a three-element numeric vector. The default value is `[0 0 0]` for color images.

Interpolation method — Interpolation method

`Bilinear` (default) | `Nearest neighbor` | `Bicubic`

Specify which interpolation method the block uses to rotate the image from these options.

- `Nearest neighbor` - The block uses the value of one nearby pixel for the new pixel value.
- `Bilinear` - The new pixel value is the weighted average of the 4 nearest pixel values.
- `Bicubic` - The new pixel value is the weighted average of the 16 nearest pixel values.

The number of pixels the block considers affects the complexity of the computation. Therefore, the `Nearest neighbor` interpolation is the most computationally efficient. However, because the accuracy of the method is proportional to the number of pixels considered, the `Bicubic` method is the most accurate.

Data Types

For details on general fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Angle values — Fixed-point parameter for angle values

`Same word length as input` (default) | `Specify word length` | `Binary point scaling`

Choose how to specify the word length and the fraction length of the angle values.

Dependencies

To enable this parameter, set the **Rotation angle source** parameter to `Specify via dialog`.

Lock data type settings against change by the fixed-point tools — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`yes`
Variable-Size Signals	`yes`

Algorithms

The Rotate block uses the three-pass shear rotation algorithm to compute its values, which differs from the algorithm used by the `imrotate` function in the Image Processing Toolbox.

Version History

Read Binary File

Read video data from binary file

Libraries:
Computer Vision Toolbox / Sinks

Description

The Read Binary File block reads the video data from a binary file and imports it into a Simulink model.

The user-specified block parameters describe the format of the video data. These parameters, along with the raw binary file, create the video data for the Simulink model.

Note This block supports code generation for only those platforms that have file I/O. The block does not support code generation using Simulink Desktop Real-Time or Simulink Real-Time™.

Ports

Output

Y' — Luminance component
3-D array

Luminance component of the video read from the binary file, specified as a 3-D array. The label of this port can be changed using the **Component1** parameter when the **Video format** parameter is set to `Custom`.

Data Types: `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Cb — Blue difference component
3-D array

Blue difference component of the video read from the binary file, specified as a 3-D array. The label of this port can be changed using the **Component2** parameter when the **Video format** parameter is set to `Custom`.

Data Types: `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Cr — Red difference component
3-D array

Red difference component of the video read from the binary file, specified as a 3-D array. The label of this port can be changed using the **Component3** parameter when the **Video format** parameter is set to `Custom`.

Data Types: `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

A — Alpha component
3-D array

Alpha component of the video read from the binary file, specified as a 3-D array. The label of this port can be changed using the **Component4** parameter when the **Video format** parameter is set to `Custom`.

Dependencies

To enable this port, use one of these options.

- Set the **Video format** parameter to `Four character codes` and set the **Four character code** parameter to `AYUV` or `IF09`.
- Set the **Video format** parameter to `Custom` and the **Number of output components** parameter to `4`.

Data Types: `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

T — Transparency component
3-D array

Transparency component of the video read from the binary file, specified as a 3-D array.

Dependencies

To enable this port, set the **Video format** parameter to `Four character codes` and set the **Four character code** parameter to `Y41T` or `Y42T`.

Data Types: `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

EOF — Last video frame indicator
scalar

The port outputs a `1` when the component ports output the last video frame. For every frame before that, it outputs a `0`.

Dependencies

To enable this port, select the **Output end-of-file indicator** parameter.

Data Types: `Boolean`

Parameters

File name — Name of binary file
`vipmen.bin` (default) | file name

Specify the name of the binary source file to read video data from.

Video format — Format of video data
`Four character codes` (default) | `Custom`

Specify the format of the video data as one of these options.

- Four character codes (FOURCC) — For more information about these codes, see `https://en.wikipedia.org/wiki/FourCC`.

- Custom — Read the video data from a binary file of a custom format.

Four character code — Format of binary file
`I420` (default) | `AYUV` | `CLJR` | `cyuv` | `GREY` | `IF09` | `IMC1` | `IMC2` | `IMC3` | `IMC4` | `IUYV` | `IY41` | `IYU1` | `IYU2` | `IYUV` | `NV12` | `NV21` | `UYNV` | `UYNY` | `V210` | `Y411` | `Y41P` | `Y41T` | `Y422` | `Y42T` | `Y8` | `Y800` | `YUNV` | `YUY2` | `YUYV` | `YV12` | `YV16` | `YVU9` | `YVYU` | ...

Specify the four character code of the binary file codec. The value of this parameter also sets the number of output ports. For information on which four character codes enable which output ports, see the table below.

Output Ports for Four Character Codes

Four Character Codes	Output Ports
I420	Y'|Cb|Cr
AYUV	Y'|Cb|Cr|A
CLJR	Y'|Cb|Cr
cyuv	Y'|Cb|Cr
GREY	Y'
IF09	Y'|Cb|Cr|A
IMC1	Y'|Cb|Cr
IMC2	Y'|Cb|Cr
IMC3	Y'|Cb|Cr
IMC4	Y'|Cb|Cr
IUYV	Y'|Cb|Cr
IY41	Y'|Cb|Cr
IYU1	Y'|Cb|Cr
IYU2	Y'|Cb|Cr
IYUV	Y'|Cb|Cr
NV12	Y'|Cb|Cr
NV21	Y'|Cb|Cr
UYNV	Y'|Cb|Cr
UYNY	Y'|Cb|Cr
V210	Y'|Cb|Cr
Y411	Y'|Cb|Cr
Y41P	Y'|Cb|Cr
Y41T	Y'|Cb|Cr|T
Y422	Y'|Cb|Cr
Y42T	Y'|Cb|Cr|T
Y8	Y'
Y800	Y'
YUNV	Y'|Cb|Cr
YUY2	Y'|Cb|Cr
YUYV	Y'|Cb|Cr
YV12	Y'|Cb|Cr
YV16	Y'|Cb|Cr
YVU9	Y'|Cb|Cr
YVYU	Y'|Cb|Cr

Dependencies

To enable this parameter, set the **Video format** parameter to `Four character codes`.

FrameSize Rows — Number of rows in output array
`120` (default) | positive integer

Specify the number of rows in the output array as a positive integer. The value of this parameter must match the dimensions of the data inside the file.

Dependencies

To enable this parameter, set the **Video format** parameter to `Four character codes`.

FrameSize Cols — Number of columns in output array
`160` (default) | positive integer

Specify the number of columns in the output array as a positive integer. The value of this parameter must match the dimensions of the data inside the file.

Dependencies

To enable this parameter, set the **Video format** parameter to `Four character codes`.

Line ordering — Output array fill direction
`Top line first` (default) | `Bottom line first`

If you select `Top line first`, the block first fills the first row of the output array with the corresponding contents of the binary file. It then fills the other rows in increasing order. When you select `Bottom line first`, the block first fills the last row of the output array with the corresponding contents of the binary file. It then fills the other rows in decreasing order.

Number of times to play file — Number of times to play the file
`1` (default) | positive integer | `inf`

Specify the number of times to repeat the binary file as a positive integer or `inf`. For any positive integer value `n` of this parameter, the block plays the binary file `n` times. For a value of `inf`, the block plays the file indefinitely until the end of simulation.

Output end-of-file indicator — Indicate when block output reaches last frame
`off` (default) | `on`

This parameter indicates when the block output reaches the last video frame in the binary file. Selecting this parameter enables the **EOF** port. The output from the **EOF** port is `1` when the block output reaches the last video frame. For all other frames, it is `0`.

Sample time — Sample period of output
`1/30` (default) | positive scalar | `-1`

Specify the sample period of the output. Sample time indicates when, during simulation the block produces output. The value of this parameter must be a positive scalar less than the simulation time or `-1`. It cannot be `0`. When set to `-1`, the block inherits the sample time from the simulink model.

Bit stream format — Specifies if data is planar or packed
`Planar` (default) | `Packed`

Specify the data format of the binary file as planar or packed. If the data is packed, use the **FrameSize Rows** and **FrameSize Cols** parameters to define the size of the output array.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`.

Number of output components — Number of components in binary file
3 (default) | 1 | 2 | 4

Specify the number of output components from the binary file. This parameter sets the number of output ports.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`.

Component1 — Name for luminance component
`Y'` (default) | component name

Specify the name for the luminance component of the output array. The luminance component is the first component from the input binary file.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, set the **Number of output components** parameter to 1 or greater.

Component2 — Name for blue difference component
`Cb` (default) | component name

Specify the name for the blue difference component of the output array. The blue difference component is the second component from the input binary file.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, set the **Number of output components** parameter to 2 or greater.

Component3 — Name for red difference component
`Cr` (default) | component name

Specify the name for the red difference component of the output array using this parameter. The red difference component is the third component from the input binary file.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, set the **Number of output components** parameter to 3 or greater.

Component4 — Name for alpha component
`Alpha` (default) | component name

Specify the name for the alpha component of the output array. The alpha component is the fourth component from the input binary file.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, set the **Number of output components** parameter to 4.

Bits1 — Size of luminance component
8 (default) | 16 | 24 | 32

Specify the size of the luminance component in the output array. The value of this parameter determines the interpretation of the video stream data as 8-bit, 16-bit, 24-bit, or 32-bit.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, and set the **Number of output components** parameter to 1 or greater.

Bits2 — Size of blue difference component
8 (default) | 16 | 24 | 32

Specify the size of the blue difference component in the output array. The value of this parameter determines the interpretation of the video stream data as 8-bit, 16-bit, 24-bit, or 32-bit.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, and set the **Number of output components** parameter to 2 or greater.

Bits3 — Size of red difference component
8 (default) | 16 | 24 | 32

Specify the size of the red difference component in the output array. The value of this parameter determines the interpretation of the video stream data as 8-bit, 16-bit, 24-bit, or 32-bit.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, and set the **Number of output components** parameter to 3 or greater.

Bits4 — Size of alpha component
8 (default) | 16 | 24 | 32

Specify the size of the alpha component in the output array. The value of this parameter determines the interpretation of the video stream data as 8-bit, 16-bit, 24-bit, or 32-bit.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, and set the **Number of output components** parameter to 4.

Rows1 — Number of rows for luminance component
`120` (default) | positive integer

Specify the number of rows for the luminance component in the output array. The value of this parameter must be a positive integer.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, and set the **Number of output components** parameter to 1 or greater.

Rows2 — Number of rows for blue difference component
`60` (default) | positive integer

Specify the number of rows for the blue difference component in the output array. The value of this parameter must be a positive integer.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, and set the **Number of output components** parameter to 2 or greater.

Rows3 — Number of rows for red difference component
`60` (default) | positive integer

Specify the number of rows for the red difference component in the output array. The value of this parameter must be a positive integer.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, and set the **Number of output components** parameter to 3 or greater.

Rows4 — Number of rows for alpha component
`288` (default) | positive integer

Specify the number of rows for the alpha component in the output array. The value of this parameter must be a positive integer.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, and set the **Number of output ports** parameter to 4.

Cols1 — Number of columns for luminance component
`160` (default) | positive integer

Specify the number of columns for the luminance component in the output array. The value of this parameter must be a positive integer.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, and set the **Number of output components** parameter to 1 or greater.

Cols2 — Number of columns for blue difference component
`80` (default) | positive integer

Specify the number of columns for the blue difference component in the output array. The value of this parameter must be a positive integer.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, and set the **Number of output components** parameter to 2 or greater.

Cols3 — Number of columns for red difference component
`80` (default) | positive integer

Specify the number of columns for the luminance component in the output array. The value of this parameter must be a positive integer.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, and set the **Number of output components** parameter to 3 or greater.

Cols4 — Number of columns for the alpha component
`352` (default) | positive integer

Specify the number of columns for the alpha component in the output array. The value of this parameter must be a positive integer.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, and set the **Number of output components** parameter to 4.

Component order in binary file — Arrangement of components in binary file
`[1 2 3]` (default) | vector of valid component identifiers

Specify the arrangement of components in the binary file. Identify the components by the assigned numerals, from 1 to 4, in desired order. You must include all the enabled components when setting this parameter.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`.

Interlaced video — Read video data from file as interlaced
`off` (default) | `on`

Select this parameter when the binary file contains interlaced video data.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`.

Input file has signed data — File has signed integers
`off` (default) | `on`

Select this parameter when the binary file contains signed integers.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`.

Byte order in binary file — Byte order of binary file
`Little endian` (default) | `Big endian`

Specify the byte order of the binary file as either little endian or big endian.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`.

Blocks
From Multimedia File | Write Binary File

Write Binary File

Write binary video data to file

Libraries:
Computer Vision Toolbox / Sinks

Description

The Write Binary File block takes the video data from a Simulink model and exports it to a binary file.

This block produces a raw binary file with no header information. It has no encoded information providing the data type, frame rate, or dimensionality. The video data for this block appears in row-major format.

Note This block supports code generation only for platforms that have file I/O available. The block does not support code generation using Simulink Desktop Real-Time or Simulink Real-Time.

Ports

Input

Y' — Luminance component of input video stream
scalar | vector | matrix

Luminance component of the input video stream, specified as a scalar, vector, or matrix. The label of this port can be changed using the **Component1** parameter when the **Video format** parameter is set to `Custom`.

Data Types: `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Cb — Blue difference component of the input video stream
scalar | vector | matrix

Blue difference component of the input video stream, specified as a scalar, vector, or matrix. The label of this port can be changed using the **Component2** parameter when the **Video format** parameter is set to `Custom`.

Data Types: `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Cr — Red difference component of input video stream
scalar | vector | matrix

Red difference component of the input video stream, specified as a scalar, vector, or matrix. The label of this port can be changed using the **Component3** parameter when the **Video format** parameter is set to `Custom`.

Data Types: int8 | int16 | int32 | uint8 | uint16 | uint32

A — Alpha component of input video stream
scalar | vector | matrix

Alpha component of the input video stream, specified as a scalar, vector, or matrix. The label of this port can be changed using the **Component4** parameter when the **Video format** parameter is set to Custom.

Dependencies

To enable this port, use one of these options.

- Set the **Video format** parameter to Four character codes, and set the **Four character code** parameter to AYUV or IF09.
- Set the **Video format** parameter to Custom, and the **Number of inputs** parameter to 4. In this case, the name of this port is **Alpha**.

Data Types: int8 | int16 | int32 | uint8 | uint16 | uint32

T — Transparency component of input video stream
scalar | vector | matrix

Transparency component of the input video stream, specified as a scalar, vector, or matrix.

Dependencies

To enable this port, set the **Video format** parameter to Four character codes, and set the **Four character code** parameter to Y41T or Y42T.

Data Types: int8 | int16 | int32 | uint8 | uint16 | uint32

Parameters

File name — Name of the binary file
output.bin (default) | file name

Specify the name of the output binary file, with a .bin extension, for the video data. Click **Save As** to specify the location for the file.

Video format — Format of the video data
Four character codes (default) | Custom

Specify the format of the video data as one of these options.

- Four character codes (FOURCC) — For more information about these codes, see https://en.wikipedia.org/wiki/FourCC.
- Custom — Read the video data from a binary file of a custom format.

Four character code — Format of binary file
I420 (default) | AYUV | CLJR | cyuv | GREY | IF09 | IMC1 | IMC2 | IMC3 | IMC4 | IUYV | IY41 | IYU1 | IYU2 | IYUV | NV12 | NV21 | UYNV | UYNY | V210 | Y411 | Y41P | Y41T | Y422 | Y42T | Y8 | Y800 | YUNV | YUY2 | YUYV | YV12 | YV16 | YVU9 | YVYU | ...

Select the four character code of the desired codec for the binary file. The value of this parameter also determines the number of input ports on the block. For information on which four character codes enable which input ports, see the table below.

Input Ports for Four Character Codes

Four Character Codes	Input Ports
I420	Y'|Cb|Cr
AYUV	Y'|Cb|Cr|A
CLJR	Y'|Cb|Cr
cyuv	Y'|Cb|Cr
GREY	Y'
IF09	Y'|Cb|Cr|A
IMC1	Y'|Cb|Cr
IMC2	Y'|Cb|Cr
IMC3	Y'|Cb|Cr
IMC4	Y'|Cb|Cr

Dependencies

To enable this parameter, set the **Video Format** parameter to `Four character codes`.

Line ordering — Binary file fill direction
`Top line first` (default) | `Bottom line first`

If you select `Top line first`, the block begins filling the binary file with the first row of the video frame. It then fills the file with the other rows in increasing order. If you select `Bottom line first`, the block begins filling the binary file with the last row of the video frame. It then fills the file with the other rows in decreasing order.

Bit stream format — Data format of binary file
`Planar` (default) | `Packed`

Specify the data format of the binary file as `Planar` or `Packed`.

Dependencies

To enable this parameter, set the **Video Format** parameter to **Custom**.

Number of inputs — Number of components in input video stream
3 (default) | 1 | 2 | 4

Specify the number of components in the input video stream. This parameter sets the number of input ports.

Dependencies

To enable this parameter, set the **Video Format** parameter to `Custom`.

Inherit size of components from input data type — All components have same number of bits
`on` (default) | `off`

Select the **Inherit size of components from input data type** parameter to indicate that all of the components have the same number of bits as the input data type. If you clear this parameter, you can specify the number of bits for each enabled component using the associated **Bits** parameter.

Dependencies

To enable this parameter, set the **Video Format** parameter to `Custom`.

Component1 — Name of luminance component input port
`Y'` (default) | component name

Specify the name of the input port for the luminance component of the input video stream.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, set the **Number of inputs** parameter to `1` or greater.

Component2 — Name of blue difference component
`Cb` (default) | component name

Specify the name of the input port for the blue difference component of the input video stream.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, set the **Number of inputs** parameter to 2 or greater.

Component3 — Name of red difference component
`Cr` (default) | component name

Specify the name of the input port for the red difference component of the input video stream.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, set the **Number of inputs** parameter to 3 or greater.

Component4 — Name of alpha component
`Alpha` (default) | component name

Specify the name of the input port for the alpha component of the input video stream.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, set the **Number of inputs** parameter to 4.

Bits1 — Size of luminance component
8 (default) | `0` | 16 | 24 | 32

Specify the size of the luminance component in the input video stream. The value of this parameter determines the interpretation of the video stream data as 8-bit, 16-bit, 24-bit, or 32-bit.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, and set the **Number of inputs** parameter to 1 or greater, and select the **Inherit size of components from input data type** parameter.

Bits2 — Size of blue difference component
8 (default) | `0` | 16 | 24 | 32

Specify the size of the blue difference component in the input video stream. The value of this parameter determines the interpretation of the video stream data as 8-bit, 16-bit, 24-bit, or 32-bit.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, and set the **Number of inputs** parameter to 2 or greater, and select the **Inherit size of components from input data type** parameter.

Bits3 — Size of red difference component
8 (default) | `0` | 16 | 24 | 32

Specify the size of the red difference component in the input video stream. The value of this parameter determines the interpretation of the video stream data as 8-bit, 16-bit, 24-bit, or 32-bit.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, and set the **Number of inputs** parameter to 3 or greater, and select the **Inherit size of components from input data type** parameter.

Bits4 — Size of alpha component
`8` (default) | `0` | `16` | `24` | `32`

Specify the size of the alpha component in the input video stream. The value of this parameter determines the interpretation of the video stream data as 8-bit, 16-bit, 24-bit, or 32-bit.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`, and set the **Number of inputs** parameter to 4, and select the **Inherit size of components from input data type** parameter.

Component order in binary file — Arrangement of components in binary file
`[1 2 3]` (default) | vector of valid component identifiers

Specify the arrangement of the components in the binary file. Identify the components by the assigned numerals, from 1 to 4, in the desired order. You must include all enabled components when setting this parameter.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`.

Interlaced video — Read video data as interlaced
`off` (default) | `on`

Select this parameter when the video stream contains interlaced video data.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`.

Write signed data to output file — Write signed data to output binary file
`off` (default) | `on`

Select this parameter when the input data is signed.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`.

Byte order in binary file — Byte order in output binary file
`Little endian` (default) | `Big endian`

Specify the byte order in the output binary file as either little endian or big endian.

Dependencies

To enable this parameter, set the **Video format** parameter to `Custom`.

Template Matching

Locate a template in an image

Libraries:
Computer Vision Toolbox / Analysis & Enhancement

Description

The Template Matching block finds the best match of a template within an input image. The block computes match metric values by shifting a template over a region of interest or the entire image, and then finds the best match location.

The block outputs either the match metric values or the one-based (*x*,*y*) coordinates of the best template match. Optionally the block can output an *N*-by-*N* matrix of the match metric values centered around the best match location.

Ports

Input

I — Image
image

Input image to use with the template. The block does not pad the input data. Therefore, it can only compute values for the match metrics between the input image and the template, where the template is positioned such that it falls entirely on the input image. A set of all such positions of the template is termed as the *valid* region of the input image. The size of the valid region is the difference between the sizes of the input and template images plus one.

$$size_{valid}=size_{input}-size_{template}+1 \quad (1\text{-}1)$$

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

T — Template
M-by-*N* matrix

Template, specified as an *M*-by-*N* matrix

The Template Matching block does not pad the input data. Therefore, it can only compute values for the match metrics between the input image and the template, where the template is positioned such that it falls entirely on the input image. A set of all such positions of the template is termed as the *valid* region of the input image. The size of the valid region is the difference between the sizes of the input and template images plus one.

$$size_{valid}=size_{input}-size_{template}+1 \quad (1\text{-}2)$$

Data Types: `single` | `double` | `uint8` | `Boolean` | `fixed point`

ROI — Region of interest
four-element vector

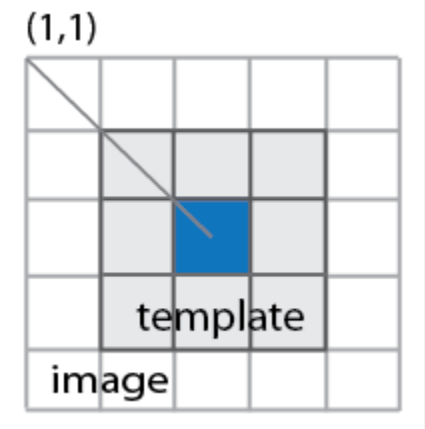
Region of interest vector in the format (*x*,*y*,*width*,*height*), where (*x*,*y*) are one-based coordinates for the upper-left corner of the region. The block outputs the best match location index relative to the top left corner of the input image.

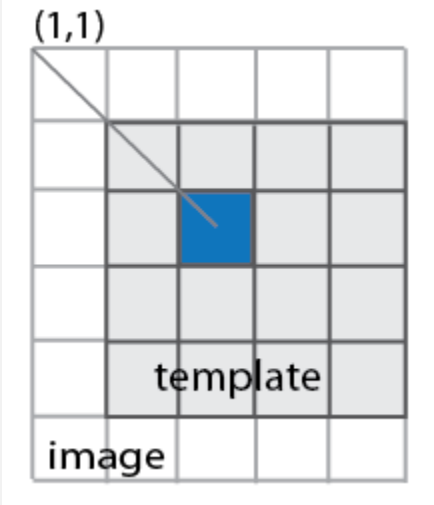
Data Types: `single` | `double` | `uint8` | `Boolean` | `fixed point`

Output

Metric — Match metric values
matrix

Matrix of match metric values. The matrix of the match metrics always implements single-step exhaustive window iteration. Therefore, the block computes the metric values at every pixel.





Dependencies

When you set the **Output** parameter to `Metric matrix`, the block outputs the valid image size.

Data Types: `single` | `double` | `uint8` | `Boolean` | `fixed point`

Loc — Best match locations
two-element vector

Best template match located at the one-based (*x*,*y*) coordinates. When in the ROI processing mode, the block treats the image around the ROI as an extension of the ROI subregion. Therefore, it computes the best match locations true to the actual boundaries of the ROI. The block outputs the best match coordinates, relative to the top-left corner of the image. The one-based [x y] coordinates of the location correspond to the center of the template. The following table shows how the block outputs the center coordinates for odd and even templates:

Odd number of pixels in template	Even number of pixels in template
	

Data Types: `uint32`

NMetric — Metric values in neighborhood of best match
N-by-*N* matrix

Metric values in the neighborhood of the best match, returned as an *N*-by-*N* matrix. *N*, specified in the mask, must be an odd number. When you select **Best match location** to return the matrix of metrics in a neighborhood around the best match, an exhaustive loop computes all the metric values for the *N*-by-*N* neighborhood. This output is particularly useful for performing template matching with subpixel accuracy.

Data Types: `single` | `double` | `uint8` | `Boolean` | `fixed point`

NValid — Valid neighborhood
off | on

Enable to track the valid neighborhood region. The neighborhood matrix of metric values is valid inside of the ROI. The block sets the **NValid** output as follows:

- `1` — The neighborhood containing the best match is completely inside the region of interest.
- `0` — The neighborhood containing the best match is completely or partially outside of the region of interest.

Dependencies

This port appears when you enable the **Output NxN matrix of metric values around best match** parameter.

Data Types: `Boolean`

ROIValid — Valid region of interest
off | on

Enable to track the valid region of interest. If the ROI lies partially outside the valid image, the block only processes the intersection of the ROI and the valid image. The block sets the **ROIValid** output as follows:

- `1` — The ROI lies completely inside the valid part of the input image.
- `0` — The ROI lies completely or partially outside of the valid part of the input image.

Dependencies

This port appears when you enable the **Output flag indicating if ROI is valid** parameter.

Data Types: `Boolean`

Parameters

Main Tab

Match metric — Match metric
`Sum of absolute differences` (default) | `Sum of squared differences` | `Maximum absolute difference`

Select match metric as one of:

- `Sum of absolute differences` (SAD)
- `Sum of squared differences` (SSD)
- `Maximum absolute difference` (MaxAD)

The block computes the match metric at each step of the iteration. Choose the match metric that best suits your application. The block calculates the global optimum for the best metric value. It uses the valid subregion of the input image intersected by the ROI, if provided.

Output — Match metric
`Match metric` (default) | `Best match location`

Select the type of output as one of:

- `Match metric` — Output the match metric matrix. This option adds the **Metric** output port to the block.
- `Best match location` — Output the [*x*,*y*] coordinates for the location of the best match. This option adds the **Loc** output port to the block. It also makes the **Search method**, **Output NxN matrix of metric values around best match**, and **Enable ROI processing** parameters available.

  The **Output** parameter on the Data Types pane appears when you set the **Output** parameter on the **Main tab** to `Metric matrix` or if you set it to `Best match location` and you enable the **Output NxN matrix of metric values around best match** parameter.

Search method — Search method
`Exhaustive` (default) | `Three-step`

Specify the search method as either `Exhaustive` or `Three-step`. The `Exhaustive` search method is computationally intensive because it searches at every pixel location of the image. However, this method provides a more precise result.

The `Three-step` search method is a fast search that uses a neighborhood approach versus a search at every pixel. The search starts with a step size equal to or slightly greater than half of the maximum search range and then employs the following steps:

1. The block compares nine search points in each step. There is a central point and eight search points located on the search area boundary.
2. The block decrements the step size by one, after each step, ending the search with a step size of one pixel.
3. At each new step, the block moves the search center to the best matching point resulting from the previous step. The number one blue circles in the figure below represent a search with a starting step size of three. The number two green circles represent the next search, with step size of two, centered around the best match found from the previous search. Finally, the number three orange circles represent the final search, with step size of one, centered around the previous best match.

Dependencies

This parameter appears when you set the **Output** parameter to `Best match location`.

Output NxN matrix of metric values around best match — Output *N*-by-*N* matrix
on (default) | off

Enable to add the **NMetric** and **NValid** ports.

Dependencies

This parameter appears when you set the **Output** parameter to `Best match location`.

N — Size of output matrix
3 (default) | integer

Size of output matrix. This value determines the size of the *N*-by-*N* output matrix centered around the best match location index. *N* must be an odd number.

Dependencies

This parameter appears when you enable the **Output NxN matrix of metric values around best match** parameter.

Enable ROI processing — Enable ROI processing
on (default) | off

Enable ROI processing.

Dependencies

- This parameter appears when you set the **Output** parameter to `Best match location`.

- When you enable this parameter, the block adds the **ROI** input port, and the **Output flag indicating if ROI is valid** parameter appears.

Output flag indicating if ROI is valid — Valid ROI
off (default) | on

Enable to add the **ROIValid** port.

Dependencies

This parameter appears when you enable the **Enable ROI processing** parameter.

Data Types Tab

For details on the fixed-point block parameters, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

Algorithms

Match Metrics

The match metrics use a difference equation with general form:

$$d_p(x, y) = \left(\sum_{i=1}^{n} |x_i - y_i|^p \right)^{1/p}$$

l_n^p denotes the metric space (R^n, d_p) for R^n $n > 1$.

Sum of Absolute Differences (SAD)

The SAD metric is also known as the *Taxicab* or *Manhattan Distance* metric. It sums the absolute values of the differences between pixels in the original image and the corresponding pixels in the template image. This metric is the l^1 norm of the difference image. The lowest SAD score estimates the best position of template within the search image. The general SAD distance metric becomes:

$$d_1(I_j, T) = \sum_{i=1}^{n} \left| I_{i,\,j} - T_i \right|$$

Sum of Squared Differences (SSD)

The SSD metric is also known as the Euclidean Distance metric. It sums the square of the absolute differences between pixels in the original image and the corresponding pixels in the template image. This metric is the square of the l^2 norm of the difference image. The general SSD distance metric becomes:

$$d_2(I_j, T) = \sum_{i=1}^{n} \left| I_{i,j} - T_i \right|^2$$

Maximum Absolute Difference (MaxAD)

The MaxAD metric is also known as the Uniform Distance metric. It sums the maximum of absolute values of the differences between pixels in the original image and the corresponding pixels in the template image. This distance metric provides the l^∞ norm of the difference image. The general MaxAD distance metric becomes:

$$d_\infty(I_j, T) = \lim_{x \to \infty} \sum_{i=1}^{n} \left| I_{i,j} - T_i \right|^p$$

which simplifies to:

$$d_\infty(I_j, T) = \max_{i}^{n} \left| I_{i,j} - T_i \right|^p$$

“Video Stabilization”

To Multimedia File

Write video frames and audio samples to multimedia file

Libraries:
Computer Vision Toolbox / Sinks

Description

The To Multimedia File block writes video frames, audio samples, or both to a multimedia file (`.avi`, `.wav`, `.mj2`, `.mp4`, or `.m4v` format).

You can compress the video frames or audio samples by selecting a compression algorithm. You can also control the type of video or audio in addition to other related properties the multimedia file receives.

If you have a Simulink Coder license, you can generate a code from a model containing this block. To run a generated executable file, you may need to add precompiled shared library files to your system path. See “Simulink Shared Library Dependencies”, and “Accelerating Simulink Models” for details.

Note This block supports code generation for platforms that have file I/O available. You cannot use this block with Simulink Desktop Real-Time software, because that product does not support file I/O.

This block performs best on platforms with Version 11 or later of Windows Media® Player software. This block supports only uncompressed RGB24 AVI files on Linux and Mac platforms.

Ports

Input

Image — Input image frame
matrix | array

Specify the input image frame as a matrix or an array. To write an intensity image frame to a multimedia file, specify it as an *M*-by-*N* matrix. For a color image frame, specify it as an *M*-by-*N*-by-3 array.

Dependencies

To enable this port:

- Set the **File type** parameter to `AVI`, `MJ-2000`, `WMV`, or `MPEG4`.
- If the **File type** parameter value is not `MJ-2000`, set the **Write** parameter to `Video and audio` or `Video only`.
- If the **File type** parameter value is `AVI` or `MPEG4`, set the **File color format** parameter to `RGB`.
- Set the **Image signal** parameter to `One multidimensional signal`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

R — Red color component of image
matrix

Specify the red color component of the input image frame as an *M*-by-*N* matrix.

Dependencies

To enable this port:

- Set the **File type** parameter to `AVI`, `MJ-2000`, `WMV`, or `MPEG4`.
- If the **File type** parameter value is not `MJ-2000`, set the **Write** parameter to `Video and audio` or `Video only`.
- If the **File type** parameter value is `AVI` or `MPEG4`, set the **File color format** parameter to `RGB`.
- Set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

G — Green color component of image
matrix

Specify the green color component of the input image frame as an *M*-by-*N* matrix.

Dependencies

To enable this port:

- Set the **File type** parameter to `AVI`, `MJ-2000`, `WMV`, or `MPEG4`.
- If the **File type** parameter value is not `MJ-2000`, set the **Write** parameter to `Video and audio` or `Video only`.
- If the **File type** parameter value is `AVI` or `MPEG4`, set the **File color format** parameter to `RGB`.
- Set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

B — Blue color component of image
matrix

Specify the blue color component of the input image frame as an *M*-by-*N* matrix.

Dependencies

To enable this port:

- Set the **File type** parameter to `AVI`, `MJ-2000`, `WMV`, or `MPEG4`.
- If the **File type** parameter value is not `MJ-2000`, set the **Write** parameter to `Video and audio` or `Video only`.
- If the **File type** parameter value is `AVI` or `MPEG4`, set the **File color format** parameter to `RGB`.
- Set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Y — Luma component of image
matrix

Specify the luma component of the input image frame as an *M*-by-*N* matrix.

Dependencies

To enable this port:

- Set the **File type** parameter to `AVI` or `MPEG4`.
- Set the **Write** parameter to `Video and audio` or `Video only`.
- Set the **File color format** parameter to `YCbCr 4:2:2`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Cb — Blue-difference chrominance component of image
matrix

Specify the blue-difference chrominance component of the input image as an *M*-by-*N*/2 matrix.

Dependencies

To enable this port:

- Set the **File type** parameter to `AVI` or `MPEG4`.
- Set the **Write** parameter to `Video and audio` or `Video only`.
- Set the **File color format** parameter to `YCbCr 4:2:2`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Cr — Red-difference chrominance component of image
matrix

Specify the red-difference chrominance component of the input image as an *M*-by-*N*/2 matrix.

Dependencies

To enable this port:

- Set the **File type** parameter to `AVI` or `MPEG4`.
- Set the **Write** parameter to `Video and audio` or `Video only`.
- Set the **File color format** parameter to `YCbCr 4:2:2`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Audio — Input audio signal
vector | matrix

Specify the input audio signal as a vector or a matrix. When specified as a matrix, the block treats each column as an independent channel.

Dependencies

To enable this port:

- Set the **File type** parameter to `AVI`, `WAV`, `WMA`, `MPEG4`, `FLAC`, or `OGG`.
- If the **File type** parameter value is `AVI`, `WMV`, or `MPEG4` set the **Write** parameter to `Video and audio` or `Audio only`.

Data Types: `single` | `double` | `int16` | `int32` | `uint8`

Parameters

File name — Name of multimedia file
`output.avi` (default) | character vector

Specify the name for the multimedia file the block writes. The block appends a file extension automatically based on the specified **File type** parameter. If the specified file name, including the file extension, already exists, the block overwrites the data in the existing file with the new input data.

By default, the block saves the file in the current working directory. To specify a different file location, click the **Save As...** button.

File type — Type of multimedia file
`AVI` (default) | `WAV` | `MJ2000` | `WMA` | `WMV` | `MPEG4` | `FLAC` | `OGG`

Specify the type of multimedia file to write. The block supports the `AVI`, `WAV`, `MJ2000`, `WMA`, `WMV`, `MPEG4`, `FLAC`, and `OGG` file formats.

Write — Type of media
`Video only` (default) | `Audio only` | `Video and audio`

Specify the type of media to write. Depending on the value of the **File type** parameter, you can select `Video only`, `Audio only`, or `Video and audio`.

Type of file	Supported type of media
`AVI`	• `Video only` • `Audio only` • `Video and audio`
`WMV`	• `Video only` • `Video and audio`
`MPEG4`	• `Video only` • `Audio only`

Dependencies

To enable this parameter, set the **File type** parameter to `AVI`, `WMV`, or `MPEG4`.

Video compressor — Video compression algorithm
`None (uncompressed)` (default) | `DV Video Encoder` | `MJPEG Compressor` | `Lossy` | `Lossless`

Specify a video compression algorithm to reduce the size of the output file. The available options depend on the value of the **File type** parameter.

- `AVI` — Select either the `DV Video Encoder` or `MJPEG Compressor` algorithm. If you do not want to reduce the size of the file, select `None (uncompressed)`.

- `MJ2000` — Select either the `Lossy` or `Lossless` algorithm.

Note The options for this parameter are the video compression algorithms installed on your system. For information about a specific video compressor, see the documentation for that compressor.

Dependencies

To enable this parameter, set the **File type** parameter to `MJ2000` or `AVI`. For the `AVI` file type, set the **Write** parameter to `Video only` or `Video and audio`.

Compression Factor (>1) — Compression factor
`10` (default) | integer greater than `1`

Specify the compression factor as an integer greater than `1`.

Dependencies

To enable this parameter, set the **File type** parameter to `MJ2000` and the **Video compressor** parameter to `Lossy`.

Video Quality (0-100) — Quality of video
`75` (default) | integer in range [0, 100]

Specify the quality of the video as an integer in the range [0, 100].

Dependencies

To enable this parameter, set the **File type** parameter to `MPEG4` and the **Write** parameter to `Video only`.

File color format — Color format of output video
`RGB` (default) | `YCbCr 4:2:2`

Specify the color format of the video for the output file. The block supports the `RGB` and `YCbCr 4:2:2` color formats.

Dependencies

To enable this parameter, set the **File type** parameter to `AVI` or `MPEG4`.

Image signal — Input port configuration for RGB video
`One multidimensional signal` (default) | `Separate color signals`

Specify how the block accepts an RGB color video input. If you select `One multidimensional signal`, the block accepts input using only the **Image** port. If you select `Separate color signals`, the block accepts an input video using three separate color channels, divided across the **R**, **G**, and **B** ports.

Dependencies

To enable this parameter:

- Set the **File type** parameter to `AVI`, `MJ-2000`, `WMV`, or `MPEG4`.
- Set the **Write** parameter to `Video and audio` or `Video only`.

- If the **File type** parameter value is `AVI` or `MPEG4`, set the **File color format** parameter to `RGB`.

Audio compressor — Audio compression algorithm
`None (uncompressed)` (default) | `CCITT A-Law` | `CCITT u-Law` | `GSM 6.10` | `IMA ADPCM` | `Microsoft ADPCM` | `PCM`

Specify an audio compression algorithm to reduce the size of the output file. The block supports the `CCITT A-Law`, `CCITT u-Law`, `GSM 6.10`, `IMA ADPCM`, `Microsoft ADPCM`, and `PCM` algorithms. If you do not want to reduce the size of the file, select `None (uncompressed)`.

Note The options for this parameter are the audio compression algorithms installed on your system. For information about a specific audio compressor, see the documentation for that compressor.

Dependencies

To enable this parameter, use either of these options:

- Set the **File type** parameter to `AVI` and set the **Write** parameter to `Video and audio` or `Audio only`.
- Set the **File type** parameter to `WAV`.

Audio data type — Audio data type
`Determine from input data type` (default) | `8-bit integer` | `16-bit integer` | `24-bit integer` | `32-bit integer` | `32-bit float` | `64-bit float`

Specify the audio data type for the output file.

Dependencies

To enable this parameter select, use either of these options:

- Set the **File type** parameter to `WAV` and the **Audio compressor** parameter to `None (uncompressed)`.
- Set the **File type** parameter to `FLAC`. This file type supports only the `8-bit integer`, `16-bit integer`, and `24-bit integer` data types.

Block Characteristics

Data Types	`double` | `integer`[a] | `single`
Direct Feedthrough	`no`
Multidimensional Signals	`no`
Variable-Size Signals	`no`
Zero-Crossing Detection	`no`

a Supports 16- and 32-bit signed and 8-bit unsigned integers.

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- Host computer only. Excludes Simulink Desktop Real-Time code generation.
- The executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed ZIP file. Using this ZIP file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “Get Started with Code Generation, Deployment, GPU, and OpenCV Support”.

Blocks

From Multimedia File | Video From Workspace | Image From File | Video To Workspace

To Simulink Image

Pack numeric matrix into a Simulink image

Libraries:
Computer Vision Toolbox / Utilities

Description

The To Simulink Image block converts matrix data to Simulink image data.

Ports

Input

Port_1 — Input signal
matrix

Input signal to the To Simulink Image block. The input is a numerical matrix.

Data Types: `integer` | `single` | `double` | `Boolean`

Output

Port_1 — Output signal
`Simulink.ImageType`

Output signal from the To Simulink Image block. The output is an image of `Simulink.ImageType` data type.

Data Types: `Simulink.ImageType`

Parameters

Output data type — Data type of output signal values
`Inherit: auto` (default) | `Simulink.ImageType(480,640,3)`

Specify the output data type of the image signal.

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

You can specify any of these options:

- Inherited data type
- Simulink image data type — Use the constructor for `Simulink.ImageType` object and specify the properties to describe the image. By default, the data type uses `Simulink.ImageType(480,640,3)` expression.

- Custom data type — Use a MATLAB expression that represents the rows, columns, and channels of the image respectively.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Value: `Inherit: auto` | `Simulink.ImageType(480,640,3)` | `<data type expression>`
Default: `Inherit: auto`

Block Characteristics

Data Types	`double` | `single` | `integer` | `Boolean` | `image`
Direct Feedthrough	`yes`
Multidimensional Signals	`yes`
Variable-Size Signals	`no`
Zero-Crossing Detection	`no`

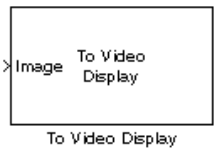
Version History

Introduced in R2022a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.



Supports C++ code generation.

From Simulink Image

To Video Display

Display images or video frames

Libraries:
Computer Vision Toolbox / Sinks

Description

The To Video Display block displays RGB or YCbCr formatted images and video frames. The display created by the block is lightweight and high performance, capable of displaying high definition video at high frame rates.

Ports

Input

Image — Input image
matrix | array

Input image or video, specified as an *M*-by-*N* matrix, *M*-by-*N*-by-*T* array, or *M*-by-*N*-by-*C*-by-*T* array. If the input is a 3-D array, the third dimension is the number of frames in the video. If the input is a 4-D array, the third dimension is the number of color channels, and the fourth dimension is the number of frames in the video.

Dependencies

To enable this port, set the **Input Color Format** parameter to RGB, and set **Image signal** to `One multidimensional signal`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

R — Red color component of image
matrix | array

Red color component of the input image or video, specified as an *M*-by-*N* matrix or *M*-by-*N*-by-*T* array. If the input is a 3-D array, the third dimension is the number of frames in the video.

Note Inputs to the **R**, **G**, and **B** ports must have the same dimensions and data type.

Dependencies

To enable this port, set the **Input Color Format** parameter to RGB, and set **Image signal** to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

G — Green color component of image
matrix | array

Green color component of the input image or video, specified as an *M*-by-*N* matrix or *M*-by-*N*-by-*T* array. If the input is a 3-D array, the third dimension is the number of frames in the video.

Note Inputs to the **R**, **G**, and **B** ports must have the same dimensions and data type.

Dependencies

To enable this port, set the **Input Color Format** parameter to RGB, and set **Image signal** to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

B — Blue color component of image
matrix | array

Blue color component of the input image or video, specified as an *M*-by-*N* matrix or *M*-by-*N*-by-*T* array. If the input is a 3-D array, the third dimension is the number of frames in the video.

Note Inputs to the **R**, **G**, and **B** ports must have the same dimensions and data type.

Dependencies

To enable this port, set the **Input Color Format** parameter to RGB, and set **Image signal** to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Y — Luma component of image
matrix | array

Luma component of the input image or video, specified as an *M*-by-*N* matrix or *M*-by-*N*-by-*T* array. If the input is a 3-D array, the third dimension is the number of frames in the video.

Dependencies

To enable this port, set the **Input Color Format** parameter to `YCbCr 4:2:2`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Cb — Blue-difference chroma component of image
matrix | array

Blue-difference chroma component of the input image or video, specified as an *M*-by-*N/2* matrix or *M*-by-*N/2*-by-*T* array. If the input is a 3-D array, the third dimension is the number of frames in the video.

Dependencies

To enable this port, set the **Input Color Format** parameter to `YCbCr 4:2:2`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Cr — Red-difference chroma component of image
matrix | array

Red-difference chroma component of the input image or video, specified as an *M*-by-*N/2* matrix or *M*-by-*N/2*-by-*T* array. If the input is a 3-D array, the third dimension is the number of frames in the video.

Dependencies

To enable this port, set the **Input Color Format** parameter to `YCbCr 4:2:2`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Parameters

View

Window size — Display window size
`Normal` (default) | `Full-screen (Esc to exit)` | `True size (1:1)`

Display the video stream in various window sizes:

- `Normal` — Modify the display size at the start of the simulation.
- `Full-screen (Esc to exit)` — Display the video stream in a full-screen window. To exit the full-screen view, press **Esc**.
- `True size (1:1)` — Display the input image at a one-to-one pixel ratio, at the start of the simulation.

Open at Start of Simulation — Open window at start of simulation
`on` (default) | `off`

To set the **Video Display** window to open automatically and display video frames when the simulation begins, select **Open at Start of Simulation**. If you clear this parameter, the block is not included during runtime, and the simulation runs in “Accelerator Mode” (Simulink).

Settings

Input Color Format — Input color format
`RGB` (default) | `YCbCr 4:2:2`

Specify the color format of the input image:

- `RGB` — Specify the input colorspace as RGB. You can select whether to input the image as a single signal or as individual color signals using the **Image signal** parameter.
- `YCbCr 4:2:2`— Specify the input colorspace as YCbCr. You must input the image as separate signals to the three input ports, **Y**, **Cb** and **Cr**.

Image signal — Configure input port
`One multidimensional signal` (default) | `Separate color signals`

Specify whether the block accepts an RGB color input as a single signal or as separate signals for each color channel..

- `One multidimensional signal` — The block accepts RGB input as a single array through one port.

- `Separate color signals` — The block accepts RGB input as three separate matrices or arrays, one for each color channel, to the **R**, **G**, and **B** ports.

Dependencies

To enable this parameter, set the **Input Color Format** parameter to `RGB`.

Block Characteristics

Data Types	`Boolean` | `double` | `integer` | `single`
Multidimensional Signals	`yes`
Variable-Size Signals	`yes`

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Note This block supports code generation for platforms that have file I/O available. You cannot use this block with Simulink Desktop Real-Time software, because that product does not support file I/O.

The generated code for this block relies on prebuilt library files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra library files when doing so. The `packNGo` function creates a single ZIP file containing all of the pieces required to run or rebuild this code. See `packNGo` for more information.

To know the code generation process of Simulink blocks, see “Simulink Coder”. To run an executable file that was generated from a model containing this block, you may need to add precompiled shared library files to your system path. See “Simulink Shared Library Dependencies” and “Accelerating Simulink Models” for details.

Usage notes and limitations:

- Host computer only. Excludes Simulink Desktop Real-Time code generation.
- The executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed ZIP file. Using this ZIP file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “Get Started with Code Generation, Deployment, GPU, and OpenCV Support”.

Top-hat

Perform morphological top-hat filtering on intensity or binary images

Libraries:
Computer Vision Toolbox / Morphological Operations

Description

The Top-hat block performs top-hat filtering on an intensity or binary image using a predefined neighborhood or structuring element. Top-hat filtering is the equivalent of subtracting the result of performing a morphological opening operation on the input image from the input image itself.

To define the structuring element that the block applies to the image, use the **Neighborhood or structuring element** parameter. Specify this element by entering a vector or matrix of `1`s and `0`s or by using the `strel` function.

This block uses two-dimensional flat structuring elements only.

Ports

Input

I — Input image
matrix

Specify an input image as a matrix of intensity values. This port is unnamed unless you set the **Neighborhood or structuring element source** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Nhood — Neighborhood values
vector | matrix

Specify neighborhood values representing a structuring element as a vector or matrix of `1`s and `0`s or by using the `strel` function.

Dependencies

To enable this port, set the **Neighborhood or structuring element source** parameter to `Input port`.

Data Types: `Boolean`

Output

Port_1 — Filtered image
matrix

The top-hat filtered image is returned as a matrix of intensity values. The size and data type of the filtered image are the same as those of the input image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Input image type — Type of input image

`Intensity` (default) | `Binary`

Specify the type of image as one of these options:

- `Intensity` — If the input image is an intensity image, select this option.
- `Binary` — If the input image is a binary image, select this option.

Neighborhood or structuring element source — Source of neighborhood or structuring element

`Specify via dialog` (default) | `Input port`

Specify the source of neighborhood or structuring element as one of these options:

- `Specify via dialog` — Use the **Neighborhood or structuring element** parameter to specify a neighborhood or structuring element.
- `Input port` — Use the **Nhood** input port to specify neighborhood values representing a structuring element.

Neighborhood or structuring element — Neighborhood or structuring element

`strel('square',4)` (default) | vector | matrix

Specify neighborhood or structuring element as a vector or matrix of `1`s and `0`s, a `strel` object or an array of `strel` objects. When you specify this value as an array of `strel` objects, the block applies each object to the entire image in turn.

If the structuring element is decomposable into smaller elements, the block executes at higher speed due to the use of a more efficient algorithm.

Dependencies

To enable this parameter, set the **Neighborhood or structuring element source** parameter, to `Specify via dialog`.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

More About

Top-hat Transform

Image processing tasks like background equalization, feature extraction, and image enhancement can be achieved using the top-hat transform. This process returns an image which contains objects that are:

- Smaller in dimension than the structuring element chosen and
- Brighter than the surroundings

Trace Boundary

Trace object boundaries in binary images

Libraries:
Computer Vision Toolbox / Analysis & Enhancement

Description

The Trace Boundary block traces object boundaries in binary images, where nonzero pixels represent objects and zero valued pixels represent the background.

Ports

Input

BW — Input binary image
matrix

Input binary image, specified as an *M*-by-*N* matrix.

Data Types: `Boolean`

Start Pt — Coordinate of boundary starting point
two-element vector

Coordinate of the boundary starting point, specified as a two-element vector in the form [*X Y*].

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Output

Pts — Coordinates of boundary points
M-by-2 matrix

Coordinates of the boundary points, returned as an *M*-by-2 matrix where each row represents a coordinate of a boundary pixel in the form [*X Y*]. *M* is the number of traced boundary pixels in the output image. Value of *M* must be less than or equal to the value specified by **Maximum number of boundary pixels** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

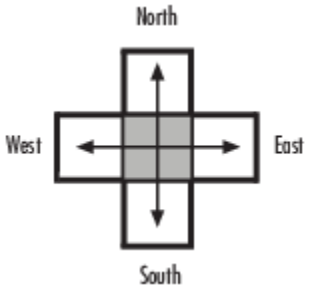
Parameters

Connectivity — Type of pixel connectivity

8 (default) | 4

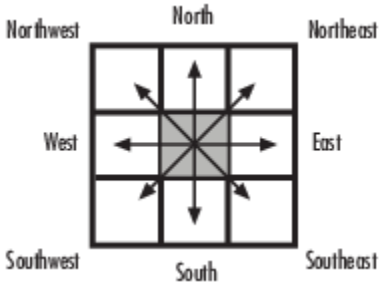
Select these options to specify how the block defines which pixels are connected to each other.

- 8 — Connect adjacent pixels in the horizontal, vertical, and diagonal directions.
- 4 — Connect adjacent pixels in only the horizontal and vertical directions.



For more information, see “Connectivity” on page 1-0 .

Initial search direction — Type of initial search direction



`North` (default) | `East` | `South` | `West` | `Northeast` | ...

Specify the type of initial search direction to find the boundary pixel connected to the starting pixel specified at **Start Pt** input port. These options are dependent on the specified **Connectivity** parameter.

For **Connectivity** parameter set as 4, the block enables `North`, `East`, `South`, and `West` search directions. This figure illustrates the four possible initial search directions with respect to the starting pixel.

For **Connectivity** parameter set as 8, the block enables additional `Northeast`, `Southeast`, `Southwest`, and `Northwest` search directions. This figure illustrates the eight possible initial search directions with respect to the starting pixel.

Trace direction — Boundary trace direction

`Clockwise` (default) | `Counterclockwise`

Select the direction to trace the boundary as `Clockwise` or `Counterclockwise`.

Maximum number of boundary pixels — Maximum number of boundary pixels

500 (default) | scalar

Specify the maximum number of boundary pixels for the starting point as a scalar. The number of rows at **Pts** output port must be less than or equal to this value.

Block Characteristics

Data Types	`Boolean`
Multidimensional Signals	`no`
Variable-Size Signals	`no`

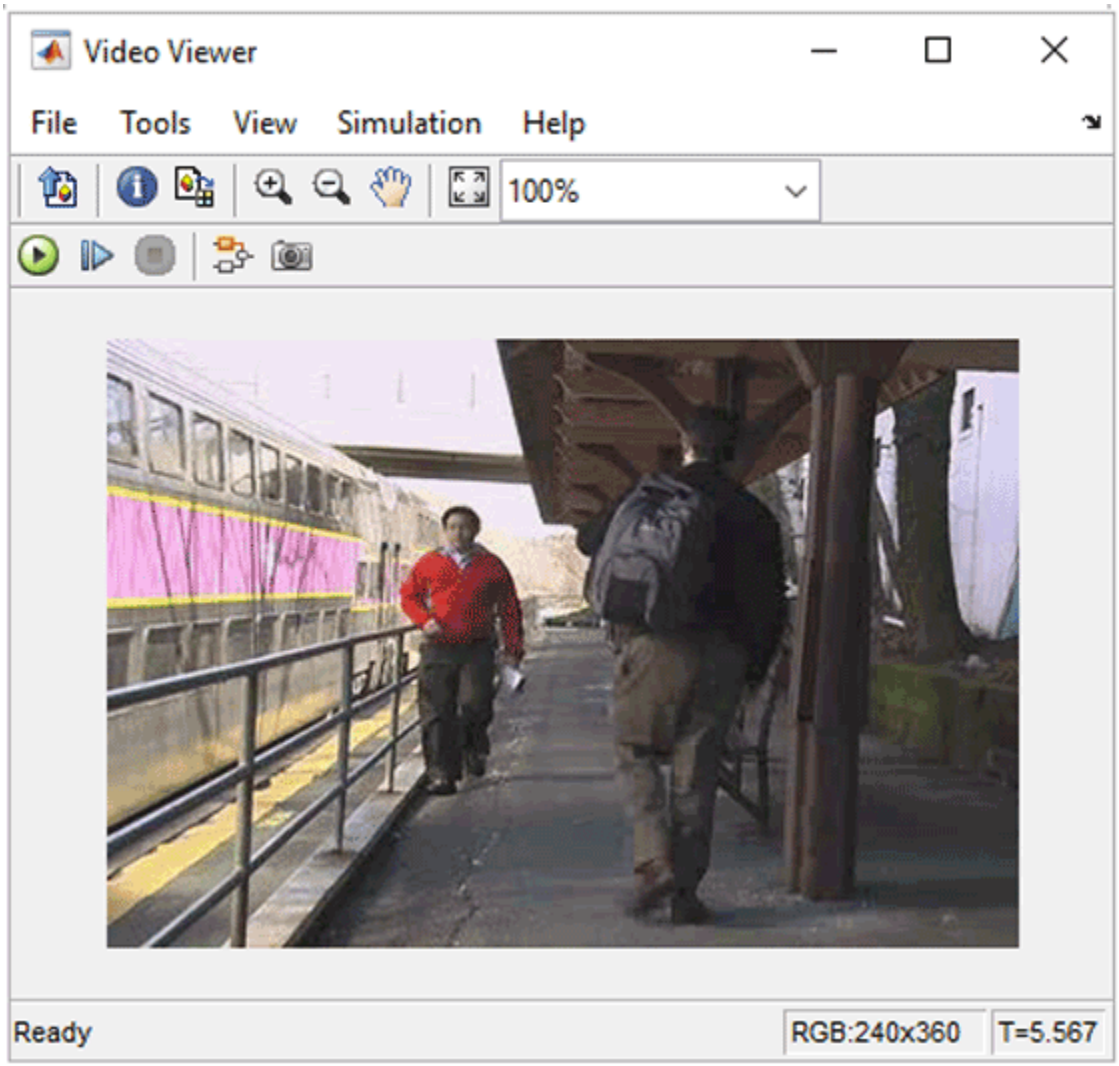
Video Viewer



Display images or video frames

Libraries:
Computer Vision Toolbox / Sinks

Description

The Video Viewer block displays images or video frames. This block provides simulation controls to play, pause, and step while streaming a video or image sequence. This block also provides tools to analyze the pixels of a region of interest.

Features of Video Viewer

- Playback control — Control video playback using the Run, Step Forward, and Stop buttons.
- Export to **Image Viewer** — To open the displayed image in a separate window using the **Image Viewer** app, select **File > Export to Image Viewer**. Alternatively, select the Export to Image Viewer button in the toolbar. For more information, see “Get Started with Image Viewer App”.
- Pixel region analysis— To open the displayed image in a separate window using the Pixel Region tool, select **Tools > Pixel Region**. Alternatively, select the Inspect pixel values button in the toolbar. For more information about Pixel Region tool, see `impixelregion`.

Ports

Input

Image — Input image or video
matrix | array

Input image or video, specified as an *M*-by-*N* matrix, *M*-by-*N*-by-*T* array, or *M*-by-*N*-by-*C*-by-*T* array. *T* is the number of frames in a video or image sequence, and *C* is the number of color channels.

Dependencies

To enable this port, select the **One Multi-Dimensional Signal** parameter. This parameter is enabled by default.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `Simulink.ImageType`

R — Red color component of image or video
matrix | array

Red color component of the image or video, specified as an *M*-by-*N* matrix or *M*-by-*N*-by-*T* array. *T* is the number of frames in a video or image sequence.

Note Inputs to the **R**, **G**, and **B** ports must all have the same dimensions and data type.

Dependencies

To enable this port, select the **Separate Color Signals** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

G — Green color component of image or video
matrix | array

Green color component of the image or video, specified as an *M*-by-*N* matrix or *M*-by-*N*-by-*T* array. *T* is the number of frames in a video or image sequence.

Note Inputs to the **R**, **G**, and **B** ports must all have the same dimensions and data type.

Dependencies

To enable this port, select the **Separate Color Signals** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

B — Blue color component of image or video
matrix | array

Blue color component of the image or video, specified as an *M*-by-*N* matrix or *M*-by-*N*-by-*T* array. *T* is the number of frames in a video or image sequence.

Note Inputs to the **R**, **G**, and **B** ports must all have the same dimensions and data type.

Dependencies

To enable this port, select the **Separate Color Signals** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Parameters

File

To access these parameters, select the **File** menu in the Video Viewer window

Open at Start of Simulation — Open video viewer window at start of simulation
`on` (default) | `off`

Select this parameter to automatically open the Video Viewer window at the start of the simulation. Clear this parameter to prevent the Video Viewer window from opening at the start of the simulation.

Separate Color Signals — Enable separate R, G, and B color channels as input
`off` (default) | `on`

Select this parameter to enable the **R**, **G**, and **B** input ports for separate color channels. If you select this parameter, the **One Multi-Dimensional Signal** parameter clears automatically.

One Multi-Dimensional Signal — Enable one multi-dimensional signal as input
`on` (default) | `off`

Select this parameter to enable the **Image** input port for one multi-dimensional signal. If you select this parameter, the **Separate Color Signals** parameter clears automatically.

File > Configuration > Edit > Core

The Video Viewer **Configuration** parameters enable you to change the behavior and appearance of the graphic user interface (GUI).

- To open the Configuration dialog box and edit parameters, select **File** > **Configuration** > **Edit**.

The **Core** tab in the Configuration dialog box lists the general settings of the GUI.

- In the **Core** tab, select `General UI` item and click the **Properties** button to open the General UI Properties dialog box.

Display the full path — Display full path of source data in the title bar
`off` (default) | `on`

Select this parameter to display the model name and full path to the source data in the title bar of the Video Viewer window. If you clear this parameter, the window displays a shortened name.

File > Configuration > Edit > Tools

The Video Viewer **Configuration** parameters enable you to change the behavior and appearance of the graphic user interface (GUI).

- To open the Configuration dialog box and edit parameters, select **File** > **Configuration** > **Edit**.

The **Tools** tab in the Configuration dialog box lists the tools associated with the Video Viewer block.

- In the **Tools** tab, select the `Image Viewer` item and click the **Properties** button to open the Image Viewer Properties dialog box.

Open new Image Viewer window for each export — Open new Image Viewer window for each exported video frame
`on` (default) | `off`

Select this parameter to open a new **Image Viewer** window for each exported video frame or image in an image sequence.

Tools > Colormap

The **Colormap** parameters enable you to display an intensity image in various colormap formats and control the output intensity range. To access these parameters, select **Tools** > **Colormap** or press **C**.

Note The **Colormap** parameters are available for intensity images only.

Colormap — Set colormap

`gray(256)` (default) | `parula(256)` | `jet(256)` | `hot(256)` | `bone(256)` | `cool(256)` | `copper(256)`

This parameter specifies the colormap in which to display the input intensity image. This block supports the `gray(256)`, `parula(256)`, `jet(256)`, `hot(256)`, `bone(256)`, and `copper(256)` colormaps.

Specify range of displayed pixel values [-Inf to Inf] — Specify range of intensity value to display
`off` (default) | `on`

Select this parameter to enable the **Min** and **Max** parameters, through which you can specify the display range of pixel intensities.

Min — Minimum intensity value
`0` (default) | numeric scalar

If a pixel has an intensity value less than or equal to the value of this parameter, **Video Viewer** displays it as the first color in the selected colormap.

Note When specifying a value for **Min**, remember that the data type of the input image or video determines the range of intensity values representing that image or video.

Dependencies

To enable this parameter, select the **Specify range of displayed pixel values [-Inf to Inf]** parameter.

Max — Maximum intensity value
255 (default) | numeric scalar

If a pixel has an intensity value higher than or equal to the value of this parameter, **Video Viewer** displays it as the last color in the selected colormap.

Note When specifying a value for **Max**, remember that the data type of the input image or video determines the range of intensity values representing that image or video.

Dependencies

To enable this parameter, select the **Specify range of displayed pixel values [-Inf to Inf]** parameter.

Simulation

To access this parameter, select the **Simulation** menu in the Video Viewer window.

Drop Frames to Improve Performance — Drop frame rate of input video signal
`on` (default) | `off`

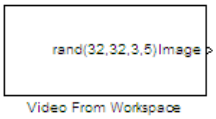
Select this parameter to reduce the frame rate of the input video signal to improve performance of the simulation. If you unselect this parameter, the block displays all the frames in the input video signal during simulation.

Block Characteristics

Data Types	`Boolean` | `double` | `integer` | `single`
Direct Feedthrough	`no`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`
Zero-Crossing Detection	`no`

Version History

Introduced before R2006a



See Also

Blocks

From Multimedia File | To Multimedia File | To Video Display | Video To Workspace | Video From Workspace | Image From Workspace | Image From File

Video From Workspace

Import video from MATLAB workspace

Libraries:
Computer Vision Toolbox / Sources

Description

The Video From Workspace block imports a video from the MATLAB workspace. The output of the block depends on the format of the video in the workspace.

- If the video is represented by an *M*-by-*N*-by-*T* array, the block outputs a grayscale video. *M* and *N* are the number of rows and columns in each video frame, and *T* is the number of frames in the video.
- If the video is represented by an *M*-by-*N*-by-*C*-by-*T* array, the block outputs a color video. *M* and *N* are the number of rows and columns in each video frame, *C* is the number of color channels, and *T* is the number of frames in the video.

Note

- If you generate code from a model that contains this block, it takes long to compile the code as the Simulink Coder puts all of the video data into the `.c` file. To shorten code generation time, convert your video data into a format supported by the From Multimedia File or Read Binary File block.
- The Video From Workspace block also supports `fi` objects. For more information on `fi` objects, see `fi`.

Ports

Output

Image — Output image or video
M-by-*N*-by-*T* array | *M*-by-*N*-by-*C*-by-*T* array

Output image or video, returned as an *M*-by-*N*-by-*T* array or *M*-by-*N*-by-*C*-by-*T* array. If the output is a 3-D array, the third dimension is the number of frames in the video. If the output is a 4-D array, the third dimension is the number of color channels, and the fourth dimension is the number of frames in the video.

Note If an RGB image of size, *M*-by-*N*-by-3 array is imported from the MATLAB workspace, the block considers the third dimension to be the number of frames and processes the image as a grayscale video with 3 identical frames.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

R — Red color component of input video
3-D array

Red color component of the input video, returned as a 3-D array. The third dimension is the number of frames in the input video.

Note The port label can be changed by using the **Output port labels** parameter.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

G — Green color component of input video
3-D array

Green color component of the input video, returned as a 3-D array. The third dimension is the number of frames in the input video.

Note The port label can be changed by using the **Output port labels** parameter.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

B — Blue color component of input video
3-D array

Blue color component of the input video, returned as a 3-D array. The third dimension is the number of frames in the input video.

Note The port label can be changed by using the **Output port labels** parameter.

Dependencies

To enable this port, set the **Image signal** parameter to `Separate color signals`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Signal — Video to read
`rand(32,32,3,5)` (default) | *M*-by-*N*-by-*T* array | *M*-by-*N*-by-*C*-by-*T* array | MATLAB workspace variable

Specify the video to read from the workspace. The value for this parameter can be a 3-D numeric array, 4-D numeric array, or a MATLAB workspace variable.

To import an AVI file from the MATLAB workspace, use this process.

1. Read the file by using the `VideoReader` function.

   ```
   mov = VideoReader('filename.avi')
   ```

2. Specify the workspace variable, in this case *mov* as the value for the **Signal** parameter. If the AVI file has an associated colormap, it must satisfy these conditions.

   - The colormap must be empty or have 256 values.
   - The data must represent a grayscale image.
   - The data type of the pixel values must be `uint8`.

Sample time — Sample period of the output video
1 (default) | `-1` | positive scalar

This parameter specifies the sample period of the output video as a positive scalar or `-1`. When set to `-1`, the block inherits the sample time from the simulink model.

Form output after final value by — Form of block output after final video frame
`Setting to zero` (default) | `Holding final value` | `Cyclic repetition`

Specify the block output for the duration of the simulation after the block generates the final video frame.

- `Setting to zero` — Generate zero-valued outputs.
- `Holding final value` — Repeat the final frame.
- `Cyclic repetition` — Repeat the video from the beginning.

Image signal — Output mode of video signal
`One multidimensional signal` (default) | `Separate color signals`

Specify the format in which the block returns a color video.

- `One multidimensional signal` — Return all color channels of the video in a single 4-D array. The third dimension is the number of color channels in the video.
- `Separate color signals` — Return each color channel of the video as a separate 3-D array. This setting enables a number of output ports on the block equal to the number of color channels in the video. Each port returns a single color channel.

Output port labels — Output port names
`R|G|B` (default) | text labels separated by vertical bars

Name the output ports. Use the vertical bar character, |, as a delimiter.

Example:: Red|Green|Blue

Dependencies

To enable this parameter, set the **Image signal** parameter to `Separate color signals`.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point` | `integer` | `single`

Blocks

Video To Workspace | Image From Workspace | Video Viewer

Video To Workspace

Export image or video to MATLAB workspace

Libraries:
Computer Vision Toolbox / Sinks

Description

The Video To Workspace block exports an image or video to the MATLAB workspace. It accepts images or videos as a matrix, 3-D array, 4-D array and converts them to a 3-D or 4-D array. The input size determines the output size.

- *M*-by-*N*, the block exports it as an *M*-by-*N*-by-2 array. *M* and *N* are the number of rows and columns, respectively, in an image frame and 2 is the number of frames in the image.
- *M*-by-*N*-by-3, the block exports it as a *M*-by-*N*-by-3-by-2 array. *M* and *N* are the number of rows and columns in a image or video frame, 3 is the number of color channels, and 2 is the number of frames in the video.
- *M*-by-*N*-by-3-by-*T*, the block exports it as a *M*-by-*N*-by-3-by-*T* array. *M* and *N* are the number of rows and columns in a video frame, 3 represents the number of color channels, and *T* is the number of frames in the video.

Note

- Simulink Coder does not generate code for this block.
- The block supports grayscale and color images, which are exported to the MATLAB workspace with an extra dimension that represents the number of frames. An image is always exported with a frame value of 2.

Ports

Input

Image — Input video
matrix | 3-D array | 4-D array

The input image or video, specified as a matrix, 3-D array, or 4-D array. The type of signal determines the dimensions of the input. Inputs are defined in terms of *M*, *N*, *C*, and *T*. *M* and *N* are the number of rows and columns in the signal respectively. *C* is the number of color channels in the signal, and *T* is the number of frames.

Input - Output

Signal Type	Input Dimensions	Output Dimensions
Grayscale image	*M*-by-*N*	*M*-by-*N*-by-2
Color image	*M*-by-*N*-by-3	*M*-by-*N*-by-3-by-2
Grayscale video	*M*-by-*N*-by-*T*	*M*-by-*N*-by-*T*
Color video	*M*-by-*N*-by-3-by-*T*	*M*-by-*N*-by-3-by-*T*

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

R — Red color channel
scalar | vector | matrix

Red color channel of the input image or video, specified as a scalar, vector, or matrix.

Note The port label can be changed using the `Input port labels` parameter.

Dependencies

To enable this port, set the **Number of inputs** parameter to a value greater than or equal to 2.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

G — Green color channel
scalar | vector | matrix

Green color channel of the input image or video, specified as a scalar, vector, or matrix.

Note The port label can be changed using the `Input port labels` parameter.

Dependencies

To enable this port, set the **Number of inputs** parameter to a value greater than or equal to 2.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

B — Blue color channel
scalar | vector | matrix

Blue color component of the input image or video, specified as a scalar, vector, or matrix.

Note The port label can be changed using the `Input port labels` parameter.

Dependencies

To enable this port, set the **Number of inputs** parameter to a value equal to 3.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Variable name — MATLAB workspace variable name
`vout` (default) | valid MATLAB variable name

Specify the MATLAB workspace variable name for the exported image or video.

Number of inputs — Number of inputs ports
`1` (default) | positive integer

Specify the number of inputs to the block. To separate the color channels in a RBG image or video, specify the number of channels. If it is a grayscale video, enter 1. If it is a color (R, G, B) video, enter 3.

Limit data points to last — Maximum number of frames to export
`10` (default) | positive integer

Specify the maximum number of frames to export to the MATLAB workspace.

Decimation — Downsample video signal
`1` (default) | positive integer

Enter the decimation factor by which to downsample the image or video.

Log fixed-point data as a fi object — Create fixed-point numeric object
`off` (default) | `on`

Select **Log fixed-point data as a fi object** to create a fi object in the MATLAB workspace when the input signal has a fixed point data type. For more information on `fi` objects, see `fi`.

Input port labels — Input port names
`R|G|B` (default)

Name the input ports using the vertical bar character as a delimiter.

Dependencies

To enable this parameter, set the **Number of inputs** parameter to a value greater than `1`.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`yes`
Variable-Size Signals	`no`

Warp

Apply projective or affine transformation

Libraries:
Computer Vision Toolbox / Geometric Transformations

Description

The Warp block transforms an image by applying projective on page 1-414 or affine on page 1-414 transformation. You can transform the entire image or a region of the image by defining a rectangular region of interest (ROI).

Ports

Input

Image — Input image
matrix | 3-D numeric array

Input image, specified as one of these values:

- matrix — For intensity images of size *M*-by-*N*.
- 3-D numeric array — For true color images of size *M*-by-*N*-by-3.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

TForm — Transformation matrix
3-by-2 matrix | 3-by-3 matrix

Transformation matrix, specified as any one of these values:

- 3-by-2 matrix — For affine transformation.
- 3-by-3 matrix — For projective transformation.

For more information about the transformations, see “Algorithms” on page 1-414.

Dependencies

To enable this input port, set the **Transformation matrix source** parameter value to `Input port`.

Data Types: `double` | `single`

ROI — Region of interest
4-element vector

Region of interest, specified as a 4-element vector of form [x_s y_s *width height*]. x_s and y_s are the x and y coordinates of the top left corner of the ROI, respectively.

If you specify the `ROI` input, the `Warp` block applies transformation only to the specified region and returns the transformed region at the output.

Dependencies

To enable this input port, select the **Enable ROI input port** parameter.

Output

Image — Transformed image
matrix | 3-D numeric array

Transformed image, returned as one of these values:

- matrix — If input is an intensity image of size *P*-by-*Q1*.
- 3-D numeric array — If input is a true color image of size *P*-by-*Q*-by-3.

The data type of the output transformed image is same as that of the input image. The size of the output transformed image is either same as the input image or equal to the value set for the **Output image position vector [x y width height]** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Err_roi — Indicator for transformed ROI outside image region
`0` | `1`

Indicator for transformed ROI outside image region, returned as `0` or `1`.

Data Types: `Boolean`

Parameters

Transformation matrix for source — Source for passing transformation matrix

`Input port` (default) | `Custom`

Source for passing transformation matrix, specified as either `Input port` or `Custom`. If you select `Custom`, you can enter the transformation matrix coefficients by using the **Transformation matrix** parameter that appears with this selection.

Transformation matrix — Value for transformation matrix

3-by-2 matrix | 3-by-3 matrix

Value for transformation matrix, specified as a 3-by-2 matrix for affine transformation or 3-by-3 matrix for projective transformation.

Dependencies

To enable this parameter, set the **Transformation matrix for source** parameter value to `Custom`.

Interpolation method — Method for interpolating transformed pixel values

`Bilinear` (default) | `Nearest neighbor` | `Bicubic`

Method for interpolating transformed pixel values, specified as `Nearest neighbor`, `Bilinear`, or `Bicubic`.

If you select `Nearest neighbor`, the block uses the value of an nearby pixel for the new pixel value. If you select `Bilinear`, the new pixel value is the weighted average of the four nearest pixel values. If you select `Bicubic`, the new pixel value is the weighted average of the sixteen nearest pixel values.

The number of pixels the block considers affects the complexity of the computation. Therefore, the `Nearest neighbor` interpolation is the most computationally efficient. However, because the accuracy of the method is proportional to the number of pixels considered, the `Bicubic` method is the most accurate. For information about the interpolation methods, see the “More About” on page 1-412 section.

Background fill value — Intensity value for background pixels in the transformed image

`0` (default) | scalar | 3-element vector

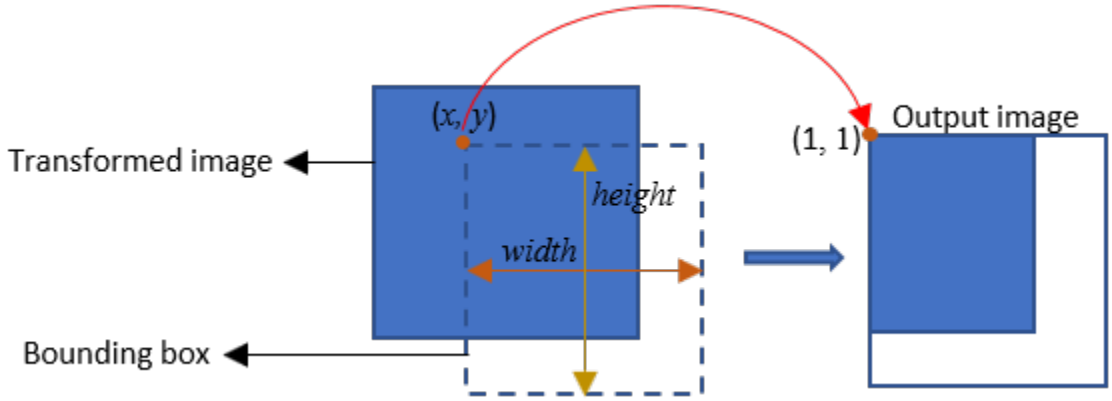
Intensity value for background pixels in the transformed image, specified as one of these values:

- scalar — If input image is a gray scale image.
- 3-element vector — If input image is a true color image. The vector is of the form [*r g b*] specifying the red (*r*), green (*g*), and blue (*b*) color channel values for the background pixels.

The default fill value is `0` and sets the background color to black.

Output image position source — Source for passing output image size

`Same as input image` (default) | `Custom`



Source for passing a value for the output image size, specified as either `Same as input image` or `Custom`.

- If you select `Same as input image`, the output transformed image is of same size as that of the input image.
- If you select `Custom`, you must specify a bounding box to output only the image region that lies within the bounding box. This selection enables the **Output image position vector [x y width height]** parameter that you can use for specifying the bounding box value.

Output image position vector [x y width height] — Size of the output image

[1 1 512 512] (default) | 4-element vector

Size of the output image, specified as a four element vector of form [*x y width height*]. When you specify this parameter, the `Warp` block creates a bounding box of specified width and height values. The size of the output image is set to the size of the bounding box and will contain the transformed image region that lies within the bounding box. If the size of the output image is greater than the size of the transformed image region within the bounding box, the intensity value of the extraneous pixels in the output image are set to the value specified for **Background fill value** parameter.

x and *y* are the spatial coordinates that define top-left corner position of the bounding box with respect to the input image.

Dependencies

To enable this parameter, set the **Output image position source** parameter value to `Custom`.

Enable ROI input port — Input ROI

off (default) | on

Select this parameter to enable the `ROI` input port and specify the ROI to be transformed.

Enable output port indicating if any part of ROI is outside input image — Output if transformed ROI is outside the specified image size

off (default) | on

Select this parameter to enable the `Err_roi` output port.

Dependencies

To enable this parameter, select the **Enable ROI input port** parameter.

Simulate using — Block simulation method
`Interpreted Execution` (default) | `Code Generation`

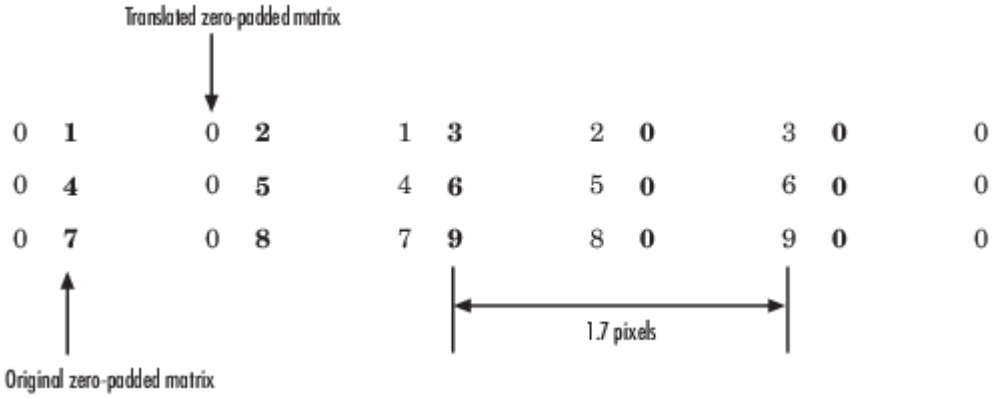
Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. For more information, see “Choosing a Simulation Mode” (Simulink).

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`yes`
Variable-Size Signals	`yes`

More About

Nearest Neighbor Interpolation



For nearest neighbor interpolation, the block uses nearby, translated, pixel values for the output pixel values.

For example, suppose this matrix, represents your input image,

1 2 3
4 5 6
7 8 9

and you want to translate this image 1.7 pixels in the positive horizontal direction using nearest neighbor interpolation. These steps illustrate the nearest neighbor interpolation algorithm followed by the block:

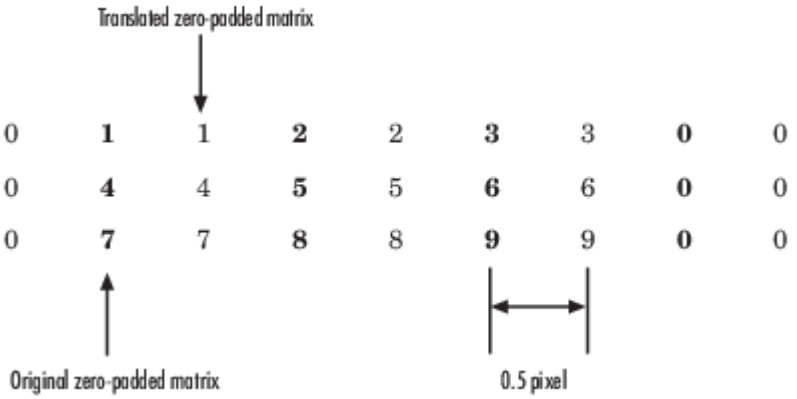
1 Zero pad the input matrix and translate it 1.7 pixels to the right.

2 Create the output matrix by replacing each input pixel value with the translated value nearest to it resulting in this matrix:

0 0 1 2 3
0 0 4 5 6
0 0 7 8 9

Note Despite specifying a value of 1.7 pixels to translate the image, this method translates the image by 2 pixels. Nearest neighbor interpolation is computationally efficient, but not as accurate as the bilinear and bicubic interpolation methods.

Bilinear Interpolation



For bilinear interpolation, the block uses the weighted average of two translated pixel values for each output pixel value.

For example, suppose this matrix, represents your input image,

1 2 3
4 5 6
7 8 9

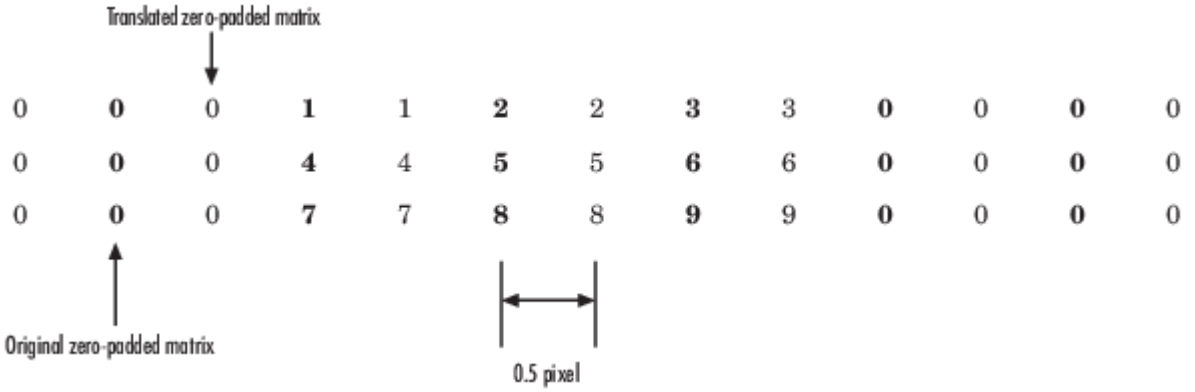
and you want to translate this image by 0.5 pixels in the positive horizontal direction using bilinear interpolation. These steps illustrate the bilinear interpolation algorithm followed by the block:

1 Zero pad the input matrix and translate it 0.5 pixels to the right.

2 Create the output matrix by replacing each input pixel value with the weighted average of the translated pixel values on either side of the input pixel. The result is this matrix which has one column more than the input matrix.

0.5 1.5 2.5 1.5
2 4.5 5.5 3
3.5 7.5 8.5 4.5

Bicubic Interpolation



For bicubic interpolation, the block uses the weighted average of four translated pixel values for each output pixel value.

For example, suppose this matrix, represents your input image,

1 2 3
4 5 6
7 8 9

and you want to translate this image by 0.5 pixels in the positive horizontal direction using bicubic interpolation. These steps illustrate the bicubic interpolation algorithm followed by the block:

1 Zero pad the input matrix and translate it by 0.5 pixels to the right.

2 Create the output matrix by replacing each input pixel value with the weighted average of the two translated values on either side. The result is this matrix which has one column more than the input matrix:

0.375	1.5	3	1.625
1.875	4.875	6.375	3.125
3.375	8.25	9.75	4.625

Algorithms

Affine Transformation

The affine transformation matrix is a 3-by-2 matrix of form

$$H = \begin{bmatrix} h_1 & h_4 \\ h_2 & h_5 \\ h_3 & h_6 \end{bmatrix}$$

where h_1, h_2,...,h_6 are transformation coefficients.

The value of the pixel located at $[x, y]$ in the input image determines the value of the pixel located at $[\widehat{x}, \widehat{y}]$ in the output transformed image. The relationship between the input and output point locations is defined by:

$$\begin{cases} \widehat{x} = xh_1 + yh_2 + h_3 \\ \widehat{y} = xh_4 + yh_5 + h_6 \end{cases}$$

Projective Transformation

The projective transformation matrix is a 3-by-3 matrix of form

$$H = \begin{bmatrix} h_1 & h_4 & h_7 \\ h_2 & h_5 & h_8 \\ h_3 & h_6 & h_9 \end{bmatrix}$$

where h_1, h_2,...,h_9 are transformation coefficients.

The value of the pixel located at $[x, y]$ in the input image determines the value of the pixel located at $[\widehat{x}, \widehat{y}]$ in the output transformed image.

The relationship between the input and output point locations is defined by:

$$\begin{cases} \widehat{x} = \dfrac{xh_1 + yh_2 + h_3}{xh_7 + yh_8 + h_9} \\ \widehat{y} = \dfrac{xh_4 + yh_5 + h_6}{xh_7 + yh_8 + h_9} \end{cases}$$

The values of pixels in the output point locations are calculated using any of these interpolation methods: Nearest neighbor, bilinear, and bicubic interpolation.

ToOpenCV

Converts Simulink data types to OpenCV data types

Libraries:
Computer Vision Toolbox Interface for OpenCV in Simulink

Description

The ToOpenCV block converts the Simulink data types to Simulink OpenCV data types.

Ports

Inputs

Port_1 — Input signal
scalar | vector | matrix | simulink bus | simulink image

Input signal to the ToOpenCV block. The input can be of different data types. Each of the input data types determines the output data type of the block.

Data Types: `uint8` | `uint16` | `int8` | `int16` | `int32` | `single` | `double` | `Simulink.ImageType` | `CV_DMATCH_BUS` | `CV_RECT_BUS` | `CV_ROTATEDRECT_BUS` | `CV_TERMCRITERIA_BUS` | `CV_SIZE_BUS` | `CV_RANGE_BUS` | `CV_POINT2I_BUS` | `CV_POINT2F_BUS` | `CV_POINT2D_BUS` | `CV_POINT3I_BUS` | `CV_POINT3F_BUS` | `CV_POINT3D_BUS`

Output

Port_1 — Output signal
scalar | vector | matrix | simulink bus | simulink image

Output signal from the ToOpenCV block. The output signal supports OpenCV types. For more information, see Mapping Input and Output Data Types on page 1-417.

Data Types: `OpenCV types`

Parameters

DataType — Data type of the Input signal of ToOpenCV block
`input data type` (default)

Specifies the input data type of the ToOpenCV block. The table on page 1-417 lists the one-to-one mapping of the input versus output data types of the ToOpenCV block.

Programmatic Use

Block Parameter: `DataType`
Type: character vector
Value: input data type
Default: `'Point2i'`

Block Characteristics

Data Types	
Direct Feedthrough	`Yes`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`

Shear

Shift rows or columns of an image or a video frame by linearly varying offset

Libraries:
Computer Vision Toolbox / Geometric Transformations

Description

The Shear block transforms an input image or a video frame by shifting the rows or columns. The block transforms the input image using either horizontal or vertical shear.

- Horizontal shear linearly shifts the rows in the image by gradually increasing the offset from left to right or right to left.
- Vertical shear linearly shifts the columns in the image by gradually increasing the offset from top to bottom or bottom to top.

Ports

Input

Image — Input image or video
matrix | array

Input image or video, specified as an *M*-by-*N* matrix, *M*-by-*N*-by-*T* array, *M*-by-*N*-by-*C* array, or *M*-by-*N*-by-*C*-by-*T* array. *T* is the number of frames in a video or image sequence, and *C* is the number of color channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

S — Shear value
vector

Shear value, specified as a two-element vector of the form, `[first last]`.

- To horizontally shear the image, the block shifts the pixels of the first and last rows using the `first` and `last` values, respectively, specified to the **S** port.
- To vertically shear the image, the block shifts the pixels of the first and last columns using the `first` and `last` values, respectively,specified to the **S** port.

Dependencies

To enable this port, set the **Shear values source** parameter to `Input port`.

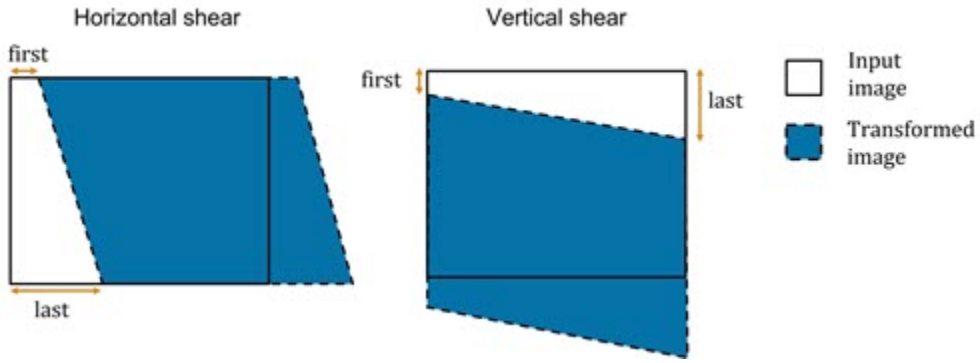
Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Output

Output — Transformed image or video
matrix | array

Transformed image or video, returned as a *P*-by-*Q* matrix, *P*-by-*Q*-by-*T* array, *P*-by-*Q*-by-*C* array, or *P*-by-*Q*-by-*C*-by-*T* array. *T* is the number of frames in a video or image sequence, and *C* is the number of color channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`



Parameters

Shear direction — Direction of transformation

`Horizontal` (default) | `Vertical`

Specify the shear direction for the input image, as one of these options:

- `Horizontal` — Shifts the rows of the input image with a linearly varying offset. Specify the offset limits of the first and the last row using the **Row/column shear values [first last]** parameter.
- `Vertical` — Shifts the columns of the input image with a linearly varying offset. Specify the offset limits of the first and the last column using the **Row/column shear values [first last]** parameter.

Output size after shear — Transformed image size

`Full` (default) | `Same as input image`

Specify the size of the transformed image as, `Full` or `Same as input image`.

- `Full` — The block outputs the entire sheared image.
- `Same as input image` — The block outputs a matrix of the same size as the input image. In this case, the output image contains the top-left portion of the sheared image, as limited by the input image dimensions.

Shear values source — Source of shear value offset limits

`Specify via dialog` (default) | `Input port`

Select the source of shear value offset limits from these options:

- `Specify via dialog` — Specify the shear value offset limits using the **Row/column shear values [first last]** parameter.
- `Input port` — Specify the shear value offset limits using the **S** port.

Row/column shear values [first last] — Shear value offset limits

`[0 3]` (default) | two-element vector

Specify the shear value offset limits as a two-element vector of the form [`first last`]. The `first` and `last` values represent the number of pixels to shift the first and last rows or columns of the input image, respectively.

For example, if you set the **Shear direction** parameter to `Horizontal` and specify the **Row/column shear values [first last]** parameter value as `[50 150]`, the block shifts the top row of the input image 50 pixels to the right and the bottom row 150 pixels to the right. To move either row to the left, specify a negative value for the corresponding element of **Row/column shear values [first last]** parameter.

Similarly, if you set the **Shear direction** parameter to `Vertical` and specify the **Row/column shear values [first last]** parameter value as `[10 50]`, the block shifts the furthest left column 10 pixels down and the furthest right column 50 pixels down. To shift either column up, specify a negative value for the corresponding element of **Row/column shear values [first last]** parameter.

Dependencies

To enable this parameter, set the **Shear values source** parameter to `Specify via dialog`.

Maximum shear value — Maximum row or column shear

`20` (default) | scalar

Specify the maximum number of pixels to shear any row or column of the input image. The shear block uses this parameter to determine the size of the sheared image. If any input to the **S** port is greater than the absolute value of the **Maximum shear value** parameter, the shear block reduces the input value to the maximum shear value.

Dependencies

To enable this parameter, set the **Shear values source** parameter to `Input port`.

Background fill value — Intensity value of the background in transformed image

`0` (default) | scalar | three-element vector

Specify the intensity value of the background of the transformed image as a scalar intensity value or a three-element vector representing an RGB triplet.

Interpolation method — Method for interpolating transformed pixel values

`Bilinear` (default) | `Nearest neighbor` | `Bicubic`

Specify the method by which to interpolate the pixel values of the sheared image, as one of these options:

- `Nearest neighbor` —The Shear block uses the value of 1 nearest pixel for the new pixel value.
- `Bilinear` — The new pixel value is the weighted average of the 4 nearest pixel values.
- `Bicubic` — The new pixel value is the weighted average of the 16 nearest pixel values.

The number of pixels the block considers for interpolation affects the complexity and accuracy of the computation. The `Nearest neighbor` interpolation, which uses the fewest pixels, is the most

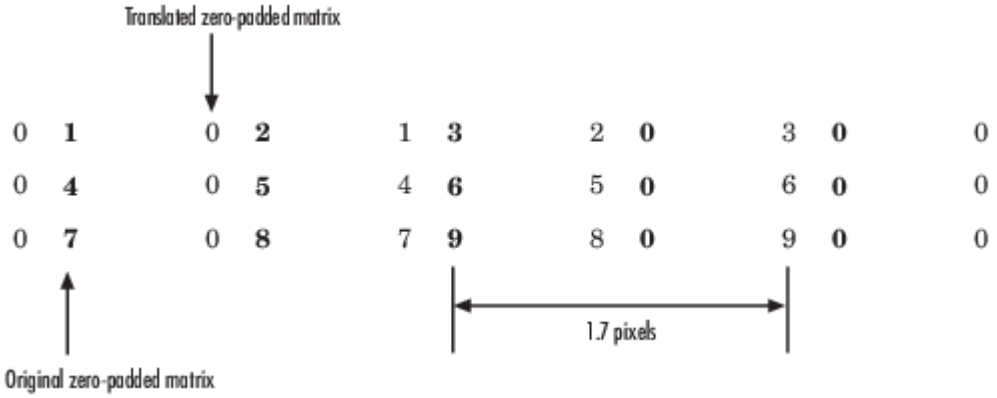
computationally efficient and least accurate while the `Bicubic` interpolation is the least computationally efficient and the most accurate. For more information about the interpolation methods and kernels, see the “More About” on page 1-425 section and the “Create and Compare Resizing Interpolation Kernels” example.

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`yes`
Variable-Size Signals	`no`

More About

Nearest Neighbor Interpolation



For nearest neighbor interpolation, the block uses nearby, translated, pixel values for the output pixel values.

For example, suppose this matrix, represents your input image,

1 2 3
4 5 6
7 8 9

and you want to translate this image 1.7 pixels in the positive horizontal direction using nearest neighbor interpolation. These steps illustrate the nearest neighbor interpolation algorithm followed by the block:

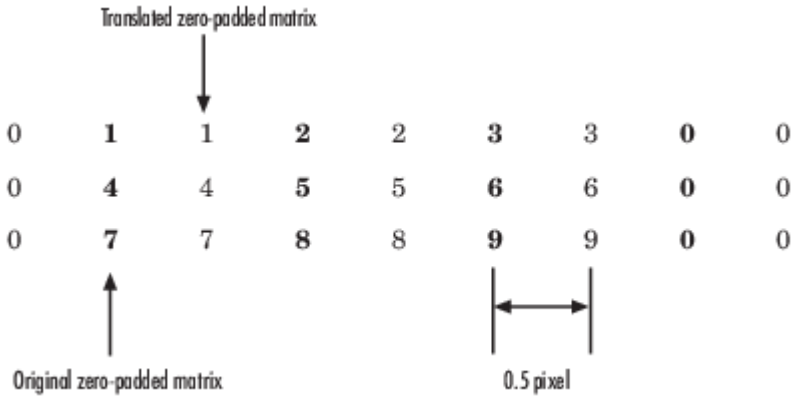
1 Zero pad the input matrix and translate it 1.7 pixels to the right.

2 Create the output matrix by replacing each input pixel value with the translated value nearest to it resulting in this matrix:

0 0 1 2 3
0 0 4 5 6
0 0 7 8 9

Note Despite specifying a value of 1.7 pixels to translate the image, this method translates the image by 2 pixels. Nearest neighbor interpolation is computationally efficient, but not as accurate as the bilinear and bicubic interpolation methods.

Bilinear Interpolation



For bilinear interpolation, the block uses the weighted average of two translated pixel values for each output pixel value.

For example, suppose this matrix, represents your input image,

1 2 3
4 5 6
7 8 9

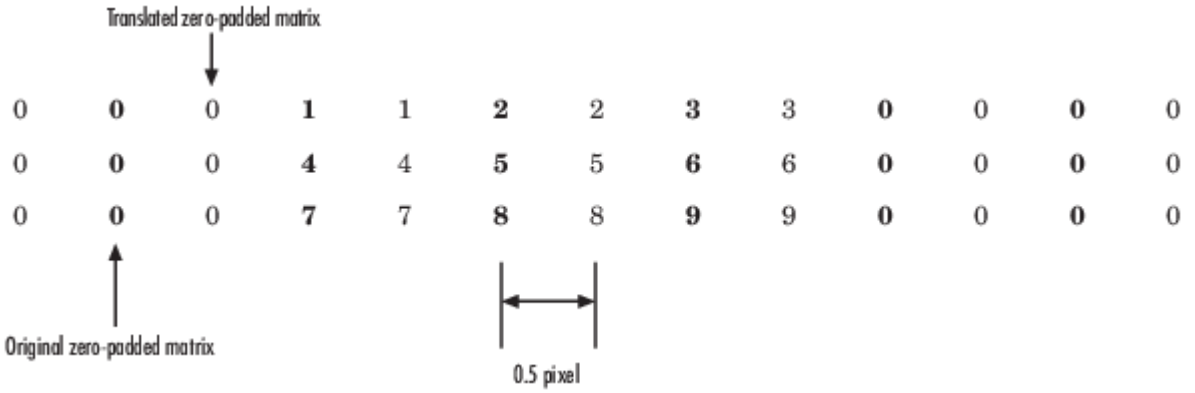
and you want to translate this image by 0.5 pixels in the positive horizontal direction using bilinear interpolation. These steps illustrate the bilinear interpolation algorithm followed by the block:

1 Zero pad the input matrix and translate it 0.5 pixels to the right.

2 Create the output matrix by replacing each input pixel value with the weighted average of the translated pixel values on either side of the input pixel. The result is this matrix which has one column more than the input matrix.

0.5 1.5 2.5 1.5
2 4.5 5.5 3
3.5 7.5 8.5 4.5

Bicubic Interpolation



For bicubic interpolation, the block uses the weighted average of four translated pixel values for each output pixel value.

For example, suppose this matrix, represents your input image,

1 2 3
4 5 6
7 8 9

and you want to translate this image by 0.5 pixels in the positive horizontal direction using bicubic interpolation. These steps illustrate the bicubic interpolation algorithm followed by the block:

1 Zero pad the input matrix and translate it by 0.5 pixels to the right.

2 Create the output matrix by replacing each input pixel value with the weighted average of the two translated values on either side. The result is this matrix which has one column more than the input matrix:

0.375	1.5	3	1.625
1.875	4.875	6.375	3.125
3.375	8.25	9.75	4.625

Algorithms

Affine Transformation

Affine image transformation includes operations such as scaling, translation, shear, and rotation. The affine transformation matrix is a 3-by-3 matrix of the form $\begin{bmatrix} a_{11} & a_{12} & 0 \\ a_{21} & a_{22} & 0 \\ a_{31} & a_{32} & 1 \end{bmatrix}$.

Consider an input image with r rows and c columns. $[r, c]$ are pixel coordinates in the input image and $[r', c']$ are pixel coordinates in the transformed image. The relationship between the input and output pixel coordinates is defined by:

$$[r'\ c'\ 1] = [r\ c\ 1] * \begin{bmatrix} a_{11} & a_{12} & 0 \\ a_{21} & a_{22} & 0 \\ a_{31} & a_{32} & 1 \end{bmatrix}$$

$$r' = ra_{11} + ca_{21} + a_{31}$$
$$c' = ra_{12} + ca_{22} + a_{32}.$$

Shear transformation is an affine transformation that transforms the input image in the horizontal direction or vertical direction or both.

To obtain a horizontal shear transformation of an image, use the transformation matrix with a horizontal shear value, s_h.

$$[r' \; c' \; 1] = [r \; c \; 1] * \begin{bmatrix} 1 & s_h & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

To obtain a vertical shear transformation of an image, use the transformation matrix with a vertical shear value, s_v.

$$[r' \; c' \; 1] = [r \; c \; 1] * \begin{bmatrix} 1 & 0 & 0 \\ s_v & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Blocks

Warp | Rotate | Translate | Resize

Resize

Enlarge or shrink entire image or region of interest within image

Libraries:
Computer Vision Toolbox / Geometric Transformations

Description

The `Resize` block enlarges or shrinks the input image or a region of interest (ROI) within the image. The block resizes along the row dimension followed by the column dimension, or vice-versa.

Ports

Input

Image — Input image or video
matrix | array

Input image or video, specified as an *M*-by-*N* matrix, *M*-by-*N*-by-*T* array, *M*-by-*N*-by-*C* array, or *M*-by-*N*-by-*C*-by-*T* array. *T* is the number of frames in a video or image sequence, and *C* is the number of color channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

ROI — Region of interest
vector

Region of interest, specified as `[x y width height]`, where `[x y]` are the coordinates for the upper-left corner of the region. `width` and `height` specify the width and the height of the region, respectively.

If you specify an input value to the `ROI` port, the `Resize` block applies the transformation only to a specified region in the input image.

Dependencies

To enable this port, select the **Enable ROI processing** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Output

Out — Resized output image or video
matrix | array

Resized output image or video, returned as an *M*-by-*N* matrix, *M*-by-*N*-by-*T* array, *M*-by-*N*-by-*C* array, or *M*-by-*N*-by-*C*-by-*T* array. *T* is the number of frames in a video or image sequence, and *C* is the number of color channels.

The data type of the resized output image is the same as that of the input image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Flag — ROI is outside image region
`0` | `1`

ROI is outside the image region, returned as `0` or `1`.

This table describes the output of the **Flag** port.

Flag Port Output	Description
`0`	ROI is completely inside the input image.
`1`	ROI is completely or partially outside the input image.

Dependencies

To enable this port, select these parameters:

- **Enable ROI processing**
- **Output flag indicating if ROI is within image bounds**

Data Types: `Boolean`

Parameters

Specify — Aspects of image to resize
`Output size as a percentage of input size` (default) | `Number of output columns and preserve aspect ratio` | `Number of output rows and preserve aspect ratio` | `Number of output rows and columns`

Specify aspects of the input image to consider for the transformation as one of these options:

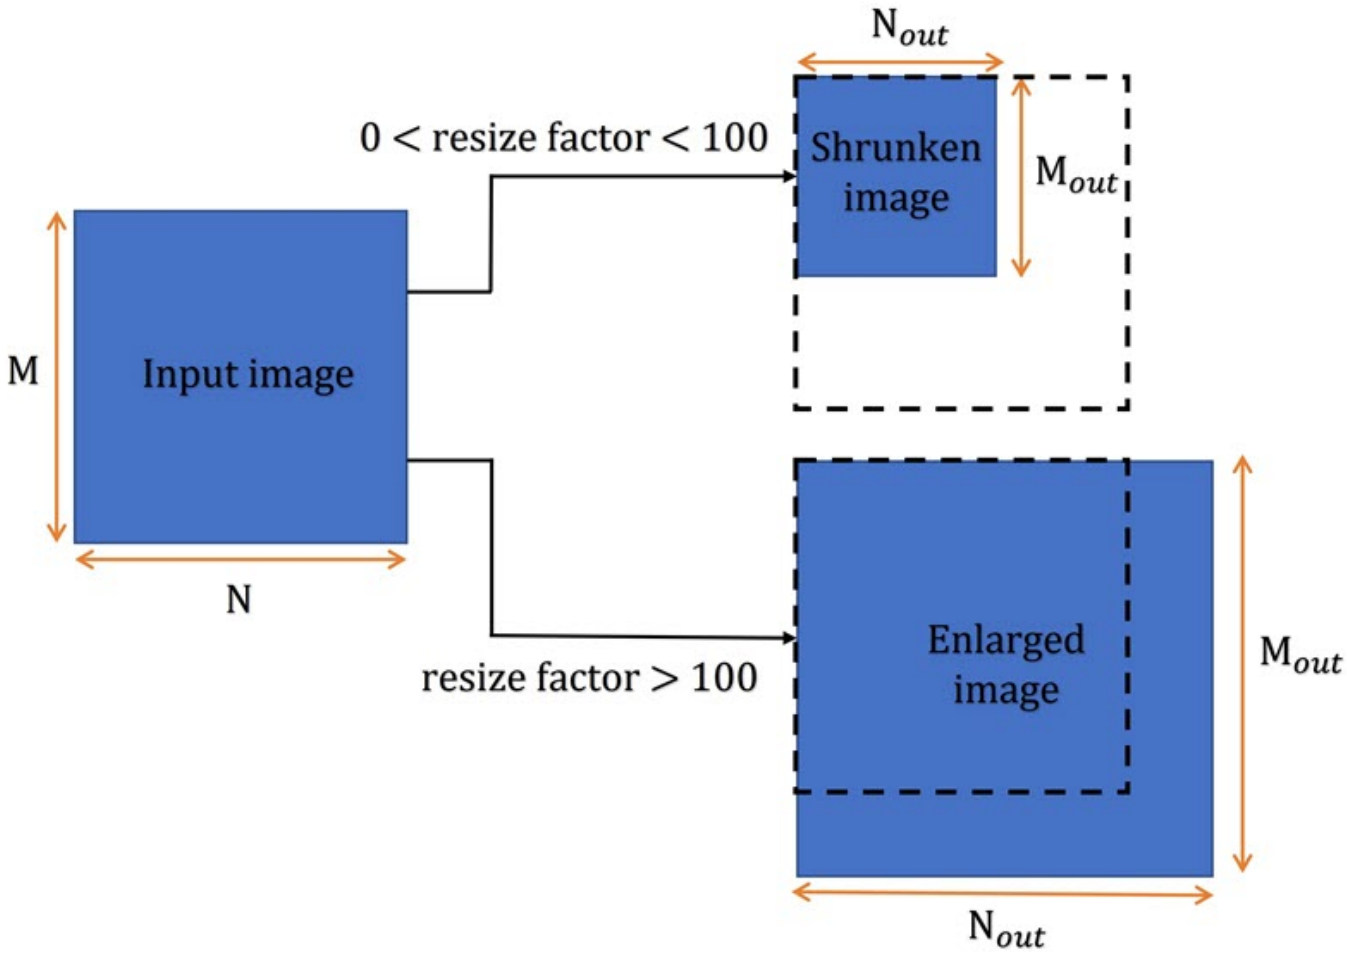
- `Output size as a percentage of input size` — Transforms the input image dimensions such that the output image dimensions are a specified percentage of the input image size. Use the **Resize factor in percentage** parameter to specify a percentage factor for the entire image or independent percentage factors for the rows and columns of the input image.
- `Number of output columns and preserve aspect ratio` — Transforms the input image column dimension to a specified number of output columns. The block calculates the number of output rows such that the output image has the same aspect ratio as the input image. Use the **Number of output columns** parameter to specify the number of output columns.
- `Number of output rows and preserve aspect ratio` — Transforms the input image row dimension to a specified number of output rows. The block calculates the number of output columns such that the output image has the same aspect ratio as the input image. Use the **Number of output rows** parameter to specify the number of output rows.
- `Number of output rows and columns` — Transforms the output image size to a specified number of rows and columns. Use the **Number of output rows and columns** parameter to specify the number of output rows and columns.

> **Note** Specifying the number of output rows and columns can change the aspect ratio of the output image.

Resize factor in percentage — Percentage factor for input image transformation
`[200 150]` (default) | scalar | two-element vector

Specify the percentage resize factor to apply to the input image as one of these options:

- Scalar — Applies the same resize factor to the rows and the columns of the input image.
- Two-element vector value — The first element of the vector specifies the percentage resize factor to apply to the rows of the image, and the second element specifies the percentage resize factor to apply to the columns.



For a scalar **Resize factor in percentage** value, *resize factor*, the block calculates the dimensions $[M_{out}\ N_{out}]$ of the output image using these equations:

$$M_{out} = \frac{M * resize\ factor}{100}$$

$$N_{out} = \frac{N * resize\ factor}{100}$$

To resize the input image, specify a resize factor value greater than zero. This table describes the effect of various resize factor values on the input image.

Resize Factor Percentage	Effect on Image
`0` < *resize factor* < `100`	The Resize block shrinks the image.
resize factor = `100`	Image size is unchanged.
resize factor > `100`	The Resize block enlarges the image.

Dependencies

To enable this parameter, set the **Specify** parameter value to `Output size as a percentage of input size`.

Number of output columns — Number of columns in output image
25 (default) | scalar

Specify the number of columns in the output image.

Dependencies

To enable this parameter, set the **Specify** parameter value to `Number of output columns and preserve aspect ratio`.

Number of output rows — Number of rows in output image
25 (default) | scalar

Specify the number of rows in the output image.

Dependencies

To enable this parameter, set the **Specify** parameter value to `Number of output rows and preserve aspect ratio`.

Number of output rows and columns — Number of rows and columns in output image
`[25 35]` (default) | two-element vector

Specify the number of rows and columns in the output image, specified as a two-element vector. The first element specifies the number of rows in the output image, and the second element is the number of columns.

Dependencies

To enable this parameter, set the **Specify** parameter value to `Number of output rows and columns`.

Interpolation method — Interpolation method
`Bilinear` (default) | `Nearest neighbor` | `Bicubic` | `Lanczos2` | `Lanczos3`

Specify the method for interpolating the pixel values of the resized image as one of these options:

- `Nearest neighbor` — The Resize block uses the value of 1 nearest pixel for the new pixel value.
- `Bilinear` — The new pixel value is the weighted average of the 4 nearest pixel values.
- `Bicubic` — The new pixel value is the weighted average of the 16 nearest pixel values.
- `Lanczos2` — The new pixel value is the weighted average of the 16 nearest pixel values, calculated using the Lanczos-2 kernel.
- `Lanczos3` — The new pixel value is the weighted average of the 36 nearest pixel values, calculated using the Lanczos-3 kernel.

The number of pixels the block considers for interpolation affects the complexity and accuracy of the computation. The `Nearest neighbor` interpolation, which uses the fewest pixels, is the most computationally efficient and least accurate while the interpolation with `Lanczos3` kernel is the least computationally efficient and the most accurate. For more information about the interpolation methods and kernels, see the “More About” on page 1-434 section and the “Create and Compare Resizing Interpolation Kernels” example.

Perform antialiasing when resize factor is between 0 and 100 — Prevent aliasing when shrinking image
`off` (default) | `on`

Select this parameter to perform low-pass filtering on the input image before shrinking it. Selecting this parameter can prevent aliasing in the output image when the value of the **Resize factor in percentage** parameter is between `0` and `100`.

Enable ROI processing — Enable ROI input
`off` (default) | `on`

Select this parameter to enable the **ROI** input port, for specifying a region of interest to resize in the input image.

Dependencies

To enable this parameter:

- Set the **Specify** parameter to `Number of output rows and columns`.
- Set the **Interpolation method** to one of these options:

- `Nearest neighbor`
- `Bilinear`
- `Bicubic`

- Clear the **Perform antialiasing when resize factor is between 0 and 100** parameter.

Output flag indicating if ROI is within image bounds — Enable flag indicating if specified ROI is outside input image region
`off` (default) | `on`

Select this parameter to enable the **Flag** port which indicates if the specified ROI value is completely or partially outside the range of the input image dimensions.

Dependencies

To enable this parameter, select the **Enable ROI processing** parameter.

Block Characteristics

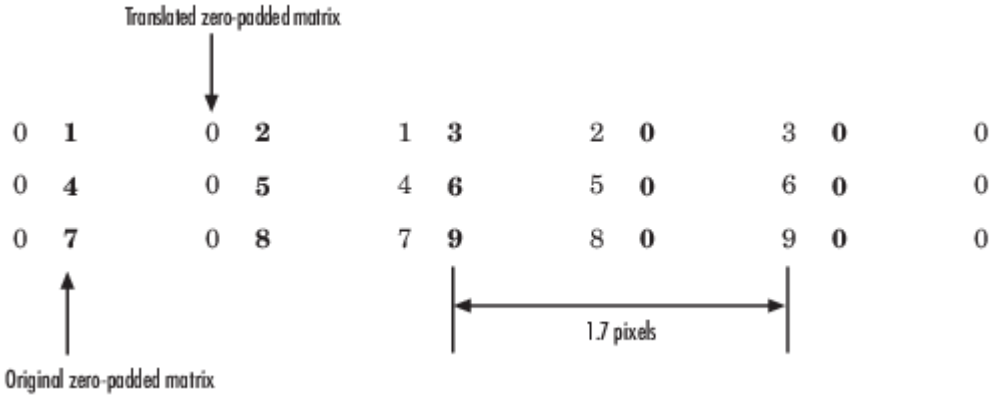
Multidimensional Signals	`yes`
Variable-Size Signals	`no`

More About

Nearest Neighbor Interpolation



For nearest neighbor interpolation, the block uses nearby, translated, pixel values for the output pixel values.

For example, suppose this matrix, represents your input image,

1 2 3
4 5 6
7 8 9

and you want to translate this image 1.7 pixels in the positive horizontal direction using nearest neighbor interpolation. These steps illustrate the nearest neighbor interpolation algorithm followed by the block:

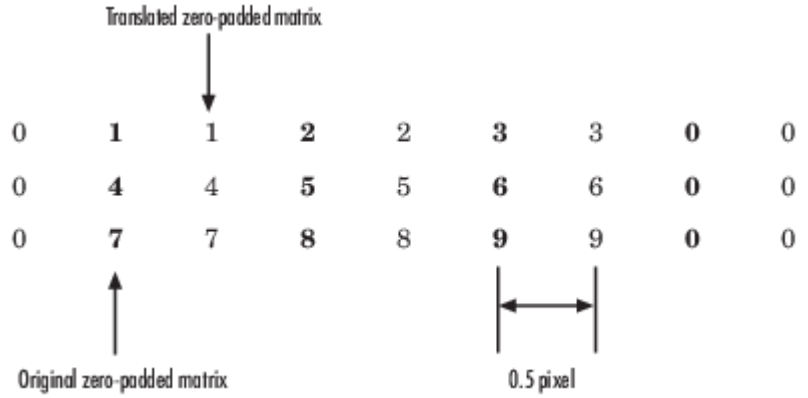
1 Zero pad the input matrix and translate it 1.7 pixels to the right.

2 Create the output matrix by replacing each input pixel value with the translated value nearest to it resulting in this matrix:

0 0 1 2 3
0 0 4 5 6
0 0 7 8 9

Note Despite specifying a value of 1.7 pixels to translate the image, this method translates the image by 2 pixels. Nearest neighbor interpolation is computationally efficient, but not as accurate as the bilinear and bicubic interpolation methods.

Bilinear Interpolation



For bilinear interpolation, the block uses the weighted average of two translated pixel values for each output pixel value.

For example, suppose this matrix, represents your input image,

1 2 3
4 5 6
7 8 9

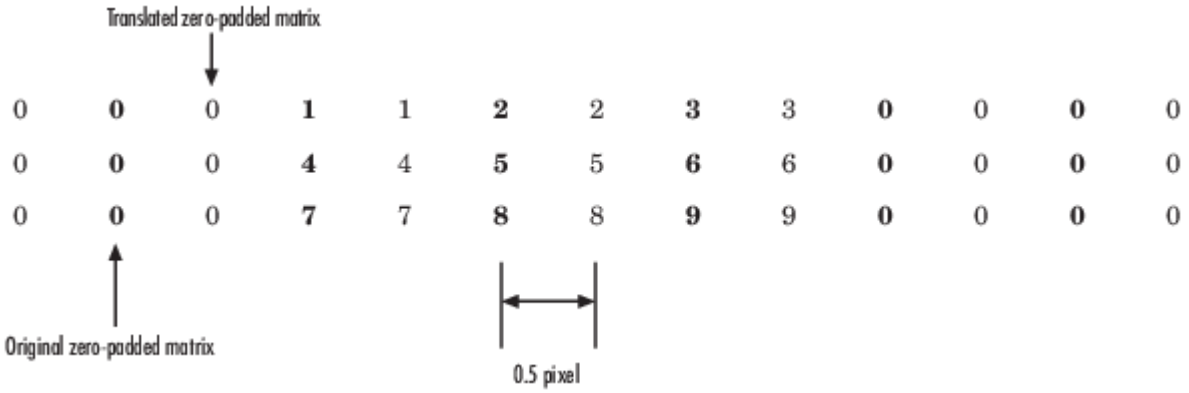
and you want to translate this image by 0.5 pixels in the positive horizontal direction using bilinear interpolation. These steps illustrate the bilinear interpolation algorithm followed by the block:

1 Zero pad the input matrix and translate it 0.5 pixels to the right.

2 Create the output matrix by replacing each input pixel value with the weighted average of the translated pixel values on either side of the input pixel. The result is this matrix which has one column more than the input matrix.

```
0.5 1.5 2.5 1.5
 2   4.5 5.5  3
3.5 7.5 8.5 4.5
```

Bicubic Interpolation



For bicubic interpolation, the block uses the weighted average of four translated pixel values for each output pixel value.

For example, suppose this matrix, represents your input image,

```
1 2 3
4 5 6
7 8 9
```

and you want to translate this image by 0.5 pixels in the positive horizontal direction using bicubic interpolation. These steps illustrate the bicubic interpolation algorithm followed by the block:

1 Zero pad the input matrix and translate it by 0.5 pixels to the right.

2 Create the output matrix by replacing each input pixel value with the weighted average of the two translated values on either side. The result is this matrix which has one column more than the input matrix:

```
0.375   1.5     3    1.625
1.875 4.875 6.375 3.125
3.375   8.25   9.75  4.625
```

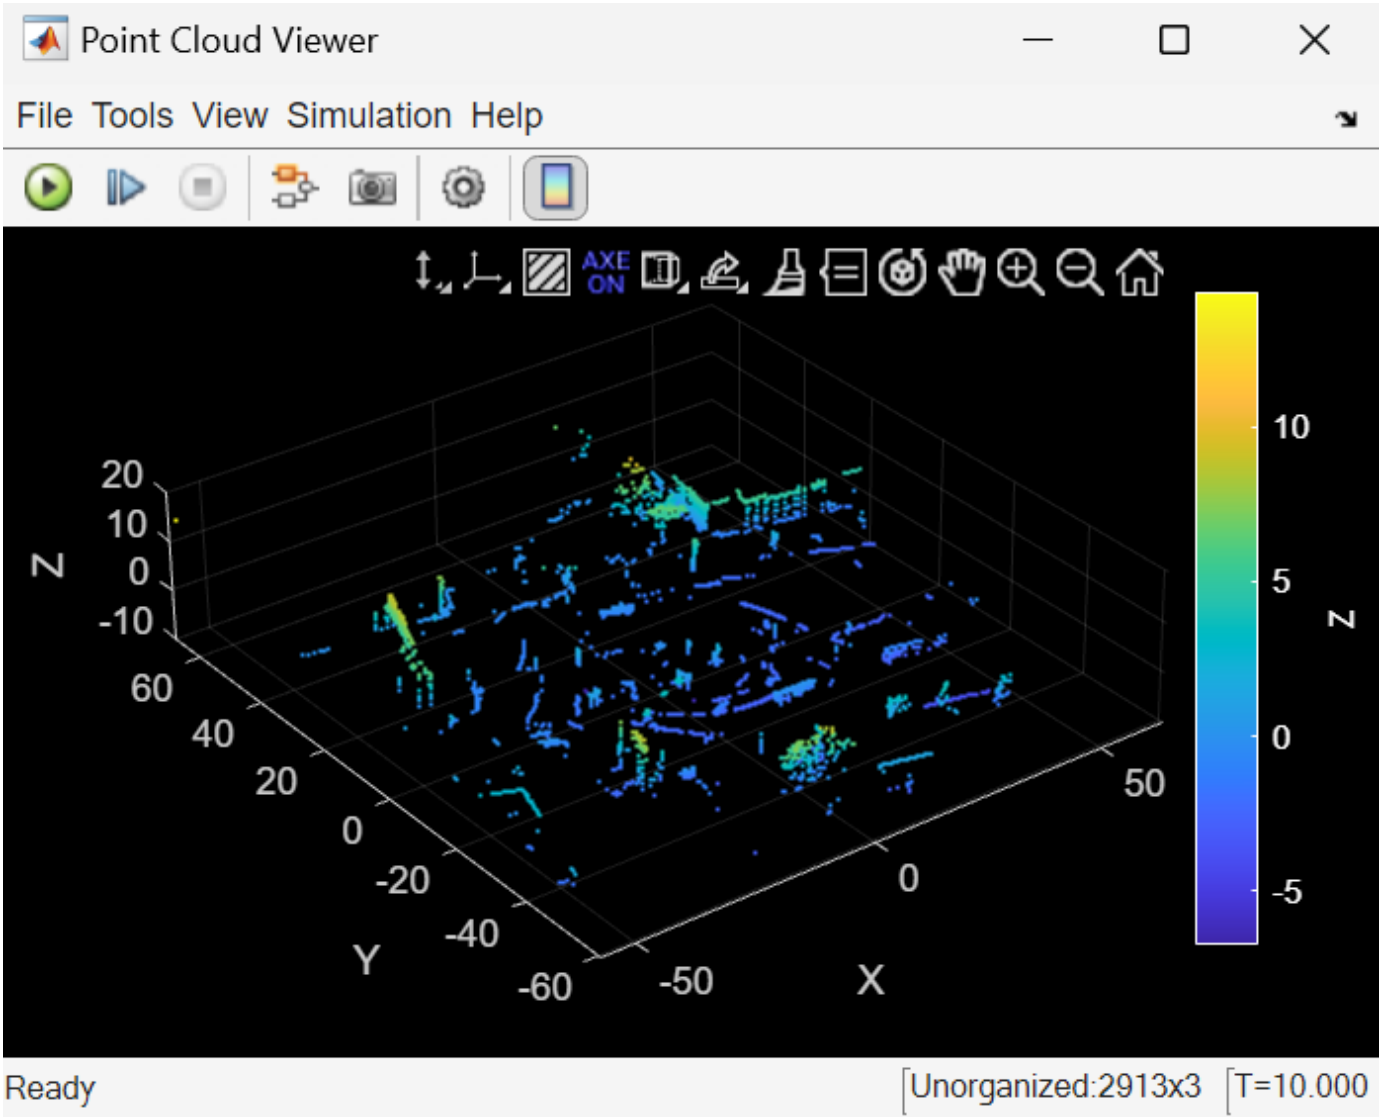
Point Cloud Viewer



Visualize streaming point cloud data sequence

Libraries:
Computer Vision Toolbox / Sinks

Description

The Point Cloud Viewer block creates a Point Cloud Viewer window to display a sequence of 3-D point cloud data that streams from a device such as a Microsoft® Kinect® or a lidar sensor. The Point Cloud Viewer block also provides simulation controls in the Point Cloud Viewer window to play, pause, and step through the streaming point cloud data sequence.

Features of Point Cloud Viewer

- Playback control — Control streaming playback of a point cloud sequence using the **Run**, **Step Forward**, and **Stop** buttons.
- Set axis limits — Limit the display of the 3-D point cloud data by setting the *x*-, *y*-, and *z*-axis limits.
- Set background color — Set the background color of the viewer window against which to display of point cloud data.
- Vertical axis direction control — Set the vertical axis direction of the point cloud data to upward-positive or downward-positive.
- View plane control — Set the view plane to change the viewing angle of the point cloud data.
- Analyze point cloud data — Inspect point cloud data using the **Data Tips** option on the axes toolbar of the Point Cloud Viewer window.
- View colorbar — View the colorbar in the Point Cloud Viewer window using the **Colorbar** button on the simulation toolbar.

Ports

Input

Location — Positions of points in 3-D coordinate space
matrix | array

Positions of the points in 3-D coordinate space, specified as:

- An *M*-by-3 matrix or *M*-by-*N*-by-3 array for a 3-D point cloud.
- An *M*-by-3-by-*T* or *M*-by-*N*-by-3-by-*T* array for a sequence of 3-D point clouds, where *T* is the total number of 3-D point clouds in the point cloud sequence.

Each array specifies the *x*-, *y*-, and *z*- coordinates of a points in the point cloud, but the format differs between unorganized point cloud and organized point clouds.

- For unorganized point clouds, you must specify **Location** as an *M*-by-3 or *M*-by-3-by-*T* array, where *M* is the total number of points, and each row provides the *xyz*-coordinates for a point.
- For organized point clouds, you must specify **Location** as an *M*-by-*N*-by-3 or an *M*-by-*N*-by-3-by-*T* array, where *M*×*N* is the total number of points, and the third dimension of the array provides the *x*-, *y*-, and *z*-coordinates for the corresponding point. Projective cameras, such as a Kinect or a lidar sensor, store points as an organized point cloud. An organized point cloud is laid out as a 2-D or a 3-D array of points that resembles an image- or video-like structure.

Data Types: `single` | `double` | `uint8` | `uint16`

Color — Color of point cloud
`[]` (default) | matrix | array

Point cloud color, specified as:

- An *M*-by-3 matrix or *M*-by-*N*-by-3 array for a 3-D point cloud.
- An *M*-by-3-by-*T* or *M*-by-*N*-by-3-by-*T* array for a sequence of 3-D point clouds, where *T* is the total number of 3-D point clouds in a point cloud sequence.

For an unorganized point cloud, specified as an *M*-by-3 matrix or *M*-by-3-by-*T* array, each row specifies the RGB color triplet for a point in the point cloud data. For an organized point cloud, specified as an *M*-by-*N*-by-3 or *M*-by-*N*-by-3-by-*T* array, each channel of the third dimension specifies the RGB color triplet for the corresponding point in the point cloud data. You can specify the same color for all points or a different color for each point.

- For the `single` or `double` data type, you must specify the **Color** RGB value in the range [0, 1].
- For the `uint8` data type, you must specify the **Color** RGB value in the range [0, 255].
- For the `uint16` data type, you must specify the **Color** RGB value in the range [0, 65535].

Note Input to the **Color** port must have the same dimensions and data type as the input to the **Location** port.

Dependencies

To enable this port, select the **File > Location and Color Port** parameter.

Data Types: `single` | `double` | `uint8` | `uint16`

Intensity — Grayscale intensities
`[]` (default) | vector | matrix | array

Grayscale intensities at each point, specified as:

- An *M*-by-1 vector for an unorganized point cloud or *M*-by-*N* matrix for an organized point cloud.
- An *M*-by-1-by-*T* array for a sequence of unorganized point clouds or *M*-by-*N*-by-*T* array for a sequence of organized point clouds. *T* is the total number of 3-D point clouds in a point cloud sequence.

Note Input to the **Intensity** port must have the same data type as input to the **Location** port.

Dependencies

To enable this port, select the **File > Location and Intensity Port** parameter.

Data Types: `single` | `double` | `uint8` | `uint16`

Parameters

File

Open at Start of Simulation — Open Point Cloud Viewer window at start of simulation
`on` (default) | `off`

Select this parameter to display the Point Cloud Viewer window at the start of the simulation. Clear this parameter to prevent the Point Cloud Viewer window from opening at the start of the simulation.

Location Port — Enable point location as input
`on` (default) | `off`

Select this parameter to enable the **Location** port for inputting the 3-D point cloud coordinates. If you select this parameter, the **Location and Color Port** and **Location and Intensity Port** parameters clear automatically.

Location and Color Port — Enable point location and color as input
`off` (default) | `on`

Select this parameter to enable both the **Location** and **Color** input ports. If you select this parameter, the **Location Port** and **Location and Intensity Port** parameters clear automatically.

Location and Intensity Port — Enable point location and intensity as input
`off` (default) | `on`

Select this parameter to enable both the **Location** and **Intensity** input ports. If you select this parameter, the **Location Port** and **Location and Color Port** parameters clear automatically.

File > Configuration > Edit > Core

The Point Cloud Viewer Configuration dialog box enables you to change the behavior and appearance of the graphic user interface (GUI).

- To open the Configuration dialog box and edit parameters, select **File** > **Configuration** > **Edit**.

The **Core** tab in the Configuration dialog box lists the general settings of the GUI.

- In the **Core** tab, select `General UI` and click **Properties** to open the General UI Properties dialog box.

Display the full path — Display full path of source data in title bar
`off` (default) | `on`

Select this parameter to display the model name and full path to the source data in the title bar of the Point Cloud Viewer window. If you clear this parameter, the window displays a shortened name.

Tools > Point Cloud Information

The Point Cloud Information dialog box displays information about the input point cloud sequence. This information includes **Source type**, **Source name**, **Frame size**, **Source data type**, and **Display data type**.

View

Bring All Point Cloud Viewer Windows Forward — Bring all Point Cloud Viewer windows to front of display
`off` (default) | `on`

Select this parameter to bring all the Point Cloud Viewer windows forward, in front of all other open windows behind.

Simulation Toolbar — Show simulation toolbar
`on` (default) | `off`

Select this parameter to show the simulation toolbar on the Point Cloud Viewer window.

To perform a relevant operation using the simulation toolbar, select the corresponding feature as described in the table.

Feature	Description
Run	Start the simulation, and view the point cloud sequence.
Step Forward	Start the simulation, view one frame of the point cloud sequence, and pause.
Stop	Stop the simulation.
Highlight Simulink Block	Highlight the Point Cloud Viewer block with a blue background in the Simulink model.

Feature	Description
Snapshot (Freeze Display)	Freeze Point Cloud Viewer window to enable you take a snapshot of the window using the **Print** or **Print Preview** option in **File** menu. **Note** Unselect this option to return the Point Cloud Viewer window to an active state from a frozen state.
Settings	Enable the **Settings** pane on the Point Cloud Viewer window.
Colorbar	View the color bar in the Point Cloud Viewer window. By default, the Point Cloud Viewer window does not display the color bar. To view the color bar, click **Colorbar** on the simulation toolbar. To hide the color bar, click **Colorbar** again. **Dependencies** To enable this parameter, select the **File** > **Location Port** or **File** > **Location and Intensity Port** parameter.

Status Bar — Show status bar
`on` (default) | `off`

Select this parameter to show the status bar on the Point Cloud Viewer window. The status bar, at the bottom of the Point Cloud Viewer window, shows this information about the point cloud sequence.

- Dimension
- Organization
- Status of the window during simulation
- Timestamp of the current frame

Highlight Simulink Block — Highlight Point Cloud Viewer block
`off` (default) | `on`

Highlight the Point Cloud Viewer block in blue in the Simulink model.

Simulation

To access this parameter, select the **Simulation** menu in the Point Cloud Viewer window.

Run — View entire point cloud sequence
`off` (default) | `on`

Select this parameter to start the simulation and view the point cloud sequence continuously from the first to the last frame. You can also perform this action by clicking **Run** on the simulation toolbar.

Continue — Continue viewing the point cloud sequence
`off` (default) | `on`

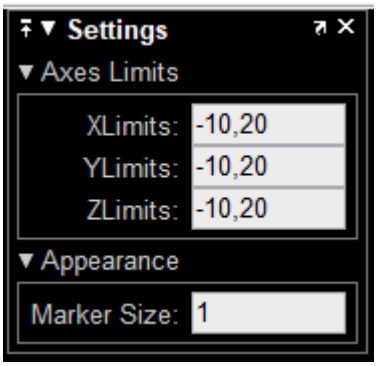
Select this parameter to continue viewing the point cloud sequence till the last frame. To enable the **Continue** parameter, start the simulation by clicking **Step Forward** on simulation toolbar.

Stop — Stop viewing the point cloud sequence
`off` (default) | `on`

Select this parameter to stop the display of the point cloud sequence. You can also perform this action by clicking **Stop** on the simulation toolbar.

Drop Frames to Improve Performance — Reduce frame rate of input point cloud sequence
`on` (default) | `off`

Select this parameter to reduce the frame rate of the input streaming point cloud sequence to improve the performance of the simulation. If you clear this parameter, the block displays every frame in the input point cloud sequence signal during the simulation.



Block Characteristics

Data Types	`Boolean` | `double` | `integer` | `single`
Direct Feedthrough	`no`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`
Zero-Crossing Detection	`no`

More About

Settings Pane

To display the **Settings** pane on the point cloud viewer window, click Settings on the simulation toolbar.

You can use the **Settings** pane to:

- Set **Axes Limits**. The Point Cloud Viewer window does not display point cloud data outside these limits. By default, the block sets the limits for each axis based on the extent of the input point cloud data along that axis.
  - **XLimits** — Range of *x*-axis coordinates, specified in the format [`minimum limit`,`maximum limit`].
  - **YLimits** — Range of *y*-axis coordinates, specified in the format [`minimum limit`,`maximum limit`].

  - **ZLimits** — Range of *z*-axis coordinates, specified in the format [`minimum limit`,`maximum limit`].
- Set the **Appearance** of the point cloud data points in the Point Cloud Viewer window by adjusting the approximate diameter of the point marker using **Marker Size**. MATLAB graphics defines the unit of measure as points. The default **Marker Size** value is `1`. A marker size larger than `6` can reduce rendering performance.

Axes Toolbar Operations

Keyboard shortcuts are enabled only for the rotate (default) mode. To view the axes toolbar operations, point to the figure and select one of these options. Click the Restore View icon to reset the display.

Feature	Description
Vertical Axis	Select an *X*-, *Y*-, or *Z*-direction to set the direction of that axis of the point cloud as the positive vertical direction. Use the keyboard arrow keys to move the point cloud with respect to the direction selected.
View Plane	Select the viewing angle of the point cloud figure as the *XY*, *YX*, *XZ*, *ZX*, *YZ*, or *ZY* plane.
Background Color	Display a color chart from which you can select a background color.
Axes On/Off	Turn the display axes on or off.
Projection	Select perspective or orthogonal view.
Export	• — Save the content as a tightly cropped image or PDF. • — Copy the content as an image. • — Copy the content as a vector graphic.
Brush	Enable data brushing mode.
Data Tips	View the point data values of a point by selecting it in the point cloud figure. The Data Tips display shows the *x*, *y*, and *z* values of the points. Point clouds for depth images and lidar contain these additional data properties:

Point Cloud Data Source	Data Value Properties
Depth image (RGB-D sensor)	**Color**, **Row**, and **Column**
Lidar	**Intensity**, **Range**, **Azimuth** angle, **Elevation** angle, **Row**, and **Column**

<table>
<tr><th>Feature</th><th>Description</th></tr>
<tr><td>Rotate 3D</td><td>Drag to rotate the point cloud figure. You can also right-click any point on the point cloud figure and select Rotate Around a Point to specify that point as the center of rotation for the figure. To return to axes rotation, right-click again and select Rotate Around Axes Center.

While in Rotate 3D mode, you can also select the color source for the point cloud by right-clicking anywhere in the point cloud figure and selecting Color Source, and then selecting an option from the list. The figure applies the active colormap to the point cloud based on the values in the selected source. For a point cloud of only position data, the Color Source options are X, Y, Z, and User Specified. Point clouds for depth image and lidar data include these additional color source options:

<table>
<tr><th>Point Cloud Data Source</th><th>Color Source Options</th></tr>
<tr><td>Depth image (RGB-D sensor)</td><td>Color, Row, and Column</td></tr>
<tr><td>Lidar</td><td>Intensity, Range, Azimuth angle, Elevation angle, Row, and Column</td></tr>
</table>
</td></tr>
<tr><td>Pan, Zoom in, and Zoom out</td><td>Maneuver the point cloud in the figure, or zoom the point cloud figure in or out.</td></tr>
<tr><td>Restore View</td><td>Restore the original view of the axes.</td></tr>
</table>

Version History

Introduced in R2023a

R2025a: Visualize point cloud data using intensity values

The block now supports an **Intensity** input port to visualize streaming point cloud data using intensity values. To enable this port, select the **File > Location and Intensity Port** parameter.

R2025a: View color bar for point cloud data

You can now view the color bar by selecting the **Colorbar** button on the simulation toolbar. This button is available when you select the **File > Location Port** or **File > Location and Intensity Port** parameter.

R2025a: View point cloud across full extent of axes

The block now automatically adjusts the default axes limits based on the input point cloud data. Automatic adjustment enables you to view the point cloud across full extent of the axes.

`pcplayer`

Translate

Translate image or video frame

Libraries:
Computer Vision Toolbox / Geometric Transformations

Description

The Translate block shifts an input image or video frame by the number of pixels in the vertical and horizontal directions specified by a two-element offset vector.

Ports

Input

Image — Input image or video
matrix | array

Input image or video, specified as an *M*-by-*N* matrix, *M*-by-*N*-by-*T* array, *M*-by-*N*-by-*C* array, or *M*-by-*N*-by-*C*-by-*T* array. *T* is the number of frames in a video or image sequence, and *C* is the number of color channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Offset — Translation value
vector

Translation value, specified as a two-element vector of the form `[vertical horizontal]`. The `vertical` value in the vector is the number of pixels to shift the image up or down in the vertical direction. The `horizontal` element is the number of pixels to shift the image left or right in the horizontal direction. The axes origin is the top-left corner of the input image.

- To translate the image downward, specify positive pixel values to the `vertical` element.
- To translate the image upward, specify negative pixel values to the `vertical` element.
- To translate the image to the right, specify positive pixel values to the `horizontal` element.
- To translate the image to the left, specify negative pixel values to the `horizontal` element.

Dependencies

To enable this port, set the **Offset source** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Output

Output — Translated image or video
matrix | array

Translated image or video, returned as a *P*-by-*Q* matrix, *P*-by-*Q*-by-*T* array, *P*-by-*Q*-by-*C* array, or *P*-by-*Q*-by-*C*-by-*T* array. *T* is the number of frames in a video or image sequence, and *C* is the number of color channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Parameters

Output size after translation — Translated image size

`Full` (default) | `Same as input image`

Specify the size of the translated image as `Full` or `Same as input image`.

- `Full` — The block outputs a matrix that contains the entire translated image.
- `Same as input image` — The block outputs a matrix of the same size as the input image, which contains a portion of the translated image.

Offset source — Source of translation value

`Specify via dialog` (default) | `Input port`

Specify the source of translation value as one of these options:

- `Specify via dialog` — Specify the translation value using the **Offset** parameter.
- `Input port` — Specify the translation value using the **Offset** port.

Offset — Translation value

`[1.5 2.3]` (default) | two-element vector

Specify the translation value as a two-element vector of the form [`vertical horizontal`]. The vertical element in the vector is the number of pixels to shift the image up or down in the vertical direction. The horizontal element is the number of pixels to shift the image left or right in the horizontal direction. The axes origin is the top-left corner of the input image.

- To translate the image downward, specify positive pixel values to the `vertical` element.
- To translate the image upward, specify negative pixel values to the `vertical` element.
- To translate the image to the right, specify positive pixel values to the `horizontal` element.
- To translate the image to the left, specify negative pixel values to the `horizontal` element.

Dependencies

To enable this parameter, set the **Offset source** parameter to `Specify via dialog`.

Maximum offset — Translation value limits

`[8 10]` (default) | two-element vector

Specify the maximum number of pixels to translate the input image in the vertical and horizontal directions, as a vector of the form [`vertical horizontal`]. The translate block uses this parameter to determine the size of the translated image when the **Output size after translation** parameter is set to `Full` and the **Offset source** parameter is set to `Input port`. If either input value to the

Offset port is greater than the corresponding value of the **Maximum offset** parameter, the translate block reduces that input translation value to the corresponding maximum translation value.

Dependencies

To enable this parameter, set the **Offset source** parameter to `Input port`.

Background fill value — Intensity or color of background in translated image

`0` (default) | scalar | RGB triplet

Specify the intensity or color of the background of the translated image as a scalar intensity value or an RGB triplet.

Interpolation method — Method for interpolating translated pixel values

`Bilinear` (default) | `Nearest neighbor` | `Bicubic`

Specify the method by which to interpolate the pixel values of the translated image as one of these options:

- `Nearest neighbor` —The Translate block uses the value of the nearest pixel for the interpolated pixel.
- `Bilinear` — The interpolated pixel value is the weighted average of the 4 nearest pixel values.
- `Bicubic` — The interpolated pixel value is the weighted average of the 16 nearest pixel values.

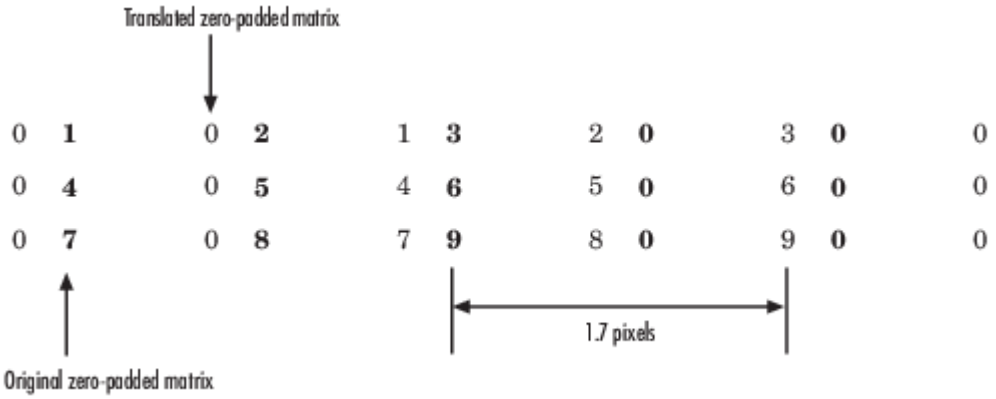
The number of pixels the block considers for interpolation affects the complexity and accuracy of the computation. The `Nearest neighbor` interpolation, which uses the fewest pixels, is the most computationally efficient and least accurate, while the `Bicubic` interpolation is the least computationally efficient and the most accurate. For more information about interpolation methods and kernels, see the “More About” on page 1-449 section and the “Create and Compare Resizing Interpolation Kernels” example.

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Multidimensional Signals	`yes`
Variable-Size Signals	`no`

More About

Nearest Neighbor Interpolation



For nearest neighbor interpolation, the block uses nearby, translated, pixel values for the output pixel values.

For example, suppose this matrix, represents your input image,

```
1 2 3
4 5 6
7 8 9
```

and you want to translate this image 1.7 pixels in the positive horizontal direction using nearest neighbor interpolation. These steps illustrate the nearest neighbor interpolation algorithm followed by the block:

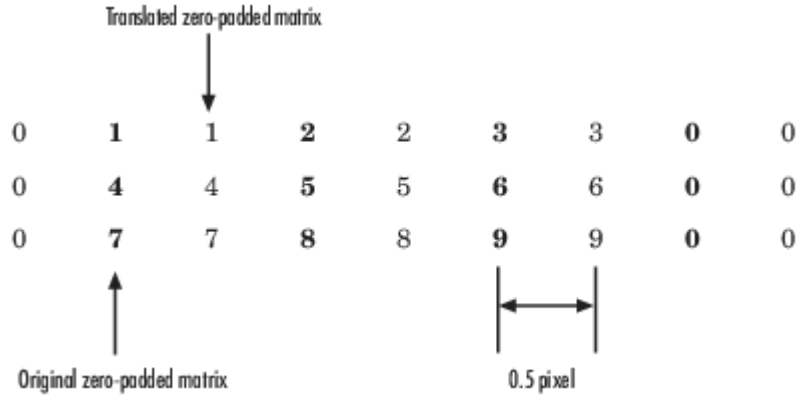
1 Zero pad the input matrix and translate it 1.7 pixels to the right.

2 Create the output matrix by replacing each input pixel value with the translated value nearest to it resulting in this matrix:

0 0 1 2 3
0 0 4 5 6
0 0 7 8 9

Note Despite specifying a value of 1.7 pixels to translate the image, this method translates the image by 2 pixels. Nearest neighbor interpolation is computationally efficient, but not as accurate as the bilinear and bicubic interpolation methods.

Bilinear Interpolation



For bilinear interpolation, the block uses the weighted average of two translated pixel values for each output pixel value.

For example, suppose this matrix, represents your input image,

1 2 3
4 5 6
7 8 9

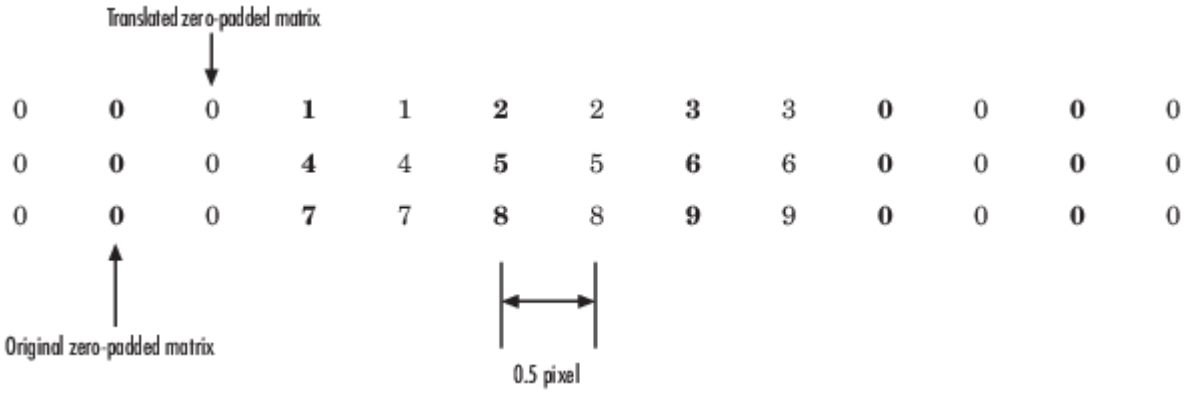
and you want to translate this image by 0.5 pixels in the positive horizontal direction using bilinear interpolation. These steps illustrate the bilinear interpolation algorithm followed by the block:

1 Zero pad the input matrix and translate it 0.5 pixels to the right.

2 Create the output matrix by replacing each input pixel value with the weighted average of the translated pixel values on either side of the input pixel. The result is this matrix which has one column more than the input matrix.

0.5 1.5 2.5 1.5
2 4.5 5.5 3
3.5 7.5 8.5 4.5

Bicubic Interpolation



For bicubic interpolation, the block uses the weighted average of four translated pixel values for each output pixel value.

For example, suppose this matrix, represents your input image,

1 2 3
4 5 6
7 8 9

and you want to translate this image by 0.5 pixels in the positive horizontal direction using bicubic interpolation. These steps illustrate the bicubic interpolation algorithm followed by the block:

1 Zero pad the input matrix and translate it by 0.5 pixels to the right.

2 Create the output matrix by replacing each input pixel value with the weighted average of the two translated values on either side. The result is this matrix which has one column more than the input matrix:

```
0.375   1.5     3    1.625
1.875 4.875 6.375 3.125
3.375   8.25   9.75  4.625
```

Objects

se3

SE(3) homogeneous transformation

Description

The `se3` object represents an SE(3) transformation as a 3-D homogeneous transformation matrix consisting of a translation and rotation for a right-handed Cartesian coordinate system.

For more information, see the “3-D Homogeneous Transformation Matrix” on page 2-8 section.

This object acts like a numerical matrix enabling you to compose poses using multiplication and division.

Creation

Syntax

```
transformation = se3
transformation = se3(rotation)
transformation = se3(rotation,translation)
transformation = se3(transformation)

transformation = se3(euler,"eul")
transformation = se3(euler,"eul",sequence)
transformation = se3(quat,"quat")
transformation = se3(quaternion)
transformation = se3(axang,"axang")
transformation = se3(angle,axis)
transformation = se3(___,translation)

transformation = se3(translation,"trvec")
transformation = se3(pose,"xyzquat")
```

Description

Rotation Matrices, Translation Vectors, and Transformation Matrices

`transformation = se3` creates an SE(3) transformation representing an identity rotation with no translation.

$$transformation = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

`transformation = se3(rotation)` creates an SE(3) transformation representing a pure rotation defined by the orthonormal rotation `rotation` with no translation. The rotation matrix is represented by the elements in the top left of the `transformation` matrix.

$$rotation = \begin{bmatrix} r_{11} & r_{12} & r_{13} \\ r_{11} & r_{22} & r_{23} \\ r_{31} & r_{32} & r_{33} \end{bmatrix}$$

$$transformation = \begin{bmatrix} r_{11} & r_{12} & r_{13} & 0 \\ r_{21} & r_{22} & r_{23} & 0 \\ r_{31} & r_{32} & r_{33} & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

`transformation = se3(rotation,translation)` creates an SE(3) transformation representing a rotation defined by the orthonormal rotation `rotation` and the translation `translation`. The function applies the rotation matrix first, then translation vector to create the transformation.

$$rotation = \begin{bmatrix} r_{11} & r_{12} & r_{13} \\ r_{11} & r_{22} & r_{23} \\ r_{31} & r_{32} & r_{33} \end{bmatrix}, translation = \begin{bmatrix} t_1 \\ t_2 \\ t_3 \end{bmatrix}$$

$$transformation = \begin{bmatrix} r_{11} & r_{12} & r_{13} & t_1 \\ r_{21} & r_{22} & r_{23} & t_2 \\ r_{31} & r_{32} & r_{33} & t_3 \\ 0 & 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & t_1 \\ 0 & 1 & 0 & t_2 \\ 0 & 0 & 1 & t_3 \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} r_{11} & r_{12} & r_{13} & 0 \\ r_{21} & r_{22} & r_{23} & 0 \\ r_{31} & r_{32} & r_{33} & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

`transformation = se3(transformation)` creates an SE(3) transformation representing a translation and rotation as defined by the homogeneous transformation `transformation`.

Other 3-D Rotation Representations

`transformation = se3(euler,"eul")` creates an SE(3) transformation from the rotations defined by the Euler angles `euler`.

`transformation = se3(euler,"eul",sequence)` specifies the sequence of the Euler angle rotations `sequence`. For example, the sequence `"ZYX"` rotates the *z*-axis, then the *y*-axis and *x*-axis.

`transformation = se3(quat,"quat")` creates an SE(3) transformation from the rotations defined by the numeric quaternions `quat`.

`transformation = se3(quaternion)` creates an SE(3) transformation from the rotations defined by the quaternion `quaternion`.

`transformation = se3(axang,"axang")` creates an SE(3) transformation from the rotations defined by the axis-angle rotation `axang`.

`transformation = se3(angle,axis)` creates an SE(3) transformation from the rotations `angle` about the rotation axis `axis`.

`transformation = se3(___,translation)` creates an SE(3) transformation from the translation vector `translation` along with any other type of rotation input arguments.

Other Translations and Transformation Representations

`transformation = se3(translation,"trvec")` creates an SE(3) transformation from the translation vector `translation`.

`transformation = se3(pose,"xyzquat")` creates an SE(3) transformation from the 3-D compact pose `pose`.

Note If any inputs contain more than one rotation, translation, or transformation, then the output `transformation` is an *N*-element array of `se3` objects corresponding to each of the *N* input rotations, translations, or transformations.

Input Arguments

`rotation` — Orthonormal rotation

3-by-3 matrix | 3-by-3-by-*N* matrix | `so3` object | *N*-element array of `so3` objects

Orthonormal rotation, specified as a 3-by-3 matrix, a 3-by-3-by-*N* array, a scalar `so3` object, or an *N*-element array of `so3` objects. *N* is the total number of rotations.

If `rotation` contains more than one rotation and you also specify `translation` at construction, the number of translations in `translation` must be one or equal to the number of rotations in `rotation`. The resulting number of transformation objects is equal to the value of the `translation` or `rotation` argument, whichever is larger.

Example: `eye(3)`

Data Types: `single` | `double`

`translation` — Translation

three-element row vector | *N*-by-3 matrix

Translation, specified as a three-element row vector or an *N*-by-3 array. *N* is the total number of translations and each translation is of the form [*x y z*].

If `translation` contains more than one translation, the number of rotations in `rotation` must be one or equal to the number of translations in `translation`. The resulting number of created transformation objects is equal to the value of the `translation` or `rotation` argument, whichever is larger.

Example: `[1 4 3]`

Data Types: `single` | `double`

`transformation` — Homogeneous transformation

4-by-4 matrix | 4-by-4-by-*N* array | `se3` object | *N*-element array of `se3` objects

Homogeneous transformation, specified as a 4-by-4 matrix, a 4-by-4-by-*N* array, a scalar `se3` object, or an *N*-element array of `se3` objects. *N* is the total number of transformations specified.

If `transformation` is an array, the resulting number of created `se3` objects is equal to *N*.

Example: `eye(4)`

Data Types: `single` | `double`

`quaternion` — Quaternion

`quaternion` object | *N*-element array of `quaternion` objects

Quaternion, specified as a scalar `quaternion` object or as an *N*-element array of `quaternion` objects. *N* is the total number of specified quaternions.

If `quaternion` is an *N*-element array, the resulting number of created `se3` objects is equal to *N*.

Example: `quaternion(1,0.2,0.4,0.2)`

`euler` — Euler angles

N-by-3 matrix

Euler angles, specified as an *N*-by-3 matrix, in radians. Each row represents one set of Euler angles with the axis-rotation sequence defined by the `sequence` argument. The default axis-rotation sequence is *ZYX*.

If `euler` is an *N*-by-3 matrix, the resulting number of created `se3` objects is equal to *N*.

Example: `[pi/2 pi pi/4]`

Data Types: `single` | `double`

`sequence` — Axis-rotation sequence

`"ZYX"` (default) | `"ZYZ"` | `"ZXY"` | `"ZXZ"` | `"YXY"` | `"YZX"` | `"YXZ"` | `"YZY"` | `"XYX"` | `"XYZ"` | `"XZX"` | `"XZY"`

Axis-rotation sequence for the Euler angles, specified as one of these string scalars:

- `"ZYX"` (default)
- `"ZYZ"`
- `"ZXY"`
- `"ZXZ"`
- `"YXY"`
- `"YZX"`
- `"YXZ"`
- `"YZY"`
- `"XYX"`
- `"XYZ"`
- `"XZX"`
- `"XZY"`

These are orthonormal rotation matrices for rotations of ϕ, ψ, and θ about the *x*-, *y*-, and *z*-axis, respectively:

$$R_x(\phi) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\phi & \sin\phi \\ 0 & -\sin\phi & \cos\phi \end{bmatrix}, R_y(\psi) = \begin{bmatrix} \cos\psi & 0 & \sin\psi \\ 0 & 1 & 0 \\ -\sin\psi & 0 & \cos\psi \end{bmatrix}, R_z(\theta) = \begin{bmatrix} \cos\theta & -\sin\theta & 0 \\ \sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

When constructing the rotation matrix from this sequence, each character indicates the corresponding axis. For example, if the sequence is `"XYZ"`, then the `se3` object constructs the rotation matrix *R* by multiplying the rotation about *x*-axis with the rotation about the *y*-axis, and then multiplying that product with the rotation about the *z*-axis:

$$R = R_x(\phi) \cdot R_y(\psi) \cdot R_z(\theta)$$

Example: `se3([pi/2 pi/3 pi/4],"eul","ZYZ")` rotates a point by `pi/4` radians about the *z*-axis, then rotates the point by `pi/3` radians about the *y*-axis, and then rotates the point by `pi/2`

radians about the *z*-axis. This is equivalent to `se3(pi/2,"rotz") * se3(pi/3,"roty") * se3(pi/4,"rotz")`

Data Types: `string` | `char`

`quat` — Numeric quaternion
N-by-4 matrix

Numeric quaternion, specified as an *N*-by-4 matrix. *N* is the number of specified quaternions. Each row represents one quaternion of the form [*qw qx qy qz*], where *qw* is a scalar number.

If `quat` is an *N*-by-4 matrix, the resulting number of created `se3` objects is equal to *N*.

Note The `se3` object normalizes the input quaternions before converting the quaternions to a rotation matrix.

Example: `[0.7071 0.7071 0 0]`

Data Types: `single` | `double`

`axang` — Axis-angle rotation
N-by-4 matrix

Axis-angle rotation, specified as an *N*-by-4 matrix in the form [*x y z theta*]. *N* is the total number of axis-angle rotations. *x*, *y*, and *z* are vector components from the *x*-, *y*-, and *z*-axis, respectively. The vector defines the axis to rotate by the angle *theta*, in radians.

If `axang` is an *N*-by-4 matrix, the resulting number of created `se3` objects is equal to *N*.

Example: `[.2 .15 .25 pi/4]` rotates the axis, defined as `0.2` in the *x*-axis, `0.15` along the *y*-axis, and `0.25` along the *z*-axis, by `pi/4` radians.

Data Types: `single` | `double`

`angle` — Single-axis-angle rotation
N-by-*M* matrix

Single-axis-angle rotation, specified as an *N*-by-*M* matrix. Each element of the matrix is an angle, in radians, about the axis specified using the `axis` argument, and the `se3` object creates an `se3` object for each angle.

If `angle` is an *N*-by-*M* matrix, the resulting number of created `se3` objects is equal to *N*.

The rotation angle is counterclockwise positive when you look along the specified axis toward the origin.

Data Types: `single` | `double`

`axis` — Axis to rotate
`"rotx"` | `"roty"` | `"rotz"`

Axis to rotate, specified as one of these options:

- `"rotx"` — Rotate about the *x*-axis:

$$R_x(\phi) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\phi & \sin\phi \\ 0 & -\sin\phi & \cos\phi \end{bmatrix}$$

- `"roty"` — Rotate about the *y*-axis:

$$R_y(\psi) = \begin{bmatrix} \cos\psi & 0 & \sin\psi \\ 0 & 1 & 0 \\ -\sin\psi & 0 & \cos\psi \end{bmatrix}$$

- `"rotz"` — Rotate about the *z*-axis:

$$R_z(\theta) = \begin{bmatrix} \cos\theta & -\sin\theta & 0 \\ \sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Use the `angle` argument to specify how much to rotate about the specified axis.

Example: `Rx = se3(phi,"rotx");`

Example: `Ry = se3(psi,"roty");`

Example: `Rz = se3(theta,"rotz");`

Data Types: `string` | `char`

pose — 3-D compact pose
N-by-7 matrix

3-D compact pose, specified as an *N*-by-7 matrix, where *N* is the total number of compact poses. Each row is a pose, comprised of a xyz position and quaternion, in the form [*x y z qw qx qy qz*]. *x*, *y*, and *z* are the positions in the *x*-, *y*-, and *z*-axes, respectively. *qw*, *qx*, *qy*, and *qz* together are the quaternion rotation.

If `pose` is an *N*-by-7 matrix, the resulting number of created `se3` objects is equal to *N*.

Data Types: `single` | `double`

Object Functions

Mathematical Operations

mtimes, *	Transformation or rotation multiplication
mrdivide, /	Transformation or rotation right division
rdivide, ./	Element-wise transformation or rotation right division
times, .*	Element-wise transformation or rotation multiplication

Utilities

interp	Interpolate between transformations
dist	Calculate distance between transformations
normalize	Normalize transformation or rotation matrix
transform	Apply rigid body transformation to points

Numerical Conversions

axang	Convert transformation or rotation into axis-angle rotations
eul	Convert transformation or rotation into Euler angles
rotm	Extract rotation matrix
quat	Convert transformation or rotation to numeric quaternion
trvec	Extract translation vector
tform	Extract homogeneous transformation
xyzquat	Convert transformation or rotation to compact 3-D pose representation

Object Conversions

so3	SO(3) rotation
quaternion	Create quaternion array
rigidtform3d	3-D rigid geometric transformation

Examples

Create SE(3) Transformation Using Euler Angles and Translation

Define an Euler-angle rotation of `[pi/2 0 pi/7]` with a `"XYZ"` rotation sequence, and a *xyz* translation of `[6 4 1]`.

```
angles = [pi/2 0 pi/7];
trvec = [6 4 1];
```

Create an SE(3) transformation using the Euler angles and the translation.

```
TF = se3(angles,"eul","XYZ",trvec)
```

```
TF = se3
    0.9010   -0.4339         0    6.0000

Algorithms

3-D Homogeneous Transformation Matrix

3-D homogeneous transformation matrices consist of both an SO(3) rotation and an *xyz*-translation.

To read more about SO(3) rotations, see the 3-D Orthonormal Rotation Matrix on page 2-15 section of the `so3` object.

The translation is along the *x*-, *y*-, and *z*-axes as a three-element column vector:

$$t = \begin{bmatrix} x \\ y \\ z \end{bmatrix}$$

The SO(3) rotation matrix R is applied to the translation vector t to create the homogeneous translation matrix T. The rotation matrix is present in the upper-left of the transformation matrix as 3-by-3 submatrix, and the translation vector is present as a three-element vector in the last column.

$$T = \begin{bmatrix} R & t \\ 0_{1x3} & 1 \end{bmatrix} = \begin{bmatrix} I_3 & t \\ 0_{1x3} & 1 \end{bmatrix} \cdot \begin{bmatrix} R & 0 \\ 0_{1x3} & 1 \end{bmatrix}$$

`so3` | `quaternion`

so3

SO(3) rotation

Description

The `so3` object represents an SO(3) rotation in 3-D in a right-handed Cartesian coordinate system.

The SO(3) rotation is a 3-by-3 orthonormal rotation matrix. For example, these are orthonormal rotation matrices for rotations of ϕ, ψ, and θ about the x-, y-, and z-axis, respectively:

$$R_x(\phi) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\phi & \sin\phi \\ 0 & -\sin\phi & \cos\phi \end{bmatrix}, R_y(\psi) = \begin{bmatrix} \cos\psi & 0 & \sin\psi \\ 0 & 1 & 0 \\ -\sin\psi & 0 & \cos\psi \end{bmatrix}, R_z(\theta) = \begin{bmatrix} \cos\theta & -\sin\theta & 0 \\ \sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

For more information, see the 3-D Orthonormal Rotation Matrix section.

This object acts like a numerical matrix, enabling you to compose rotations using multiplication and division.

Creation

Syntax

```
rotation = so3
rotation = so3(rotation)
rotation = so3(quaternion)
rotation = so3(transformation)

rotation = so3(euler,"eul")
rotation = so3(euler,"eul",sequence)
rotation = so3(quat,"quat")
rotation = so3(axang,"axang")
rotation = so3(angle,axis)
```

Description

3-D Rotation Representations

`rotation = so3` creates an SO(3) rotation representing an identity rotation with no translation.

$$rotation = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

`rotation = so3(rotation)` creates an SO(3) rotation representing a pure rotation defined by the orthonormal rotation `rotation`.

$$rotation = \begin{bmatrix} r_{11} & r_{12} & r_{13} \\ r_{11} & r_{22} & r_{23} \\ r_{31} & r_{32} & r_{33} \end{bmatrix}$$

`rotation = so3(quaternion)` creates an SO(3) rotation from the rotations defined by the quaternion `quaternion`.

`rotation = so3(transformation)` creates an SO(3) rotation from the SE(3) transformation `transformation`.

Other Numeric 3-D Rotation Representations

`rotation = so3(euler,"eul")` creates an SO(3) rotation from the rotations defined by the Euler angles `euler`.

`rotation = so3(euler,"eul",sequence)` specifies the sequence of the Euler angle rotations `sequence`. For example, the sequence `"ZYX"` rotates the *z*-axis, then the *y*-axis and *x*-axis.

`rotation = so3(quat,"quat")` creates an SO(3) rotation from the rotations defined by the numeric quaternions `quat`.

`rotation = so3(axang,"axang")` creates an SO(3) rotation from the rotations defined by the axis-angle rotation `axang`.

`rotation = so3(angle,axis)` creates an SO(3) rotation from the rotations `angle` about the rotation axis `axis`.

Note If any inputs contain more than one rotation, then the output `rotation` is an *N*-element array of `so3` objects corresponding to each of the *N* input rotations.

Input Arguments

`rotation` — Orthonormal rotation

3-by-3 matrix | 3-by-3-by-*N* matrix | `so3` object | *N*-element array of `so3` objects

Orthonormal rotation, specified as a 3-by-3 matrix, a 3-by-3-by*N* array, a scalar `so3` object, or an *N*-element array of `so3` objects. *N* is the total number of rotations.

If `rotation` is an array, the resulting number of created `so3` objects in the output array is equal to *N*.

Example: `eye(3)`

`transformation` — Homogeneous transformation

4-by-4 matrix | 4-by-4-by-*N* array | `se3` object | *N*-element array of `se3` objects

Homogeneous transformation, specified as a 4-by-4 matrix, a 4-by-4-by-*N* array, a scalar `se3` object, or an *N*-element array of `se3` objects. *N* is the total number of transformations specified.

If `transformation` is an array, the resulting number of created `so3` objects is equal to *N*.

Example: `eye(4)`

Data Types: `single` | `double`

`quaternion` — Quaternion
`quaternion` object | *N*-element array of `quaternion` objects

Quaternion, specified as a scalar `quaternion` object or as an *N*-element array of `quaternion` objects. *N* is the total number of specified quaternions.

If `quaternion` is an *N*-element array, the resulting number of created `so3` objects is equal to *N*.

Example: `quaternion(1,0.2,0.4,0.2)`

`euler` — Euler angles
N-by-3 matrix

Euler angles, specified as an *N*-by-3 matrix, in radians. Each row represents one set of Euler angles with the axis-rotation sequence defined by the `sequence` argument. The default axis-rotation sequence is *ZYX*.

If `euler` is an *N*-by-3 matrix, the resulting number of created `so3` objects is equal to *N*.

Example: `[pi/2 pi pi/4]`

Data Types: `single` | `double`

`sequence` — Axis-rotation sequence
`"ZYX"` (default) | `"ZYZ"` | `"ZXY"` | `"ZXZ"` | `"YXY"` | `"YZX"` | `"YXZ"` | `"YZY"` | `"XYX"` | `"XYZ"` | `"XZX"` | `"XZY"`

Axis-rotation sequence for the Euler angles, specified as one of these string scalars:

- `"ZYX"` (default)
- `"ZYZ"`
- `"ZXY"`
- `"ZXZ"`
- `"YXY"`
- `"YZX"`
- `"YXZ"`
- `"YZY"`
- `"XYX"`
- `"XYZ"`
- `"XZX"`
- `"XZY"`

These are orthonormal rotation matrices for rotations of ϕ, ψ, and θ about the *x*-, *y*-, and *z*-axis, respectively:

$$R_x(\phi) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\phi & \sin\phi \\ 0 & -\sin\phi & \cos\phi \end{bmatrix}, R_y(\psi) = \begin{bmatrix} \cos\psi & 0 & \sin\psi \\ 0 & 1 & 0 \\ -\sin\psi & 0 & \cos\psi \end{bmatrix}, R_z(\theta) = \begin{bmatrix} \cos\theta & -\sin\theta & 0 \\ \sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

When constructing the rotation matrix from this sequence, each character indicates the corresponding axis. For example, if the sequence is `"XYZ"`, then the `so3` object constructs the

rotation matrix R by multiplying the rotation about x-axis with the rotation about the y-axis, and then multiplying that product with the rotation about the z-axis:

$$R = R_x(\phi) \cdot R_y(\psi) \cdot R_z(\theta)$$

Example: `so3([pi/2 pi/3 pi/4],"eul","ZYZ")` rotates a point by `pi/4` radians about the z-axis, then rotates the point by `pi/3` radians about the y-axis, and then rotates the point by `pi/2` radians about the z-axis. This is equivalent to `so3(pi/2,"rotz") * so3(pi/3,"roty") * so3(pi/4,"rotz")`

Data Types: `string` | `char`

`quat` — Numeric quaternion
N-by-4 matrix

Numeric quaternion, specified as an *N*-by-4 matrix. *N* is the number of specified quaternions. Each row represents one quaternion of the form [*qw qx qy qz*], where *qw* is a scalar number.

If `quat` is an *N*-by-4 matrix, the resulting number of created `so3` objects is equal to *N*.

Note The `so3` object normalizes the input quaternions before converting the quaternions to a rotation matrix.

Example: `[0.7071 0.7071 0 0]`

Data Types: `single` | `double`

`axang` — Axis-angle rotation
N-by-4 matrix

Axis-angle rotation, specified as an *N*-by-4 matrix in the form [*x y z theta*]. *N* is the total number of axis-angle rotations. *x*, *y*, and *z* are vector components from the *x*-, *y*-, and *z*-axis, respectively. The vector defines the axis to rotate by the angle *theta*, in radians.

If `axang` is an *N*-by-4 matrix, the resulting number of created `so3` objects is equal to *N*.

Example: `[.2 .15 .25 pi/4]` rotates the axis, defined as `0.2` in the *x*-axis, `0.15` along the *y*-axis, and `0.25` along the *z*-axis, by `pi/4` radians.

Data Types: `single` | `double`

`angle` — Single-axis-angle rotation
N-by-*M* matrix

Single-axis-angle rotation, specified as an *N*-by-*M* matrix. Each element of the matrix is an angle, in radians, about the axis specified using the `axis` argument, and the `so3` object creates an `so3` object for each angle.

If `angle` is an *N*-by-*M* matrix, the resulting number of created `so3` objects is equal to *N*.

The rotation angle is counterclockwise positive when you look along the specified axis toward the origin.

Data Types: `single` | `double`

`axis` — Axis to rotate
`"rotx"` | `"roty"` | `"rotz"`

Axis to rotate, specified as one of these options:

- `"rotx"` — Rotate about the x-axis:

$$R_x(\phi) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\phi & \sin\phi \\ 0 & -\sin\phi & \cos\phi \end{bmatrix}$$

- `"roty"` — Rotate about the y-axis:

$$R_y(\psi) = \begin{bmatrix} \cos\psi & 0 & \sin\psi \\ 0 & 1 & 0 \\ -\sin\psi & 0 & \cos\psi \end{bmatrix}$$

- `"rotz"` — Rotate about the z-axis:

$$R_z(\theta) = \begin{bmatrix} \cos\theta & -\sin\theta & 0 \\ \sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Use the `angle` argument to specify how much to rotate about the specified axis.

Example: `Rx = so3(phi,"rotx");`

Example: `Ry = so3(psi,"roty");`

Example: `Rz = so3(theta,"rotz");`

Data Types: `string` | `char`

Object Functions

Mathematical Operations

mtimes, *	Transformation or rotation multiplication
mrdivide, /	Transformation or rotation right division
rdivide, ./	Element-wise transformation or rotation right division
times, .*	Element-wise transformation or rotation multiplication

Utilities

interp	Interpolate between transformations
dist	Calculate distance between transformations
normalize	Normalize transformation or rotation matrix
transform	Apply rigid body transformation to points

Numerical Conversions

axang	Convert transformation or rotation into axis-angle rotations
eul	Convert transformation or rotation into Euler angles
rotm	Extract rotation matrix
quat	Convert transformation or rotation to numeric quaternion
trvec	Extract translation vector

tform	Extract homogeneous transformation
xyzquat	Convert transformation or rotation to compact 3-D pose representation

Object Conversions

se3	SE(3) homogeneous transformation
quaternion	Create quaternion array
rigidtform3d	3-D rigid geometric transformation

Examples

Convert SO(3) Rotation to Euler Angles

Create SO(3) rotation defined by a Euler angles.

```
eul1 = [pi/4 pi/3 pi/8]
```

```
eul1 = 1×3

    0.7854    1.0472    0.3927
```

```
R = so3(eul1,"eul")
```

```
R = so3
    0.3536   -0.4189    0.8364
    0.3536    0.8876    0.2952
   -0.8660    0.1913    0.4619
```

Get the Euler angles from the transformation.

```
eul2 = eul(R)
```

```
eul2 = 1×3

    0.7854    1.0472    0.3927
```

Algorithms

3-D Orthonormal Rotation Matrix

SO(3) rotation matrices are 3-by-3 orthonormal matrices that represent any rotation in 3-D Euclidean space. SO(3) rotations have many special properties. For example, SO(3) rotation matrices are in the 3-D special orthogonal group, so the product of two SO(3) rotation matrices is an SO(3) rotation matrix. This enables you to compose rotations from multiple rotations. For example, these are orthonormal rotation matrices for rotations of ϕ, ψ, and θ about the x-, y-, and z-axis, respectively:

$$R_x(\phi) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\phi & \sin\phi \\ 0 & -\sin\phi & \cos\phi \end{bmatrix}, R_y(\psi) = \begin{bmatrix} \cos\psi & 0 & \sin\psi \\ 0 & 1 & 0 \\ -\sin\psi & 0 & \cos\psi \end{bmatrix}, R_z(\theta) = \begin{bmatrix} \cos\theta & -\sin\theta & 0 \\ \sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Depending on the order in which you multiply these *x*-, *y*-, and *z*-axis rotations, you can construct compound matrices that represent any rotation in 3-D Euclidean space.

These are other properties of SO(3) rotations:

- Each column is both orthogonal and a unit vector, meaning that none of the columns are multiples of each other.
- The determinant of the matrix is positive 1.
- The inverse of the matrix is the same as the transpose of the matrix: $R^{-1} = R^T$.

groundingDinoObjectDetector

Detect and localize objects using Grounding DINO object detector

Description

Add-On Required: This feature requires the Computer Vision Toolbox Model for Grounding DINO Object Detection add-on.

The `groundingDinoObjectDetector` object creates a Grounding DINO vision-language object detector for zero-shot object detection. This detector identifies and localizes arbitrary objects in an image using natural language descriptions (text prompts). Use the `groundingDinoObjectDetector` object to create a pretrained Grounding DINO object detector with either a Swin-Tiny or Swin-Base backbone network. You can then use the `detect` function of the `groundingDinoObjectDetector` object to detect objects in an unknown image. This feature also requires the Deep Learning Toolbox™ license.

Creation

Syntax

```
detector = groundingDinoObjectDetector
detector = groundingDinoObjectDetector(name)
detector = groundingDinoObjectDetector( ___ ,Name=Value)
```

Description

`detector = groundingDinoObjectDetector` creates a pretrained Grounding DINO object detector by using Swin-Tiny as the backbone network.

`detector = groundingDinoObjectDetector(name)` creates a pretrained Grounding DINO object detector using the backbone network specified by `name`.

`detector = groundingDinoObjectDetector( ___ ,Name=Value)` sets writable properties using one or more name-value arguments. Use this syntax to set the `ClassNames` and `ClassDescriptions` properties of the object detector.

You can use the `ClassDescriptions` property to provide natural language queries for detection and the `ClassNames` property to assign output labels for annotation. The `ClassNames` property is required. If you specify only `ClassNames`, the object uses its value for both detection and annotation. You can specify `ClassDescriptions` in addition to `ClassNames` if you want to provide more details about the objects to detect.

You can specify these properties either when creating the object or as name-value arguments when calling the `detect` function.

- If you do not specify these properties at the time of object creation, you must specify at least the `ClassNames` name-value argument when you call the `detect` function.
- If you specify these properties at object creation and when calling the `detect` function, the values specified in the `detect` function override the values set in the detector object.

Input Arguments

`name` — Name of backbone network

`"swin-tiny"` (default) | `"swin-base"`

Name of the backbone network, specified as `"swin-tiny"` or `"swin-base"`.

- Use `"swin-tiny"` as the backbone for applications that require low latency and resource efficiency, such as in real-time or edge deployments. The network offers faster inference with lower memory usage than the `"swin-base"` network.
- Use `"swin-base"` for applications that require high accuracy in environments with sufficient computational resources.

The pretrained detector with Swin-Tiny as the backbone network is trained on the O365, GoldG, and Cap4M datasets. The pretrained detector with Swin-Base as the backbone network is trained on the COCO, O365, GoldG, Cap4M, OpenImage, ODinW-35, and RefCOCO datasets.

This argument sets the `ModelName` property as a character vector.

Data Types: `char` | `string`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

`ClassNames` — Labels

string scalar | string array | cell array of character vectors | categorical vector

Labels, specified as a string scalar, string array, cell array of character vectors, or categorical vector.

- If you do not specify `ClassDescriptions`, the object uses the values in `ClassNames` as both output labels for annotation and natural language queries for detection. In this case, the total number of words across all elements, with each comma also counted as a word, must not exceed 255 words.
- If you specify `ClassDescriptions`, the object uses the values in `ClassNames` as output labels for annotation, and the word limit does not apply.

If you specify both `ClassNames` and `ClassDescriptions`, the number of elements in them must match.

This argument sets the `ClassNames` property.

Data Types: `char` | `string` | `cell` | `categorical`

`ClassDescriptions` — Natural language queries

string scalar | string array | cell array of character vectors | categorical vector

Natural language queries, specified as a string scalar, string array, cell array of character vectors, or categorical vector. The total number of words across all elements, with each comma also counted as a word, must not exceed 255 words. Each entry must correspond to an element in `ClassNames`. This argument sets the `ClassDescriptions` property.

In general, the `ClassDescriptions` are more detailed and descriptive than the `ClassNames` to guide the detection process. The queries provide additional context about an object, such as its appearance, color, size, or activity.

For an example, if you want to detect a brown-colored dog lying on grass, you can specify `ClassDescriptions` as `"brown dog lying on grass"` to query the Grounding DINO object detector, and specify the corresponding `ClassNames` as `"dog"` to label the detected object.

Data Types: `char` | `string` | `cell` | `categorical`

Properties

`ModelName` — Name of backbone network

`'swin-tiny'` (default) | `'swin-base'`

This property is read-only after object creation.

Name of the backbone network, represented as `'swin-tiny'` or `'swin-base'`.

Data Types: `char`

`ClassNames` — Labels

`[]` (default) | string scalar | string array | cell array of character vectors | categorical vector

This property is read-only after object creation.

Labels, specified as a string scalar, string array, cell array of character vectors, or categorical vector. The default value is `[]`. To set this property, specify the property value using the `ClassNames` name, value argument .

`ClassDescriptions` — Natural language queries

`[]` (default) | string scalar | string array | cell array of character vectors | categorical vector

This property is read-only after object creation.

Natural language queries, represented as a string scalar, string array, cell array of character vectors, or categorical vector. The default value is `[]`. To set this property, specify the property value using the `ClassDescriptions` name, value argument .

If you do not specify `ClassDescriptions` property, the object uses the values in `ClassNames` as both output labels for annotation and natural language queries for detection.

Object Functions

detect Detect objects using Grounding DINO object detector

Examples

Perform Zero-Shot Object Detection Using Grounding DINO

Read an input image into the workspace.

```
I = imread("visionteam.jpg");
```

Display the input image.

```
figure
imshow(I)
```

Create a Grounding DINO object detector using the Swin-Base network as the backbone network.

```
name = "swin-base";
detector = groundingDinoObjectDetector(name);
```

Specify the class names for the detector to use as output labels for the detection results.

```
labels = {'Holding paper','Holding jacket'};
```

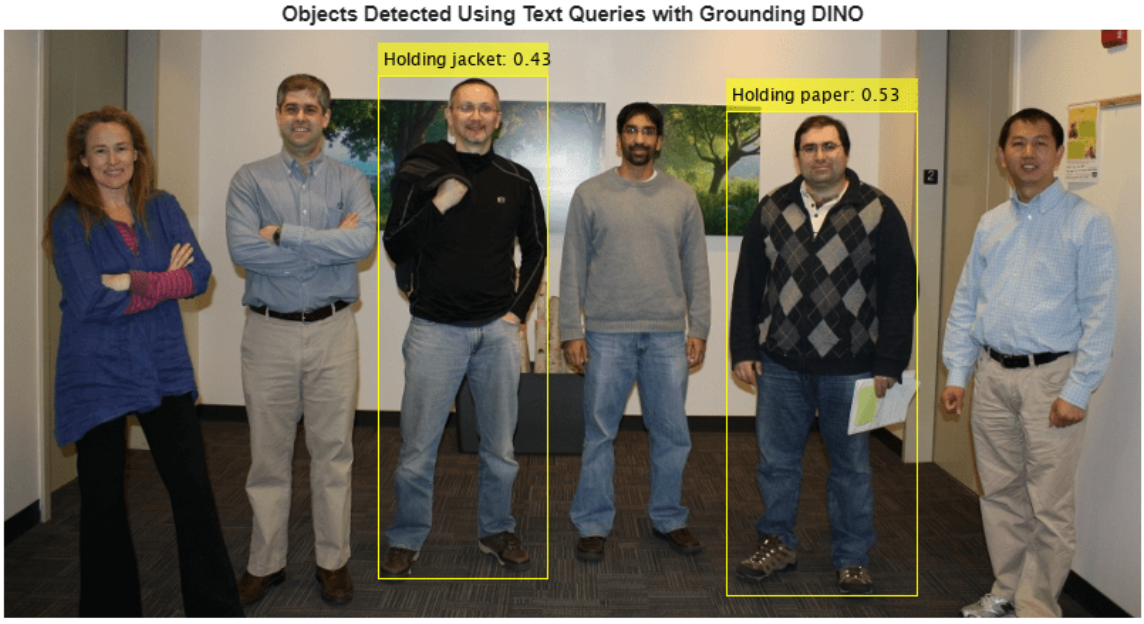
Specify the class descriptions for the detector to use as text queries for performing object detection.

```
descriptions = {'Person holding paper','Person holding jacket'};
```

Detect objects in the image using the specified class names and descriptions.

```
[bboxes,scores,labels] = detect(detector,I,ClassNames=labels,ClassDescriptions=descriptions);
```

Format the detected labels and scores for image annotation.



```
outputLabels = compose("%s: %.2f",string(labels),scores);
```

Annotate the detected objects in the image.

```
detections = insertObjectAnnotation(I,"rectangle",bboxes,outputLabels);
```

Display the image, annotated with the detection results.

```
imshow(detections)
title("Objects Detected Using Text Queries with Grounding DINO")
```

Detect License Plates Using Grounding DINO

This example uses a small vehicle dataset that contains 295 images. Many of these images come from the Caltech Cars 1999 and 2001 datasets, available at the Caltech Computational Vision website created by Pietro Perona and used with permission.

Unzip the vehicle images to the working folder.

```
fileNames = unzip("vehicleDatasetImages.zip");
```

Create an `imageDatastore` object to read the images for object detection.

```
imds = imageDatastore(fileNames);
```

Load a pretrained Grounding DINO object detector with a Swin-Base backbone network. Use the `classNames` name-value argument to specify text prompts for detecting the car and the license plate.

To improve detection accuracy and establish semantic context, specify both license plate and car as text prompts. This ensures that language-guided query selection correctly assigns the vehicle's large-scale features to car, preventing them from being falsely localized as the license plate.

```
detector = groundingDinoObjectDetector("swin-base",classNames=["License plate","car"]);
```

Read images from the image datastore using the `read` function. Detect cars and license plates in each image using the `detect` function of the `groundingDINOObjectDetector` object.

```
detectionResults = detect(detector,imds);
```

Visualize Detection Results

Extract the bounding boxes, detection scores, and labels from the results table. Iterate over the images in the datastore and filter detections to include only license plates. For each image, display the image and overlay bounding boxes with the corresponding attention scores when license plates are detected.

```
figure
allBoxes  = detectionResults.Boxes;
allScores = detectionResults.Scores;
allLabels = detectionResults.Labels;
for i = 1:length(imds.Files)
    img = readimage(imds,i);
    idx = (allLabels{i} == "License plate");
    plateBoxes = allBoxes{i}(idx,:);
    plateScores = cellstr(string(allScores{i}(idx)));

    imshow(img);

    if isempty(plateBoxes)
        title(sprintf("Image %d: No license plate detections",i));
    else
        annotatedImg = insertObjectAnnotation(img,'rectangle',plateBoxes,plateScores,...
            'LineWidth',3);
        imshow(annotatedImg);
        title(sprintf("Image %d: License plate(s) detected",i));
    end
    pause(0.1)
end
```

Topics

“Get Started with Vision-Language Models”
“Automatically Label Ground Truth Using Vision-Language Model”

detect

Detect objects using Grounding DINO object detector

Syntax

```
bboxes = detect(detector,I)
[bboxes,scores] = detect(detector,I)
[bboxes,scores,labels] = detect(detector,I)
detectionResults = detect(detector,ds)
[___] = detect(___,roi)
[___] = detect(___,Name=Value)
```

Description

`bboxes = detect(detector,I)` detects objects in an image or an array of images, `I`, using a Grounding DINO object detector, `detector`. The function returns the locations of objects detected in the input image as sets of bounding boxes.

`[bboxes,scores] = detect(detector,I)` also returns the class-specific attention scores for each bounding box.

`[bboxes,scores,labels] = detect(detector,I)` returns a categorical array of the labels assigned to the bounding boxes.

`detectionResults = detect(detector,ds)` detects objects in all the images stored in the datastore `ds`.

`[___] = detect(___,roi)` detects objects within the rectangular search region `roi`, in addition to any combination of arguments from previous syntaxes.

`[___] = detect(___,Name=Value)` specifies options using one or more name-value arguments.

Examples

Perform Zero-Shot Object Detection Using Grounding DINO

Read an input image into the workspace.

```

imds = imageDatastore(fileNames);
```

Load a pretrained Grounding DINO object detector with a Swin-Base backbone network. Use the `classNames` name-value argument to specify text prompts for detecting the car and the license plate.

To improve detection accuracy and establish semantic context, specify both license plate and car as text prompts. This ensures that language-guided query selection correctly assigns the vehicle's large-scale features to car, preventing them from being falsely localized as the license plate.

```
detector = groundingDinoObjectDetector("swin-base",classNames=["License plate","car"]);
```

Read images from the image datastore using the `read` function. Detect cars and license plates in each image using the `detect` function of the `groundingDINOObjectDetector` object.

```
detectionResults = detect(detector,imds);
```

Visualize Detection Results

Extract the bounding boxes, detection scores, and labels from the results table. Iterate over the images in the datastore and filter detections to include only license plates. For each image, display the image and overlay bounding boxes with the corresponding attention scores when license plates are detected.

```
figure
allBoxes  = detectionResults.Boxes;
allScores = detectionResults.Scores;
allLabels = detectionResults.Labels;
for i = 1:length(imds.Files)
    img = readimage(imds,i);
    idx = (allLabels{i} == "License plate");
    plateBoxes = allBoxes{i}(idx,:);
    plateScores = cellstr(string(allScores{i}(idx)));

    imshow(img);

    if isempty(plateBoxes)
        title(sprintf("Image %d: No license plate detections",i));
    else
        annotatedImg = insertObjectAnnotation(img,'rectangle',plateBoxes,plateScores,...
            'LineWidth',3);
        imshow(annotatedImg);
        title(sprintf("Image %d: License plate(s) detected",i));
    end
    pause(0.1)
end
```

Input Arguments

`detector` — Grounding DINO object detector

`groundingDinoObjectDetector` object

Grounding DINO object detector, specified as a `groundingDinoObjectDetector` object.

`I` — Test image

matrix | 3-D array

Test image, specified as a matrix for a grayscale image or a 3-D array of size *height*-by-*width*-by-3 for an RGB image.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single`

`ds` — Test images

`ImageDatastore` object | `CombinedDatastore` object | `TransformedDatastore` object

Test images, specified as an `ImageDatastore` object, `CombinedDatastore` object, or `TransformedDatastore` object containing the full paths of the test images. The images in the datastore must be grayscale or RGB images.

`roi` — Search region of interest

vector of form [*x y width height*]

Search region of interest, specified as a vector of form [*x y width height*]. The values of *x* and *y* specify the coordinates of the upper-left corner of a rectangular region, and *width* and *height* specify its size in pixels.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `detect(detector,I,ExecutionEnvironment="gpu")` to use the GPU to run the detector.

`ClassNames` — Labels

string scalar | string array | cell array of character vectors | categorical vector

Labels, specified as a string scalar, string array, cell array of character vectors, or categorical vector.

- If you do not specify `ClassDescriptions`, the object uses the values in `ClassNames` as both output labels for annotation and natural language queries for detection. In this case, the total number of words across all elements, with each comma also counted as a word, must not exceed 255 words.
- If you specify `ClassDescriptions`, the object uses the values in `ClassNames` as output labels for annotation, and the word limit does not apply.

If you specify both `ClassNames` and `ClassDescriptions`, the number of elements in them must match.

This argument sets the `ClassNames` property.

Data Types: `char` | `string` | `cell` | `categorical`

`ClassDescriptions` — Natural language queries

string scalar | string array | cell array of character vectors | categorical vector

Natural language queries, specified as a string scalar, string array, cell array of character vectors, or categorical vector. The total number of words across all elements, with each comma also counted as a word, must not exceed 255 words. Each entry must correspond to an element in `ClassNames`. This argument sets the `ClassDescriptions` property.

In general, the `ClassDescriptions` are more detailed and descriptive than the `ClassNames` to guide the detection process. The queries provide additional context about an object, such as its appearance, color, size, or activity.

For an example, if you want to detect a brown-colored dog lying on grass, you can specify `ClassDescriptions` as `"brown dog lying on grass"` to query the Grounding DINO object detector, and specify the corresponding `ClassNames` as `"dog"` to label the detected object.

Data Types: `char` | `string` | `cell` | `categorical`

`MinSize` — Minimum region size

`[1 1]` (default) | vector of form [*height width*]

Minimum region size, specified as a vector of the form [*height width*]. Units are in pixels. The minimum region size defines the size of the smallest region that can contain the object.

`MaxSize` — Maximum region size

`size(I)` (default) | vector of the form [*height width*]

Maximum region size, specified as a vector of the form [*height width*]. Units are in pixels. The maximum region size defines the size of the largest region that contain the object.

By default, `MaxSize` is set to the height and width of the input image `I`. To reduce computation time, set this value to the known maximum region size for the objects that can be detected in the input test image.

`MiniBatchSize` — Minimum batch size
4 (default) | positive integer

Minimum batch size, specified as a scalar value. Use the `MiniBatchSize` to process a large collection of image. Images are grouped into minibatches and processed as a batch, which can improve computational efficiency at the cost of increased memory demand.

`Threshold` — Detection threshold
`0.25` (default) | scalar in range [0, 1]

Detection threshold, specified as a scalar in the range [0, 1]. The function removes detections that have attention scores less than this threshold value. To reduce false positives, increase this value.

`SelectStrongest` — Select strongest bounding box
`true` (default) | `false`

Select the strongest bounding box for each detected object, specified as `true` or `false`.

- `true` — Returns only the strongest bounding box for each object. After object detection, the `detect` function calls the `selectStrongestBboxMulticlass` function, which uses nonmaximal suppression to eliminate overlapping bounding boxes based on their attention scores.

  By default, the `detect` function make this call to the `selectStrongestBboxMulticlass` function:

  ```
  selectStrongestBboxMulticlass(bboxes,scores,labels, ...
                                RatioType="Union", ...
                                OverlapThreshold=0.5);
  ```

- `false` — Returns all detected bounding boxes. You can then write your own custom function to eliminate overlapping bounding boxes.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as `"auto"`, `"gpu"`, or `"cpu"`.

- `"auto"` — Use a GPU if it is available. Otherwise, use the CPU.
- `"gpu"` — Use the GPU. To use a GPU, you must have a Parallel Computing Toolbox™ license and a CUDA enabled NVIDIA® GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Use the CPU.

Output Arguments

`bboxes` — Locations of detected objects
M-by-4 matrix

Locations of the detected objects within the input image, returned as an *M*-by-4 matrix. *M* is the number of bounding boxes detected in the image. Each row of the matrix is of the form [*x y width height*]. The *x* and *y* values specify the coordinates of the upper-left corner, and *width* and *height* specify the size, of the corresponding bounding box, in pixels.

`scores` — Attention scores
M-by-1 numeric vector

Attention scores for each bounding box, returned as an *M*-by-1 numeric vector. *M* is the number of bounding boxes detected in the image. Each element indicates the attention score for a bounding box in the corresponding image, and values are in the range [0, 1].

`labels` — Labels for bounding boxes
M-by-1 categorical vector

Labels for bounding boxes, returned as an *M*-by-1 categorical vector. *M* is the number of bounding boxes detected in the image.

`detectionResults` — Detection results
three-column table

Detection results when the input is a datastore, `ds`, returned as a table with these columns, in which each row corresponds to an image.

`bboxes`	`scores`	`labels`
Predicted bounding boxes, defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y width height*], where: • *M* is the number of detections in the image. • *x* and `y` specify the coordinates of the upper-left corner of the rectangle, in pixels. • *width* specifies the width of the rectangle, which is its length along the *x*-axis, in pixels. • *height* specifies the height of the rectangle, which is its length along the *y*-axis, in pixels.	Attention scores for each bounding box, returned as an *M*-by-1 numeric vector with values in the range [0, 1].	Labels assigned to the bounding boxes, returned as an *M*-by-1 categorical vector.

faceDetector

Detect faces using pretrained RetinaFace face detector

Description

Add-On Required: This feature requires the Computer Vision Toolbox Model for RetinaFace Face Detection add-on.

The `faceDetector` function object stores a pretrained RetinaFace face detector used to detect faces in images. The RetinaFace face detector is trained on the WIDER FACE data set. When creating the `faceDetector` object, you can load a RetinaFace face detector that uses either MobileNet-0.25 or ResNet-50 as the backbone network.

Note This functionality requires Deep Learning Toolbox and the Computer Vision Toolbox Model for RetinaFace Face Detection. You can install the Computer Vision Toolbox Model for RetinaFace Face Detection from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Creation

Syntax

```
detector = faceDetector
detector = faceDetector(name)
detector = faceDetector( ___ ,InputSize=inputSize)
```

Description

`detector = faceDetector` returns a RetinaFace face detector object that uses MobileNet-0.25 as the backbone network. The lightweight architecture of MobileNet-0.25 enables the face detector to maintain a good balance between detection accuracy and computational efficiency.

`detector = faceDetector(name)` returns a pretrained RetinaFace face detector object that uses MobileNet-0.25 or ResNet-50 as the backbone network. You can specify the name of the face detector by using the input argument `name`, which determines the choice of backbone network.

`detector = faceDetector( ___ ,InputSize=inputSize)` specifies the image size to use for inference in addition to any combination of input arguments from previous syntaxes.

Input Arguments

`name` — Name of RetinaFace face detector

`"small-network"` | `"large-network"`

Name of the RetinaFace face detector, specified as one of these values.

- `"small-network"` — Specify this value to use MobileNet-0.25 as the backbone network.

The small network, with its few layers, provides faster inference times due to its reduced parameters and computational complexity. Use the small network to detect faces in images with simple and uniform backgrounds, where facial features are distinguishable. Additionally, you can use the small network to detect faces in large batches of images, where detection speed and computational efficiency are crucial.

- `"large-network"` — Specify this value to use ResNet-50 as the backbone network.

  The large network, with its numerous layers, provides higher accuracy in detection results at the cost of reduced computational efficiency. Use the large network to achieve high accuracy in detecting faces within images that have complex or cluttered backgrounds, as well as in images containing numerous faces.

The `name` argument sets the `ModelName` property.

Data Types: `char` | `string`

`inputSize` — Inference image size
`[640 640]` (default) | two-element row vector of integers

Inference image size, specified as a two-element row vector of integers of the form `[H W]`. H and W correspond to the height and width of the input image, respectively.

If the resolution of the face class to be detected in the test image is too small, increase the `inputSize` value for better detection accuracy. However, increasing the `inputSize` value also increases the computational cost.

The `inputSize` argument sets the `InputSize` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Properties

`ModelName` — Name of RetinaFace face detector
`'small-network'` (default) | `'large-network'`

Name of the RetinaFace face detector, represented as `'small-network'` or `'large-network'`. To set this property, use the `name` argument, when calling the `faceDetector` function.

This property is read-only after object creation.

`ClassNames` — Name of object class
`'face'`

This property is read-only.

Name of the object class to detect, represented as `'face'`.

`InputSize` — Image size used for inference
`[640 640]` (default) | two-element row vector of integers

Image size used for inference, represented as a two-element row vector of integers of the form `[H W]`. H and W correspond to the height and width of the input image, respectively.

This property is read-only after object creation. By default, the `InputSize` property value is set to the network's input size `[640 640]`, which is the size of the training images. To set this property, use the `inputSize` argument when calling the `faceDetector` function.

The `detect` function resizes the test image to the dimensions specified by the `InputSize` property before performing the detections.

Object Functions

detect Detect faces in images using deep learning based face detector

Examples

Detect Faces in Image Using RetinaFace Detector

Read an input image into the MATLAB® workspace.

```
I = imread("visionteam1.jpg");
```

Create a face detector object using the `faceDetector` function. The default configuration of the object loads a small, pretrained RetinaFace deep learning detector for face detection. The small network uses MobileNet-0.25 as the backbone network.

```
detector = faceDetector
```

```
detector =
  faceDetector with properties:

     ModelName: "small-network"
    ClassNames: face
     InputSize: [640 640]
```

Detect faces in the image using the `detect` function of the `faceDetector` object. The `detect` function returns bounding boxes, detection scores, and labels for the detected faces.

```
[bboxes,scores,labels] = detect(detector,I);
```

Overlay bounding boxes, labels, and scores on the image using the `insertObjectAnnotation` function.

```
detectedImg = insertObjectAnnotation(I,"rectangle",bboxes,scores);
```

Display the detection results.

```
table(bboxes,scores,labels)
```

```
ans=6×3 table
             bboxes              scores     labels
    ____________________________    _______    ______

    571     70     38     61    0.99237     face
    333     99     31     40    0.98568     face
    217    122     21     31    0.96641     face
    107    124     37     47    0.99897     face
    510    128     29     38    0.97089     face
```

```
    648    132     26     38    0.99424     face
```

```
figure
imshow(detectedImg)
```

Detect Faces in Video Using RetinaFace Detector

Create a face detector object using the `faceDetector` function. Specify the detector name as "`large-network`". This configuration loads a pretrained RetinaFace face detector with ResNet-50 as the backbone network for face detection.

```
detector = faceDetector("large-network");
```

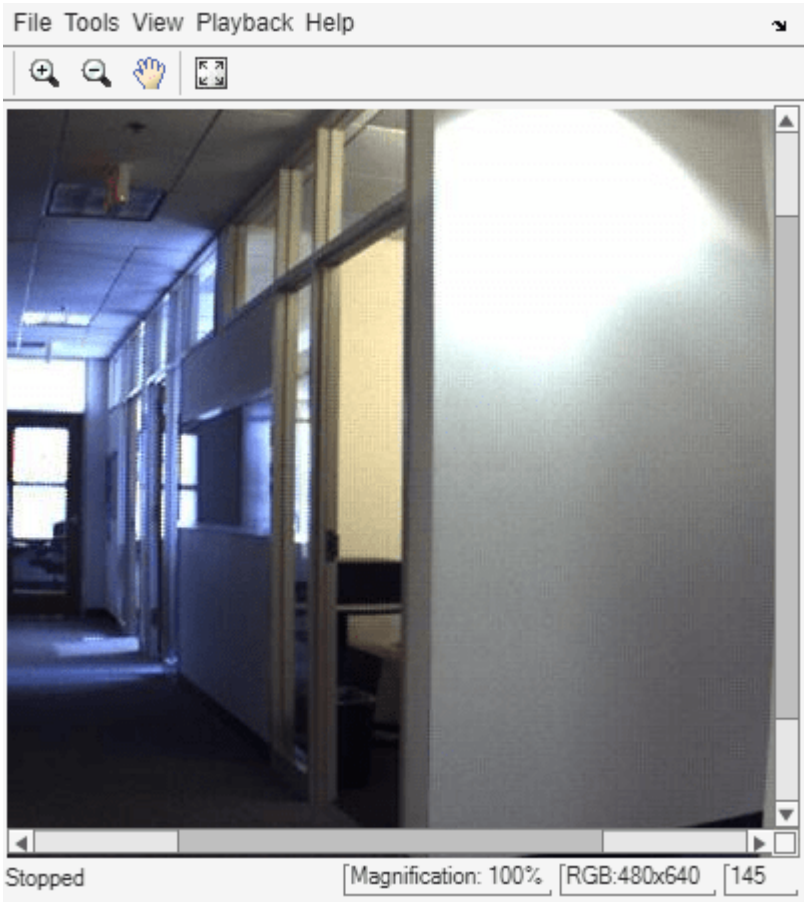
Create a `VideoReader` object to read video data from a video file.

```
reader = VideoReader('handshake_right.avi');
```

Configure a `VideoPlayer` object to display the video frames and the face detection results.

```
videoPlayer = vision.VideoPlayer(Position=[0 0 400 400]);
```

Read and iterate over each frame in the video using a `while` loop. Perform these steps to detect faces and display the detection results.



- Step 1: Read the current video frame with the `readFrame` function of the `VideoReader` object.
- Step 2: Detect faces in the video frame using the `detect` function of the `faceDetector` object. The `detect` function returns bounding boxes and detection scores for the detected faces.
- Step 3: Overlay bounding boxes and scores on the video frame using the `insertObjectAnnotation` function.

- Step 4: Display the annotated frame using the `step` function of the `VideoPlayer` object.

```
while hasFrame(reader)
    % Step 1 %
    videoFrame = readFrame(reader);
    % Step 2 %
    [bboxes,scores] = detect(detector,videoFrame);
    % Step 3 %
    videoFrame= insertObjectAnnotation(videoFrame,"rectangle",bboxes,scores);
    % Step 4 %
    step(videoPlayer,videoFrame)
end
```

Call the `release` function to free up the resources allocated to the `VideoPlayer` object.

```
release(videoPlayer)
```

Detect and Blur Faces in Video

Create a face detector object using the `faceDetector` function. By default, the function uses the RetinaFace detector with a small backbone network for face detection.

```
detector = faceDetector;
```

Create a `VideoReader` object to read video data from a video file.

```
reader = VideoReader('tilted_face.avi');
```

Configure a `VideoPlayer` object to display the video frames and the face detection results.

```
videoPlayer = vision.VideoPlayer(Position=[0 0 600 600]);
```

Read and iterate over each frame in the video using a `while` loop. Perform these steps to detect faces and display the detection results.

- Step 1: Read the current video frame with the `readFrame` function of the `VideoReader` object.
- Step 2: Detect faces in the video frame using the `detect` function of the `faceDetector` object. The `detect` function returns bounding boxes for the detected faces.
- Step 3: If the current frame has detected faces, use the helper function `helperBlurFaces` to blur the faces in the frame. The helper function applies Gaussian filtering to blur the areas of the frame defined by the bounding boxes. This effectively obscures the detected faces.
- Step 4: Display the processed frame using the `step` function of the `VideoPlayer` object.

```
while hasFrame(reader)
    % Step 1 %
    videoFrame = readFrame(reader);
    % Step 2 %
    bboxes = detect(detector,videoFrame,Threshold=0.2);
    % Step 3 %
    if ~isempty(bboxes)
        videoFrame = helperBlurFaces(videoFrame,bboxes);
    end
    % Step 4 %
    step(videoPlayer,videoFrame)
end
```

Call the `release` function to free up the resources allocated to the `VideoPlayer` object.

```
release(videoPlayer)
```

The `helperBlurFaces` function applies Gaussian filtering to the regions defined by each bounding box, which correspond to detected faces.

```
function I = helperBlurFaces(I,bbox)
for j=1:size(bbox,1)
    xbox = round(bbox(j,:));
    subImage = imcrop(I,xbox);
    blurred = imgaussfilt(subImage,12);
    I(xbox(2):xbox(2)+xbox(4),xbox(1):xbox(1)+xbox(3),1:end) = blurred;
end
end
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `faceDetector` object supports the generation of generic code only, which does not depend on any third-party libraries.
- The `roi` argument of the `detect` object function must be a code generation constant (`coder.const()`) and a 1-by-4 vector.
- The `AutoResize` name-value argument of the `detect` object function must be a code generation constant (`coder.const()`).
- The `detect` object function supports only the `Threshold`, `SelectStrongest`, `MinSize`, `MaxSize`, `MiniBatchSize`, and `AutoResize` name-value arguments.
- The `detect` object function does not support code generation for the `ds` input argument, which specifies a datastore of test images.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

detect

Detect faces in images using deep learning based face detector

Syntax

```
bboxes = detect(detector,I)
[bboxes,scores] = detect(detector,I)
[bboxes,scores,labels] = detect(detector,I)
detectionResults = detect(detector,ds)
[___] = detect(___,roi)
[___] = detect(___,Name=Value)
```

Description

Add-On Required: This feature requires the Computer Vision Toolbox Model for RetinaFace Face Detection add-on.

`bboxes = detect(detector,I)` detects faces within a single image or an array of images, `I`, using a pretrained RetinaFace face detector, `detector`. The `detect` function returns the locations of detected faces in the input image as a set of bounding boxes.

Note This functionality requires Deep Learning Toolbox and the Computer Vision Toolbox Model for RetinaFace Face Detection. You can install the Computer Vision Toolbox Model for RetinaFace Face Detection from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

`[bboxes,scores] = detect(detector,I)` returns the confidence scores for the bounding boxes along with their locations.

`[bboxes,scores,labels] = detect(detector,I)` also returns a categorical array of the labels assigned to the bounding boxes.

`detectionResults = detect(detector,ds)` returns a table containing the predicted face bounding boxes, their associated confidence scores, and the corresponding labels for all the images in the input datastore `ds`.

`[___] = detect(___,roi)` detects faces within the rectangular region of interest `roi`, in addition to any combination of arguments from previous syntaxes.

`[___] = detect(___,Name=Value)` specifies options using one or more name-value arguments. For example, `Threshold=0.75` specifies a detection threshold of 0.75.

Examples

Detect Faces in Image Using RetinaFace Detector

Read an input image into the MATLAB® workspace.

```
I = imread("visionteam1.jpg");
```

Create a face detector object using the `faceDetector` function. The default configuration of the object loads a small, pretrained RetinaFace deep learning detector for face detection. The small network uses MobileNet-0.25 as the backbone network.

```
detector = faceDetector
```

```
detector =
  faceDetector with properties:

     ModelName: "small-network"
    ClassNames: face
     InputSize: [640 640]
```

Detect faces in the image using the `detect` function of the `faceDetector` object. The `detect` function returns bounding boxes, detection scores, and labels for the detected faces.

```
[bboxes,scores,labels] = detect(detector,I);
```

Overlay bounding boxes, labels, and scores on the image using the `insertObjectAnnotation` function.

```
detectedImg = insertObjectAnnotation(I,"rectangle",bboxes,scores);
```

Display the detection results.

```
table(bboxes,scores,labels)
```

```
ans=6×3 table
             bboxes                scores     labels
    ___________________________    _______    ______

```

Detect Faces Within Region of Interest

Create a face detector object using the `faceDetector` function. Specify the detector name as "`large-network`". This configuration loads a pretrained RetinaFace face detector with ResNet-50 as the backbone network for face detection. The network has many layers and offers improved detection accuracy.

```
detector = faceDetector("large-network")
```

```
detector =
  faceDetector with properties:

     ModelName: "large-network"
    ClassNames: face
     InputSize: [640 640]
```

Read an input image into the MATLAB® workspace.

```
I = imread("boats.png");
```

Specify a region of interest (ROI) in the image to detect faces.

```
roi = [5 400 400 200];
```

Display the image and the ROI.

```
roiImg = insertObjectAnnotation(I,"rectangle",roi,"ROI");
figure
imshow(roiImg)
```

Detect faces in the specified ROI using the `detect` function of the `faceDetector` object.

```
[bboxes,scores,labels] = detect(detector,I,roi);
```

Display the computed bounding boxes, scores, and the corresponding labels as a table.

```
table(bboxes,scores,labels)
```

```
ans=2×3 table
            bboxes              scores     labels
    ____________________________    _______    ______

    253    551      7     10    0.94679     face

```

Overlay bounding boxes and scores on the image using the `insertObjectAnnotation` function.

```
detectedImg = insertObjectAnnotation(roiImg,"rectangle",bboxes,scores);
```

Display the detection results.

```
figure
imshow(detectedImg)
```

Detect Faces in Video Using RetinaFace Detector

Create a face detector object using the `faceDetector` function. Specify the detector name as "`large-network`". This configuration loads a pretrained RetinaFace face detector with ResNet-50 as the backbone network for face detection.

```
detector = faceDetector("large-network");
```

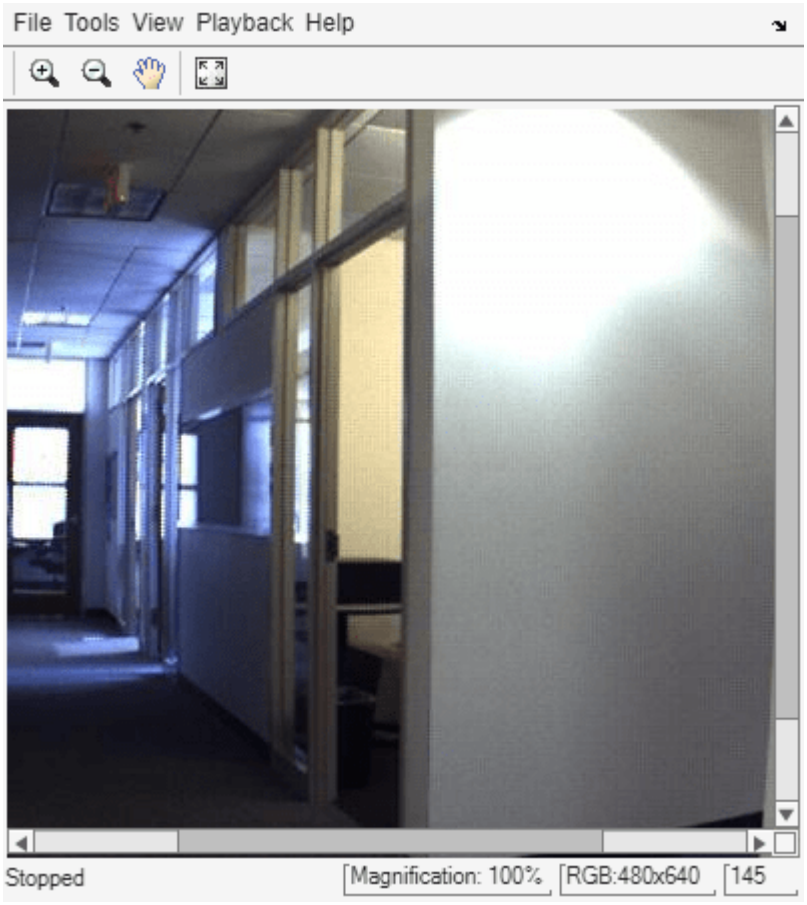
Create a `VideoReader` object to read video data from a video file.

```
reader = VideoReader('handshake_right.avi');
```

Configure a `VideoPlayer` object to display the video frames and the face detection results.

```
videoPlayer = vision.VideoPlayer(Position=[0 0 400 400]);
```

Read and iterate over each frame in the video using a `while` loop. Perform these steps to detect faces and display the detection results.



- Step 1: Read the current video frame with the `readFrame` function of the `VideoReader` object.
- Step 2: Detect faces in the video frame using the `detect` function of the `faceDetector` object. The `detect` function returns bounding boxes and detection scores for the detected faces.
- Step 3: Overlay bounding boxes and scores on the video frame using the `insertObjectAnnotation` function.
- Step 4: Display the annotated frame using the `step` function of the `VideoPlayer` object.

```
while hasFrame(reader)
    % Step 1 %
    videoFrame = readFrame(reader);
```

```
    % Step 2 %
    [bboxes,scores] = detect(detector,videoFrame);
    % Step 3 %
    videoFrame= insertObjectAnnotation(videoFrame,"rectangle",bboxes,scores);
    % Step 4 %
    step(videoPlayer,videoFrame)
end
```

Call the `release` function to free up the resources allocated to the `VideoPlayer` object.

```
release(videoPlayer)
```

Detect and Blur Faces in Video

Create a face detector object using the `faceDetector` function. By default, the function uses the RetinaFace detector with a small backbone network for face detection.

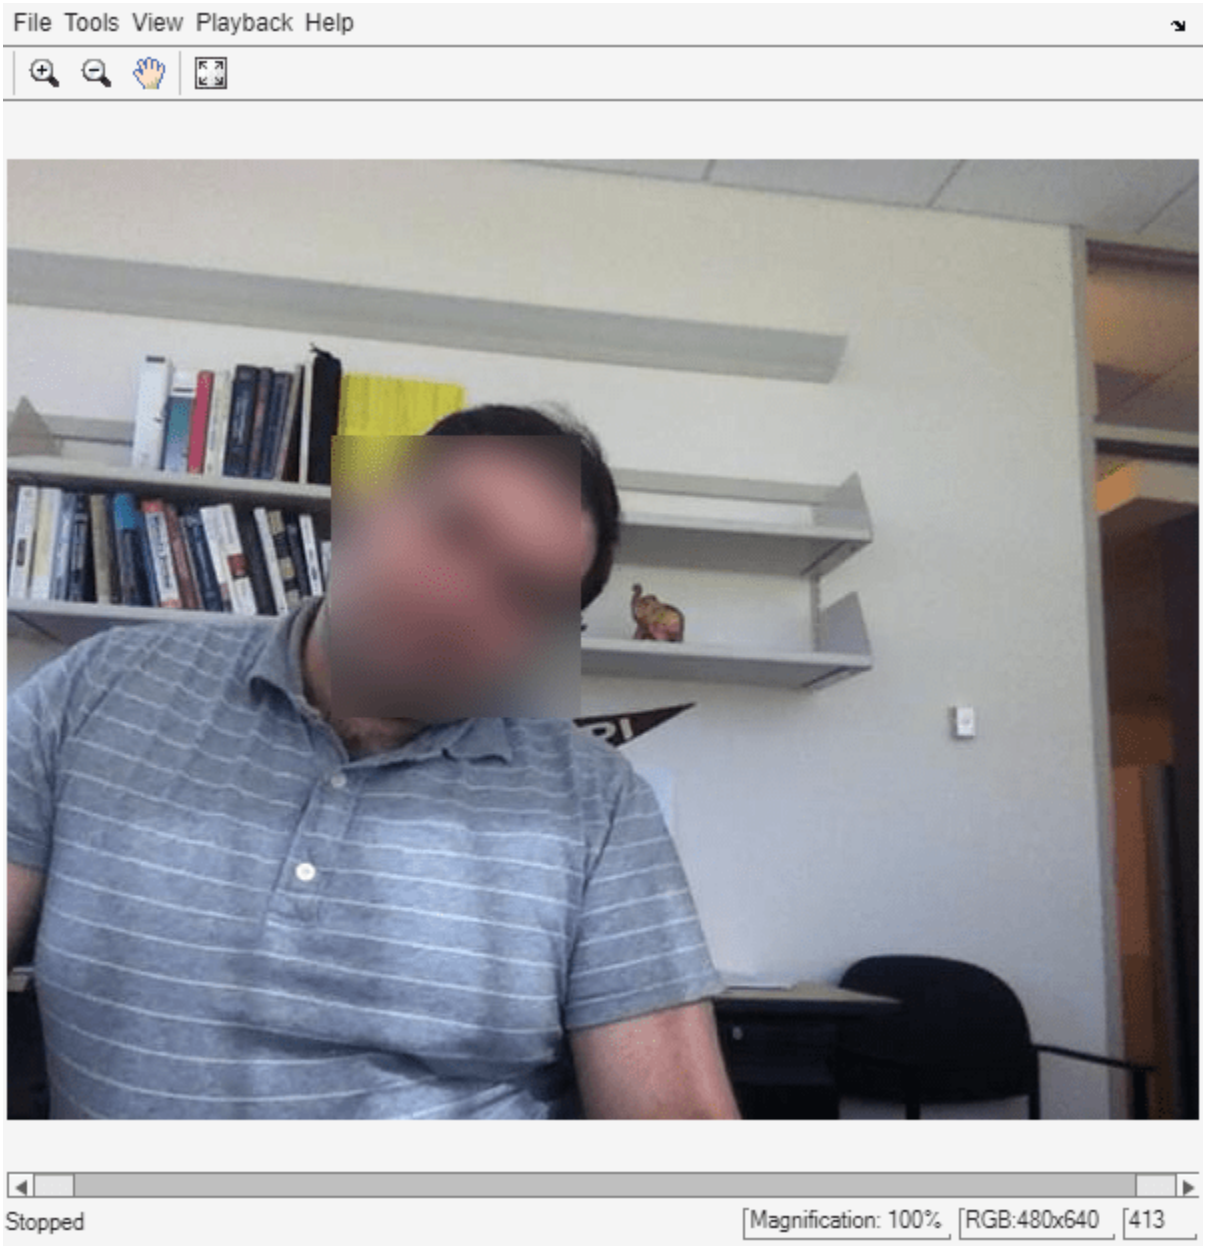
```
detector = faceDetector;
```

Create a `VideoReader` object to read video data from a video file.

```
reader = VideoReader('tilted_face.avi');
```

Configure a `VideoPlayer` object to display the video frames and the face detection results.

```
videoPlayer = vision.VideoPlayer(Position=[0 0 600 600]);
```



Read and iterate over each frame in the video using a `while` loop. Perform these steps to detect faces and display the detection results.

- Step 1: Read the current video frame with the `readFrame` function of the `VideoReader` object.
- Step 2: Detect faces in the video frame using the `detect` function of the `faceDetector` object. The `detect` function returns bounding boxes for the detected faces.
- Step 3: If the current frame has detected faces, use the helper function `helperBlurFaces` to blur the faces in the frame. The helper function applies Gaussian filtering to blur the areas of the frame defined by the bounding boxes. This effectively obscures the detected faces.
- Step 4: Display the processed frame using the `step` function of the `VideoPlayer` object.

```
while hasFrame(reader)
    % Step 1 %
    videoFrame = readFrame(reader);
    % Step 2 %
    bboxes = detect(detector,videoFrame,Threshold=0.2);
    % Step 3 %
    if ~isempty(bboxes)
        videoFrame = helperBlurFaces(videoFrame,bboxes);
    end
    % Step 4 %
    step(videoPlayer,videoFrame)
end
```

Call the `release` function to free up the resources allocated to the `VideoPlayer` object.

```
release(videoPlayer)
```

The `helperBlurFaces` function applies Gaussian filtering to the regions defined by each bounding box, which correspond to detected faces.

```
function I = helperBlurFaces(I,bbox)
for j=1:size(bbox,1)
    xbox = round(bbox(j,:));
    subImage = imcrop(I,xbox);
    blurred = imgaussfilt(subImage,12);
    I(xbox(2):xbox(2)+xbox(4),xbox(1):xbox(1)+xbox(3),1:end) = blurred;
end
end
```

Input Arguments

`detector` — Pretrained RetinaFace face detector

`faceDetector` object

Pretrained RetinaFace face detector, specified as a `faceDetector` object. The face detector has been trained on the WIDER FACE data set.

`I` — Test images

matrix | 3-D numeric array | 4-D numeric array

Test images, specified as one of these values:

- A matrix of form *H*-by-*W* for a grayscale image.
- A 3-D numeric array of form *H*-by-*W*-by-*3* for an RGB image.
- A 4-D numeric array of form *H*-by-*W*-by-*C*-by-*T* for a batch of test images.

H and *W* are the height and width of the images, respectively. *C* is the number of color channels. The value of *C* is 1 for grayscale images and 3 for RGB images. *T* is the number of images in the batch.

When the test image size does not match the network input size, the detector resizes the input image to the value of the `InputSize` property of `detector`, unless you specify `AutoResize` as `false`.

The detector is sensitive to the intensity range of the test images. It was trained on images with an intensity range of [0, 255]. For accurate results, ensure that the test images also have an intensity range of [0, 255].

Data Types: `uint8` | `uint16` | `int16` | `double` | `single`

`ds` — Datastore of test images

`ImageDatastore` object | `CombinedDatastore` object | `TransformedDatastore` object

Datastore of test images, specified as an `ImageDatastore` object, `CombinedDatastore` object, or `TransformedDatastore` object containing the full filenames of the test images. The images in the datastore must be grayscale or RGB images.

`roi` — Region of interest to search

vector of form [*x y width height*]

Region of interest (ROI) to search, specified as a vector of the form [*x y width height*]. The first two elements of the vector specify the coordinates of the upper-left corner of a region, and the third and fourth elements specify the size of that region, in pixels. If the input data is a datastore, the `detect` function applies the same ROI to every image in the datastore.

Note To specify the ROI to search, you must specify `AutoResize` value as `true`, enabling the function to automatically resize the input test images to the network input size.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `detect(detector,I,Threshold=0.25)` specifies a detection threshold of 0.25.

`Threshold` — Detection threshold
`0.5` (default) | scalar in range `[0, 1]`

Detection threshold, specified as a scalar in the range `[0, 1]`. The function removes detections that have scores less than this threshold value.

- To reduce false positives, at the possible expense of missing some detections, increase this value.
- To increase the sensitivity of the detector for detecting faces under challenging lighting conditions, pose variations, and occlusion, decrease the detection threshold. However, this might result in false positives.

`SelectStrongest` — Strongest bounding box selection
`true` or `1` (default) | `false` or `0`

Strongest bounding box selection, specified as a numeric or logical `1` (`true`) or `0` (`false`).

- `true` — Returns only the strongest bounding box for each detected face. The `detect` function calls the `selectStrongestBboxMulticlass` function, which uses nonmaximal suppression to eliminate overlapping bounding boxes based on their confidence scores.

  By default, the `detect` function uses this call to the `selectStrongestBboxMulticlass` function.

  ```
  selectStrongestBboxMulticlass(bboxes,scores,labels, ...
                                RatioType="Union", ...
                                OverlapThreshold=0.45);
  ```

- `false` — Return all detected bounding boxes. You can write a custom function to eliminate overlapping bounding boxes.

`MinSize` — Minimum region size
`[1 1]` (default) | vector of form [*height width*]

Minimum region size containing a face, specified as a vector of the form [*height width*]. Units are in pixels. The minimum region size defines the size of the smallest face in the test image. When you know the minimum size, you can reduce computation time by setting `MinSize` to that value.

`MaxSize` — Maximum region size
`size(I)` (default) | vector of form [*height width*]

Maximum region size, specified as a vector of the form [*height width*]. Units are in pixels. The maximum region size defines the size of the largest face in the test image.

By default, `MaxSize` is set to the height and width of the input image `I`. To reduce computation time, set this value to the known maximum region size in which to detect a face in the input test image.

`MiniBatchSize` — Minimum batch size
`16` (default) | positive integer

Minimum batch size, specified as a positive integer. Adjust the `MiniBatchSize` value to help process a large collection of images. The `detect` function groups images into minibatches of the specified size and processes them as a batch, which can improve computational efficiency at the cost of increased memory requirements. Decrease the minibatch size to use less memory.

`AutoResize` — Automatic resizing of input images
`true` or `1` (default) | `false` or `0`

Automatic resizing of the input images to preserve the aspect ratio, specified as a numeric or logical `1` (`true`) or `0` (`false`). When you specify `AutoResize` as `true`, the `detect` function resizes images to the nearest `InputSize` dimension, while preserving the aspect ratio. Specify `AutoResize` as `false` when performing image tiling-based inference, or inference at full test image size.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as one of these values:

- `"auto"` — Use a GPU if Parallel Computing Toolbox is installed and a supported GPU device is available. Otherwise, use the CPU.
- `"gpu"` — Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Use the CPU.

`Acceleration` — Performance optimization
`"auto"` (default) | `"mex"` | `"none"`

Performance optimization, specified as one of these options:

- `"auto"` — Automatically apply a number of compatible optimizations suitable for the input network and hardware resource.
- `"mex"` — Compile and execute a MEX function. This option is available only when using a GPU. Using a GPU requires Parallel Computing Toolbox and a CUDA-enabled NVIDIA GPU. If Parallel Computing Toolbox or a suitable GPU is not available, then the `detect` function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"none"` — Do not use acceleration.

Using the `Acceleration` options `"auto"` and `"mex"` can offer performance benefits on subsequent calls with compatible parameters, at the expense of an increased initial run time. Use performance optimization when you plan to call the function multiple times using new input data.

The `"mex"` option generates and executes a MEX function based on the network and parameters used in the function call. You can have several MEX functions associated with a single network at one time. Clearing the network variable also clears any MEX functions associated with that network.

The `"mex"` option is available only for input data specified as a numeric array, cell array of numeric arrays, table, or image datastore. No other types of datastore support the `"mex"` option.

The `"mex"` option is available only when you are using a GPU. You must also have a C/C++ compiler installed. For setup instructions, see “Set Up Compiler” (GPU Coder).

`"mex"` acceleration does not support all layers. For a list of supported layers, see “Supported Layers” (GPU Coder).

Output Arguments

bboxes — Locations of detected faces

M-by-4 matrix | *B*-by-1 cell array

Locations of the detected faces within the input image or images, returned as one of these options:

- *M*-by-4 matrix — Returned when the input is a single test image. *M* is the number of bounding boxes detected in an image. Each row of the matrix is of the form [*x y width height*]. The *x* and *y* values specify the coordinates of the upper-left corner, and *width* and *height* specify the size, of the corresponding bounding box, in pixels.
- *B*-by-1 cell array — Returned when the input is a batch of images, where *B* is the number of test images in the batch. Each cell in the array contains an *M*-by-4 matrix specifying the bounding boxes detected within the corresponding image.

scores — Detection confidence scores

M-by-1 numeric vector | *B*-by-1 cell array

Detection confidence scores for each bounding box, returned as one of these options:

- *M*-by-1 numeric vector — Returned when the input is a single test image. *M* is the number of bounding boxes detected in the image.
- *B*-by-1 cell array — Returned when the input is a batch of test images, where *B* is the number of test images in the batch. Each cell in the array contains an *M*-element row vector, where each element indicates the detection score for a bounding box in the corresponding image.

Each confidence score value is in the range `[0, 1]`.

labels — Labels for bounding boxes

M-by-1 categorical vector | *B*-by-1 cell array

Labels for bounding boxes, returned as one of these options:

- *M*-by-1 categorical vector — Returned when the input is a single test image. *M* is the number of bounding boxes detected in the image.
- *B*-by-1 cell array — Returned when the input is a batch of test images. *B* is the number of test images in the batch. Each cell in the array contains an *M*-by-1 categorical vector containing the class name.

By default, the output label value is `"face"`.

detectionResults — Detection results

three-column table

Detection results when the input is a datastore of test images, `ds`, returned as a table with these columns:

bboxes	scores	labels
Predicted bounding boxes, defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y width height*], where: • *M* is the number of axis-aligned rectangles. • *x* and `y` specify the coordinates of the upper-left corner of the rectangle, in pixels. • *width* specifies the width of the rectangle, which is its length along the *x*-axis, in pixels. • *height* specifies the height of the rectangle, which is its length along the *y*-axis, in pixels.	Confidence scores of the detected class for each bounding box, returned as an *M*-by-1 numeric vector with values in the range `[0, 1]`.	Labels assigned to the bounding boxes, returned as an *M*-by-1 categorical vector. By default, the value is `"face"`.

Version History

Introduced in R2025a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `roi` argument of the `detect` object function must be a code generation constant (`coder.const()`) and a 1-by-4 vector.
- The `AutoResize` name-value argument of the `detect` object function must be a code generation constant (`coder.const()`).
- The `detect` object function supports only the `Threshold`, `SelectStrongest`, `MinSize`, `MaxSize`, `MiniBatchSize`, and `AutoResize` name-value arguments.

- The `detect` object function does not support code generation for the `ds` input argument, which specifies a datastore of test images.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

GPU Arrays

multiCameraParameters

Store multi-camera system parameters

Description

The `multiCameraParameters` object stores the intrinsic and extrinsic parameters of a multi-camera system estimated during multi-camera calibration.

Creation

Create a `multiCameraParameters` object using the `estimateMultiCameraParameters` function.

Properties

Extrinsic Parameters

`CameraPoses` — Pose of each camera relative to origin camera
numCameras-element vector of `rigidtform3d` objects

This property is read-only.

Pose of each camera relative to the origin camera `ReferenceCameraIndex`, specified as a *numCameras*-element vector of `rigidtform3d` objects. *numCameras* represents the number of cameras.

`ReferenceCameraIndex` — Index of origin camera
integer

This property is read-only.

Index of the origin camera, specified as an integer. This camera defines the reference coordinate system, and all other camera poses are defined relative to this reference camera. The pose of the reference camera is represented as `rigidtform3d(eye(4))`.

`NumCameras` — Number of cameras in system
integer

Number of cameras in the system, specified as an integer.

Intrinsic Parameters

`Intrinsics` — Intrinsic parameters for all cameras in multi-camera system
numCameras-element cell array

This property is read-only.

Intrinsic parameters for all cameras in the multi-camera system, specified as a *numCameras*-element cell array containing `cameraIntrinsics` objects, `fisheyeIntrinsics` objects, or a combination of both. *numCameras* is the number of cameras.

Accuracy of Estimated Parameters

`MeanReprojectionError` — Average Euclidean distance
scalar

This property is read-only.

Average Euclidean distance between reprojected points and detected points over all image pairs, specified as a scalar in pixels.

Data Types: `double`

`MeanReprojectionErrorPerCamera` — Average reprojection error for each camera
numCameras-element vector

This property is read-only.

Average reprojection error for each camera, specified a *numCameras*-element vector. *numCameras* is the number of cameras.

`MeanReprojectionErrorPerImage` — Average reprojection error of each image
numViews-by-*numCameras* vector

This property is read-only.

Average reprojection error of each image in pixels, specified as an *numViews*-by-*numCameras* vector.

`MeanReprojectionErrorPerView` — Average reprojection error of each view
numViews-by-1 vector

This property is read-only.

Average reprojection error of each view in pixels, specified as an *numViews*-by-1 vector

`ReprojectedPoints` — World points reprojected onto calibration images
numKeyPoints-by-2-by-*numViews*-by-*numCameras*-by-*patternCount* matrix

This property is read-only.

World points reprojected onto calibration images, specified as a *numKeyPoints*-by-2-by-*numViews*-by-*numCameras*-by-*patternCount* matrix.

Settings Used to Estimate Multi-Camera Parameters

`PatternCount` — Number of unique calibration patterns captured in calibration images
scalar

This property is read-only.

Number of unique calibration patterns captured in the calibration images, specified as a scalar.

`PatternPoses` — Poses of calibration patterns relative to reference pattern
P-element vector

This property is read-only.

Poses of calibration patterns relative to the reference pattern, specified as a *P*-element vector of `rigidtform3d` objects, where *P* represents the number of calibration patterns. The reference pattern is the first element of the `PatternPoses` vector, stored as `PatternPoses(1)`. Subsequent elements represent the poses of other patterns relative to this reference pattern. The reference pattern's pose is given by `rigidtform3d(eye(4))`.

`NumViews` — Number of pattern views to estimate camera poses
integer

This property is read-only.

Number of pattern views to estimate camera poses, specified as an integer.

`CovisibilityMatrix` — Covisibility of cameras
numCameras-by-*numCameras* logical matrix

This property is read-only.

Covisibility of cameras based on the calibration images, specified as a *numCameras*-by-*numCameras* logical matrix. *numCameras* is the number of cameras.

`WorldPoints` — World coordinates of pattern keypoints
numKeyPoints-by-2 matrix

This property is read-only.

World coordinates of pattern keypoints in the calibration pattern, specified as a *numKeyPoints*-by-2 matrix. *numKeyPoints* is the number of keypoints in the pattern.

`WorldUnits` — Units of world points
`"mm"` (default) | character vector | string scalar

This property is read-only.

Units of world points, specified as a character vector or string scalar. This value describes the unit of measure.

Examples

Calibrate a Multi-Camera System using a ChArUco board

Estimate the relative position and orientation of six cameras with overlapping fields of view by using calibration images that contain a single ChArUco board.

Download the calibration images.

```
calibImagesURL = "https://www.mathworks.com/supportfiles/vision/data/overlapping-cameras-charuco
calibImagesDir = fullfile(pwd,"overlapping-cameras-charuco");
calibImagesZip = fullfile(pwd,"overlapping-cameras-charuco.zip");
if ~exist(calibImagesZip,"file")
    disp("Downloading calibration images (52 MB)...")
    websave(calibImagesZip,calibImagesURL);
end
```

```
Downloading calibration images (52 MB)...
```

```
if ~exist(calibImagesDir,"dir")
    unzip(calibImagesZip,pwd)
end
```

Specify calibration image filenames for each camera.

```
numCameras = 6;
camDirPrefix = "Cam00";
imageFiles = cell(1,numCameras);
for i = 1:numCameras
    camDir = fullfile(calibImagesDir,camDirPrefix+i);
    imds = imageDatastore(camDir);
    imageFiles{i} = imds.Files;
end
imageFiles = [imageFiles{:}];
```

Define the ChArUco board properties. Specify checker size and marker size in centimeters.

```
markerFamily = "DICT_6X6_1000";
patternDims = [5 5];
markerSize = 6.8;   % in cm
checkerSize = 9.15; % in cm
numKeyPoints = prod(patternDims - 1);
minMarkerId = 144;
```

Detect the key points of the ChArUco board in the calibration images.

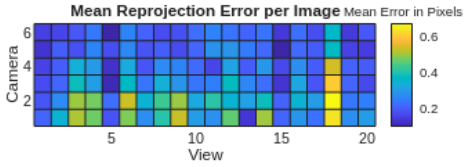
```
imagePoints = detectPatternPoints(imageFiles,"charuco-board",patternDims, ...
    markerFamily,checkerSize,markerSize,MinMarkerID=minMarkerId);
```

```
[==================================================] 100%
Elapsed time: 00:00:09
Estimated time remaining: 00:00:00
```

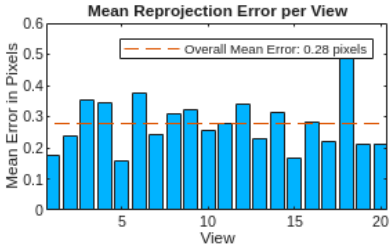
Generate the world points for the pattern.

```
worldPoints = patternWorldPoints("charuco-board",patternDims,checkerSize);
```

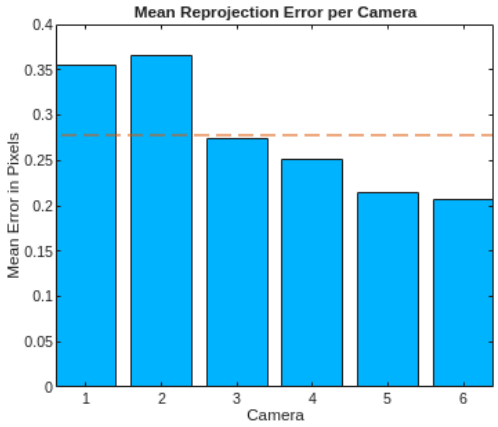
Load the intrinsic parameters of the six cameras. These parameters have been estimated using the “Using the Single Camera Calibrator App”.



```
ld = load("sixCameraIntrinsics.mat");
```



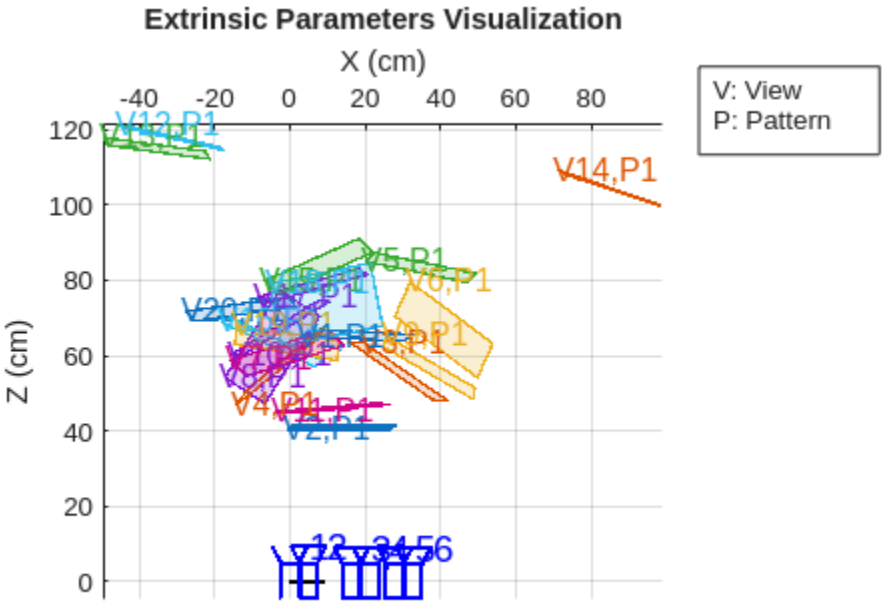
Perform multi-camera calibration.



```
params = estimateMultiCameraParameters(imagePoints,worldPoints,ld.intrinsics,WorldUnits="cm");
```

Visualize the calibration accuracy.

```
figure(Position=[100,100,1000,400])
showReprojectionErrors(params)
```



Visualize the camera extrinsic parameters.

```
figure
showExtrinsics(params)
view(2)
```

Version History

Introduced in R2025a

R2026a: New properties to support multiple calibration patternsPatternCount and PatternPoses properties

Added the `PatternCount`, `PatternPoses` `MeanReprojectionErrorPerView`, `MeanReprojectionErrorPerImage`, and `ReprojectedPoints` properties to support multiple calibration patterns.

R2026a: Computation of the `MeanReprojectionError` property has changed

The `MeanReprojectionError` property is computed as the mean of `MeanReprojectionErrorPerImage` over all images, omitting `NaN` values.

peopleDetector

Detect people using pretrained deep learning object detector

Description

Add-On Required: This feature requires the Computer Vision Toolbox Model for RTMDet Object Detection add-on.

The `peopleDetector` object creates a deep learning object detector, trained on the COCO data set, to detect people in an image of arbitrary size. This feature also requires the Deep Learning Toolbox product.

Creation

Syntax

```
detector = peopleDetector
detector = peopleDetector(name)
detector = peopleDetector( ___ ,Name=Value)
```

Description

`detector = peopleDetector` returns a deep learning-based people detector object that is pretrained on the COCO data set for people detection.

`detector = peopleDetector(name)` returns a deep learning-based people detector object of the specified model `name` that is pretrained on the COCO data set.

`detector = peopleDetector( ___ ,Name=Value)` sets the `InputSize` property of the detector using name-value arguments in addition to any combination of arguments from previous syntaxes.

Input Arguments

`name` — Name of pretrained people detector model
`"small-network"` (default) | `"tiny-network"` | `"medium-network"` | `"large-network"`

Name of the pretrained people detector model trained on the COCO data set, specified as one of these values.

- `"tiny-network"` — This pretrained people detector deep learning model has the fewest filters and fewest convolutional layers. Use the `"tiny-network"` model when you have few available computational resources and require the fastest performance in terms of speed and real-time inference.
- `"small-network"` — Use `"small-network"` for a higher level of accuracy than `"tiny-network"` when moderate computational resources are available.
- `"medium-network"` — Use `"medium-network"` for a higher level of accuracy than `"small-network"` when more computational resources, such as GPU hardware, are available.

- `"large-network"` — This pretrained people detector deep learning model has the largest number of filters and convolutional layers. Use the `"large-network"` network for the highest level accuracy in people detection at the expense of computational cost and speed.

Data Types: `char` | `string`

Properties

`ModelName` — Name for people detector

`'small-network'` (default) | `'tiny-network'` | `'medium-network'` | `'large-network'`

This property is read-only.

Name for the people detector, stored as a character vector. By default, this property value is set to the value of the `name` input argument.

`ClassNames` — Name of object class

`{'person'}`

This property is read-only.

Name of the object class to be detected, stored as a cell array of character vector. By default, the value is `'person'`.

`InputSize` — Image size used for inference

`[640 640]` (default) | two-element row vector of integers

Image size to be used for inference, stored as a two-element row vector of integers of the form `[`*`H W`*`]`. *H* and *W* correspond to the height and width of the input image, respectively.

By default, the `InputSize` property value is set to the network's input size `[640 640]`, which is the size of the training images.

To set a custom value for this property, specify the property and its value as a name,value pair when creating the object. For example, `InputSize=[224 224]` sets the `InputSize` property to `[224 224]`.

The `detect` function resizes the test image to the dimensions specified by the `InputSize` property before performing the detections. If the resolution of the person class to be detected is too small in the test image, increase the `InputSize` property value for better detection accuracy. However, increasing the `InputSize` property value will also increase the computational cost.

Object Functions

detect Detect people using pretrained deep learning-based people detector

Examples

Detect People Using People Detector

Load the `"large-network"` pretrained deep learning-based people detector model.

```
detector = peopleDetector("large-network");
```

Read an image into the workspace.

```
I = imread("occlusion.png");
```

Detect all the people in the image regardless of their scale, orientation, or occlusion level.

```
[bboxes,scores] = detect(detector,I);
```

Annotate the detected people with bounding boxes, and display their detection scores.

```
detectedImg = insertObjectAnnotation(I,"rectangle",bboxes,scores);
figure
imshow(detectedImg)
```

Version History

Introduced in R2024b

R2025a: Generate C/C++ code using MATLAB Coder

The `peopleDetector` object now supports the generation of C/C++ code (requires MATLAB Coder).

R2025a: Generate CUDA code using GPU Coder

The `peopleDetector` object now supports the generation of CUDA code (requires GPU Coder™).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `peopleDetector` object supports the generation of generic code only, which does not depend on any third-party libraries.
- The `roi` argument of the `detect` object function must be a code generation constant (`coder.const()`) and a 1-by-4 vector.
- The `AutoResize` name-value argument of the `detect` object function must be a code generation constant (`coder.const()`).
- The `detect` object function supports only the `Threshold`, `SelectStrongest`, `MinSize`, `MaxSize`, `MiniBatchSize`, and `AutoResize` name-value arguments.
- The `detect` object function does not support code generation for the `ds` input argument, which specifies a datastore of test images.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

detect

Detect people using pretrained deep learning-based people detector

Syntax

```
bboxes = detect(detector,I)
[bboxes,scores] = detect(detector,I)
[bboxes,scores,labels] = detect(detector,I)
detectionResults = detect(detector,ds)
[___] = detect(___,roi)
[___] = detect(___,Name=Value)
```

Description

`bboxes = detect(detector,I)` detects people within a single image or a batch of images, `I`, using a pretrained deep learning-based people detector, `detector`. The `detect` function returns the locations of detected people in the input image as a set of bounding boxes.

Note This functionality requires Deep Learning Toolbox.

`[bboxes,scores] = detect(detector,I)` returns the confidence scores for the bounding boxes along with their locations.

`[bboxes,scores,labels] = detect(detector,I)` also returns a categorical array of person labels assigned to the bounding boxes.

`detectionResults = detect(detector,ds)` returns a table of predicted people for all the images in the input datastore `ds`.

`[___] = detect(___,roi)` detects people within the rectangular region of interest `roi`, in addition to any combination of arguments from previous syntaxes.

`[___] = detect(___,Name=Value)` specifies options using one or more name-value arguments. For example, `Threshold=0.75` specifies a detection threshold of 0.75.

Examples

Detect People Within ROI Using Pretrained People Detector

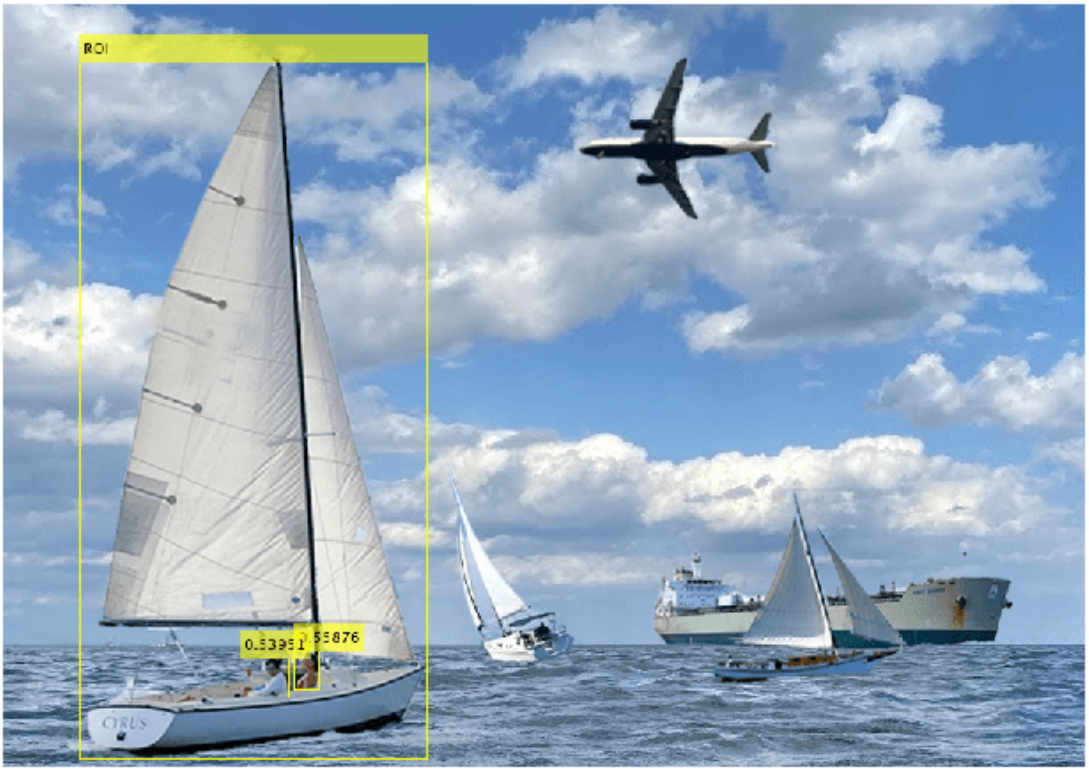
Load the default pretrained people detector model.

```
detector = peopleDetector;
```

Read a test image into the workspace.

```
I = imread("boats.png");
```

Specify a rectangular region of interest (ROI) that encloses the first boat within the test image.



```
roiBox = [65 50 295 590];
```

Detect people in the first boat in the image using a `Threshold` value of 0.45.

```
[bboxes,scores] = detect(detector,I,roiBox,Threshold=0.45);
```

Annotate the detected people with bounding boxes and their detection scores.

```
img = insertObjectAnnotation(I,"rectangle",roiBox,"ROI");
detectedImg = insertObjectAnnotation(img,"rectangle",bboxes,scores);
figure
imshow(detectedImg)
```

Input Arguments

`detector` — people detector

`peopleDetector` object

People detector, specified as a `peopleDetector` object.

`I` — Test images

matrix | 3-D numeric array | 4-D numeric array

Test images, specified as one of these values:

- A matrix of form *H*-by-*W* for a grayscale image.
- A 3-D numeric array of form *H*-by-*W*-by-*3* for an RGB image.
- A 4-D numeric array of form *H*-by-*W*-by-*C*-by-*T* for a batch of test images.

H and *W* are the height and width of the images, respectively. *C* is the number of color channels. The value of *C* is:

- 1 for grayscale images.
- 3 for RGB images.

T is the number of images in the batch.

When the test image size does not match the network input size, the detector resizes the input image to the value of the `InputSize` property of `detector`, unless you specify `AutoResize` as `false`.

The detector is sensitive to the range of the test image. Therefore, ensure that the test image range is similar to the range of the images used to train the detector. For example, if the detector was trained on `uint8` images, rescale this input image to the range [0, 255] by using the `im2uint8` or `rescale` function.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single`

`ds` — Datastore of test images
`ImageDatastore` object | `CombinedDatastore` object | `TransformedDatastore` object

Datastore of test images, specified as an `ImageDatastore` object, `CombinedDatastore` object, or `TransformedDatastore` object containing the full filenames of the test images. The images in the datastore must be grayscale or RGB images.

`roi` — Region of interest to search
vector of form [*x y width height*]

Region of interest (ROI) to search, specified as a vector of the form [*x y width height*]. The vector specifies the upper-left corner and size of a region, in pixels. If the input data is a datastore, the `detect` function applies the same ROI to every image in the datastore.

Note To specify the ROI to search, the `AutoResize` value must be `true`, enabling the function to automatically resize the input test images to the network input size.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `detect(detector,I,Threshold=0.5)` specifies a detection threshold of 0.5.

`Threshold` — Detection threshold
`0.25` (default) | scalar in range `[0, 1]`

Detection threshold, specified as a scalar in the range `[0, 1]`. The function removes detections that have scores less than this threshold value. To reduce false positives, at the possible expense of missing some detections, increase this value.

`SelectStrongest` — Strongest bounding box selection
`true` or `1` (default) | `false` or `0`

Strongest bounding box selection, specified as a numeric or logical `1` (`true`) or `0` (`false`).

- `true` — Returns only the strongest bounding box for each detected person. The `detect` function calls the `selectStrongestBboxMulticlass` function, which uses nonmaximal suppression to eliminate overlapping bounding boxes based on their confidence scores.

  By default, the `detect` function uses this call to the `selectStrongestBboxMulticlass` function.

  ```
  selectStrongestBboxMulticlass(bboxes,scores,labels, ...
                                RatioType="Union", ...
                                OverlapThreshold=0.45);
  ```

- `false` — Return all detected bounding boxes. You can write a custom function to eliminate overlapping bounding boxes.

`MinSize` — Minimum region size
`[1 1]` (default) | vector of form [*height width*]

Minimum region size containing a person, specified as a vector of the form [*height width*]. Units are in pixels. The minimum region size defines the size of the smallest person that the trained network can detect. When you know the minimum size, you can reduce computation time by setting `MinSize` to that value.

`MaxSize` — Maximum region size
`size(I)` (default) | vector of form [*height width*]

Maximum region size, specified as a vector of the form [*height width*]. Units are in pixels. The maximum region size defines the size of the largest person that the trained network can detect.

By default, `MaxSize` is set to the height and width of the input image `I`. To reduce computation time, set this value to the known maximum region size in which to detect people in the input test image.

`MiniBatchSize` — Minimum batch size
`16` (default) | positive integer

Minimum batch size, specified as a positive integer. Adjust the `MiniBatchSize` value to help process a large collection of images. The `detect` function groups images into minibatches of the specified size and processes them as a batch, which can improve computational efficiency at the cost of increased memory demand. Increase the minibatch size to decrease processing time. Decrease the minibatch size to use less memory.

`AutoResize` — Automatic resizing of input images
`true` or `1` (default) | `false` or `0`

Automatic resizing of input images to preserve the aspect ratio, specified as a numeric or logical `1` (`true`) or `0` (`false`). When `AutoResize` is set to `true`, the `detect` function resizes images to the nearest `InputSize` dimension, while preserving the aspect ratio. Set `AutoResize` to logical `false` when performing image tiling-based inference, or inference at full test image size.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as one of these values:

- `"auto"` — Use a GPU if Parallel Computing Toolbox is installed and a supported GPU device is available. Otherwise, use the CPU.
- `"gpu"` — Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Use the CPU.

`Acceleration` — Performance optimization
`"auto"` (default) | `"mex"` | `"none"`

Performance optimization, specified as one of these options:

- `"auto"` — Automatically apply a number of compatible optimizations suitable for the input network and hardware resource.
- `"mex"` — Compile and execute a MEX function. This option is available only when using a GPU. Using a GPU requires Parallel Computing Toolbox and a CUDA-enabled NVIDIA GPU. If Parallel Computing Toolbox or a suitable GPU is not available, then the `detect` function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"none"` — Do not use acceleration.

Using the `Acceleration` options `"auto"` and `"mex"` can offer performance benefits on subsequent calls with compatible parameters, at the expense of an increased initial run time. Use performance optimization when you plan to call the function multiple times using new input data.

The `"mex"` option generates and executes a MEX function based on the network and parameters used in the function call. You can have several MEX functions associated with a single network at one time. Clearing the network variable also clears any MEX functions associated with that network.

The `"mex"` option is available only for input data specified as a numeric array, cell array of numeric arrays, table, or image datastore. No other types of datastore support the `"mex"` option.

The `"mex"` option is available only when you are using a GPU. You must also have a C/C++ compiler installed. For setup instructions, see “Set Up Compiler” (GPU Coder).

`"mex"` acceleration does not support all layers. For a list of supported layers, see “Supported Layers” (GPU Coder).

Output Arguments

`bboxes` — Locations of people detected
M-by-4 matrix | *B*-by-1 cell array

Locations of people detected within the input image or images, returned as one of these options:

- *M*-by-4 matrix — Returned when the input is a single test image. *M* is the number of bounding boxes detected in an image. Each row of the matrix is of the form [*x y width height*]. The *x* and *y* values specify the upper-left corner coordinates, and *width* and *height* specify the size, of the corresponding bounding box, in pixels.

- *B*-by-1 cell array — Returned when the input is a batch of images, where *B* is the number of test images in the batch. Each cell in the array contains an *M*-by-4 matrix specifying the bounding boxes detected within the corresponding image.

`scores` — Detection confidence scores

M-by-1 numeric vector | *B*-by-1 cell array

Detection confidence scores for each bounding box in the range `[0, 1]`, returned as one of these options:

- *M*-by-1 numeric vector — Returned when the input is a single test image. *M* is the number of bounding boxes detected in the image.
- *B*-by-1 cell array — Returned when the input is a batch of test images, where *B* is the number of test images in the batch. Each cell in the array contains an *M*-element row vector, where each element indicates the detection score for a bounding box in the corresponding image.

`labels` — Labels for bounding boxes

M-by-1 categorical vector | *B*-by-1 cell array

Labels for bounding boxes, returned as one of these options:

- *M*-by-1 categorical vector — Returned when the input is a single test image. *M* is the number of bounding boxes detected in the image.
- *B*-by-1 cell array — Returned when the input is a batch of test images. *B* is the number of test images in the batch. Each cell in the array contains an *M*-by-1 categorical vector containing the class name.

`detectionResults` — Detection results

three-column table

Detection results when the input is a datastore of test images, `ds`, returned as a table with these columns:

`bboxes`	`scores`	`labels`
Predicted bounding boxes, defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and `y` specify the upper-left corner coordinates of the rectangle, in pixels. • *w* specifies the width of the rectangle, which is its length along the *x*-axis, in pixels. • *h* specifies the height of the rectangle, which is its length along the *y*-axis, in pixels.	Confidence scores of the person class for each bounding box, returned as an *M*-by-1 numeric vector with values in the range `[0, 1]`.	Predicted person class labels assigned to the bounding boxes, returned as an *M*-by-1 categorical vector.

Version History

Introduced in R2024b

R2025a: Generate C/C++ code using MATLAB Coder

The `detect` object function now supports the generation of C/C++ code (requires MATLAB Coder).

R2025a: Generate CUDA code using GPU Coder

The `detect` object function now supports the generation of CUDA code (requires GPU Coder).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `peopleDetector` object supports the generation of generic code only, which does not depend on any third-party libraries.
- The `roi` argument of the `detect` object function must be a code generation constant (`coder.const()`) and a 1-by-4 vector.
- The `AutoResize` name-value argument of the `detect` object function must be a code generation constant (`coder.const()`).
- The `detect` object function supports only the `Threshold`, `SelectStrongest`, `MinSize`, `MaxSize`, `MiniBatchSize`, and `AutoResize` name-value arguments.
- The `detect` object function does not support code generation for the `ds` input argument, which specifies a datastore of test images.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

rtmdetObjectDetector

Detect objects using RTMDet object detector

Description

The `rtmdetObjectDetector` object creates an Real-Time Model for object Detection (RTMDet), which is a one-stage, real-time, anchor-free object detector, for detecting objects in an image of arbitrary size. Using this object, you can create a pretrained RTMDet object detector by using RTMDet deep learning networks trained on the COCO data set.

Creation

Syntax

```
detector = rtmdetObjectDetector
detector = rtmdetObjectDetector(name)
detector = rtmdetObjectDetector( ___ ,Name=Value)
```

Description

`detector = rtmdetObjectDetector` creates a RTMDet object detector trained to detect 80 object classes from the COCO data set using a CSP-Darknet network.

`detector = rtmdetObjectDetector(name)` creates a pretrained RTMDet object detector by using the specified RTMDet deep learning network name trained on the COCO data set.

`detector = rtmdetObjectDetector( ___ ,Name=Value)` sets the `InputSize`, and `NormalizationStatistics` properties of the detector using one or more name-value arguments in addition to any combination of arguments from previous syntaxes.

Note This functionality requires Deep Learning Toolbox and the Computer Vision Toolbox Model for RTMDet Object Detection. You can install the Computer Vision Toolbox Model for RTMDet Object Detection from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Input Arguments

`name` — Name of pretrained RTMDet deep learning network
`"small-network-coco"` (default) | `"tiny-network-coco"` | `"medium-network-coco"` | `"large-network-coco"`

Name of the pretrained RTMDet deep learning network, created using CSP-DarkNet as the base network and trained on the COCO data set, specified as one of these values.

- `"tiny-network-coco"` — Pretrained RTMDet-tiny deep learning network. This RTMDet network has the fewest filters and fewest convolutional layers. Use RTMDet-tiny when you have few

available computational resources, and require the fastest performance in terms of speed and real-time inference.

- `"small-network-coco"` — Pretrained RTMDet-small deep learning network. Use RTMDet-small for a higher level of accuracy than RTMDet-tiny when moderate computational resources are available.
- `"medium-network-coco"` — Pretrained RTMDet-medium deep learning network. Use RTMDet-medium for a higher level of accuracy than RTMDet-small when more computational resources, such as GPU hardware are available.
- `"large-network-coco"` — Pretrained RTMDet-large deep learning network. This RTMDet network has the largest number of filters and convolutional layers. Use the RTMDet-large network for the highest level accuracy in object detection at the expense of computational cost and speed.

Tip To improve accuracy and the performance of complex detection tasks, you can increase the pretrained model size at the expense of decreased inference speed, larger computation time, and greater memory requirements. Use RTMDet-tiny for real-time inference at the expense of detection accuracy. Use RTMDet-small for near-real-time applications due to fast inference. Use RTMDet-medium and RTMDet-large when sufficient computational resources are available for the largest accuracy, at the expense of lower computation speeds.

Data Types: `char` | `string`

Properties

`ModelName` — Name for object detector

character vector

This property is read-only.

Name for the object detector, stored as a character vector. By default, this property value is set to the value of the `name` input argument.

`ClassNames` — Names of object classes

cell array of character vectors

This property is read-only.

Names of 80 object classes in COCO data set stored as a cell array. The detector is pre-trained on the COCO data set.

`InputSize` — Image size to be used for inference

`[640 640 3]` (default) | three-element row vector of integers

This property is read-only.

Image size to be used for inference, stored as a three-element row vector of integers of the form `[`*`H W C`*`]`, where *H*, *W*, and *C* correspond to the height, width, and number of channels in the input image, respectively.

By default, the `InputSize` property value is set to the network's input size `[640 640 3]`, which is the size of the training images.

To set a custom value for this property, specify the property and its value as a name,value pair when creating the object. For example, `InputSize=[224 224 3]` sets the `InputSize` property to `[224 224 3]`.

The `detect` function resizes the test image to the dimensions specified by the `InputSize` property before performing the detections.

`NormalizationStatistics` — *Z*-score normalization values for the object detector
1-by-1 structure (default) | structure

Z-score normalization statistics, stored as a structure with the fields `Mean` and `StandardDeviation`, which contain the values from the COCO data set:

Field	Description	Default Value
`Mean`	1-by-*C* vector of means per channel.	`[123.6750 116.2800 103.5300]`
`StandardDeviation`	1-by-*C* vector of standard deviations per channel.	`[58.3950 57.1200 57.3750]`

The number of channels *C* must match the number of channels in the image dimensions specified by `InputSize`.

Object Functions

detect Detect objects using RTMDet object detector

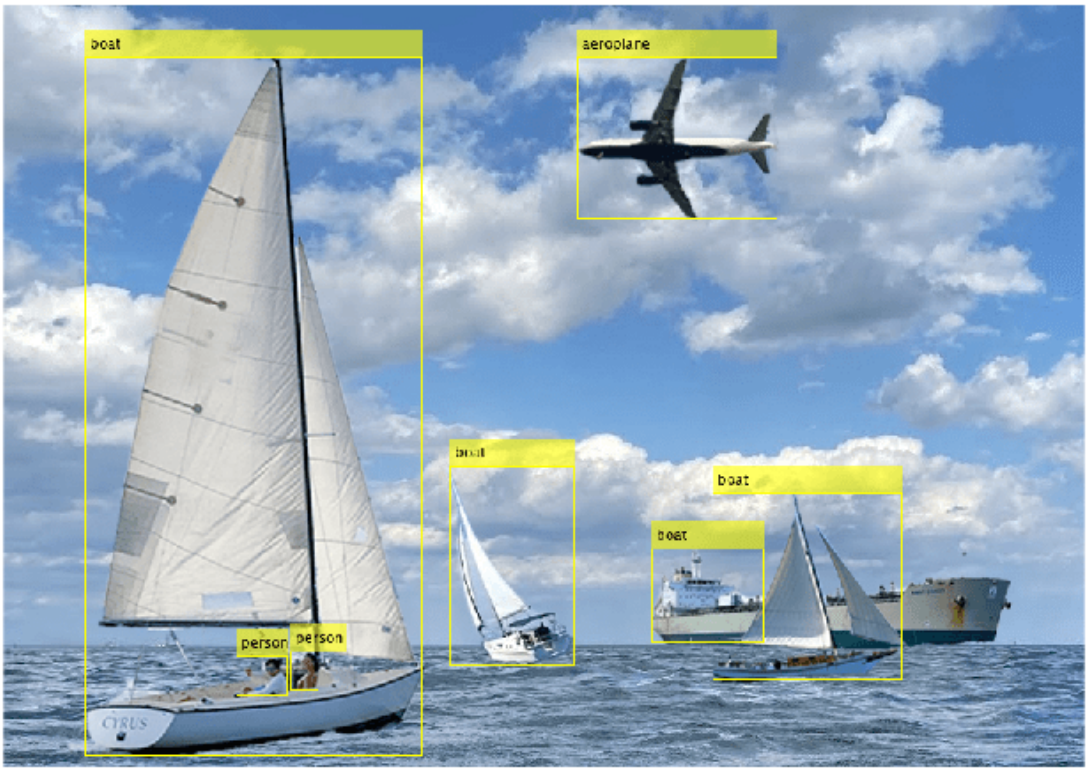
Examples

Detect Objects Using Pretrained RTMDet Object Detector

Specify the name of a pretrained RTMDet deep learning network.

```
modelname = "medium-network-coco";
```

Create an RTMDet object detector by using the pretrained RTMDet network.



```
detector = rtmdetObjectDetector(modelname);
```

Read a test image into the workspace, and detect objects in it by using the pretrained RTMDet object detector with a `Threshold` value of 0.55.

```
img = imread("boats.png");
[bboxes,scores,labels] = detect(detector,img,Threshold=0.55);
```

Display the bounding boxes and predicted class labels of the detected objects.

```
detectedImg = insertObjectAnnotation(img,"rectangle",bboxes,labels);
figure
imshow(detectedImg)
```

detect

Detect objects using RTMDet object detector

Syntax

```
bboxes = detect(detector,I)
[bboxes,scores] = detect(detector,I)
[bboxes,scores,labels] = detect(detector,I)
detectionResults = detect(detector,ds)
[___] = detect(___,roi)
[___] = detect(___,Name=Value)
```

Description

`bboxes = detect(detector,I)` detects objects within a single image or a batch of images, `I`, using an RTMDet object detector, `detector`. The `detect` function returns the locations of detected objects in the input image as a set of bounding boxes.

Note This functionality requires Deep Learning Toolbox and the Computer Vision Toolbox Model for RTMDet Object Detection. You can install the Computer Vision Toolbox Model for RTMDet Object Detection from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

`[bboxes,scores] = detect(detector,I)` returns the class-specific confidence scores for the bounding boxes along with their locations.

`[bboxes,scores,labels] = detect(detector,I)` also returns a categorical array of labels assigned to the bounding boxes.

`detectionResults = detect(detector,ds)` returns a table of predicted objects for all the images in the input datastore `ds`.

`[___] = detect(___,roi)` detects objects within the rectangular region of interest `roi`, in addition to any combination of arguments from previous syntaxes.

`[___] = detect(___,Name=Value)` specifies options using one or more name-value arguments. For example, `Threshold=0.5` specifies a detection threshold of 0.5.

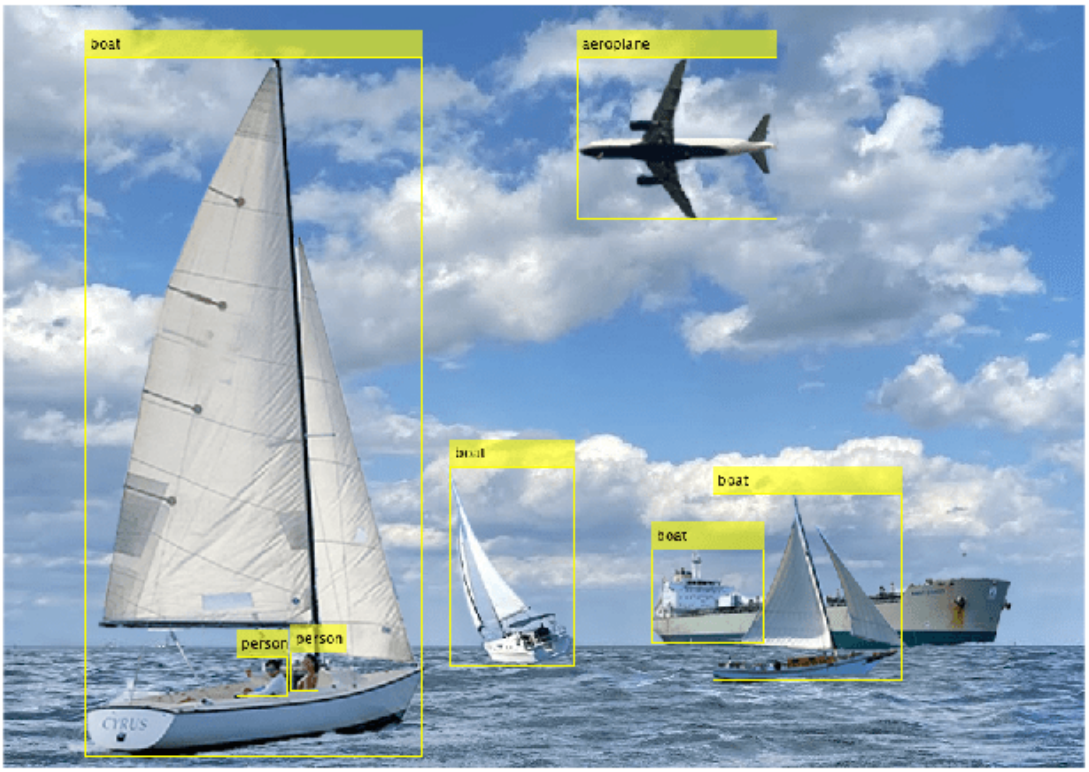
Examples

Detect Objects Using Pretrained RTMDet Object Detector

Specify the name of a pretrained RTMDet deep learning network.

```
modelname = "medium-network-coco";
```

Create an RTMDet object detector by using the pretrained RTMDet network.



```
detector = rtmdetObjectDetector(modelname);
```

Read a test image into the workspace, and detect objects in it by using the pretrained RTMDet object detector with a `Threshold` value of 0.55.

```
img = imread("boats.png");
[bboxes,scores,labels] = detect(detector,img,Threshold=0.55);
```

Display the bounding boxes and predicted class labels of the detected objects.

```
detectedImg = insertObjectAnnotation(img,"rectangle",bboxes,labels);
figure
imshow(detectedImg)
```

Detect Objects in Image Datastore Using RTMDet Object Detector

Load a pretrained RTMDet object detector.

```
detector = rtmdetObjectDetector("tiny-network-coco");
```

Read the test datastore, and store it as an image datastore object.

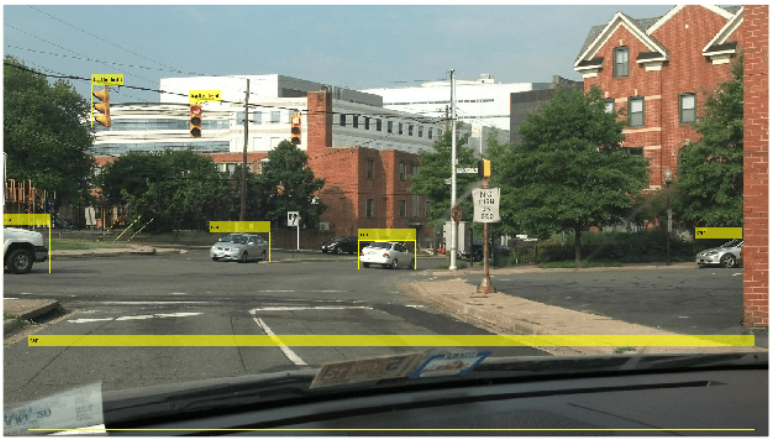
```
location = fullfile(matlabroot,"toolbox","vision","visiondata","stopSignImages");
imds = imageDatastore(location);
```

Detect objects in the test datastore. Set the `Threshold` value to 0.6 and `MiniBatchSize` value to 16.

```
detectionResults = detect(detector,imds,Threshold=0.6,MiniBatchSize=16);
```

Read an image from the test data set, and extract the corresponding detection results.

```
num = 4;
I = readimage(imds,num);
bboxes = detectionResults.Boxes{num};
labels = detectionResults.Labels{num};
scores = detectionResults.Scores{num};
```



Display the table of detection results.

```
results = table(bboxes,labels,scores)
```

```
results=7×3 table

```

Display the bounding boxes and predicted class labels of the detected objects in the image selected from the test datastore.

```
detectedImg = insertObjectAnnotation(I,"rectangle",bboxes,labels);
figure
imshow(detectedImg)
```

Detect Objects Within ROI by Using RTMDet Object Detector

Load a pretrained RTMDet object detector.

```
detector = rtmdetObjectDetector("large-network-coco");
```

Read a test image.

```
img = imread("parkinglot_left.png");
```

Specify a rectangular region of interest (ROI) within the test image.

```
roiBox = [525 120 50 75];
```

Detect objects within the specified ROI.

```
[bboxes,scores,labels] = detect(detector,img,roiBox);
```

Display the bounding boxes and corresponding class labels of the detected objects within the ROI.

```
img = insertObjectAnnotation(img,"rectangle",roiBox,"ROI",AnnotationColor="yellow");
detectedImg = insertObjectAnnotation(img,"rectangle",bboxes,labels);
figure
imshow(detectedImg)
```

Input Arguments

`detector` — RTMDet object detector

`rtmdetObjectDetector` object

RTMDet object detector, specified as an `rtmdetObjectDetector` object.

`I` — Test images

H-by-*W*-by-*C* numeric array | *H*-by-*W*-by-*C*-by-*B* numeric array

Test images, specified as a numeric array of size *H*-by-*W*-by-*C* or *H*-by-*W*-by-*C*-by-*B*. You must specify real and nonsparse grayscale or RGB images.

- *H* — Height of the input images.
- *W* — Width of the input images.
- *C* — Number of channels. The channel size of each image must be equal to the input channel size of the network. For example, for grayscale images, *C* must be `1`. For RGB color images, it must be `3`.
- *B* — Number of test images in the batch. The `detect` function computes the object detection results for each test image in the batch.

When the test image size does not match the network input size, the detector resizes the input image to the value of the `InputSize` property of `detector`, unless you specify `AutoResize` as `false`.

The detector is sensitive to the range of the test image. Therefore, ensure that the test image range is similar to the range of the images used to train the detector. For example, if the detector was trained on `uint8` images, rescale this input image to the range [0, 255] by using the `im2uint8` or `rescale` function.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single`

`ds` — Datastore of test images
`ImageDatastore` object | `CombinedDatastore` object | `TransformedDatastore` object

Datastore of test images, specified as an `ImageDatastore` object, `CombinedDatastore` object, or `TransformedDatastore` object containing the full filenames of the test images. The images in the datastore must be grayscale or RGB images.

`roi` — Region of interest to search
vector of the form [*x y width height*]

Region of interest (ROI) to search, specified as a vector of form [*x y width height*]. The vector specifies the upper-left corner and size of a region, in pixels. If the input data is a datastore, the `detect` function applies the same ROI to every image.

Note To specify the ROI to search, the `AutoResize` value must be `true`, enabling the function to automatically resize the input test images to the network input size.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `detect(detector,I,Threshold=0.25)` specifies a detection threshold of 0.25.

`Threshold` — Detection threshold
`0.25` (default) | scalar in range `[0, 1]`

Detection threshold, specified as a scalar in the range `[0, 1]`. The function removes detections that have scores less than this threshold value. To reduce false positives, at the possible expense of missing some detections, increase this value.

`SelectStrongest` — Strongest bounding box selection
`true` or `1` (default) | `false` or `0`

Strongest bounding box selection, specified as a numeric or logical `1` (`true`) or `0` (`false`).

- `true` — Returns only the strongest bounding box for each object. The `detect` function calls the `selectStrongestBboxMulticlass` function, which uses nonmaximal suppression to eliminate overlapping bounding boxes based on their confidence scores.

  By default, the `detect` function uses this call to the `selectStrongestBboxMulticlass` function.

```
selectStrongestBboxMulticlass(bboxes,scores,labels, ...
                              RatioType="Union", ...
                              OverlapThreshold=0.5);
```

- `false` — Return all detected bounding boxes. You can write a custom function to eliminate overlapping bounding boxes.

`MinSize` — Minimum region size
`[1 1]` (default) | vector of form [*height width*]

Minimum region size containing an object, specified as a vector of the form [*height width*]. Units are in pixels. The minimum region size defines the size of the smallest object that the trained network can detect. When you know the minimum size, you can reduce computation time by setting `MinSize` to that value.

`MaxSize` — Maximum region size
`size(I)` (default) | vector of form [*height width*]

Maximum region size, specified as a vector of the form [*height width*]. Units are in pixels. The maximum region size defines the size of the largest object that the trained network can detect.

By default, `MaxSize` is set to the height and width of the input image `I`. To reduce computation time, set this value to the known maximum region size in which to detect objects in the input test image.

`MiniBatchSize` — Minimum batch size
`16` (default) | positive integer

Minimum batch size, specified as a positive integer. Adjust the `MiniBatchSize` value to help process a large collection of images. The `detect` function groups images into minibatches of the specified size and processes them as a batch, which can improve computational efficiency at the cost of increased memory demand. Decrease the minibatch size to use less memory.

`AutoResize` — Automatic resizing of input images
`true` or `1` (default) | `false` or `0`

Automatic resizing of input images to preserve the aspect ratio, specified as a numeric or logical `1` (`true`) or `0` (`false`). When `AutoResize` is set to `true`, the `detect` function resizes images to the nearest `InputSize` dimension, while preserving the aspect ratio. Set `AutoResize` to logical `false` or `0` when performing image tiling-based inference.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as one of these values:

- `"auto"` — Use a GPU if Parallel Computing Toolbox is installed and a supported GPU device is available. Otherwise, use the CPU.
- `"gpu"` — Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Use the CPU.

`Acceleration` — Performance optimization
`"auto"` (default) | `"mex"` | `"none"`

Performance optimization, specified as one of these options:

- `"auto"` — Automatically apply a number of compatible optimizations suitable for the input network and hardware resource.
- `"mex"` — Compile and execute a MEX function. This option is available only when using a GPU. Using a GPU requires Parallel Computing Toolbox and a CUDA-enabled NVIDIA GPU. If Parallel Computing Toolbox or a suitable GPU is not available, then the `detect` function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"none"` — Do not use acceleration.

Using the `Acceleration` options `"auto"` and `"mex"` can offer performance benefits on subsequent calls with compatible parameters, at the expense of an increased initial run time. Use performance optimization when you plan to call the function multiple times using new input data.

The `"mex"` option generates and executes a MEX function based on the network and parameters used in the function call. You can have several MEX functions associated with a single network at one time. Clearing the network variable also clears any MEX functions associated with that network.

The `"mex"` option is available only for input data specified as a numeric array, cell array of numeric arrays, table, or image datastore. No other types of datastore support the `"mex"` option.

The `"mex"` option is available only when you are using a GPU. You must also have a C/C++ compiler installed. For setup instructions, see “Set Up Compiler” (GPU Coder).

`"mex"` acceleration does not support all layers. For a list of supported layers, see “Supported Layers” (GPU Coder).

Output Arguments

bboxes — Locations of objects detected

M-by-4 matrix | *B*-by-1 cell array

Locations of objects detected within the input image or images, returned as one of these options:

- *M*-by-4 matrix — Returned when the input is a single test image. *M* is the number of bounding boxes detected in an image. Each row of the matrix is of the form [*x y width height*]. The *x* and *y* values specify the upper-left corner coordinates, and *width* and *height* specify the size, of the corresponding bounding box, in pixels.
- *B*-by-1 cell array — Returned when the input is a batch of images, where *B* is the number of test images in the batch. Each cell in the array contains an *M*-by-4 matrix specifying the bounding boxes detected within the corresponding image.

scores — Detection confidence scores

M-by-1 numeric vector | *B*-by-1 cell array

Detection confidence scores for each bounding box in the range `[0, 1]`, returned as one of these options:

- *M*-by-1 numeric vector — Returned when the input is a single test image. *M* is the number of bounding boxes detected in the image.

- *B*-by-1 cell array — Returned when the input is a batch of test images, where *B* is the number of test images in the batch. Each cell in the array contains an *M*-element row vector, where each element indicates the detection score for a bounding box in the corresponding image.

A higher score indicates higher confidence in the detection. The confidence score for each detection is a product of the corresponding objectness score and maximum class probability. The objectness score is the probability that the object in the bounding box belongs to a class in the image. The maximum class probability is the largest probability that a detected object in the bounding box belongs to a particular class.

`labels` — Labels for bounding boxes

M-by-1 categorical vector | *B*-by-1 cell array

Labels for bounding boxes, returned as one of these options:

- *M*-by-1 categorical vector — Returned when the input is a single test image. *M* is the number of bounding boxes detected in the image.
- *B*-by-1 cell array — Returned when the input is an array of test images. *B* is the number of test images in the batch. Each cell in the array contains an *M*-by-1 categorical vector containing the names of the object classes.

`detectionResults` — Detection results

three-column table

Detection results when the input is a datastore of test images, `ds`, returned as a table with these columns:

`bboxes`	`scores`	`labels`
Predicted bounding boxes, defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and `y` specify the upper-left corner coordinates of the rectangle, in pixels. • *w* specifies the width of the rectangle, which is its length along the *x*-axis, in pixels. • *h* specifies the height of the rectangle, which is its length along the *y*-axis, in pixels.	Class-specific confidence scores for each bounding box, returned as an *M*-by-1 numeric vector with values in the range `[0, 1]`.	Predicted object labels assigned to bounding boxes, returned as an *M*-by-1 categorical vector. All categorical data returned by the datastore must contain the same categories.

Version History

Introduced in R2024b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `MiniBatchSize` name-value argument is not supported for code generation when the image input `I` is an *H*-by-*W*-by-*C*-by-*B* numeric array of images. All images will processed in one batch.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

opticalFlowRAFT

Estimate optical flow using RAFT deep learning algorithm

Description

Use the `opticalFlowRAFT` object to estimate the motion direction and velocity between previous and current video frames using the recurrent all-pairs field transforms (RAFT) algorithm. This algorithm uses a deep learning network trained on the Kubric [3 on page 2-90] dataset. The RAFT optical flow estimation algorithm outperforms approaches like Farneback by delivering greater accuracy, particularly in areas with minimal texture, motion blur, and under difficult camera movements. It provides dense (per-pixel) and highly accurate estimations, but requires more time and memory. For quicker but less precise dense optical flow estimation, opt for `opticalFlowFarneback`, a traditional vision algorithm that does not rely on deep learning.

Note This functionality requires Deep Learning Toolbox and the Computer Vision Toolbox Model for RAFT Optical Flow Estimation. You can install the Computer Vision Toolbox Model for RAFT Optical Flow Estimation from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Creation

Syntax

```
flowModel = opticalFlowRAFT
```

Description

`flowModel = opticalFlowRAFT` returns an optical flow object that estimates the motion direction and velocity between the previous and current video frames.

Object Functions

estimateFlow	Estimate optical flow between two frames
reset	Reset the internal state of the optical flow estimation object

Examples

Estimate Optical Flow in Consecutive Image Frames

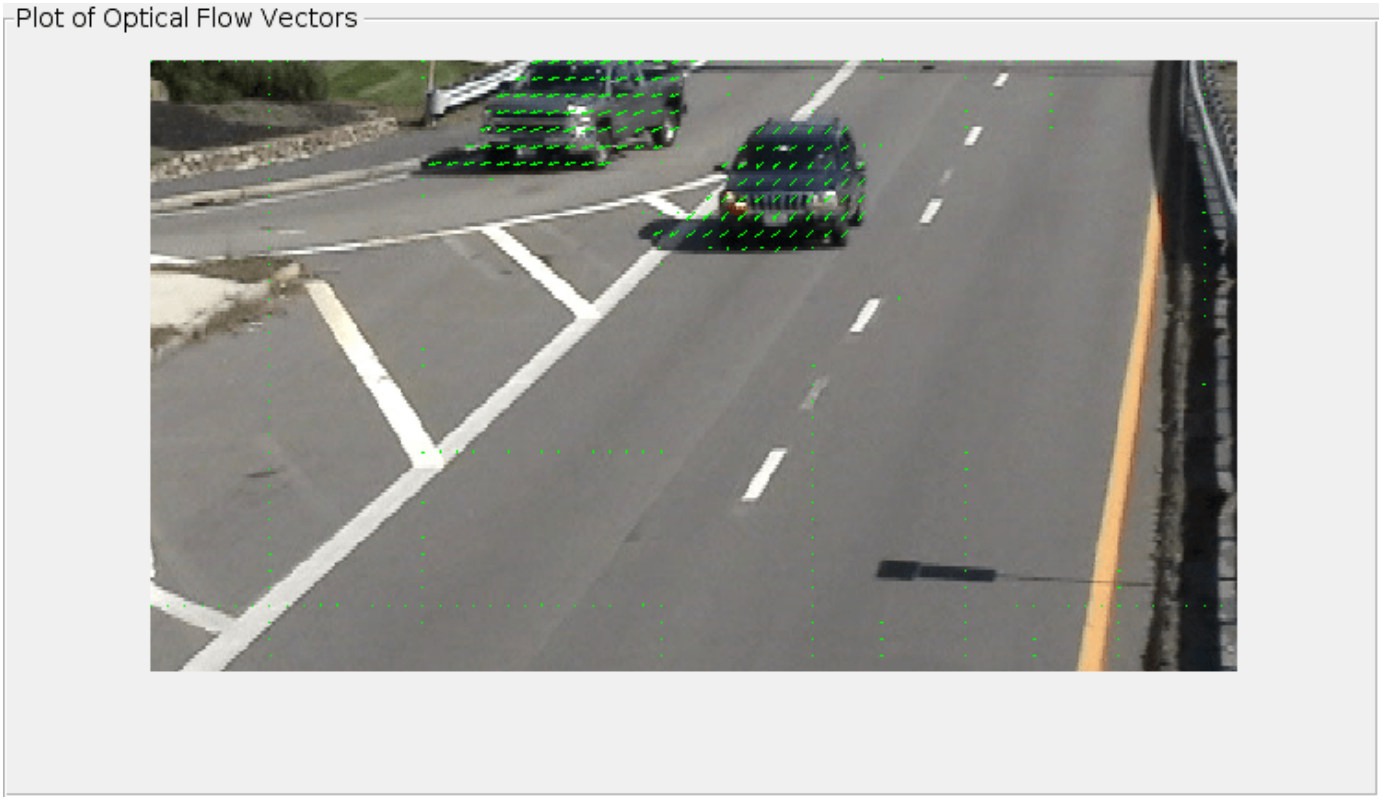
Create a RAFT optical flow object.

```
flowModel = opticalFlowRAFT;
```

Create an object to read the input video file.

```
vidReader = VideoReader("visiontraffic.avi",CurrentTime=11);
```

Create a custom figure window to visualize the optical flow vectors.



```
h = figure;
movegui(h);
hViewPanel = uipanel(h, Position=[0 0 1 1], Title="Plot of Optical Flow Vectors");
hPlot = axes(hViewPanel);
```

Read consecutive image frames to estimate optical flow. Display the current frame and overlay optical flow vectors using a quiver plot. The `estimateFlow` function calculates the optical flow between two consecutive frames.

Note that the function internally stores the previous frame and utilizes it implicitly for optical flow estimation. Consequently, when the function is called for the first time on a sequence of frames, it will return a zero flow. This is because, in the absence of a genuine previous frame, the initial frame is treated as both the current and previous frame, leading to no detectable motion between the two. This is consistent with the argument structure and behavior of established optical flow estimation methods, such as `opticalFlowFarneback`.

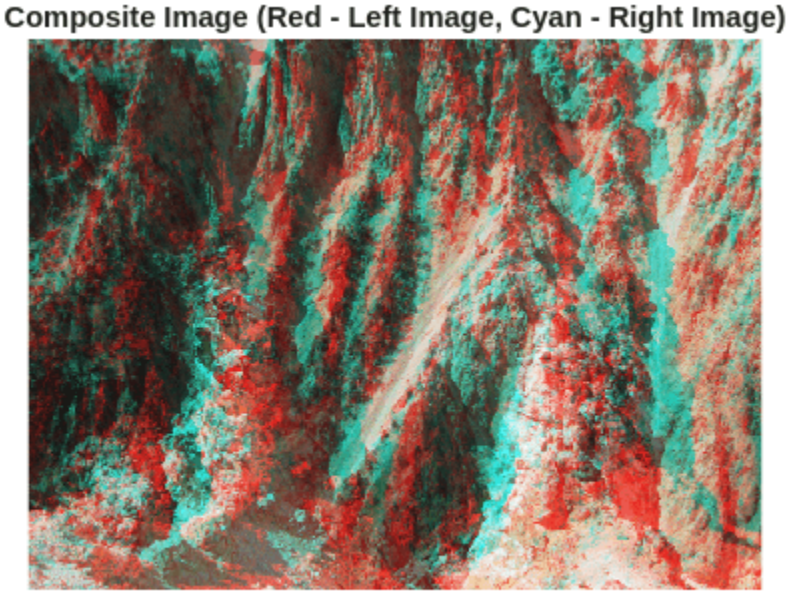
```
while hasFrame(vidReader)
    frame = readFrame(vidReader);
    flow = estimateFlow(flowModel,frame);

    imshow(frame)
    hold on
    plot(flow,DecimationFactor=[10 10],ScaleFactor=0.45,Parent=hPlot,color="g");
    hold off
    pause(10^-3)
end
```

Reset the `opticalFlowRAFT` object after the video processing has completed. This clears the internal state of the object, including the saved previous frame.

```
reset(flowModel);
```

Memory-Efficient RAFT Optical Flow for Large Images Using Rescaling



RAFT provides accurate optical flow estimation, but it can be memory-intensive when applied to large images or run on GPUs with limited memory. In such cases, processing high-resolution frames directly may lead to out-of-memory (OOM) errors. A practical solution is to downscale the input images before passing them to the RAFT model, compute optical flow at the reduced resolution, and then rescale the resulting flow field back to the original size of the imagery. This example demonstrates how to apply this memory-efficient strategy, allowing you to use RAFT on larger images or resource-constrained hardware while preserving meaningful flow estimates.

Load Image Pair

Load two images and visualize their pixel-wise differences due to camera motion using a red-cyan composite image.

```
I1 = imread("yellowstone_left.png");
I2 = imread("yellowstone_right.png");

figure
imshow(stereoAnaglyph(I1, I2))
title("Composite Image (Red - Left Image, Cyan - Right Image)")
```

Display the spatial dimensions of the images.

```
disp(size(I1, [1 2]))
```

```
   480   640
```

Create `opticalFlowRAFT` Object

Create an `opticalFlowRAFT` object for computing optical flow between two images.

```
raft = opticalFlowRAFT;
```

Estimate Optical Flow on Full Resolution Images

Estimate optical flow on the images at original resolution. This gives the most accurate result but may cause into slow runtime and high memory consumption.

```
estimateFlow(raft, I1);
flowFull = estimateFlow(raft, I2);
```

Estimate Optical Flow on Downsampled Images

Create Downscaled Images

Scale the image dimensions by a factor of 0.5 for illustrative purpose. A small resolution image can result in faster optical flow computation and less memory consumption.

```
I1Small = imresize(I1, 0.5);
I2Small = imresize(I2, 0.5);
```

Display the resized image dimensions.

```
disp(size(I1Small, [1 2]))
```

```
   240   320
```

Estimate Flow on Downscaled Images

Compute optical flow on downscaled images. Use the same opticalFlowRAFT model instantiated earlier after resetting it.

```
reset(raft);
estimateFlow(raft, I1Small);
flowLowRes = estimateFlow(raft, I2Small);
```

Scale Estimated Flow to Original Resolution

Upsample and scale the lower resolution optical flow back to the original image resolution.

```
origDims = size(I1, [1 2]);
scaleX = origDims(2) / size(flowLowRes.Magnitude, 2);
scaleY = origDims(1) / size(flowLowRes.Magnitude, 1);

flowX = imresize(flowLowRes.Vx, origDims, "bilinear") * scaleX;
flowY = imresize(flowLowRes.Vy, origDims, "bilinear") * scaleY;

flowUpscaled = opticalFlow(flowX, flowY);
```

Compare Optical Flow at Original and Downscaled Resolutions

Visually compare optical flow computed directly on the original high-resolution images with optical flow computed on downscaled images and then rescaled back to the original size. This comparison

illustrates how the downscale-upscale workflow approximates the original flow while reducing memory usage.

```
figure
subplot(1,2,1)
imshow(I1)
hold on
plot(flowFull, DecimationFactor=[40 40], ScaleFactor=0.75, Color="g");
hold off
title("Optical Flow at Full Resolution")

subplot(1,2,2)
imshow(I1)
hold on
plot(flowUpscaled, DecimationFactor=[40 40], ScaleFactor=0.75, Color="g");
hold off
title("Optical Flow at Half Resolution")
```

The bilinear interpolation in the image resizing operations can introduce numerical inaccuracies and overly-smoothed results in the upscaled optical flow. This reduced accuracy is a trade-off against the lower memory consumption when optical flow computation is performed on lower resolution imagery.

estimateFlow

Estimate optical flow between two frames

Syntax

```
flow = estimateFlow(flowModel,I)
flow = estimateFlow(flowModel,I,Name=Value)
```

Description

`flow = estimateFlow(flowModel,I)` estimates the optical flow between the current frame `I` and the previous frame using the recurrent all-pairs field transforms (RAFT) deep learning algorithm.

RAFT optical flow estimation outperforms methods like Farneback by delivering higher accuracy, particularly in areas with minimal texture and under difficult camera movements.

`flow = estimateFlow(flowModel,I,Name=Value)` specifies options using one or more name-value arguments in addition to the previous syntax. For example, `MaxIterations=10` sets the number of refinement iterations to `10`.

Examples

Estimate Optical Flow in Consecutive Image Frames

Create a RAFT optical flow object.

```
flowModel = opticalFlowRAFT;
```

Create an object to read the input video file.

```
vidReader = VideoReader("visiontraffic.avi",CurrentTime=11);
```

Create a custom figure window to visualize the optical flow vectors.

```
h = figure;
movegui(h);
hViewPanel = uipanel(h, Position=[0 0 1 1], Title="Plot of Optical Flow Vectors");
hPlot = axes(hViewPanel);
```

Read consecutive image frames to estimate optical flow. Display the current frame and overlay optical flow vectors using a quiver plot. The `estimateFlow` function calculates the optical flow between two consecutive frames.

Note that the function internally stores the previous frame and utilizes it implicitly for optical flow estimation. ```
reset(raft);
estimateFlow(raft, I1Small);
flowLowRes = estimateFlow(raft, I2Small);
```

Scale Estimated Flow to Original Resolution

Upsample and scale the lower resolution optical flow back to the original image resolution.

```
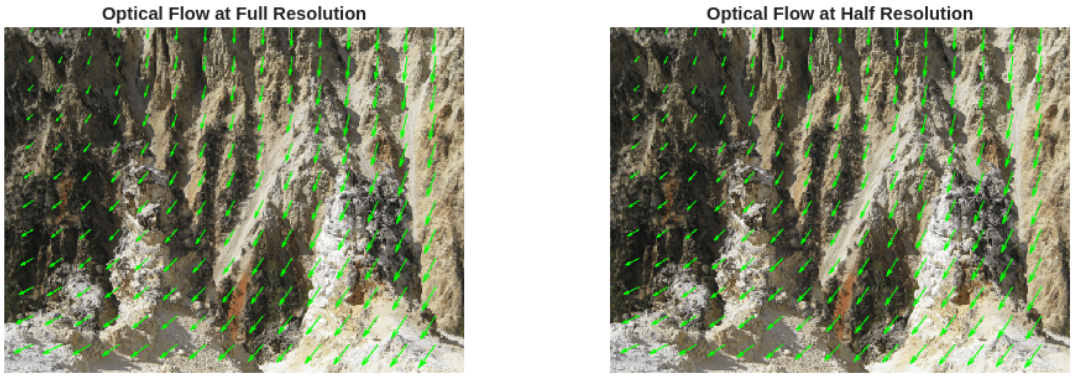
origDims = size(I1, [1 2]);
scaleX = origDims(2) / size(flowLowRes.Magnitude, 2);
scaleY = origDims(1) / size(flowLowRes.Magnitude, 1);

flowX = imresize(flowLowRes.Vx, origDims, "bilinear") * scaleX;
flowY = imresize(flowLowRes.Vy, origDims, "bilinear") * scaleY;



flowUpscaled = opticalFlow(flowX, flowY);
```

Compare Optical Flow at Original and Downscaled Resolutions

Visually compare optical flow computed directly on the original high-resolution images with optical flow computed on downscaled images and then rescaled back to the original size. This comparison illustrates how the downscale-upscale workflow approximates the original flow while reducing memory usage.

```
figure
subplot(1,2,1)
imshow(I1)
hold on
plot(flowFull, DecimationFactor=[40 40], ScaleFactor=0.75, Color="g");
hold off
title("Optical Flow at Full Resolution")

subplot(1,2,2)
imshow(I1)
hold on
plot(flowUpscaled, DecimationFactor=[40 40], ScaleFactor=0.75, Color="g");
hold off
title("Optical Flow at Half Resolution")
```

The bilinear interpolation in the image resizing operations can introduce numerical inaccuracies and overly-smoothed results in the upscaled optical flow. This reduced accuracy is a trade-off against the lower memory consumption when optical flow computation is performed on lower resolution imagery.

Input Arguments

`flowModel` — Optical flow object

`opticalFlowRAFT` object

Optical flow object, specified as an `opticalFlowRAFT` object.

`I` — Current video frame

2-D grayscale image | RGB image

Current video frame, specified as a 2-D grayscale or RGB image. When the input image is of type `uint8` or `int16`, the pixel values must be in the range `[0,255]`. When the input image is of type `single` or `double`, the pixels values must be in the range `[0,1]`. The RAFT model requires input images to have a minimum dimension of more than 57 pixels on the shortest side.

When initializing motion estimation in a video, the first frame is duplicated as its own "previous frame" to ensure the calculated motion (optical flow) starts from zero, as there is no actual prior frame to compare with.

Data Types: `single` | `double` | `int16` | `uint8`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `estimateFlow(flowModel,I,MaxIterations=10)` sets the number of refinement iterations to `10`.

`MaxIterations` — Number of refinement iterations

`12` (default) | integer

Number of refinement iterations, specified as an integer. Increasing the number of refinement iterations enhances the precision of the optical flow estimation from its initial prediction by iteratively

refining the calculation. Decreasing this value accelerates the algorithm's execution but compromises on accuracy. A typical value is 12.

`Tolerance` — Acceptable difference between consecutive refinement iterations
`1e-5` (default) | scalar

Acceptable difference between consecutive refinement iterations, specified as a scalar. The tolerance level set for iterations in estimating optical flow, beginning with an initial prediction, determines the acceptable deviation between each successive iteration. If the variation in optical flow between two successive updates falls below this tolerance threshold, the iteration process is halted. Opting for larger tolerance values can speed up the process but at the expense of reduced accuracy.

`ExecutionEnvironment` — Processing execution environment
`"auto"` (default) | `"CPU"` | `"GPU"`

Processing execution environment to perform the model's inference, specified as `"cpu"`, `"gpu"`, or `"auto"`.

- `"auto"` — Use a local GPU if one is available. Otherwise, use the local CPU.
- `"cpu"` — Use the local CPU.
- `"gpu"` — Use the local GPU.

`Acceleration` — Acceleration
`"auto"` (default) | `"none"`

Acceleration, specified as `"auto"` or `"none"`. The `"auto"` acceleration setting increases memory usage but also speeds up execution.

Output Arguments

`flow` — Optical flow velocity matrices
`opticalFlow` object

Optical flow velocity matrices, returned as an `opticalFlow` object.

Tips

- Using RAFT for optical flow estimation on a GPU requires a minimum of 12 GB of memory.
- The RAFT model, being fully convolutional, can process images of any size in theory, with the only limitation being the available GPU memory.

Version History

Introduced in R2024b

Extended Capabilities

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU acceleration.

By default, the `estimateFlow` function uses a GPU if one is available. You can specify the hardware that the `estimateFlow` function uses by setting the `ExecutionEnvironment` name-value argument.

For more information, see “Scale Up Deep Learning in Parallel, on GPUs, and in the Cloud” (Deep Learning Toolbox).

`reset` | `imwarp`

Topics
“Automate Labeling of Objects in Video Using RAFT Optical Flow”

reset

Reset the internal state of the optical flow estimation object

Syntax

```
reset(flowModel)
```

Description

`reset(flowModel)` resets the internal state of the optical flow estimation object, `flowModel`. The previous frame is reset to its initial value which is a uniform image of intensity value `0`. To reuse an `opticalFlowRAFT` object for a new video, call `reset` to clear cached frame information from a previously processed video.

Examples

Estimate Optical Flow in Consecutive Image Frames

Create a RAFT optical flow object.

```
flowModel = opticalFlowRAFT;
```

Create an object to read the input video file.

```
vidReader = VideoReader("visiontraffic.avi",CurrentTime=11);
```

Create a custom figure window to visualize the optical flow vectors.

```
h = figure;
movegui(h);
hViewPanel = uipanel(h, Position=[0 0 1 1], Title="Plot of Optical Flow Vectors");
hPlot = axes(hViewPanel);
```

Read consecutive image frames to estimate optical flow. Display the current frame and overlay optical flow vectors using a quiver plot. The `estimateFlow` function calculates the optical flow between two consecutive frames.

Note that the function internally stores the previous frame and utilizes it implicitly for optical flow estimation. Consequently, when the function is called for the first time on a sequence of frames, it will return a zero flow. This is because, in the absence of a genuine previous frame, the initial frame is treated as both the current and previous frame, leading to no detectable motion between the two. This is consistent with the argument structure and behavior of established optical flow estimation methods, such as `opticalFlowFarneback`.

```
while hasFrame(vidReader)
    frame = readFrame(vidReader);
    flow = estimateFlow(flowModel,frame);

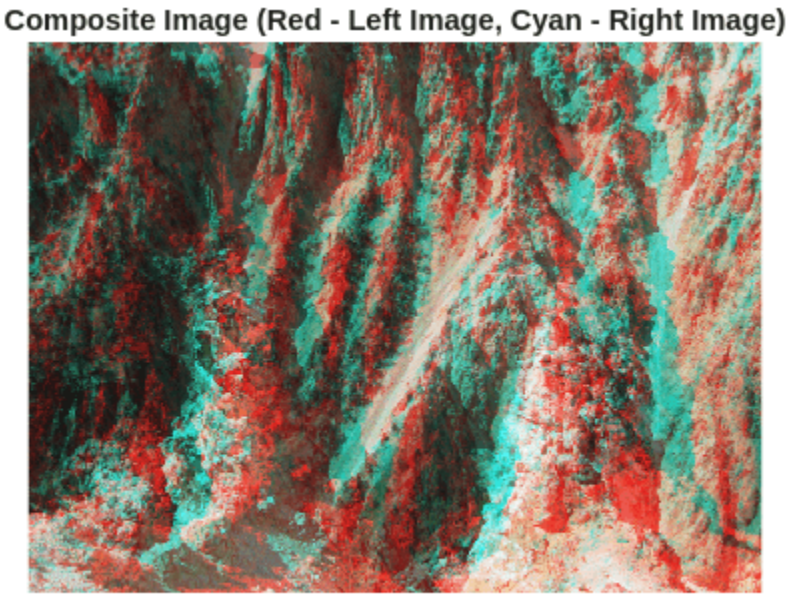
    imshow(frame)
    hold on
```

```
    plot(flow,DecimationFactor=[10 10],ScaleFactor=0.45,Parent=hPlot,color="g");
    hold off
    pause(10^-3)
end
```

Reset the `opticalFlowRAFT` object after the video processing has completed. This clears the internal state of the object, including the saved previous frame.

```
reset(flowModel);
```

Memory-Efficient RAFT Optical Flow for Large Images Using Rescaling



RAFT provides accurate optical flow estimation, but it can be memory-intensive when applied to large images or run on GPUs with limited memory. In such cases, processing high-resolution frames directly may lead to out-of-memory (OOM) errors. A practical solution is to downscale the input images before passing them to the RAFT model, compute optical flow at the reduced resolution, and then rescale the resulting flow field back to the original size of the imagery. This example demonstrates how to apply this memory-efficient strategy, allowing you to use RAFT on larger images or resource-constrained hardware while preserving meaningful flow estimates.

Load Image Pair

Load two images and visualize their pixel-wise differences due to camera motion using a red-cyan composite image.

```
I1 = imread("yellowstone_left.png");
I2 = imread("yellowstone_right.png");
```

```
figure
imshow(stereoAnaglyph(I1, I2))
title("Composite Image (Red - Left Image, Cyan - Right Image)")
```

Display the spatial dimensions of the images.

```
disp(size(I1, [1 2]))
```

```
   480   640
```

Create `opticalFlowRAFT` Object

Create an `opticalFlowRAFT` object for computing optical flow between two images.

```
raft = opticalFlowRAFT;
```

Estimate Optical Flow on Full Resolution Images

Estimate optical flow on the images at original resolution. This gives the most accurate result but may cause into slow runtime and high memory consumption.

```
estimateFlow(raft, I1);
flowFull = estimateFlow(raft, I2);
```

Estimate Optical Flow on Downsampled Images

Create Downscaled Images

Scale the image dimensions by a factor of 0.5 for illustrative purpose. A small resolution image can result in faster optical flow computation and less memory consumption.

```
I1Small = imresize(I1, 0.5);
I2Small = imresize(I2, 0.5);
```

Display the resized image dimensions.

```
disp(size(I1Small, [1 2]))
```

```
   240   320
```

Estimate Flow on Downscaled Images

Compute optical flow on downscaled images. Use the same opticalFlowRAFT model instantiated earlier after resetting it.

```
reset(raft);
estimateFlow(raft, I1Small);
flowLowRes = estimateFlow(raft, I2Small);
```

Scale Estimated Flow to Original Resolution

Upsample and scale the lower resolution optical flow back to the original image resolution.

```
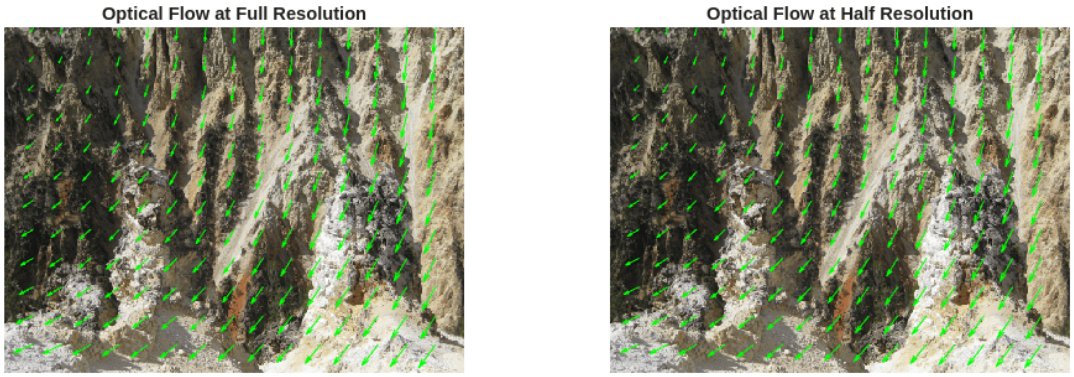
origDims = size(I1, [1 2]);
scaleX = origDims(2) / size(flowLowRes.Magnitude, 2);
scaleY = origDims(1) / size(flowLowRes.Magnitude, 1);

flowX = imresize(flowLowRes.Vx, origDims, "bilinear") * scaleX;
flowY = imresize(flowLowRes.Vy, origDims, "bilinear") * scaleY;



flowUpscaled = opticalFlow(flowX, flowY);
```

Compare Optical Flow at Original and Downscaled Resolutions

Visually compare optical flow computed directly on the original high-resolution images with optical flow computed on downscaled images and then rescaled back to the original size. This comparison illustrates how the downscale-upscale workflow approximates the original flow while reducing memory usage.

```
figure
subplot(1,2,1)
imshow(I1)
hold on
plot(flowFull, DecimationFactor=[40 40], ScaleFactor=0.75, Color="g");
hold off
title("Optical Flow at Full Resolution")

subplot(1,2,2)
imshow(I1)
hold on
plot(flowUpscaled, DecimationFactor=[40 40], ScaleFactor=0.75, Color="g");
hold off
title("Optical Flow at Half Resolution")
```

The bilinear interpolation in the image resizing operations can introduce numerical inaccuracies and overly-smoothed results in the upscaled optical flow. This reduced accuracy is a trade-off against the lower memory consumption when optical flow computation is performed on lower resolution imagery.

Input Arguments

`flowModel` — Object for optical flow estimation

`opticalFlowRAFT` object

Object for optical flow estimation, specified as an `opticalFlowRAFT` object.

Version History

Introduced in R2024b

dbowLoopDetector

Detect loop closure using visual features

Description

Use `dbowLoopDetector` object to create loop detector database.

Creation

Syntax

```
loopDetector = dbowLoopDetector()
loopDetector = dbowLoopDetector(bag)
```

Description

`loopDetector = dbowLoopDetector()` creates a loop detector database using a default internal vocabulary. It detects loop closures in visual simultaneous localization and mapping (vSLAM) using visual features.

`loopDetector = dbowLoopDetector(bag)` creates a loop detector database specified by feature descriptors in `bag`.

Object Functions

addVisualFeatures	Add image features to database
detectLoop	Detect loop closure using visual features

Examples

Implement Loop Closure Detection and Add New Image

Load an existing binary visual vocabulary for loop detection.

```
bag = bagOfFeaturesDBoW("bagOfFeatures.bin.gz");
```

Initialize the loop detector using the loaded vocabulary.

```
loopDetector = dbowLoopDetector(bag);
```

Read a new image and detect ORB features in the image.

```
I = imread("cameraman.tif");
points = detectORBFeatures(I);
imshow(I)
hold on
plot(points,Showscale=false)
```

Extract ORB features from the detected points in the image. The `extractFeatures` function returns features and their corresponding locations. This code focuses on only the features for loop closure detection.

```
features = extractFeatures(I,points);
```

Perform loop closure detection with the extracted features.

```
loopViewIds = detectLoop(loopDetector,features);
```

Update the loop detector's database with features from the new image by specifying the new image as the 100th view in the sequence. This supports loop detection in future images similar to the current one.

```
viewId = 100;
addVisualFeatures(loopDetector,viewId,features);
```

Loop Closure Detection in a Sequence of Images

Load a pre-existing binary vocabulary for feature description.

```
bag = bagOfFeaturesDBoW("bagOfFeatures.bin.gz");
```

Initialize the loop detector with the loaded vocabulary.

```
loopDetector = dbowLoopDetector(bag);
```

Use a single image to simulate adding different views.

```
I = im2gray(imread("cameraman.tif"));
points = detectORBFeatures(I);
[features,points] = extractFeatures(I,points);
```

Initialize an image view set to manage and store views.

```
vSet = imageviewset;
```

Add the first view with random features for initialization.

```
zeroFeatures = binaryFeatures(zeros(size(points,1),32,"like",uint8(0)));
vSet = addView(vSet,1,"Features",zeroFeatures,"Points",points);
addVisualFeatures(loopDetector,1,zeroFeatures);
fig = figure;
tlo = tiledlayout(fig,1,3,TileSpacing='None');
for i = 1:3
    ax = nexttile(tlo);
    imshow(I,Parent=ax)
    title(["Camera View ", num2str(i)])
end
```

Sequentially add three views with actual features to simulate potential loop candidates.

```
for viewId = 2:4
    vSet = addView(vSet,viewId,"Features",features,"Points",points);
    addVisualFeatures(loopDetector,viewId,features);
end
```

Add two new connected views to the image sequence. First, add a previous view with a cropped section of the original image to represent the view from a camera. The resulting cropped image represents the previous frame in the sequence.

```
prevViewId = 5;
prevView = I(100:200,100:200);
```

```
figure
imshow(prevView)
title("Camera View 5")
```

Detect ORB features in the cropped frame with the pyramid level set to 3. Add the features to the image viewset as a new view.

```
prevPoints = detectORBFeatures(prevView,NumLevels=3);
[prevFeatures,prevPoints] = extractFeatures(prevView,prevPoints);
vSet = addView(vSet,prevViewId,"Features",prevFeatures,"Points",prevPoints);
addVisualFeatures(loopDetector,prevViewId,prevFeatures);
```

Add a current view, connected to the previous one with another cropped section.

```
currViewId = 6;
currView = I(50:200, 50:200);
currPoints = detectORBFeatures(currView,NumLevels=3);
[currFeatures, currPoints] = extractFeatures(currView,currPoints);
vSet = addView(vSet,currViewId,"Features",currFeatures,"Points",currPoints);
vSet = addConnection(vSet,prevViewId,currViewId,"Matches",[1:10; 1:10]');
imshow(currView)
title("Current Camera View 6")
```

Identify views connected to the current key frame.

```
covisViews = connectedViews(vSet, currViewId);
covisViewsIds = covisViews.ViewId;
```

Perform loop closure detection by comparing current features against those from connected views. Use 75% of the maximum score among connected views for the threshold.

```
relativeThreshold = 0.75;
loopViewIds = detectLoop(loopDetector,currFeatures,covisViewsIds,relativeThreshold)
```

```
loopViewIds = 1×3 int32 row vector

   2   3   4
```

The detected loop candidates show that the current camera view 6 is visually most similar to views 2,3, and 4.This suggests that these earlier views share significant visual features with the current view.

```
fig= figure;
tlo = tiledlayout(fig,1,4,TileSpacing='None');
for i = 1:4
    ax = nexttile(tlo);
    if i == 1
        imshow(currView,Parent=ax)
        title("Current Camera View 6")
    else
        imshow(I,Parent=ax)
        title(["Camera View ", num2str(i)])
    end

end
```

addVisualFeatures

Add image features to database

Syntax

```
addVisualFeatures(loopDetector,viewId,features)
```

Description

`addVisualFeatures(loopDetector,viewId,features)` adds ORB feature descriptors into the bag of words (BoW) loop detector database, `loopDetector`. The function adds `features` extracted from images uniquely identified by its view identifier `viewId`.

Examples

Add Image Features to Loop Detector Database

Create a loop detector.

```
loopDetector = dbowLoopDetector;
```

Get query image features and assign it as the 100th view.

```
viewId = 100;
I = imread("cameraman.tif");
points = detectORBFeatures(I);
[features,~] = extractFeatures(I,points);
```

Add image features for the 100th view ID to the loop detector database.

```
addVisualFeatures(loopDetector,viewId,features);
```

Input Arguments

`loopDetector` — BoW loop detector database
`dbowLoopDetector` object

BoW loop detector database, specified as a `dbowLoopDetector` object.

`viewId` — Unique view identifier
integer

Unique view identifier, specified as an integer.

`features` — ORB feature descriptors
`binaryFeatures` object

ORB feature descriptors, specified as a `binaryFeatures` object.

Version History

Introduced in R2024b

Objects

`dbowLoopDetector` | `bagOfFeaturesDBoW` | `binaryFeatures`

detectLoop

Detect loop closure using visual features

Syntax

```
[loopViewIDs,similarityScores] = detectLoop(loopDetector,features)
[loopViewIDs,similarityScores] = detectLoop( ___ ,connectedViewIds,
relativeThreshold)
[ ___ ] = detectLoop( ___ ,NumResults=Value)
```

Description

`[loopViewIDs,similarityScores] = detectLoop(loopDetector,features)` compares oriented FAST and rotated BRIEF (ORB) `features`, against features in a prepopulated `loopDetector` BoW database. It returns the indices of images, `loopViewIDs`, in the database that resemble the feature descriptors in `features` and it returns a quantitative measure of how similar each detected pair of images is in `similarityScores`.

By using the `detectLoop` function with the specified inputs, you can effectively search a database for images that are similar to a given set of query images, while ignoring those that are closely connected.

`[loopViewIDs,similarityScores] = detectLoop( ___ ,connectedViewIds, relativeThreshold)` finds images within a BoW database that are similar to an image represented by ORB feature descriptors, `features`, while ignoring those that are closely connected, specified by `connectedViewIds`. The `relativeThreshold` allows you to fine-tune the sensitivity of the search to ensure that only the most relevant, non-connected similar images are identified and returned.

`[ ___ ] = detectLoop( ___ ,NumResults=Value)` sets the maximum number of results to return in addition to all input arguments from the previous syntax. Specify `Value` as a positive integer. The default value is set to `20`.

Examples

Implement Loop Closure Detection and Add New Image

Load an existing binary visual vocabulary for loop detection.

```
bag = bagOfFeaturesDBoW("bagOfFeatures.bin.gz");
```

Initialize the loop detector using the loaded vocabulary.

```
loopDetector = dbowLoopDetector(bag);
```

Read a new image and detect ORB features in the image.

```
I = imread("cameraman.tif");
points = detectORBFeatures(I);
imshow(I)
```

```
hold on
plot(points,Showscale=false)
```

Extract ORB features from the detected points in the image. The `extractFeatures` function returns features and their corresponding locations. This code focuses on only the features for loop closure detection.

```
features = extractFeatures(I,points);
```

Perform loop closure detection with the extracted features.

```
loopViewIds = detectLoop(loopDetector,features);
```

Update the loop detector's database with features from the new image by specifying the new image as the 100th view in the sequence. This supports loop detection in future images similar to the current one.

```
viewId = 100;
addVisualFeatures(loopDetector,viewId,features);
```

Loop Closure Detection in a Sequence of Images

Load a pre-existing binary vocabulary for feature description.

```
bag = bagOfFeaturesDBoW("bagOfFeatures.bin.gz");
```

Initialize the loop detector with the loaded vocabulary.

```
loopDetector = dbowLoopDetector(bag);
```

Use a single image to simulate adding different views.

```
I = im2gray(imread("cameraman.tif"));
points = detectORBFeatures(I);
[features,points] = extractFeatures(I,points);
```

Initialize an image view set to manage and store views.

```
vSet = imageviewset;
```

Add the first view with random features for initialization.

```
zeroFeatures = binaryFeatures(zeros(size(points,1),32,"like",uint8(0)));
vSet = addView(vSet,1,"Features",zeroFeatures,"Points",points);
addVisualFeatures(loopDetector,1,zeroFeatures);
fig = figure;
tlo = tiledlayout(fig,1,3,TileSpacing='None');
for i = 1:3
    ax = nexttile(tlo);
    imshow(I,Parent=ax)
    title(["Camera View ", num2str(i)])
end
```

Sequentially add three views with actual features to simulate potential loop candidates.

```
for viewId = 2:4
    vSet = addView(vSet,viewId,"Features",features,"Points",points);
    addVisualFeatures(loopDetector,viewId,features);
end
```

Add two new connected views to the image sequence. First, add a previous view with a cropped section of the original image to represent the view from a camera. The resulting cropped image represents the previous frame in the sequence.

```
prevViewId = 5;
prevView = I(100:200,100:200);
```

```
figure
imshow(prevView)
title("Camera View 5")
```

Detect ORB features in the cropped frame with the pyramid level set to 3. Add the features to the image viewset as a new view.

```
prevPoints = detectORBFeatures(prevView,NumLevels=3);
[prevFeatures,prevPoints] = extractFeatures(prevView,prevPoints);
vSet = addView(vSet,prevViewId,"Features",prevFeatures,"Points",prevPoints);
addVisualFeatures(loopDetector,prevViewId,prevFeatures);
```

Add a current view, connected to the previous one with another cropped section.

```
currViewId = 6;
currView = I(50:200, 50:200);
currPoints = detectORBFeatures(currView,NumLevels=3);
[currFeatures, currPoints] = extractFeatures(currView,currPoints);
vSet = addView(vSet,currViewId,"Features",currFeatures,"Points",currPoints);
vSet = addConnection(vSet,prevViewId,currViewId,"Matches",[1:10; 1:10]');
imshow(currView)
title("Current Camera View 6")
```

Identify views connected to the current key frame.

```
covisViews = connectedViews(vSet, currViewId);
covisViewsIds = covisViews.ViewId;
```

Perform loop closure detection by comparing current features against those from connected views. Use 75% of the maximum score among connected views for the threshold.

```
relativeThreshold = 0.75;
loopViewIds = detectLoop(loopDetector,currFeatures,covisViewsIds,relativeThreshold)
```

```
loopViewIds = 1×3 int32 row vector

   2   3   4
```

The detected loop candidates show that the current camera view 6 is visually most similar to views 2,3, and 4.This suggests that these earlier views share significant visual features with the current view.

```
fig= figure;
tlo = tiledlayout(fig,1,4,TileSpacing='None');
for i = 1:4
    ax = nexttile(tlo);
    if i == 1
        imshow(currView,Parent=ax)
        title("Current Camera View 6")
    else
        imshow(I,Parent=ax)
        title(["Camera View ", num2str(i)])
    end

end
```

Input Arguments

`loopDetector` — BoW loop detector database

`dbowLoopDetector` object

BoW loop detector database, specified as `dbowLoopDetector` object. This prepopulated database of images is search to find similar images.

`features` — ORB feature descriptors

`binaryFeatures` object

ORB feature descriptors, specified as a `binaryFeatures` object. These features are used to search the database for similar images.

`connectedViewIds` — Connected view identifiers

M-element vector

Connected view identifiers, specified as an *M*-element vector. The length *M*, is the number of images considered connected at the time of the query. For example, if the value of `connectedViewIds = [2 5 7]`, this means that the images or views with indices 2,5, and 7 in the database are considered connected to the current query images. The function will ignore these indices during its search for similar images, focusing instead on finding matches among the non-connected images.

`relativeThreshold` — Relative threshold

scalar value

Relative threshold for filtering search results, specified as a scalar value between 0 and 1. Use this threshold to help exclude less similar images by setting a minimum similarity score based on the connected images scores.

A value of 0.75 (or 75%) is recommended for the `relativeThreshold`. This setting means that only images with similarity scores greater than 75% of the minimum score among the connected views are returned, ensuring a high relevance of the detected loops

Output Arguments

`loopViewIDs` — Image indices in loop detector database

M-element vector

Image indices in loop detector database, returned as an *M*-element vector. *M* is the number of queries. The indices points to an image that is similar to the query image, excluding those marked as connected. These indices allow you to locate the matching images within the database.

`similarityScores` — Similarity score between each matched image and query image

M-element vector

Similarity score between each matched image and query image, returned as an *M*-element vector. *M* is the number of queries. Higher scores indicate closer matches.

The function calculates the minimum similarity score among the connected views. It then multiplies this minimum score by the `relativeThreshold` to establish a cutoff score. Only non-connected images with similarity scores above this cut-off are considered significant and included in the results.

bagOfFeaturesDBoW

Bag of visual words using DBoW2 library

Description

Use the `bagOfFeaturesDBoW` object to create a bag of words (BoW) vocabulary to use for loop closure detection with vSLAM algorithms. This object uses the distributed bag of words DBoW2 library. This object supports only oriented FAST and rotated BRIEF (ORB) features.

Creation

Syntax

```
bag = bagOfFeaturesDBoW(imds)
bag = bagOfFeaturesDBoW(features)
bag = bagOfFeaturesDBoW( ___ ,Name=Value)
bag = bagOfFeaturesDBoW(vocabularyFileName)
```

Description

`bag = bagOfFeaturesDBoW(imds)` creates a bag of features from images specified by the datastore `imds`. The algorithm uses oriented fast and rotated brief (ORB) features to create the visual vocabulary.

`bag = bagOfFeaturesDBoW(features)` creates a bag of features from ORB feature descriptors specified by `features`.

`bag = bagOfFeaturesDBoW( ___ ,Name=Value)` sets properties by using one or more name-value arguments in addition to the previous syntax. For example, `Normalization="L2"` sets the normalization to `L2`.

`bag = bagOfFeaturesDBoW(vocabularyFileName)` loads an existing DBoW vocabulary file.

Input Arguments

`imds` — Images
`ImageDatastore` object

Images, specified as an `ImageDatastore` object.

`features` — ORB feature descriptors
cell array of `binaryFeatures`

ORB feature descriptors, specified as a cell array of `binaryFeatures` objects.

`vocabularyFileName` — DBoW vocabulary file
character string

DBoW vocabulary file, specified as a character string.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

`TreeProperties` — Vocabulary tree properties

`[5 10]` (default) | 2-element vector

Vocabulary tree properties, specified as a 2-element vector of the form [*depthLevel*,*branchingFactor*]. *depthLevel* is the number of levels in the vocabulary tree, specified as an integer. *branchingFactor* is the factor to control the amount that the vocabulary can grow at successive levels in the tree, specified as an integer.

The capacity of a vocabulary tree to represent visual words is determined by the formula: `branchingFactor` x `depthLevel`. Commonly, the *depthLevel* ranges from 1 to 6, while the `branchingFactor` varies between 10 and 500. To identify the optimal values for these parameters, conducting empirical analysis is recommended.

Increasing the branching factor enlarges the vocabulary, potentially improving the accuracy of image similarity assessments. However, this adjustment also leads to an increase in the time required to encode images. Implementing a vocabulary tree with multiple levels can facilitate the creation of vocabularies comprising over 10,000 visual words. Although this multi-level approach streamlines the encoding process for images associated with large vocabularies, it necessitates a more extended setup phase.

Alternatively, for vocabularies containing only 100 to 1,000 visual words, employing a tree with a single level is advisable. This configuration simplifies the structure and accelerates the creation process, albeit for smaller vocabularies.

`Normalization` — Type of normalization applied to features

`L1` (default) | `L2`

Type of normalization applied to the features, specified as `L1` or `L2`. Normalization is the method by which to evaluate the similarity or dissimilarity between the feature descriptors for the bag of features.

- `L1` — Calculates the sum of the absolute values of the vector elements.
- `L2` — Calculates the square root of the sum of the squared values of the vector elements.

Properties

`DepthLevel` — Number of levels in the vocabulary tree

integer

This property is read-only.

Number of levels in the vocabulary tree, returned as an integer. The `Normalization` property sets this value.

The `TreeProperties` name-value argument sets this property.

`BranchingFactor` — Number of branches of every node

integer

This property is read-only.

Number of branches of every node in the vocabulary tree, returned as an integer. The `Normalization` property sets this value.

The `TreeProperties` name-value argument sets this property.

`Normalization` — Type of normalization applied to features
`L1` (default) | `L2`

Type of normalization applied to the features, returned as an `L1` or `L2`.

The `Normalization` name-value argument sets this property.

Examples

Create Bag of Features Using an Existing Vocabulary File

Create a bag of features object using an existing distributed bag of words (DBoW) vocabulary file.

```
bag = bagOfFeaturesDBoW("bagOfFeatures.bin.gz")
```

```
bag =
  bagOfFeaturesDBoW with properties:

         DepthLevel: 5
    BranchingFactor: 10
      Normalization: 'L1'
```

Create Bag of Features Using Image Datastore

Create an image datastore for a set of images with stop signs.

```
folder=fullfile(toolboxdir("vision"),"visiondata","stopSignImages");
imds=imageDatastore(folder);
```

Visualize an image from the datastore.

```
imshow(preview(imds))
```

Create a bag of features vocabulary representation from the images in the datastore.

```
bag = bagOfFeaturesDBoW(imds)
```

```
bag =
  bagOfFeaturesDBoW with properties:

         DepthLevel: 5
    BranchingFactor: 10
      Normalization: 'L1'
```

Create Bag of Features Using Image Features

Read an image.

```
I = imread("cameraman.tif");
imshow(I)
```

Detect ORB features in the image.

```
points = detectORBFeatures(I);
imshow(I)
hold on
plot(points,ShowScale=false)
```

Extract ORB features from the detected points in the image. The `extractFeatures` function returns features and their corresponding locations. This code focuses on only the features for loop closure detection.

```
features = extractFeatures(I,points);
```

Create a bag of features using the extracted ORB features. Specify L2 normalization method to normalize image encodings in the bag.

```
bag = bagOfFeaturesDBoW({features},Normalization="L2")
```

```
bag =
  bagOfFeaturesDBoW with properties:

         DepthLevel: 5
    BranchingFactor: 10
      Normalization: 'L2'
```

You can now apply this bag to tasks such as loop closure detection in visual SLAM workflows using the `dbowLoopDetector` object.

trajectoryErrorMetrics

Store accuracy metrics for trajectories

Description

The `trajectoryErrorMetrics` object stores accuracy metrics for trajectories, including both absolute trajectory error and relative trajectory error, across a sequence of poses.

Creation

Create a `trajectoryErrorMetrics` object by using the `compareTrajectories` function.

Properties

`AbsoluteError` — Absolute trajectory error
M-by-2 matrix (default)

This property is read-only.

Absolute trajectory error, specified as an *M*-by-2 matrix of the form [*absRotationError*,*absTranslationError*]. *M* specifies the number of poses. *absRotationError* specifies the absolute rotation error in degrees and *absTranslationError* specifies the absolute translation error. The *absRotationError* is the magnitude of the rotation angle in degrees, obtained by converting the rotation matrix in *AbsoluteError_i* to the angle-axis representation. The *absTranslationError* is the Euclidean norm of the translation vector derived from *AbsoluteError_i*.

The absolute trajectory pose error calculates the exact differences between where a robot thinks it is (estimated pose), and its actual location (ground truth), at specific times. It quantifies how accurately the estimated path aligns with the actual (ground truth) path. Mathematically, if P_i^{est} is the i-th estimated pose and P_i^{gt} is the corresponding ground truth pose, then the absolute pose error of the i-th estimated pose can be defined as the:

$$AbsoluteError_i = \left\| P_i^{est} - P_i^{gt} \right\|$$

or as,

$$AbsoluteError_i = P_i^{gt} \cdot (P_i^{est})^{-1}$$

`RelativeError` — Relative trajectory pose error
M-by-2 matrix (default)

This property is read-only.

Relative trajectory pose error, specified as an *M*-by-2 matrix of the form [*relRotationError*,*relTranslationError*]. *M* specifies the number of poses. *relRotationError* specifies the relative rotation error in degrees and *relTranslationError* specifies the relative translation error.

The *relRotationError* represents the magnitude of the rotation angle, measured in degrees. This value is obtained after converting the rotation matrix in $RelativeError_{i+\Delta}$ to the angle-axis representation.

The *relTranslationError* is the Euclidean norm of the translation component extracted from $RelativeError_{i+\Delta}$.

The relative pose error calculates the differences in the robot's movement over a set distance or interval, rather than its exact position at a specific point in time. It measures how much the robot's estimated change in position (estimated relative pose) deviates from the actual change in position (ground truth relative pose) over this interval. This helps in assessing the accuracy of the robot's perception of its own movement over time.

To compute relative pose error, compare pairs of poses $(P_i^{est}, P_{i+\Delta}^{est})$ from the estimated trajectory $(P_i^{gt}, P_{i+\Delta}^{gt})$ from the actual (ground truth) trajectory, spaced by a set distance.

The error is the difference in movement between these pairs.

$$RelativeError_{i+\Delta} = \left\| \left(P_i^{est}\right)^{-1} \bullet P_{i+\Delta}^{est} - \left(P_i^{gt}\right)^{-1} \bullet P_{i+\Delta}^{gt} \right\|$$

or,

$$RelativeError_{i+\Delta} = \left(P_i^{gt}\right)^{-1} \cdot P_{i+\Delta}^{gt} \cdot \left(\left(P_i^{est}\right)^{-1} \cdot P_{i+\Delta}^{est}\right)^{-1}$$

`AbsoluteRMSE` — Root mean square of absolute trajectory error
2-element vector (default)

This property is read-only.

Root mean square (RMS) of absolute trajectory error, specified as a 2-element vector of the form [*absRotationRMS*,*absTranslationRMS*]. The RMS is calculated as:

- *absRotationRMS* = `rms`(*absRotationRMS*)
- *absTranslationRMS* = `rms`(*absTranslationRMS*)

The absolute pose error can be summarized over the entire trajectory by taking the root mean square of the individual errors.

$$AbsoluteRMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n} AbsoluteError_i^2}$$

`RelativeRMSE` — Root mean square of relative trajectory error
2-element vector (default)

This property is read-only.

Root mean square of relative (RMS) trajectory error, specified as a 2-element vector of the form [*relRotationRMS*,*relTranslationRMS*]. The RMS is calculated as:

- *relRotationRMS* = `rms`(*relRotationRMS)*
- *relTranslationRMS* = `rms`(*relTranslationRMS*)

The relative pose error can be summarized over the entire trajectory by taking the root mean square of the individual errors.

$$RelativeRMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n} RelativeError_i^2}$$

`compareTrajectories`

Objects

`rgbdvslam` | `monovslam` | `stereovslam`

plot

Plot aligned estimated trajectory and error metrics

Syntax

```
plot(metrics,metricType)
ax = plot( ___ )
plot( ___ ,Name=Value)
```

Description

`plot(metrics,metricType)` plots the aligned estimated trajectory and error values, color-coding the trajectory based on the specified metric type `metricType`, and the error values, linearly mapped to colors in the current colormap.

`ax = plot( ___ )` additionally returns the axes handle.

`plot( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to the previous syntax. For example, `ShowGroundTruth=false`, suppresses the display of the ground truth trajectory.

Input Arguments

`metrics` — Trajectory Error metrics

`trajectoryErrorMetrics`object

Trajectory Error metrics, specified as a `trajectoryErrorMetrics` object.

`metricType` — Metric type

`"absolute-rotation"` | `"absolute-translation` | `"relative-rotation"` | `"relative-translation"`

Metric type, specified as `"absolute-rotation"`, `"absolute-translation`, `"relative-rotation"`, or `"relative-translation"`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `plot(metric,metricType,ShowGroundTruth=false)`, suppresses the display of the ground truth trajectory.

`VerticalAxis` — Point cloud vertical axis and direction

`"YDown"` (default) | `"ZUp"` | `"ZDown"` | `"XUp"` | `"XDown"` | `"YUp"`

Point cloud vertical axis and direction, specified as `"ZUp"`, `"ZDown"`, `"XUp"`, `"XDown"`, `"YUp"`, or `"YDown"`. This argument sets the axis of the point cloud as the vertical axis, with the positive direction based on the value specified.

`ShowGroundTruth` — Display ground truth trajectory
`false` (default) | `true`

Display ground truth trajectory, specified as `true` or `false`.

`Parent` — Axes on which to display visualization
`Axes` graphics object

Axes on which to display the visualization, specified as an `Axes` graphics object. To create an `Axes` object, use the `axes` function. To display the visualization in a new figure, leave `Parent` unspecified.

Output Arguments

`ax` — Axes handle
`Axes` graphics object (default)

Axes handle, returned as an `axes` graphics object.

Version History

Introduced in R2024b

stereovslam

Feature-based visual simultaneous localization and mapping (vSLAM) and visual-inertial sensor fusion with stereo camera

Description

Use the `stereovslam` object to perform visual simultaneous localization and mapping (vSLAM) with stereo camera data. To learn more about visual SLAM, see “Implement Visual SLAM in MATLAB”.

The `stereovslam` object extracts Oriented FAST and Rotated BRIEF (ORB) features from incrementally read images, and then tracks those features to estimate camera poses, identify key frames, and reconstruct a 3-D environment. The vSLAM algorithm also searches for loop closures using the bag-of-features algorithm, and then optimizes the camera poses using pose graph optimization. You can enhance the accuracy and robustness of the SLAM by integrating this object with IMU data to perform visual-inertial sensor fusion.

Note The `stereovslam` object requires Navigation Toolbox™.

Creation

Syntax

```
vslam = stereovslam(intrinsics,baseline)
vslam = stereovslam(reprojectionMatrix,imageSize)
vslam = stereovslam( ___ ,imuParameters)
vslam = stereovslam( ___ ,PropertyName=Value)
```

Description

`vslam = stereovslam(intrinsics,baseline)` creates a stereo visual SLAM object, `vslam`, using the rectified stereo camera intrinsic parameters `intrinsics`, and the `baseline` distance between the rectified left and right cameras.

The object represents 3-D map points and camera poses in world coordinates, and assumes the camera pose of the first key frame is an identity `rigidtform3d` transform.

Note The `stereovslam` object runs on multiple threads internally, which can delay the processing of an image frame added by using the `addFrame` function. Additionally, the object running on multiple threads means the current frame the object is processing can be different than the recently added frame.

`vslam = stereovslam(reprojectionMatrix,imageSize)` creates a stereo visual SLAM object `vslam` using the stereo camera reprojection matrix, `reprojectionMatrix`, and the image size, `imageSize`.

`vslam = stereovslam( ___ ,imuParameters)` performs stereo visual-inertial SLAM based on the specified `imuParameters`.

`vslam = stereovslam( ___ ,PropertyName=Value)` sets properties using one or more name-value arguments in addition to any combination of input arguments from previous syntaxes. For example, `MaxNumPoints=850` sets the maximum number of ORB feature points to extract from each image to `850`.

Input Arguments

`intrinsics` — Rectified stereo camera intrinsic parameters

`cameraIntrinsics` object

Rectified stereo camera intrinsic parameters, specified as a `cameraIntrinsics` object.

This argument sets the `Intrinsics` property.

`baseline` — Distance between rectified left and right cameras

nonnegative scalar

Distance between the rectified left and right cameras, specified as a nonnegative scalar. Stereo vSLAM algorithms typically track the primary (or left) camera, in which case the baseline is greater than zero. A negative baseline value indicates a negative disparity range, and the vSLAM algorithm tracks the secondary (or right) camera instead.

This argument sets the `Baseline` property.

`reprojectionMatrix` — Reprojection matrix

4-by-4 matrix

Reprojection matrix, specified as a 4-by-4 matrix of the form:

$$\begin{bmatrix} 1 & 0 & 0 & -cx \\ 0 & 1 & 0 & -cy \\ 0 & 0 & 0 & f \\ 0 & 0 & 1/b & 0 \end{bmatrix},$$

where f and (cx,cy) are the focal length and principal point of rectified primary camera, respectively. b is the baseline of the virtual rectified stereo camera.

You can obtain the reprojection matrix by using the `rectifyStereoImages` function.

`imageSize` — Image size produced by camera

two-element vector

Image size produced by the camera, in pixels, specified as a two-element vector of the form [*nrows ncols*]. The elements *nrows* and *ncols* represent represents the number of rows and columns, respectively.

`imuParameters` — IMU parameters

`factorIMUParameters` object

IMU parameters, specified as a `factorIMUParameters` object. The object contains the noise, bias, and sample rate information about the inertial measurement unit (IMU).

Properties

Camera Parameters

`Intrinsics` — Camera intrinsic parameters

`cameraIntrinsics` object

This property is read-only.

Camera intrinsic parameters, stored as a `cameraIntrinsics` object.

Use the `intrinsics` argument to set this property.

`Baseline` — Distance between rectified left and right cameras

nonnegative scalar

Distance between the rectified left and right cameras, stored as a nonnegative scalar. Stereo vSLAM algorithms typically track the primary (or left) camera, in which case the baseline is greater than zero. A negative baseline value indicates a negative disparity range, and the vSLAM algorithm tracks the secondary (or right) camera instead.

Use the `baseline` argument to set this property.

`DisparityRange` — Disparity range

`[0 48]` (default) | two-element vector of integers

This property is read-only.

Disparity range, specified as a two-element vector of integers of the form [*min max*]. The elements specify the minimum and maximum disparity, respectively. The range must be within the width of the image, and the difference between the minimum and the maximum must be divisible by 16.

`UniquenessThreshold` — Minimum value of uniqueness

`15` (default) | nonnegative integer

Minimum value of uniqueness, specified as a nonnegative integer.

The function marks the estimated disparity value K for a pixel as unreliable if:

$$v < V \times (1 + 0.01 \times \texttt{UniquenessThreshold}),$$

where V is the sum of the absolute difference (SAD) corresponding to the disparity value K, and v is the smallest SAD value over the whole disparity range, excluding K, K–1, and K+1.

Increasing the value of `UniquenessThreshold` results in the function marking disparity values for more pixels as unreliable. To turn off the uniqueness threshold, set this value to `0`.

Feature Extraction

`ScaleFactor` — Scale factor for image decomposition

`1.2` (default) | scalar greater than 1

This property is read-only after object creation.

Scale factor for image decomposition, stored as a scalar greater than 1. The scale factor is also referred to as the pyramid decimation ratio. Increasing the value of `ScaleFactor` reduces the

number of pyramid levels, but reduce computation time. Decreasing this value (down to just over 1), increases the number of pyramid levels, which can improve tracking performance, at the cost of computation speed. The scale value at each level of decomposition is `ScaleFactor`$^{(level\text{-}1)}$, where *level* is any value in the range [0, `Numlevels`-1]. Given the input image of size *M*-by-*N*, the image size at each level of composition is M_{level}-by-N_{level}, where:

$$M_{level} = \frac{M}{ScaleFactor^{(level\ -\ 1)}}$$

$$N_{level} = \frac{N}{ScaleFactor^{(level\ -\ 1)}}$$

`NumLevels` — Number of decomposition levels
`8` (default) | integer greater than or equal to `1`

This property is read-only after object creation.

Number of decomposition levels, specified as an integer greater than or equal to `1`. Increase this value to extract keypoints from the image at more levels of decomposition. Along with the `ScaleFactor` value, `NumLevels` controls the number of pyramid levels on which the object evaluates feature points.

The image size at each decomposition level limits the number of levels at which you can extract keypoints. The image size at a level of decomposition must be at least 63-by-63 for keypoint detection. The maximum level of decomposition is calculated as

$$level_{\max} = \text{floor}\left(\frac{\log(\min(M,N))\ -\ \log(63)}{\log(\text{ScaleFactor})}\right) + 1$$

If either the default value or the specified value of `NumLevels` is greater than $level_{max}$, the object modifies `NumLevels` to $level_{max}$ and returns a warning.

`MaxNumPoints` — Maximum number of ORB feature points uniformly extracted from each image
`1000` | positive integer

This property is read-only after object creation.

Maximum number of ORB feature points uniformly extracted from each image, specified as a positive integer. Values are typically in the range of [800, 2000], depending on the resolution of the image. When the number of extracted features is less than the value of `MaxNumPoints`, then the object uses all feature points.

Tracking

`TrackFeatureRange` — Range for the number of feature points to identify key frame
`[30 100]` | two-element vector of positive integers

This property is read-only after object creation.

Key frame feature point range, stored as a two-element vector of positive integers in the form [*lowerLimit upperLimit*]. This property specifies the minimum and maximum numbers of tracked features points a frame must contain for the object to identify it as a key frame. The `TrackFeatureRange` and the `SkipMaxFrames` properties enable you to control the frequency at which frames in the tracking process become key frames.

The success of tracking depends on the number of tracked points in the current frame, with one of these results:

- Tracking is lost — The number of tracked feature points in the current frame is less than the *lowerLimit* set by the `TrackFeatureRange` argument. This indicates that the image does not contain enough features, or that the camera is moving too fast. To improve the tracking, you can increase the *upperLimit* value of the `TrackFeatureRange` property and decrease the `SkipMaxFrames` property to add key frames more frequently.
- Tracking is successful — The object identifies the current frame as a key frame. The number of tracked feature points in the current frame is in the range set by `TrackFeatureRange`.
- Tracking adds key frames too frequently — The number of tracked feature points in the current frame is greater than the *upperLimit* set by the `TrackFeatureRange` property. This indicates that the camera is moving very slowly, which produces an unnecessary number of key frames. To improve the tracking, you can reduce the frequency of adding key frames by increasing the value of the `SkipMaxFrames` property.

For more details, see the `addFrame` object function and “How to Improve Accuracy in Visual SLAM”.

`SkipMaxFrames` — Maximum number of skipped frames
`20` | positive integer

This property is read-only after object creation.

Maximum number of skipped frames, stored as a positive integer. When the number of tracked features is consistently greater than the *upperLimit* set by the `TrackFeatureRange` property, use the `SkipMaxFrames` property to control the frequency at which the object adds new key frames. The object identifies the current frame as a key frame when the number of skipped frames since the most recently added key frame equals the value of `SkipMaxFrames`. For more details, see “How to Improve Accuracy in Visual SLAM”.

`LoopClosureThreshold` — Minimum number of matched feature points between loop closure key frames
`60` | positive integer

This property is read-only after object creation.

Minimum number of matched feature points between loop closure key frames, stored as a positive integer.

`CustomBagOfFeatures` — Custom bag of features for loop detection
`[]` (default) | `bagOfFeaturesDBoW` object

This property is read-only after object creation.

Custom bag of features for loop detection, specified as a `bagOfFeaturesDBoW` object. The `bagOfFeaturesDBoW` enables you to create a custom bag of words (BoW) from feature descriptors, alongside options to utilize a built-in vocabulary or load a custom one from a specified file.

`Verbose` — Progress information display
`[]` (default) | `1` | `2` | `3`

This property is read-only after object creation.

Progress information display, specified as `[]`, `1`, `2`, or `3`. Paths to the location of log files, when they are created, is displayed on the command line. For more details, see “How to Improve Accuracy in Visual SLAM”.

Verbose value	Display description	Display location
`[]` or `false`	Display is turned off	—
`1` or `true`	Stages of vSLAM execution	Command window
`2`	Stages of vSLAM execution, with details on how the frame is processed, such as the artifacts used to initialize the map.	Log file in a temporary folder
`3`	Stages of vSLAM, artifacts used to initialize the map, poses and map points before and after bundle adjustment, and loop closure optimization data.	Log file in a temporary folder

IMU Fusion

`CameraToIMUTransform` — IMU sensor transformation
`rigidtform3d`

This property is read-only after object creation.

IMU sensor transformation, specified as a `rigidtform3d` object. The transformation describes the rotation and translation of the camera in the coordinate system of the IMU sensor.

`NumPosesThreshold` — Number of estimated camera poses to trigger camera-IMU alignment
`30` (default) | integer equal to or greater than 2

This property is read-only after object creation.

Number of estimated camera poses to trigger camera-IMU alignment, specified as an integer equal to or greater than 2. The process of aligning camera and IMU data is initiated after a specific number of camera poses have been estimated. This alignment serves two primary purposes: first, to estimate a scale factor that translates the up-to-scale results from a monocular camera into actual world units (meters), and second, to synchronize the IMU and camera frames, effectively eliminating the influence of gravity on accelerometer data. The timing for this alignment, determined by a threshold for the number of camera poses, is key to its success. A threshold set too low may not provide enough data for accurate calibration, while one set too high risks incorporating noise from measurement drift into the calibration. For a more in-depth understanding of this calibration technique, see the `estimateGravityRotationAndPoseScale` function.

`AlignmentFraction` — Subset of pose estimates
`0.8` (default) | scalar in the range (0,1]

This property is read-only after object creation.

Subset of pose estimates, specified as a scalar in the range of (0,1]. This value specifies a fraction of the number of recent pose estimates, calculated as `round(NumPosesThreshold*AlignmentFraction)`, for use in the camera-IMU alignment

process. It effectively filters out initial, potentially noisy pose estimates, ensuring only the most relevant data contributes to the alignment for improved accuracy.

Object Functions

addFrame	Add pair of color and depth images to stereo visual SLAM object
checkStatus	Check status of stereo visual SLAM object
hasNewKeyFrame	Check if new key frame added in stereo visual SLAM object
isDone	End-of-processing status for stereo visual SLAM object
mapPoints	Build 3-D map of world points from stereo vSLAM object
plot	Plot 3-D map points and estimated camera trajectory in stereo visual SLAM
poses	Absolute camera poses of stereo key frames
reset	Reset stereo visual SLAM object

Examples

Stereo Visual SLAM Using UTIAS Data Set

Perform stereo visual simultaneous localization and mapping (vSLAM) using the data from the UTIAS Long-Term Localization and Mapping Dataset provided by University of Toronto Institute for Aerospace Studies. You can download the data to a directory using a web browser, or by running this code:

```
ftpObj = ftp("asrl3.utias.utoronto.ca");
tempFolder = fullfile(tempdir);
dataFolder = [tempFolder,'2020-vtr-dataset\UTIAS-In-The-Dark\'];
zipFileName = [dataFolder,'run_000005.zip'];
folderExists = exist(dataFolder,"dir");
```

Create a folder in a temporary directory to save the downloaded file and extract its contents.

```
if ~folderExists
    mkdir(dataFolder)
    disp("Downloading run_000005.zip (818 MB). This download can take a few minutes.")
    mget(ftpObj,"/2020-vtr-dataset/UTIAS-In-The-Dark/run_000005.zip",tempFolder);

    disp("Extracting run_000005.zip (818 MB) ...")
    unzip(zipFileName,dataFolder);
end
```

Create two `imageDatastore` objects to store the stereo images.

```
imgFolderLeft = [dataFolder,'\images\left\'];
imgFolderRight = [dataFolder,'\images\right\'];
imdsLeft = imageDatastore(imgFolderLeft);
imdsRight = imageDatastore(imgFolderRight);
```

Specify the intrinsic parameters and the baseline of the stereo camera, and use them to create a stereo visual SLAM object. The focal length, principal point, and image size is in pixels, and the baseline is in meters.

```
focalLength = [387.777 387.777];
principalPoint = [257.446 197.718];
imageSize = [384 512];
intrinsics = cameraIntrinsics(focalLength,principalPoint,imageSize);
```

```
baseline = 0.239965;

vslam = stereovslam(intrinsics,baseline,MaxNumPoints=600, ...
    TrackFeatureRange=[30 120],SkipMaxFrames=5);
```

Process each pair of stereo images and visualize the camera poses and 3-D map points.

```
for i = 1:numel(imdsLeft.Files)
    leftImage = readimage(imdsLeft,i);
    rightImage = readimage(imdsRight,i);
    addFrame(vslam,leftImage,rightImage);

    if hasNewKeyFrame(vslam)
        % Query 3-D map points and camera poses
        xyzPoints = mapPoints(vslam);
        [camPoses,viewIds] = poses(vslam);

        % Display 3-D map points and camera trajectory
        plot(vslam);
    end

    % Get current status of system
    status = checkStatus(vslam);

    % Stop adding frames when tracking is lost
    if status == uint8(0)
        break
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    plot(vslam)
end
```

```
reset(vslam)
```

Tips

- The `stereovslam` object:
  - Does not account for lens distortion. You can undistort the images by using the `undistortImage` function before adding images.
  - Assumes images have been rectified. You can rectify undistorted stereo images by using the `rectifyStereoImages` function before adding images.
  - Runs on multiple threads internally, which can delay the processing of an image frame added by using the `addFrame` function. Additionally, the object running on multiple threads means the current frame the object is processing can be different than the most recently added frame.
- The camera poses are the poses of the primary camera, which corresponds to the input image `I1` added by the `addFrame` object function.
- The object represents 3-D map points and camera poses in world coordinates. The object assumes the camera pose of the first key frame is an identity `rigidtform3d` transform.

Version History

Introduced in R2024a

R2025a: `stereovslam` available in Navigation Toolbox with Computer Vision Toolbox license

You can use the `stereovslam` object in Navigation Toolbox if you have a Computer Vision Toolbox license.

R2024b: Set disparity map for stereo vSLAM images

Use the `DisparityMap` name-value argument of the `addFrame` function.

R2024b: Add ability to specify custom bag of words

Use the `CustomBagOfFeatures` name-value argument to specify a custom bag of words vocabulary as a `bagOfFeaturesDBoW` object.

R2024b: `Verbose` property enhanced to display progress information
Behavior changed in R2024b

The `Verbose` property added values of `1`, `2`, and `3` to display levels of progress information.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

To compile the generated code for non-host target, these dependencies must be installed:

- OpenCV 4.7.0
- Ceres-solver 2.2.0 library — Download the source and build it as a shared library, on your remote device.
- eigen3 Library

When generating portable C code with a C++ compiler, you must specify hierarchical packing with non-minimal headers. For more information on packaging options, see the `packNGo` function.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

addFrame

Add pair of color and depth images to stereo visual SLAM object

Syntax

```
addFrame(vslam,I1,I2)
addFrame( ___ ,gyro,accel)
addFrame( ___ ,DisparityMap=Value)
```

Description

`addFrame(vslam,I1,I2)` adds the pair of RGB or grayscale stereo images, `I1` and `I2`, to the stereo visual SLAM object `vslam`.

Note The `stereovslam` object runs on multiple threads internally, which can delay the processing of an image frame added by using the `addFrame` function. Additionally, the object running on multiple threads means the current frame the object is processing can be different than the recently added frame.

`addFrame( ___ ,gyro,accel)` adds IMU gyroscope and acceleration measurements for visual-inertial fusion.

`addFrame( ___ ,DisparityMap=Value)` sets the disparity map for the stereo input images `I1` and `I2`. The disparity map must be a single or double matrix and the same width and height as the input images. If unspecified, the function defaults to calculating frame disparity using semi-global block matching.

Examples

Stereo Visual SLAM Using UTIAS Data Set

Perform stereo visual simultaneous localization and mapping (vSLAM) using the data from the UTIAS Long-Term Localization and Mapping Dataset provided by University of Toronto Institute for Aerospace Studies. You can download the data to a directory using a web browser, or by running this code:

```
ftpObj = ftp("asrl3.utias.utoronto.ca");
tempFolder = fullfile(tempdir);
dataFolder = [tempFolder,'2020-vtr-dataset\UTIAS-In-The-Dark\'];
zipFileName = [dataFolder,'run_000005.zip'];
folderExists = exist(dataFolder,"dir");
```

Create a folder in a temporary directory to save the downloaded file and extract its contents.

```
if ~folderExists
    mkdir(dataFolder)
    disp("Downloading run_000005.zip (818 MB). This download can take a few minutes.")
    mget(ftpObj,"/2020-vtr-dataset/UTIAS-In-The-Dark/run_000005.zip",tempFolder);
```

```
    disp("Extracting run_000005.zip (818 MB) ...")
    unzip(zipFileName,dataFolder);
end
```

Create two `imageDatastore` objects to store the stereo images.

```
imgFolderLeft = [dataFolder,'\images\left\'];
imgFolderRight = [dataFolder,'\images\right\'];
imdsLeft = imageDatastore(imgFolderLeft);
imdsRight = imageDatastore(imgFolderRight);
```

Specify the intrinsic parameters and the baseline of the stereo camera, and use them to create a stereo visual SLAM object. The focal length, principal point, and image size is in pixels, and the baseline is in meters.

```
focalLength = [387.777 387.777];
principalPoint = [257.446 197.718];
imageSize = [384 512];
intrinsics = cameraIntrinsics(focalLength,principalPoint,imageSize);
baseline = 0.239965;

vslam = stereovslam(intrinsics,baseline,MaxNumPoints=600, ...
    TrackFeatureRange=[30 120],SkipMaxFrames=5);
```

Process each pair of stereo images and visualize the camera poses and 3-D map points.

```
for i = 1:numel(imdsLeft.Files)
    leftImage = readimage(imdsLeft,i);
    rightImage = readimage(imdsRight,i);
    addFrame(vslam,leftImage,rightImage);

    if hasNewKeyFrame(vslam)
        % Query 3-D map points and camera poses
        xyzPoints = mapPoints(vslam);
        [camPoses,viewIds] = poses(vslam);

        % Display 3-D map points and camera trajectory
        plot(vslam);
    end

    % Get current status of system
    status = checkStatus(vslam);

    % Stop adding frames when tracking is lost
    if status == uint8(0)
        break
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    plot(vslam)
end
```

```
reset(vslam)
```

Input Arguments

`vslam` — Stereo visual SLAM object

`stereovslam` object

Stereo visual SLAM object, specified as a `stereovslam` object.

`I1` — Image 1

RGB image | grayscale image

Image 1, specified as a nonsparse RGB or grayscale image. The stereo visual slam object tracks the pose of camera 1, the left camera, which corresponds to image `I1` in the stereo camera system. The input images must be undistorted and rectified. You can undistort and then rectify the images by using the `undistortImage` and `rectifyStereoImages` functions, respectively, before adding the images.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

`I2` — Image 2

RGB image | grayscale image

Image 2, specified as a nonsparse RGB or grayscale image. Image 2 corresponds to the right camera in the stereo camera system. The input images must be undistorted and rectified. You can undistort

and then rectify the images by using the `undistortImage` and `rectifyStereoImages` functions, respectively, before adding the images.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

`gyro` — Gyroscope measurement
N-by-3 matrix

Gyroscope measurement, specified as an *N*-by-3 matrix. Each row of the matrix represents the *x*, *y*, and *z* components of the gyroscope measurement for a single frame, of the form [*gx*,*gy*,*gz*]. *N* represents the total number of frames. *N* represents the number of IMU measurements between the previous and current camera frames. The number of gyroscope and accelerometer measurements must be equal.

`accel` — Acceleration measurement
N-by-3 matrix

Acceleration measurement, specified as an *N*-by-3 matrix. Each row of the matrix represents the *x*, *y*, and *z* components of the acceleration measurement for a single frame, of the form [*ax*,*ay*,*az*]. *N* represents the number of IMU measurements between the previous and current camera frames. The number of gyroscope and accelerometer measurements must be equal.

Version History

Introduced in R2024a

R2024b: Set disparity map for stereo vSLAM images

Use the frame disparity by using the `DisparityMap` name-value argument.

hasNewKeyFrame

Check if new key frame added in stereo visual SLAM object

Syntax

```
hasAdded = hasNewKeyFrame(vslam)
```

Description

`hasAdded = hasNewKeyFrame(vslam)` returns a logical value that indicates if a new key frame has been added within the stereo visual simultaneous localization and mapping (vSLAM) object `vslam`.

Examples

Stereo Visual SLAM Using UTIAS Data Set

Perform stereo visual simultaneous localization and mapping (vSLAM) using the data from the UTIAS Long-Term Localization and Mapping Dataset provided by University of Toronto Institute for Aerospace Studies. You can download the data to a directory using a web browser, or by running this code:

```
ftpObj = ftp("asrl3.utias.utoronto.ca");
tempFolder = fullfile(tempdir);

vslam = stereovslam(intrinsics,baseline,MaxNumPoints=600, ...
    TrackFeatureRange=[30 120],SkipMaxFrames=5);
```

Process each pair of stereo images and visualize the camera poses and 3-D map points.

```
for i = 1:numel(imdsLeft.Files)
    leftImage = readimage(imdsLeft,i);
    rightImage = readimage(imdsRight,i);
    addFrame(vslam,leftImage,rightImage);

    if hasNewKeyFrame(vslam)
        % Query 3-D map points and camera poses
        xyzPoints = mapPoints(vslam);
        [camPoses,viewIds] = poses(vslam);

        % Display 3-D map points and camera trajectory
        plot(vslam);
    end

    % Get current status of system
    status = checkStatus(vslam);

    % Stop adding frames when tracking is lost
    if status == uint8(0)
        break
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    plot(vslam)
end
```

```
reset(vslam)
```

Input Arguments

`vslam` — Stereo visual SLAM object
`stereovslam` object

Stereo visual SLAM object, specified as a `stereovslam` object.

Output Arguments

`hasAdded` — New key frame status
`false` or `0` | `true` or `1`

New key frame status, returned as a logical `0` (`false`) or `1` (`true`). A value of `true` indicates that a new key frame has been added within the stereo visual SLAM object `vslam`. A value of `false` indicates that no new key frame has been added. The object considers an image frame to be a key frame if the number of tracked feature points in the current frame satisfies one these conditions:

- The number of tracked feature points is within the limits specified by the `TrackFeatureRange` property of the `stereovslam` object `vslam`.
- The number of tracked feature points is greater than the upper limit specified by the `TrackFeatureRange` property of the `stereovslam` object `vslam`, and the number of skipped

frames since adding the last key frame equals the value of the `SkipMaxFrames` property of `vslam`.

The `hasNewKeyFrame` object function returns `true` only when the `stereovslam` object has added one or more new key frames since the last `hasNewKeyFrame` call. For example, if the `stereovslam` object adds only one key frame, then two consecutive calls to `hasNewKeyFrame` return `true` and `false`, respectively.

checkStatus

Check status of stereo visual SLAM object

Syntax

```
status = checkStatus(vslam)
```

Description

`status = checkStatus(vslam)` returns the current status of the stereo visual SLAM object. The frame the object is currently processing might be different than the most recently added frame.

Examples

Stereo Visual SLAM Using UTIAS Data Set

Perform stereo visual simultaneous localization and mapping (vSLAM) using the data from the UTIAS Long-Term Localization and Mapping Dataset provided by University of Toronto Institute for Aerospace Studies. You can download the data to a directory using a web browser, or by running this code:

```
ftpObj = ftp("asrl3.utias.utoronto.ca");
tempFolder = fullfile(tempdir);
dataFolder = [tempFolder,'2020-vtr-dataset\UTIAS-In-The-Dark\'];
zipFileName = [dataFolder,'run_000005.zip'];
folderExists = exist(dataFolder,"dir");
```

Create a folder in a temporary directory to save the downloaded file and extract its contents.

```
if ~folderExists
    mkdir(dataFolder)
    disp("Downloading run_000005.zip (818 MB). This download can take a few minutes.")
    mget(ftpObj,"/2020-vtr-dataset/UTIAS-In-The-Dark/run_000005.zip",tempFolder);

    disp("Extracting run_000005.zip (818 MB) ...")
    unzip(zipFileName,dataFolder);
end
```

Create two `imageDatastore` objects to store the stereo images.

```
imgFolderLeft = [dataFolder,'\images\left\'];
imgFolderRight = [dataFolder,'\images\right\'];
imdsLeft = imageDatastore(imgFolderLeft);
imdsRight = imageDatastore(imgFolderRight);
```

Specify the intrinsic parameters and the baseline of the stereo camera, and use them to create a stereo visual SLAM object. The focal length, principal point, and image size is in pixels, and the baseline is in meters.

```
focalLength = [387.777 387.777];
principalPoint = [257.446 197.718];
```

```
imageSize = [384 512];
intrinsics = cameraIntrinsics(focalLength,principalPoint,imageSize);
baseline = 0.239965;

vslam = stereovslam(intrinsics,baseline,MaxNumPoints=600, ...
    TrackFeatureRange=[30 120],SkipMaxFrames=5);
```

Process each pair of stereo images and visualize the camera poses and 3-D map points.

```
for i = 1:numel(imdsLeft.Files)
    leftImage = readimage(imdsLeft,i);
    rightImage = readimage(imdsRight,i);
    addFrame(vslam,leftImage,rightImage);

    if hasNewKeyFrame(vslam)
        % Query 3-D map points and camera poses
        xyzPoints = mapPoints(vslam);
        [camPoses,viewIds] = poses(vslam);

        % Display 3-D map points and camera trajectory
        plot(vslam);
    end

    % Get current status of system
    status = checkStatus(vslam);

    % Stop adding frames when tracking is lost
    if status == uint8(0)
        break
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    plot(vslam)
end
```

```
reset(vslam)
```

Input Arguments

`vslam` — Stereo visual SLAM object

`stereovslam` object

Stereo visual SLAM object, specified as a `stereovslam` object.

Output Arguments

`status` — Current status of stereo visual SLAM object

`TrackingLost` enumeration | `TrackingSuccessful` enumeration | `FrequentKeyFrames` enumeration

Current status of the stereo visual SLAM object, returned as a `TrackingLost`, `TrackingSuccessful`, or `FrequentKeyFrames` enumeration. This table describes these enumerations.

Enumeration Value	Numeric Value	Description
`TrackingLost`	`uint8(0)`	Tracking is lost. The number of tracked feature points in the frame currently being processed is less than the lower limit of the `TrackFeatureRange` property of `vslam`. This indicates the image does not contain enough features, or that the camera is moving too fast. If the object does not accept enough frames as key frames, to improve tracking, you can increase the *upperLimit* value of the `TrackFeatureRange` property and decrease the `SkipMaxFrames` property to add key frames more frequently.
`TrackingSuccessful`	`uint8(1)`	Tracking is successful. The number of tracked feature points in the frame currently being processed is between the lower limit and upper limit values of the `TrackFeatureRange` property of `vslam`.
`FrequentKeyFrames`	`uint8(2)`	Tracking adds key frames too frequently. The number of tracked feature points in the frame currently being processed is greater than the upper limit of the `TrackFeatureRange` property of `vslam`.

isDone

End-of-processing status for stereo visual SLAM object

Syntax

```
done = isDone(vslam)
```

Description

`done = isDone(vslam)` returns a logical value indicating whether the stereo visual SLAM object has finished processing its frames. A value of `true` indicates the object is in an idle state. A value of `false` indicates the object is processing one or more frames.

Examples

Stereo Visual SLAM Using UTIAS Data Set

Perform stereo visual simultaneous localization and mapping (vSLAM) using the data from the UTIAS Long-Term Localization and Mapping Dataset provided by University of Toronto Institute for Aerospace Studies. You can download the data to a directory using a web browser, or by running this code:

mapPoints

Build 3-D map of world points from stereo vSLAM object

Syntax

```
xyzPoints = mapPoints(vslam)
```

Description

`xyzPoints = mapPoints(vslam)` builds a sparse 3-D map of world points, `xyzPoints`, from the input images in the stereo visual simultaneous localization and mapping (vSLAM) object `vslam`.

Examples

Stereo Visual SLAM Using UTIAS Data Set

Perform stereo visual simultaneous localization and mapping (vSLAM) using the data from the UTIAS Long-Term Localization and Mapping Dataset provided by University of Toronto Institute for Aerospace Studies. You can download the data to a directory using a web browser, or by running this code:

end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    plot(vslam)
end
```

```
reset(vslam)
```

Input Arguments

`vslam` — Stereo visual SLAM object

`stereovslam` object

Stereo visual SLAM object, specified as a `stereovslam` object.

Output Arguments

`xyzPoints` — World point coordinates of 3-D map

M-by-3 matrix

World point coordinates of 3-D map, returned as an *M*-by-3 matrix. *M* is the number of points, and each point is of the form [*X Y Z*].

poses

Absolute camera poses of stereo key frames

Syntax

```
camPoses = poses(vslam)
[camPoses,keyFrameIDs] = poses(vslam)
```

Description

`camPoses = poses(vslam)` returns the absolute primary camera poses `camPoses` of the key frames from the visual simultaneous localization and mapping (vSLAM) object `vslam`.

`[camPoses,keyFrameIDs] = poses(vslam)` returns the IDs `keyFrameIDs` of the key frames corresponding to the primary camera poses. The IDs represent the order in which the image frames have been added to the `vslam` object by the `addFrame` object function.

Examples

Stereo Visual SLAM Using UTIAS Data Set

Perform stereo visual simultaneous localization and mapping (vSLAM) using the data from the UTIAS Long-Term Localization and Mapping Dataset provided by University of Toronto Institute for Aerospace Studies. You can download the data to a directory using a web browser, or by running this code:

    status = checkStatus(vslam);

    % Stop adding frames when tracking is lost
    if status == uint8(0)
        break
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    plot(vslam)
end
```

```
reset(vslam)
```

Input Arguments

`vslam` — Stereo visual SLAM object
`stereovslam` object

Stereo visual SLAM object, specified as a `stereovslam` object.

Output Arguments

`camPoses` — Absolute primary camera poses of key frames
M-element array of `rigidtform3d` objects

Absolute primary camera poses of the key frames, returned as an *M*-element array of `rigidtform3d` objects.

`keyFrameIDs` — Key frame IDs for absolute primary camera poses
M-element array of integers

Key frame IDs for the absolute primary camera poses, returned as an *M*-element array of integers. Each element specifies the key frame ID for the camera pose in the corresponding element of `camPoses`. The IDs represent the order in which the image frames have been added to `vslam` by the `addFrame` object function.

plot

Plot 3-D map points and estimated camera trajectory in stereo visual SLAM

Syntax

```
plot(vslam)
plot(vslam,Name=Value)
ax = plot( ___ )
```

Description

`plot(vslam)` plots the 3-D map points and estimated camera trajectory from the visual SLAM object `vslam`.

`plot(vslam,Name=Value)` specifies options using one or more name-value arguments. For example, `MarkerSize=10` sets the diameter of the marker size to 10 points.

`ax = plot( ___ )` returns the axes handle for the 3-D mapped points of the plot, using any combination of input arguments from previous syntaxes.

Examples

Stereo Visual SLAM Using UTIAS Data Set

Perform stereo visual simultaneous localization and mapping (vSLAM) using the data from the UTIAS Long-Term Localization and Mapping Dataset provided by University of Toronto Institute for Aerospace Studies. You can download the data to a directory using a web browser, or by running this code:

```
ftpObj = ftp("asrl3.utias.utoronto.ca");
tempFolder = fullfile(tempdir);
dataFolder = [tempFolder,'2020-vtr-dataset\UTIAS-In-The-Dark\'];

if ~folderExists
    mkdir(dataFolder)
    disp("Downloading run_000005.zip (818 MB). This download can take a few minutes.")
    mget(ftpObj,"/2020-vtr-dataset/UTIAS-In-The-Dark/run_000005.zip",tempFolder);

    disp("Extracting run_000005.zip (818 MB) ...")
    unzip(zipFileName,dataFolder);
end
```

Create two `imageDatastore` objects to store the stereo images.

```
imgFolderLeft = [dataFolder,'\images\left\'];
imgFolderRight = [dataFolder,'\images\right\'];
```

```
imdsLeft = imageDatastore(imgFolderLeft);
imdsRight = imageDatastore(imgFolderRight);
```

Specify the intrinsic parameters and the baseline of the stereo camera, and use them to create a stereo visual SLAM object. The focal length, principal point, and image size is in pixels, and the baseline is in meters.

```
focalLength = [387.777 387.777];
principalPoint = [257.446 197.718];
imageSize = [384 512];
intrinsics = cameraIntrinsics(focalLength,principalPoint,imageSize);
baseline = 0.239965;

vslam = stereovslam(intrinsics,baseline,MaxNumPoints=600, ...
    TrackFeatureRange=[30 120],SkipMaxFrames=5);
```

Process each pair of stereo images and visualize the camera poses and 3-D map points.

```
for i = 1:numel(imdsLeft.Files)
    leftImage = readimage(imdsLeft,i);
    rightImage = readimage(imdsRight,i);
    addFrame(vslam,leftImage,rightImage);

    if hasNewKeyFrame(vslam)
        % Query 3-D map points and camera poses
        xyzPoints = mapPoints(vslam);
        [camPoses,viewIds] = poses(vslam);

        % Display 3-D map points and camera trajectory
        plot(vslam);
    end

    % Get current status of system
    status = checkStatus(vslam);

    % Stop adding frames when tracking is lost
    if status == uint8(0)
        break
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    plot(vslam)
end
```

```
reset(vslam)
```

Input Arguments

`vslam` — Stereo visual SLAM object

`stereovslam` object

Stereo visual SLAM object, specified as a `stereovslam` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `plot(vslam,MarkerSize=10)`, sets the diameter of the marker to 10 points.

`MarkerSize` — Diameter of markers for 3-D map points

`6` (default) | positive integer

Diameter of markers for the 3-D map points, specified as a positive integer in points.

`MarkerColor` — Color of markers for 3-D map points

`[0 1 0]` (default) | RGB triplet | short or long color name

Color of the markers for the 3-D map points, specified as an RGB triplet or a short or long color name. Each value within an RGB triplet must be in the range [`0 1`].

`ColorSource` — Colormap source for the markers
`"Y"` (default) | `"X"` | `"Z"` | `"MarkerColor"`

Colormap source for markers, specified as `"X"`, `"Y"`, `"Z"`, or `"MarkerColor"`.

`CameraSize` — Width of camera base
`0.1` (default) | positive scalar

Width of the camera base, specified as a positive scalar in the data units of the axes.

`CameraColor` — Color of camera
`[1 0 0]` (default) | RGB triplet | short or long color name

Color of the camera, specified as an RGB triplet or a short or long color name. Each value within an RGB triplet must be in the range [`0 1`].

`Parent` — Axes for visualization
`Axes` object | `UIAxes` object

Axes for visualization, specified as an `Axes` graphics object or a `UIAxes` object. Use this name-value argument to visualize the plot in a UI for which you have specified `Figure` and `Axes` properties.

Output Arguments

`ax` — Axes handle
`Axes` graphics object

Axes handle, returned as an `axes` graphics object.

reset

Reset stereo visual SLAM object

Syntax

`reset(vslam)`

Description

`reset(vslam)` resets all internal processes and clears all data in the `stereovslam` object.

Examples

Stereo Visual SLAM Using UTIAS Data Set

Perform stereo visual simultaneous localization and mapping (vSLAM) using the data from the UTIAS Long-Term Localization and Mapping Dataset provided by University of Toronto Institute for Aerospace Studies. You can download the data to a directory using a web browser, or by running this code:

```
ftpObj = ftp("asrl3.utias.utoronto.ca");
tempFolder = fullfile(tempdir);
dataFolder = [tempFolder,'2020-vtr-dataset\UTIAS-In-The-Dark\'];
zipFileName = [dataFolder,'run_000005.zip'];
folderExists = exist(dataFolder,"dir");
```

Create a folder in a temporary directory to save the downloaded file and extract its contents.

```
if ~folderExists
    mkdir(dataFolder)
    disp("Downloading run_000005.zip (818 MB). This download can take a few minutes.")
    mget(ftpObj,"/2020-vtr-dataset/UTIAS-In-The-Dark/run_000005.zip",tempFolder);

    disp("Extracting run_000005.zip (818 MB) ...")
    unzip(zipFileName,dataFolder);
end
```

Create two `imageDatastore` objects to store the stereo images.

```
imgFolderLeft = [dataFolder,'\images\left\'];
imgFolderRight = [dataFolder,'\images\right\'];
imdsLeft = imageDatastore(imgFolderLeft);
imdsRight = imageDatastore(imgFolderRight);
```

Specify the intrinsic parameters and the baseline of the stereo camera, and use them to create a stereo visual SLAM object. The focal length, principal point, and image size is in pixels, and the baseline is in meters.

```
focalLength = [387.777 387.777];
principalPoint = [257.446 197.718];
imageSize = [384 512];
```

```
intrinsics = cameraIntrinsics(focalLength,principalPoint,imageSize);
baseline = 0.239965;

vslam = stereovslam(intrinsics,baseline,MaxNumPoints=600, ...
    TrackFeatureRange=[30 120],SkipMaxFrames=5);
```

Process each pair of stereo images and visualize the camera poses and 3-D map points.

```
for i = 1:numel(imdsLeft.Files)
    leftImage = readimage(imdsLeft,i);
    rightImage = readimage(imdsRight,i);
    addFrame(vslam,leftImage,rightImage);

    if hasNewKeyFrame(vslam)
        % Query 3-D map points and camera poses
        xyzPoints = mapPoints(vslam);
        [camPoses,viewIds] = poses(vslam);

        % Display 3-D map points and camera trajectory
        plot(vslam);
    end

    % Get current status of system
    status = checkStatus(vslam);

    % Stop adding frames when tracking is lost
    if status == uint8(0)
        break
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    plot(vslam)
end
```

```
reset(vslam)
```

Input Arguments

`vslam` — Stereo visual SLAM object

`stereovslam` object

Stereo visual SLAM object, specified as a `stereovslam` object.

Version History

Introduced in R2024a

rgbdvslam

Feature-based visual simultaneous localization and mapping (vSLAM) and visual-inertial sensor fusion with RGB-D camera

Description

Use the `rgbdvslam` object to perform visual simultaneous localization and mapping (vSLAM) with RGB-D camera data. RGB-D vSLAM combines depth information from sensors, such as RGB-D cameras or depth sensors, with RGB images to simultaneously estimate the camera pose and create a map of the environment. To learn more about visual SLAM, see “Implement Visual SLAM in MATLAB”.

The `rgbdvslam` object extracts Oriented FAST and Rotated BRIEF (ORB) features from incrementally read images, and then tracks those features to estimate camera poses, identify key frames, and reconstruct a 3-D environment. The vSLAM algorithm also searches for loop closures using the bag-of-features algorithm, and then optimizes the camera poses using pose graph optimization. You can enhance the accuracy and robustness of the SLAM by integrating this object with IMU data to perform visual-inertial sensor fusion.

Note The `rgbdvslam` object requires Navigation Toolbox.

Creation

Syntax

```
vslam = rgbdvslam(intrinsics)
vslam = rgbdvslam(intrinsics,depthScaleFactor)
vslam = rgbdvslam( ___ ,imuParameters)
vslam = rgbdvslam(intrinsics,PropertyName=Value)
```

Description

`vslam = rgbdvslam(intrinsics)` creates an RGB-D visual SLAM object, `vslam`, by using the specified camera intrinsic parameters.

The `rgbdvslam` object assumes the color and the depth images have been preregistered with one-to-one correspondence.

The object represents 3-D map points and camera poses in world coordinates, and assumes the camera pose of the first key frame is an identity `rigidtform3d` transform.

Note The `rgbdvslam` object runs on multiple threads internally, which can delay the processing of an image frame added by using the `addFrame` function. Additionally, the object running on multiple threads means the current frame the object is processing can be different than the recently added frame.

`vslam = rgbdvslam(intrinsics,depthScaleFactor)` specifies the depth correction factor of the RGB-D camera, which the camera manufacturer usually provides. Use this syntax when the depth scale factor for the sensor is not equal to `1`.

`vslam = rgbdvslam( ___ ,imuParameters)` performs RGB-D visual-inertial SLAM based on the specified `imuParameters`.

`vslam = rgbdvslam(intrinsics,PropertyName=Value)` sets properties using one or more name-value arguments. For example, `MaxNumPoints=850` sets the maximum number of ORB feature points to extract from each image to `850`.

Input Arguments

`intrinsics` — Camera intrinsic parameters
`cameraIntrinsics` object

Camera intrinsic parameters, specified as a `cameraIntrinsics` object.

This argument sets the `Intrinsics` property.

`depthScaleFactor` — Depth scale factor
scalar

Depth scale factor, specified as a scalar in real-world units, such as meters. The depth scale factor is the conversion factor that relates the depth values of the depth sensor to real-world distances, and is typically expressed in the same units as the depth measurements provided by the sensor, such as millimeters, centimeters, or meters. This value provides the necessary information to transform the depth measurements into the metric scale. Use the `depthScaleFactor` argument when the value for the sensor you are using is not equal to `1`.

For the world 3-D coordinates (X, Y, Z), where Z is the depth at any pixel coordinate (u, v), $Z = P/$ `depthScaleFactor`, where P represents the intensity value of the depth image at pixel (u, v).

This argument sets the `DepthScaleFactor` property.

`imuParameters` — IMU parameters
`factorIMUParameters` object

IMU parameters, specified as a `factorIMUParameters` object. The object contains the noise, bias, and sample rate information about the inertial measurement unit (IMU).

Properties

Camera Parameters

`Intrinsics` — Camera intrinsic parameters
`cameraIntrinsics` object

This property is read-only.

Camera intrinsic parameters, stored as a `cameraIntrinsics` object.

Use the `intrinsics` argument to set this property.

`DepthScaleFactor` — Depth scale factor

scalar

This property is read-only after object creation.

Depth scale factor, specified as a scalar in real-world units (e.g., meters). The depth scale factor depends on the depth sensor, and it is typically expressed in the same unit as the depth measurements provided by the sensor (e.g., millimeters, centimeters, or meters). It is the conversion factor that relates the depth values to real-world distances. In other words, it provides the necessary information to transform the depth measurements into metric scale.

For the world 3-D coordinates (X,Y,Z), where Z represents depth at any pixel coordinate (u,v), Z would be computed as $Z = P/$`depthScaleFactor`, where P represents the intensity value of the depth image at pixel (u,v).

Use the `depthScaleFactor` argument to set this property.

`DepthRange` — Depth range of RGB-D camera

`[0.5 5]` (default) | two-element vector

This property is read-only after object creation.

Depth range of the RGB-D camera, specified as a two-element vector, in world units. The range specifies the minimum and maximum depth values of the camera, which you can use to filter out invalid depth values in the depth images.

Feature Extraction

`ScaleFactor` — Scale factor for image decomposition

`1.2` (default) | scalar greater than 1

This property is read-only after object creation.

Scale factor for image decomposition, stored as a scalar greater than 1. The scale factor is also referred to as the pyramid decimation ratio. Increasing the value of `ScaleFactor` reduces the number of pyramid levels, but reduce computation time. Decreasing this value (down to just over 1), increases the number of pyramid levels, which can improve tracking performance, at the cost of computation speed. The scale value at each level of decomposition is $\texttt{ScaleFactor}^{(level\text{-}1)}$, where *level* is any value in the range [0, `Numlevels`-1]. Given the input image of size M-by-N, the image size at each level of composition is M_{level}-by-N_{level}, where:

$$M_{level} = \frac{M}{ScaleFactor^{(level\ -\ 1)}}$$

$$N_{level} = \frac{N}{ScaleFactor^{(level\ -\ 1)}}$$

`NumLevels` — Number of decomposition levels

`8` (default) | integer greater than or equal to `1`

This property is read-only after object creation.

Number of decomposition levels, specified as an integer greater than or equal to `1`. Increase this value to extract keypoints from the image at more levels of decomposition. Along with the `ScaleFactor` value, `NumLevels` controls the number of pyramid levels on which the object evaluates feature points.

The image size at each decomposition level limits the number of levels at which you can extract keypoints. The image size at a level of decomposition must be at least 63-by-63 for keypoint detection. The maximum level of decomposition is calculated as

$$level_{\max} = \text{floor}\left(\frac{\log(\min(M,N)) - \log(63)}{\log(\text{ScaleFactor})}\right) + 1$$

If either the default value or the specified value of `NumLevels` is greater than $level_{max}$, the object modifies `NumLevels` to $level_{max}$ and returns a warning.

`MaxNumPoints` — Maximum number of ORB feature points uniformly extracted from each image

`1000` | positive integer

This property is read-only after object creation.

Maximum number of ORB feature points uniformly extracted from each image, specified as a positive integer. Values are typically in the range of [800, 2000], depending on the resolution of the image. When the number of extracted features is less than the value of `MaxNumPoints`, then the object uses all feature points.

Tracking

`TrackFeatureRange` — Range for the number of feature points to identify key frame

`[30 100]` | two-element vector of positive integers

This property is read-only after object creation.

Key frame feature point range, stored as a two-element vector of positive integers in the form [*lowerLimit upperLimit*]. This property specifies the minimum and maximum numbers of tracked features points a frame must contain for the object to identify it as a key frame. The `TrackFeatureRange` and the `SkipMaxFrames` properties enable you to control the frequency at which frames in the tracking process become key frames.

The success of tracking depends on the number of tracked points in the current frame, with one of these results:

- Tracking is lost — The number of tracked feature points in the current frame is less than the *lowerLimit* set by the `TrackFeatureRange` argument. This indicates that the image does not contain enough features, or that the camera is moving too fast. To improve the tracking, you can increase the *upperLimit* value of the `TrackFeatureRange` property and decrease the `SkipMaxFrames` property to add key frames more frequently.
- Tracking is successful — The object identifies the current frame as a key frame. The number of tracked feature points in the current frame is in the range set by `TrackFeatureRange`.
- Tracking adds key frames too frequently — The number of tracked feature points in the current frame is greater than the *upperLimit* set by the `TrackFeatureRange` property. This indicates that the camera is moving very slowly, which produces an unnecessary number of key frames. To improve the tracking, you can reduce the frequency of adding key frames by increasing the value of the `SkipMaxFrames` property.

For more details, see the `addFrame` object function and “How to Improve Accuracy in Visual SLAM”.

`SkipMaxFrames` — Maximum number of skipped frames

`20` | positive integer

This property is read-only after object creation.

Maximum number of skipped frames, stored as a positive integer. When the number of tracked features is consistently greater than the *upperLimit* set by the `TrackFeatureRange` property, use the `SkipMaxFrames` property to control the frequency at which the object adds new key frames. The object identifies the current frame as a key frame when the number of skipped frames since the most recently added key frame equals the value of `SkipMaxFrames`. For more details, see “How to Improve Accuracy in Visual SLAM”.

`LoopClosureThreshold` — Minimum number of matched feature points between loop closure key frames
`60` | positive integer

This property is read-only after object creation.

Minimum number of matched feature points between loop closure key frames, stored as a positive integer.

`CustomBagOfFeatures` — Custom bag of features for loop detection
`[]` (default) | `bagOfFeaturesDBoW` object

This property is read-only after object creation.

Custom bag of features for loop detection, specified as a `bagOfFeaturesDBoW` object. The `bagOfFeaturesDBoW` enables you to create a custom bag of words (BoW) from feature descriptors, alongside options to utilize a built-in vocabulary or load a custom one from a specified file.

`Verbose` — Progress information display
`[]` (default) | `1` | `2` | `3`

This property is read-only after object creation.

Progress information display, specified as `[]`, `1`, `2`, or `3`. Paths to the location of log files, when they are created, is displayed on the command line. For more details, see “How to Improve Accuracy in Visual SLAM”.

Verbose value	Display description	Display location
`[]` or `false`	Display is turned off	—
`1` or `true`	Stages of vSLAM execution	Command window
`2`	Stages of vSLAM execution, with details on how the frame is processed, such as the artifacts used to initialize the map.	Log file in a temporary folder
`3`	Stages of vSLAM, artifacts used to initialize the map, poses and map points before and after bundle adjustment, and loop closure optimization data.	Log file in a temporary folder

IMU Fusion

`CameraToIMUTransform` — IMU sensor transformation
`rigidtform3d`

This property is read-only after object creation.

IMU sensor transformation, specified as a `rigidtform3d` object. The transformation describes the rotation and translation of the camera in the coordinate system of the IMU sensor.

`NumPosesThreshold` — Number of estimated camera poses to trigger camera-IMU alignment
`30` (default) | integer equal to or greater than 2

This property is read-only after object creation.

Number of estimated camera poses to trigger camera-IMU alignment, specified as an integer equal to or greater than 2. The process of aligning camera and IMU data is initiated after a specific number of camera poses have been estimated. This alignment serves two primary purposes: first, to estimate a scale factor that translates the up-to-scale results from a monocular camera into actual world units (meters), and second, to synchronize the IMU and camera frames, effectively eliminating the influence of gravity on accelerometer data. The timing for this alignment, determined by a threshold for the number of camera poses, is key to its success. A threshold set too low may not provide enough data for accurate calibration, while one set too high risks incorporating noise from measurement drift into the calibration. For a more in-depth understanding of this calibration technique, see the `estimateGravityRotationAndPoseScale` function.

`AlignmentFraction` — Subset of pose estimates
`0.8` (default) | scalar in the range (0,1]

This property is read-only after object creation.

Subset of pose estimates, specified as a scalar in the range of (0,1]. This value specifies a fraction of the number of recent pose estimates, calculated as `round(NumPosesThreshold*AlignmentFraction)`, for use in the camera-IMU alignment process. It effectively filters out initial, potentially noisy pose estimates, ensuring only the most relevant data contributes to the alignment for improved accuracy.

Object Functions

addFrame	Add pair of color and depth images to RGB-D visual SLAM object
hasNewKeyFrame	Check if new key frame added in RGB-D visual SLAM object
checkStatus	Check status of visual RGB-D SLAM object
isDone	End-of-processing status for RGB-D visual SLAM object
mapPoints	Build 3-D map of world points from RGB-D vSLAM object
poses	Absolute camera poses of RGB-D vSLAM key frames
plot	Plot 3-D map points and estimated camera trajectory in RGB-D visual SLAM
reset	Reset RGB-D visual SLAM object

Examples

RGB-D Visual SLAM Using TUM RGB-D Data Set

Perform RGB-D visual simultaneous localization and mapping (vSLAM) using the data from the TUM RGB-D Benchmark. You can download the data to a temporary directory using a web browser or by running this code:

```
baseDownloadURL = "https://vision.in.tum.de/rgbd/dataset/freiburg3/rgbd_dataset_freiburg3_long_o
dataFolder = fullfile(tempdir,"tum_rgbd_dataset",filesep);
```

```
options = weboptions(Timeout=Inf);
tgzFileName = dataFolder+"fr3_office.tgz";
folderExists = exist(dataFolder,"dir");

% Create a folder in a temporary directory to save the downloaded file
if ~folderExists
    mkdir(dataFolder)
    disp("Downloading fr3_office.tgz (1.38 GB). This download can take a few minutes.")
    websave(tgzFileName,baseDownloadURL,options);

    % Extract contents of the downloaded file
    disp("Extracting fr3_office.tgz (1.38 GB) ...")
    untar(tgzFileName,dataFolder);
end
```

Create two `imageDatastore` objects. One to store the color images and the other to store the depth images.

```
colorImageFolder = dataFolder+"rgbd_dataset_freiburg3_long_office_household/rgb/";
depthImageFolder = dataFolder+"rgbd_dataset_freiburg3_long_office_household/depth/";

imdsColor = imageDatastore(colorImageFolder);
imdsDepth = imageDatastore(depthImageFolder);
```

Select the synchronized pair of color and depth images.

```
data = load("rgbDepthPairs.mat");
imdsColor=subset(imdsColor, data.indexPairs(:, 1));
imdsDepth=subset(imdsDepth, data.indexPairs(:, 2));
```

Specify your camera intrinsic parameters, and use them to create an RGB-D visual SLAM object.

```
intrinsics = cameraIntrinsics([535.4 539.2],[320.1 247.6],[480 640]);
depthScaleFactor = 5000;
vslam = rgbdvslam(intrinsics,depthScaleFactor);
```

Process each pair of color and depth images, and visualize the camera poses and 3-D map points.

```
for i = 1:numel(imdsColor.Files)
    colorImage = readimage(imdsColor,i);
    depthImage = readimage(imdsDepth,i);
    addFrame(vslam,colorImage,depthImage);

    if hasNewKeyFrame(vslam)
        % Query 3-D map points and camera poses
        xyzPoints = mapPoints(vslam);
        [camPoses,viewIds] = poses(vslam);

        % Display 3-D map points and camera trajectory
        plot(vslam);
    end

    % Get current status of system
    status = checkStatus(vslam);

    % Stop adding frames when tracking is lost
    if status == uint8(0)
        break
```

```
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    plot(vslam);
end
```

```
reset(vslam);
```

RGB-D Visual-Inertial SLAM Using OpenLORIS-Scene Data Set

Perform RGB-D visual-inertial SLAM using the data from the OpenLORIS-Scene Dataset. Download the data to a temporary directory using a web browser or by running this code:

```
dataFolder  = fullfile(tempdir,"OpenLORIS-Scene",filesep);
downloadURL = "https://ssd.mathworks.com/supportfiles/shared_nav_vision/data/OpenLORIS-Scene_cor
zipFileName = dataFolder+"corridor1-4.zip";

if ~isfolder(dataFolder)
    mkdir(dataFolder);
    disp("Downloading corridor1-4.zip (1.13 GB). This download can take a few minutes.");
    options = weboptions('Timeout', Inf);
    websave(zipFileName, downloadURL, options);
    unzip(zipFileName, dataFolder);
end
```

Create two `imageDatastore` objects. One to store the color images and the other to store the depth images.

```
imageFolder = fullfile(dataFolder,"OpenLORIS-Scene_corridor1-4");
imdsColor = imageDatastore(fullfile(imageFolder,"color"));
imdsDepth = imageDatastore(fullfile(imageFolder,"aligned_depth"));
```

Load the IMU measurements data and the camera-to-IMU transform.

```
data    = load("corridor4_IMU_data.mat");
gyro    = data.gyroDataCell;
accel   = data.accelDataCell;
cam2IMU = data.cam2IMU;
```

Specify the camera intrinsics, the IMU parameters, and use them to create an RGB-D visual-inertial SLAM object.

```
% Camera intrinsic and IMU parameters can be found in the downloaded
% sensors.yaml file
intrinsics = cameraIntrinsics([6.1145098876953125e+02, 6.1148571777343750e+02],...
    [4.3320397949218750e+02, 2.4947302246093750e+02], [480, 848]);

imuParams = factorIMUParameters(AccelerometerBiasNoise=2.499999936844688e-05*eye(3),...
       AccelerometerNoise=0.00026780980988405645*eye(3),...
       GyroscopeNoise=1.0296060281689279e-05*eye(3),...
       GyroscopeBiasNoise=2.499999993688107e-07*eye(3),...
       SampleRate=250);

depthScaleFactor = 1000;
vslam = rgbdvslam(intrinsics, depthScaleFactor, imuParams, SkipMaxFrames=10,...
    CameraToIMUTransform=cam2IMU, TrackFeatureRange = [30, 150], DepthRange= [0.1, 6.5], ...
    NumPosesThreshold=20, MaxNumPoints=1.2e3);
```

Process image data and IMU data, and visualize the camera poses and 3-D map points. The abrupt changes observed in the camera poses demonstrate that the camera trajectories have been successfully aligned with the IMU predictions, which is an essential step in visual-inertial SLAM. This process transforms the camera poses into the IMU's coordinate system.

```
for i = 1:numel(imdsColor.Files)
    colorImage  = readimage(imdsColor,i);
    depthImage  = readimage(imdsDepth,i);
    addFrame(vslam, colorImage, depthImage, gyro{i}, accel{i});

    if hasNewKeyFrame(vslam)
        plot(vslam);
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    if hasNewKeyFrame(vslam)
        ax = plot(vslam);
    end
end
view(ax, 0, 90)
```

```
reset(vslam);
```

Version History

Introduced in R2024a

R2025a: `rgbdvslam` available in Navigation Toolbox with Computer Vision Toolbox license

You can use the `rgbdvslam` object in Navigation Toolbox if you have a Computer Vision Toolbox license.

R2024b: Add ability to specify custom bag of words

Use the `CustomBagOfFeatures` name-value argument to specify a custom bag of words vocabulary as a `bagOfFeaturesDBoW` object.

R2024b: `Verbose` property enhanced to display progress information
Behavior changed in R2024b

The `Verbose` property added values of `1`, `2`, and `3` to display levels of progress information.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

To compile the generated code for non-host target, these dependencies must be installed:

- OpenCV 4.7.0
- Ceres-solver 2.2.0 library — Download the source and build it as a shared library, on your remote device.
- eigen3 Library

When generating portable C code with a C++ compiler, you must specify hierarchical packing with non-minimal headers. For more information on packaging options, see the `packNGo` function.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

addFrame

Add pair of color and depth images to RGB-D visual SLAM object

Syntax

```
addFrame(vslam,colorImage,depthImage)
addFrame( ___ ,gyro,accel)
```

Description

`addFrame(vslam,colorImage,depthImage)` adds the pair of color and depth images, `colorImage` and `depthImage` respectively, to the RGB-D visual SLAM object `vslam`. The color and depth images must be preregistered with a one-to-one correspondence.

Note The `rgbdvslam` object runs on multiple threads internally, which can delay the processing of an image frame added by using the `addFrame` function. Additionally, the object running on multiple threads means the current frame the object is processing can be different than the recently added frame.

`addFrame( ___ ,gyro,accel)` adds IMU gyroscope and acceleration measurements for visual-inertial fusion.

Examples

RGB-D Visual SLAM Using TUM RGB-D Data Set

Perform RGB-D visual simultaneous localization and mapping (vSLAM) using the data from the TUM RGB-D Benchmark. You can download the data to a temporary directory using a web browser or by running this code:

    if hasNewKeyFrame(vslam)
        % Query 3-D map points and camera poses
        xyzPoints = mapPoints(vslam);
        [camPoses,viewIds] = poses(vslam);

        % Display 3-D map points and camera trajectory
        plot(vslam);
    end

    % Get current status of system
    status = checkStatus(vslam);

    % Stop adding frames when tracking is lost
    if status == uint8(0)
        break
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    plot(vslam);
end
```

```
reset(vslam);
```

RGB-D Visual-Inertial SLAM Using OpenLORIS-Scene Data Set

Perform RGB-D visual-inertial SLAM using the data from the OpenLORIS-Scene Dataset. Download the data to a temporary directory using a web browser or by running this code:

```
dataFolder  = fullfile(tempdir,"OpenLORIS-Scene",filesep);
downloadURL = "https://ssd.mathworks.com/supportfiles/shared_nav_vision/data/OpenLORIS-Scene_cor
zipFileName = dataFolder+"corridor1-4.zip";

if ~isfolder(dataFolder)
    mkdir(dataFolder);
    disp("Downloading corridor1-4.zip (1.13 GB). This download can take a few minutes.");
    options = weboptions('Timeout', Inf);
    websave(zipFileName, downloadURL, options);
    unzip(zipFileName, dataFolder);
end
```

Create two `imageDatastore` objects. One to store the color images and the other to store the depth images.

```
imageFolder = fullfile(dataFolder,"OpenLORIS-Scene_corridor1-4");
imdsColor = imageDatastore(fullfile(imageFolder,"color"));
imdsDepth = imageDatastore(fullfile(imageFolder,"aligned_depth"));
```

Load the IMU measurements data and the camera-to-IMU transform.

```
data    = load("corridor4_IMU_data.mat");
gyro    = data.gyroDataCell;
accel   = data.accelDataCell;
cam2IMU = data.cam2IMU;
```

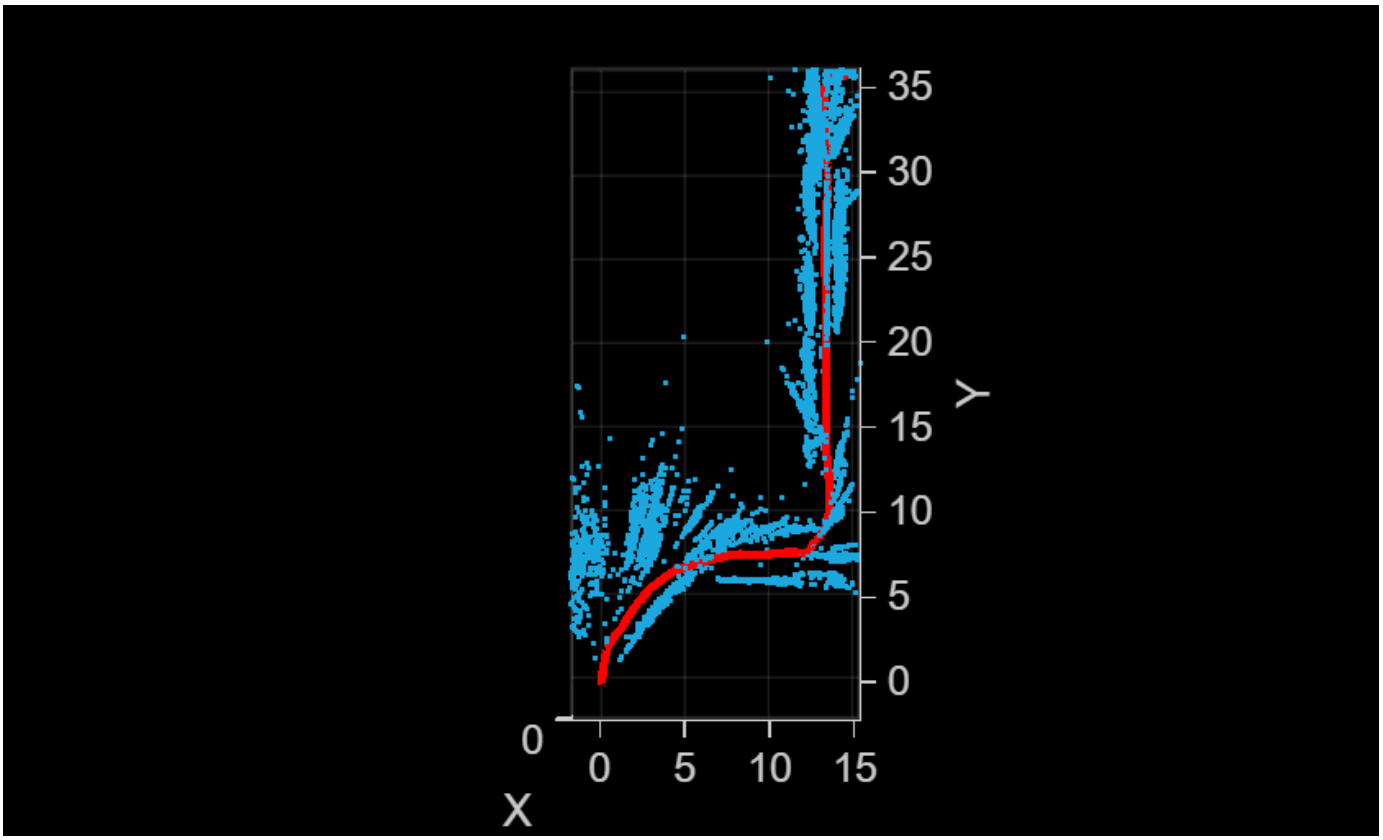
Specify the camera intrinsics, the IMU parameters, and use them to create an RGB-D visual-inertial SLAM object.

```
% Camera intrinsic and IMU parameters can be found in the downloaded
% sensors.yaml file
intrinsics = cameraIntrinsics([6.1145098876953125e+02, 6.1148571777343750e+02],...
    [4.3320397949218750e+02, 2.4947302246093750e+02], [480, 848]);

imuParams = factorIMUParameters(AccelerometerBiasNoise=2.499999936844688e-05*eye(3),...
       AccelerometerNoise=0.00026780980988405645*eye(3),...
       GyroscopeNoise=1.0296060281689279e-05*eye(3),...
       GyroscopeBiasNoise=2.499999993688107e-07*eye(3),...
       SampleRate=250);

depthScaleFactor = 1000;
vslam = rgbdvslam(intrinsics, depthScaleFactor, imuParams, SkipMaxFrames=10,...
    CameraToIMUTransform=cam2IMU, TrackFeatureRange = [30, 150], DepthRange= [0.1, 6.5], ...
    NumPosesThreshold=20, MaxNumPoints=1.2e3);
```

Process image data and IMU data, and visualize the camera poses and 3-D map points. The abrupt changes observed in the camera poses demonstrate that the camera trajectories have been successfully aligned with the IMU predictions, which is an essential step in visual-inertial SLAM. This process transforms the camera poses into the IMU's coordinate system.



```
for i = 1:numel(imdsColor.Files)
    colorImage  = readimage(imdsColor,i);
```

```
    depthImage  = readimage(imdsDepth,i);
    addFrame(vslam, colorImage, depthImage, gyro{i}, accel{i});

    if hasNewKeyFrame(vslam)
        plot(vslam);
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    if hasNewKeyFrame(vslam)
        ax = plot(vslam);
    end
end
view(ax, 0, 90)
```

```
reset(vslam);
```

Input Arguments

`vslam` — RGB-D visual SLAM object

`rgbdvslam` object

RGB-D visual SLAM object, specified as an `rgbdvslam` object.

`colorImage` — Color image
RGB image | grayscale image

Color image, specified as a nonsparse RGB or grayscale image. The color and depth images must be preregistered with a one-to-one correspondence.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

`depthImage` — Depth image
grayscale image

Color image, specified as a nonsparse grayscale image. The color and depth images must be preregistered with a one-to-one correspondence.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

`gyro` — Gyroscope measurement
N-by-3 matrix

Gyroscope measurement, specified as an *N*-by-3 matrix. Each row of the matrix represents the *x*, *y*, and *z* components of the gyroscope measurement for a single frame, of the form [*gx*,*gy*,*gz*]. *N* represents the total number of frames. *N* represents the number of IMU measurements between the previous and current camera frames. The number of gyroscope and accelerometer measurements must be equal.

`accel` — Acceleration measurement
N-by-3 matrix

Acceleration measurement, specified as an *N*-by-3 matrix. Each row of the matrix represents the *x*, *y*, and *z* components of the acceleration measurement for a single frame, of the form [*ax*,*ay*,*az*]. *N* represents the number of IMU measurements between the previous and current camera frames. The number of gyroscope and accelerometer measurements must be equal.

Topics
“Simulate RGB-D Visual SLAM System with Cosimulation in Gazebo and Simulink” (ROS Toolbox)

hasNewKeyFrame

Check if new key frame added in RGB-D visual SLAM object

Syntax

```
hasAdded = hasNewKeyFrame(vslam)
```

Description

`hasAdded = hasNewKeyFrame(vslam)` returns a logical value that indicates if a new key frame has been added within the RGB-D visual simultaneous localization and mapping (vSLAM) object `vslam`.

Examples

RGB-D Visual SLAM Using TUM RGB-D Data Set

Perform RGB-D visual simultaneous localization and mapping (vSLAM) using the data from the TUM RGB-D Benchmark. You can download the data to a temporary directory using a web browser or by running this code:

```
baseDownloadURL = "https://vision.in.tum.de/rgbd/dataset/freiburg3/rgbd_dataset_freiburg3_long_o
dataFolder = fullfile(tempdir,"tum_rgbd_dataset",filesep);
options = weboptions(Timeout=Inf);
tgzFileName = dataFolder+"fr3_office.tgz";
folderExists = exist(dataFolder,"dir");

% Create a folder in a temporary directory to save the downloaded file
if ~folderExists
    mkdir(dataFolder)
    disp("Downloading fr3_office.tgz (1.38 GB). This download can take a few minutes.")
    websave(tgzFileName,baseDownloadURL,options);

    % Extract contents of the downloaded file
    disp("Extracting fr3_office.tgz (1.38 GB) ...")
    untar(tgzFileName,dataFolder);
end
```

Create two `imageDatastore` objects. One to store the color images and the other to store the depth images.

```
colorImageFolder = dataFolder+"rgbd_dataset_freiburg3_long_office_household/rgb/";
depthImageFolder = dataFolder+"rgbd_dataset_freiburg3_long_office_household/depth/";

imdsColor = imageDatastore(colorImageFolder);
imdsDepth = imageDatastore(depthImageFolder);
```

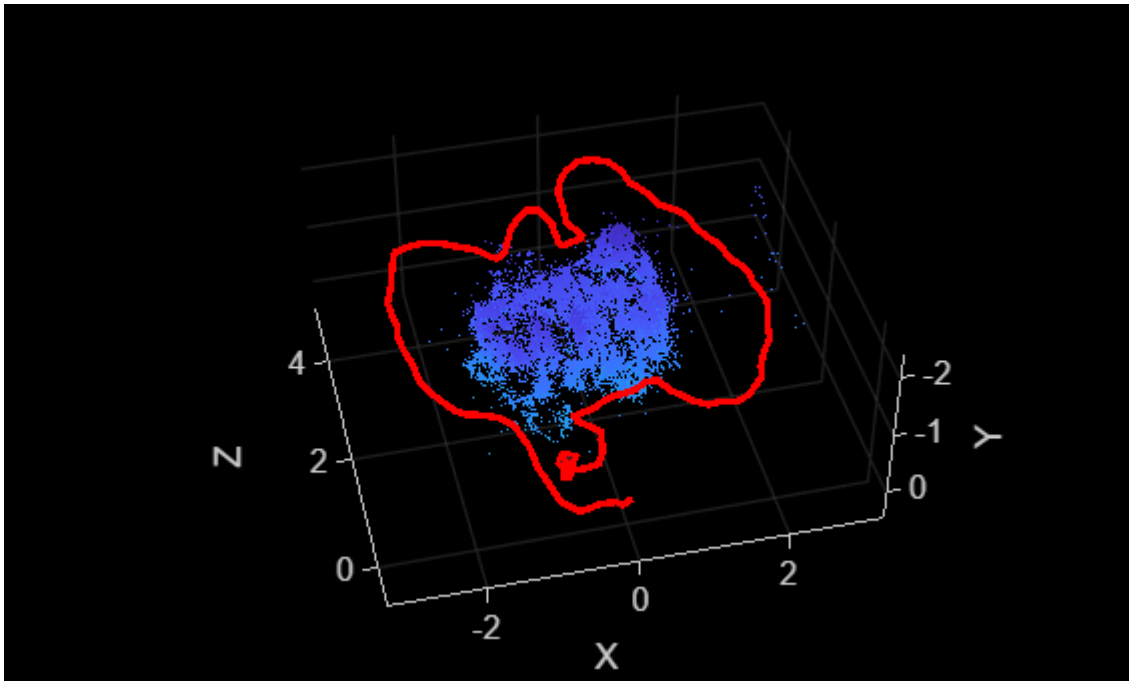
Select the synchronized pair of color and depth images.

```
data = load("rgbDepthPairs.mat");
imdsColor=subset(imdsColor, data.indexPairs(:, 1));
imdsDepth=subset(imdsDepth, data.indexPairs(:, 2));
```

Specify your camera intrinsic parameters, and use them to create an RGB-D visual SLAM object.

```
intrinsics = cameraIntrinsics([535.4 539.2],[320.1 247.6],[480 640]);
depthScaleFactor = 5000;
vslam = rgbdvslam(intrinsics,depthScaleFactor);
```

Process each pair of color and depth images, and visualize the camera poses and 3-D map points.



```
for i = 1:numel(imdsColor.Files)
    colorImage = readimage(imdsColor,i);
    depthImage = readimage(imdsDepth,i);
    addFrame(vslam,colorImage,depthImage);

    if hasNewKeyFrame(vslam)
        % Query 3-D map points and camera poses
        xyzPoints = mapPoints(vslam);
        [camPoses,viewIds] = poses(vslam);

        % Display 3-D map points and camera trajectory
        plot(vslam);
    end

    % Get current status of system
    status = checkStatus(vslam);

    % Stop adding frames when tracking is lost
    if status == uint8(0)
        break
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    plot(vslam);
end
```

```
reset(vslam);
```

RGB-D Visual-Inertial SLAM Using OpenLORIS-Scene Data Set

Perform RGB-D visual-inertial SLAM using the data from the OpenLORIS-Scene Dataset. Download the data to a temporary directory using a web browser or by running this code:

```

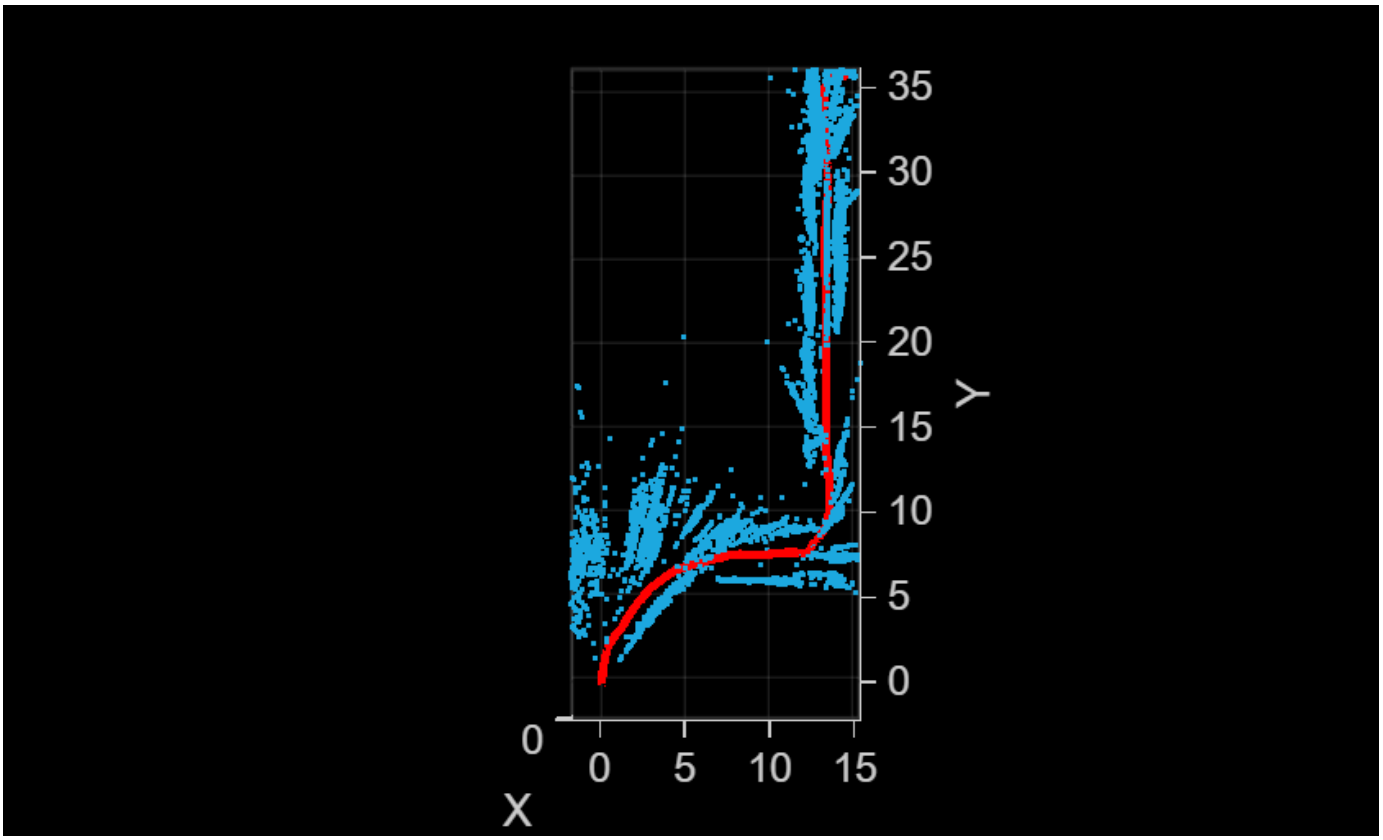
       SampleRate=250);

depthScaleFactor = 1000;
vslam = rgbdvslam(intrinsics, depthScaleFactor, imuParams, SkipMaxFrames=10,...
    CameraToIMUTransform=cam2IMU, TrackFeatureRange = [30, 150], DepthRange= [0.1, 6.5], ...
    NumPosesThreshold=20, MaxNumPoints=1.2e3);
```



Process image data and IMU data, and visualize the camera poses and 3-D map points. The abrupt changes observed in the camera poses demonstrate that the camera trajectories have been successfully aligned with the IMU predictions, which is an essential step in visual-inertial SLAM. This process transforms the camera poses into the IMU's coordinate system.

```
for i = 1:numel(imdsColor.Files)
    colorImage  = readimage(imdsColor,i);
    depthImage  = readimage(imdsDepth,i);
    addFrame(vslam, colorImage, depthImage, gyro{i}, accel{i});

    if hasNewKeyFrame(vslam)
        plot(vslam);
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    if hasNewKeyFrame(vslam)
        ax = plot(vslam);
    end
end
view(ax, 0, 90)
```

```
reset(vslam);
```

Input Arguments

`vslam` — RGB-D visual SLAM object

`rgbdvslam` object

RGB-D visual SLAM object, specified as an `rgbdvslam` object.

Output Arguments

`hasAdded` — New key frame status

`false` or `0` | `true` or `1`

New key frame status, returned as a logical `0` (`false`) or `1` (`true`). A value of `true` indicates that a new key frame has been added within the RGB-D visual SLAM object `vslam`. A value of `false` indicates that no new key frame has been added. The object considers an image frame to be a key frame if the number of tracked feature points in the current frame satisfies one these conditions:

- The number of tracked feature points is within the limits specified by the `TrackFeatureRange` property of the `rgbdvslam` object `vslam`.
- The number of tracked feature points is greater than the upper limit specified by the `TrackFeatureRange` property of the `rgbdvslam` object `vslam`, and the number of skipped

frames since adding the last key frame equals the value of the `SkipMaxFrames` property of `vslam`.

The `hasNewKeyFrame` object function returns `true` only when the `rgbdvslam` object has added one or more new key frames since the last `hasNewKeyFrame` call. For example, if the `rgbdvslam` object adds only one key frame, then two consecutive calls to `hasNewKeyFrame` return `true` and `false`, respectively.

checkStatus

Check status of visual RGB-D SLAM object

Syntax

```
status = checkStatus(vslam)
```

Description

`status = checkStatus(vslam)` returns the current status of the RGB-D visual SLAM object. The frame the object is currently processing might be different than the most recently added frame.

Examples

RGB-D Visual SLAM Using TUM RGB-D Data Set

Perform RGB-D visual simultaneous localization and mapping (vSLAM) using the data from the TUM RGB-D Benchmark. You can download the data to a temporary directory using a web browser or by running this code:

```
baseDownloadURL = "https://vision.in.tum.de/rgbd/dataset/freiburg3/rgbd_dataset_freiburg3_long_o

```

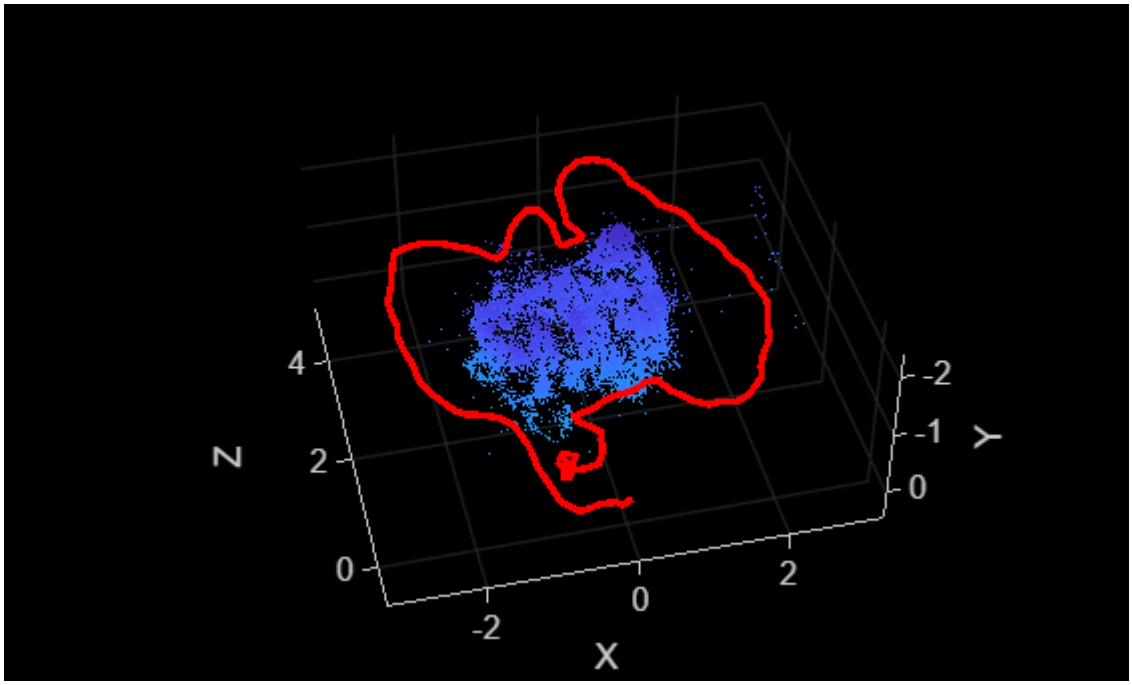
Process each pair of color and depth images, and visualize the camera poses and 3-D map points.



```
for i = 1:numel(imdsColor.Files)
    colorImage = readimage(imdsColor,i);
    depthImage = readimage(imdsDepth,i);
    addFrame(vslam,colorImage,depthImage);

    if hasNewKeyFrame(vslam)
        % Query 3-D map points and camera poses
        xyzPoints = mapPoints(vslam);
        [camPoses,viewIds] = poses(vslam);

        % Display 3-D map points and camera trajectory
        plot(vslam);
    end

    % Get current status of system
    status = checkStatus(vslam);

    % Stop adding frames when tracking is lost
    if status == uint8(0)
        break
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    plot(vslam);
end
```

```
reset(vslam);
```

Input Arguments

`vslam` — RGB-D visual SLAM object

`rgbdvslam` object

RGB-D visual SLAM object, specified as an `rgbdvslam` object.

Output Arguments

`status` — Current status of RGB-D visual SLAM object

`TrackingLost` enumeration | `TrackingSuccessful` enumeration | `FrequentKeyFrames` enumeration

Current status of the RGB-D visual SLAM object, returned as a `TrackingLost`, `TrackingSuccessful`, or `FrequentKeyFrames` enumeration. This table describes these enumerations.

Enumeration Value	Numeric Value	Description
`TrackingLost`	`uint8(0)`	Tracking is lost. The number of tracked feature points in the frame currently being processed is less than the lower limit of the `TrackFeatureRange` property of `vslam`. This indicates the image does not contain enough features, or that the camera is moving too fast. If the object does not accept enough frames as key frames, to improve tracking, you can increase the *upperLimit* value of the `TrackFeatureRange` property and decrease the `SkipMaxFrames` property to add key frames more frequently.
`TrackingSuccessful`	`uint8(1)`	Tracking is successful. The number of tracked feature points in the frame currently being processed is between the lower limit and upper limit values of the `TrackFeatureRange` property of `vslam`.
`FrequentKeyFrames`	`uint8(2)`	Tracking adds key frames too frequently. The number of tracked feature points in the frame currently being processed is greater than the upper limit of the `TrackFeatureRange` property of `vslam`.

isDone

End-of-processing status for RGB-D visual SLAM object

Syntax

```
done = isDone(vslam)
```

Description

`done = isDone(vslam)` returns a logical value indicating whether the RGB-D visual SLAM object has finished processing its frames. A value of `true` indicates the object is in an idle state. A value of `false` indicates the object is processing one or more frames.

Examples

RGB-D Visual SLAM Using TUM RGB-D Data Set

Perform RGB-D visual simultaneous localization and mapping (vSLAM) using the data from the TUM RGB-D Benchmark. You can download the data to a temporary directory using a web browser or by running this code:

RGB-D Visual-Inertial SLAM Using OpenLORIS-Scene Data Set

Perform RGB-D visual-inertial SLAM using the data from the OpenLORIS-Scene Dataset. Download the data to a temporary directory using a web browser or by running this code:

```
dataFolder  = fullfile(tempdir,"OpenLORIS-Scene",filesep);
downloadURL = "https://ssd.mathworks.com/supportfiles/shared_nav_vision/data/OpenLORIS-Scene_cor
zipFileName = dataFolder+"corridor1-4.zip";

if ~isfolder(dataFolder)
    mkdir(dataFolder);
    disp("Downloading corridor1-4.zip (1.13 GB). This download can take a few minutes.");
    options = weboptions('Timeout', Inf);
    websave(zipFileName, downloadURL, options);
    unzip(zipFileName, dataFolder);
end
```

Create two `imageDatastore` objects. One to store the color images and the other to store the depth images.

```
imageFolder = fullfile(dataFolder,"OpenLORIS-Scene_corridor1-4");
imdsColor = imageDatastore(fullfile(imageFolder,"color"));
imdsDepth = imageDatastore(fullfile(imageFolder,"aligned_depth"));
```

Load the IMU measurements data and the camera-to-IMU transform.

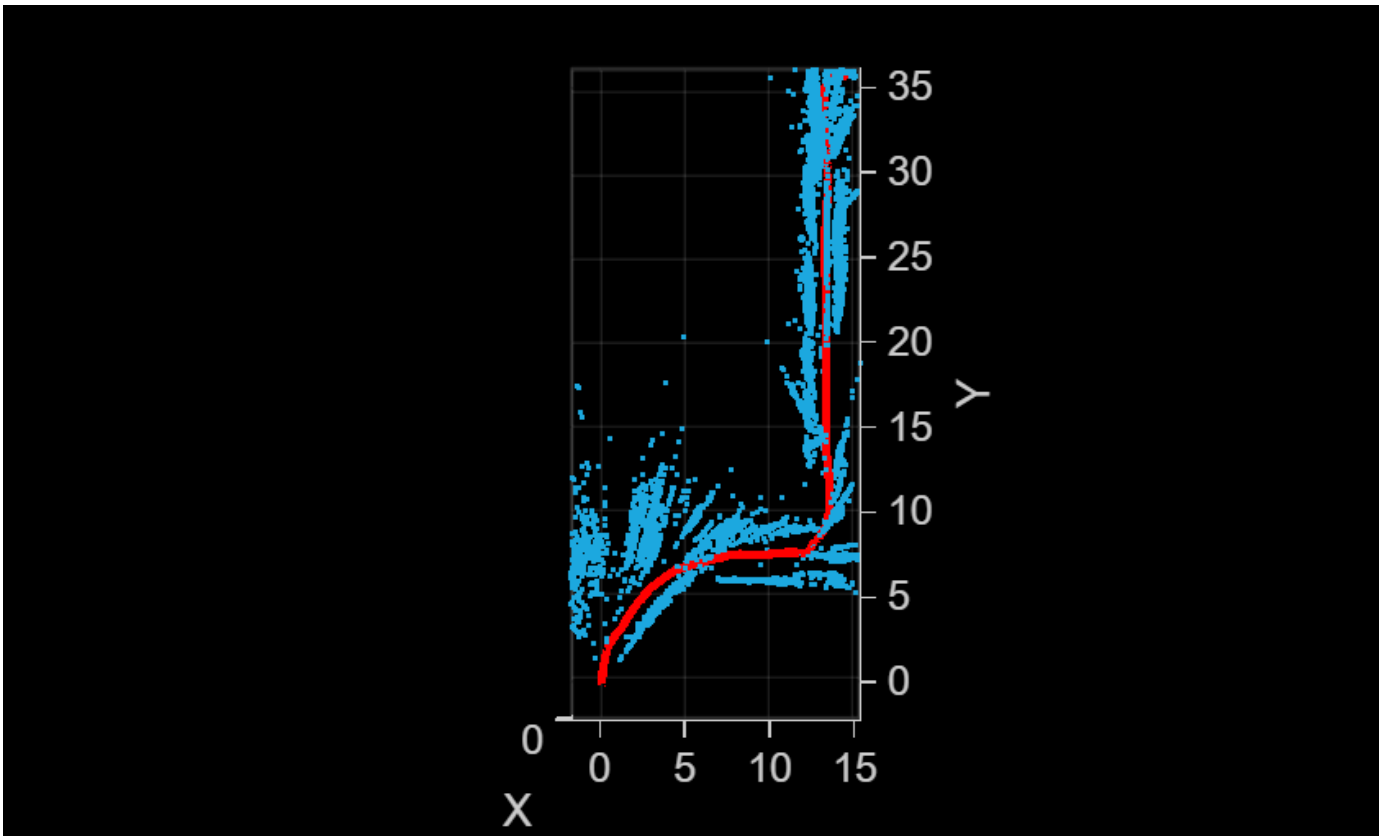
```
data    = load("corridor4_IMU_data.mat");
gyro    = data.gyroDataCell;
accel   = data.accelDataCell;
cam2IMU = data.cam2IMU;
```

Specify the camera intrinsics, the IMU parameters, and use them to create an RGB-D visual-inertial SLAM object.

```
% Camera intrinsic and IMU parameters can be found in the downloaded
% sensors.yaml file
intrinsics = cameraIntrinsics([6.1145098876953125e+02, 6.1148571777343750e+02],...
    [4.3320397949218750e+02, 2.4947302246093750e+02], [480, 848]);

imuParams = factorIMUParameters(AccelerometerBiasNoise=2.499999936844688e-05*eye(3),...
       AccelerometerNoise=0.00026780980988405645*eye(3),...
       GyroscopeNoise=1.0296060281689279e-05*eye(3),...
       GyroscopeBiasNoise=2.499999993688107e-07*eye(3),...
       SampleRate=250);

depthScaleFactor = 1000;
vslam = rgbdvslam(intrinsics, depthScaleFactor, imuParams, SkipMaxFrames=10,...
    CameraToIMUTransform=cam2IMU, TrackFeatureRange = [30, 150], DepthRange= [0.1, 6.5], ...
    NumPosesThreshold=20, MaxNumPoints=1.2e3);
```



Process image data and IMU data, and visualize the camera poses and 3-D map points. The abrupt changes observed in the camera poses demonstrate that the camera trajectories have been successfully aligned with the IMU predictions, which is an essential step in visual-inertial SLAM. This process transforms the camera poses into the IMU's coordinate system.

```
for i = 1:numel(imdsColor.Files)
    colorImage  = readimage(imdsColor,i);
    depthImage  = readimage(imdsDepth,i);
    addFrame(vslam, colorImage, depthImage, gyro{i}, accel{i});

    if hasNewKeyFrame(vslam)
        plot(vslam);
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    if hasNewKeyFrame(vslam)
        ax = plot(vslam);
    end
end
view(ax, 0, 90)
```

```
reset(vslam);
```

Input Arguments

`vslam` — RGB-D visual SLAM object

`rgbdvslam` object

RGB-D visual SLAM object, specified as an `rgbdvslam` object.

Version History

Introduced in R2024a

Functions

`addFrame` | `hasNewKeyFrame` | `checkStatus` | `mapPoints` | `poses` | `plot` | `reset`

mapPoints

Build 3-D map of world points from RGB-D vSLAM object

Syntax

```
xyzPoints = mapPoints(vslam)
```

Description

`xyzPoints = mapPoints(vslam)` builds a sparse 3-D map of world points, `xyzPoints`, from the input images in the RGB-D visual simultaneous localization and mapping (vSLAM) object `vslam`.

Examples

RGB-D Visual SLAM Using TUM RGB-D Data Set

Perform RGB-D visual simultaneous localization and mapping (vSLAM) using the data from the TUM RGB-D Benchmark. You can download the data to a temporary directory using a web browser or by running this code:

```
baseDownloadURL = "https://vision.in.tum.de/rgbd/dataset/freiburg3/rgbd_dataset_freiburg3_long_o
dataFolder = fullfile(tempdir,"tum_rgbd_dataset",filesep);
options = weboptions(Timeout=Inf);
tgzFileName = dataFolder+"fr3_office.tgz";
folderExists = exist(dataFolder,"dir");

% Create a folder in a temporary directory to save the downloaded file
if ~folderExists
    mkdir(dataFolder)
    disp("Downloading fr3_office.tgz (1.38 GB). This download can take a few minutes.")
    websave(tgzFileName,baseDownloadURL,options);

    % Extract contents of the downloaded file
    disp("Extracting fr3_office.tgz (1.38 GB) ...")
    untar(tgzFileName,dataFolder);
end
```

Create two `imageDatastore` objects. One to store the color images and the other to store the depth images.

```
colorImageFolder = dataFolder+"rgbd_dataset_freiburg3_long_office_household/rgb/";
depthImageFolder = dataFolder+"rgbd_dataset_freiburg3_long_office_household/depth/";

imdsColor = imageDatastore(colorImageFolder);
imdsDepth = imageDatastore(depthImageFolder);
```

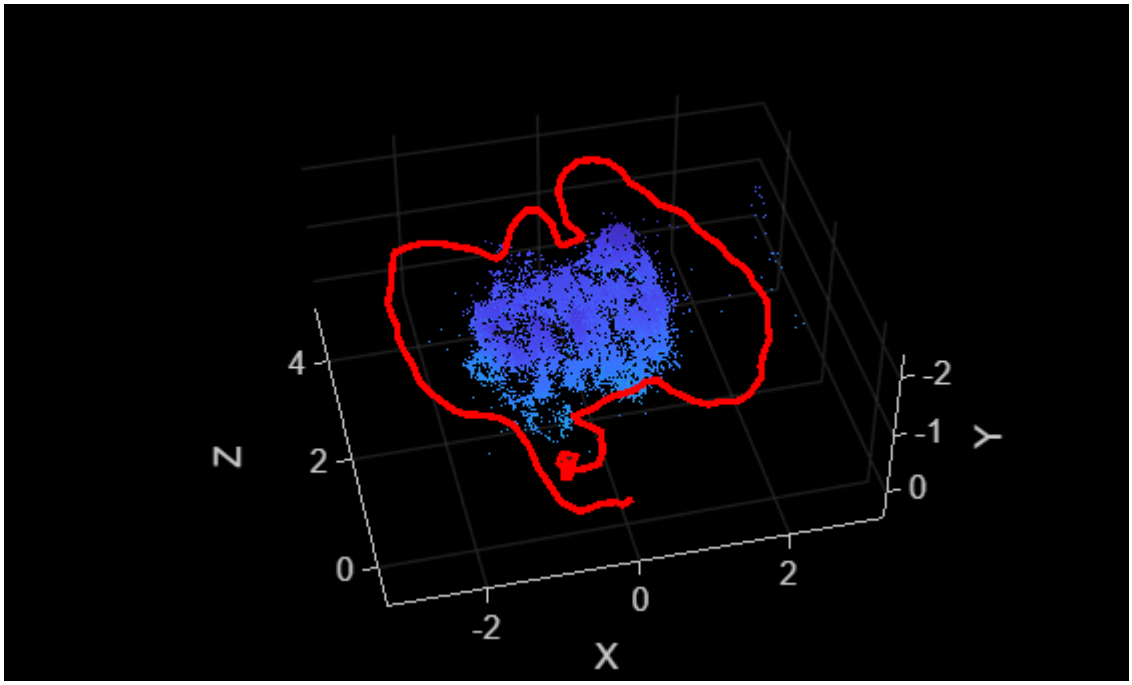
Select the synchronized pair of color and depth images.

```
data = load("rgbDepthPairs.mat");
imdsColor=subset(imdsColor, data.indexPairs(:, 1));
imdsDepth=subset(imdsDepth, data.indexPairs(:, 2));
```

Specify your camera intrinsic parameters, and use them to create an RGB-D visual SLAM object.

```
intrinsics = cameraIntrinsics([535.4 539.2],[320.1 247.6],[480 640]);
depthScaleFactor = 5000;
vslam = rgbdvslam(intrinsics,depthScaleFactor);
```

Process each pair of color and depth images, and visualize the camera poses and 3-D map points.



```
for i = 1:numel(imdsColor.Files)
    colorImage = readimage(imdsColor,i);
    depthImage = readimage(imdsDepth,i);
    addFrame(vslam,colorImage,depthImage);

    if hasNewKeyFrame(vslam)
        % Query 3-D map points and camera poses
        xyzPoints = mapPoints(vslam);
        [camPoses,viewIds] = poses(vslam);

        % Display 3-D map points and camera trajectory
        plot(vslam);
    end

    % Get current status of system
    status = checkStatus(vslam);

    % Stop adding frames when tracking is lost
    if status == uint8(0)
        break
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    plot(vslam);
end
```

```
reset(vslam);
```

Input Arguments

`vslam` — RGB-D visual SLAM object

`rgbdvslam` object

RGB-D visual SLAM object, specified as an `rgbdvslam` object.

Output Arguments

`xyzPoints` — World point coordinates of 3-D map

M-by-3 matrix

World point coordinates of 3-D map, returned as an *M*-by-3 matrix. *M* is the number of points, and each point is of the form [*X Y Z*].

poses

Absolute camera poses of RGB-D vSLAM key frames

Syntax

```
camPoses = poses(vslam)
[camPoses,keyFrameIDs] = poses(vslam)
```

Description

`camPoses = poses(vslam)` returns the absolute camera poses `camPoses` of the key frames from the RGB-D visual simultaneous localization and mapping (vSLAM) object `vslam`.

`[camPoses,keyFrameIDs] = poses(vslam)` returns the IDs `keyFrameIDs` of the key frames corresponding to the camera poses. The IDs represent the order in which the image frames have been added to the `vslam` object by the `addFrame` object function.

imdsDepth = imageDatastore(depthImageFolder);
```

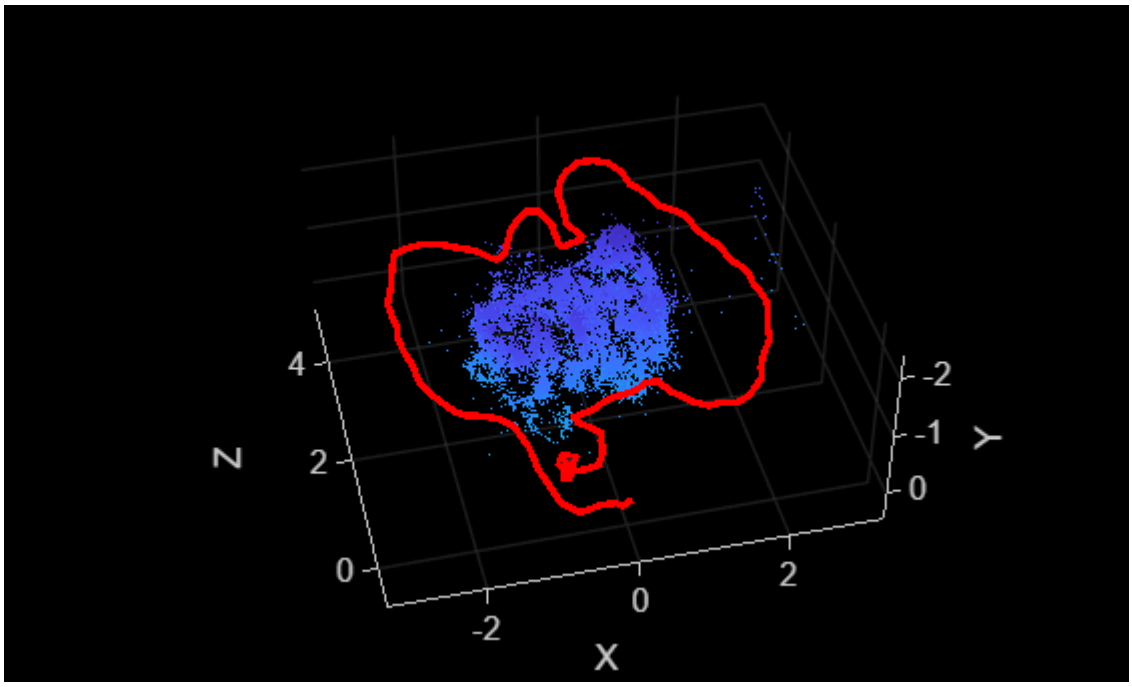
Select the synchronized pair of color and depth images.

```
data = load("rgbDepthPairs.mat");
imdsColor=subset(imdsColor, data.indexPairs(:, 1));
imdsDepth=subset(imdsDepth, data.indexPairs(:, 2));
```

Specify your camera intrinsic parameters, and use them to create an RGB-D visual SLAM object.

```
intrinsics = cameraIntrinsics([535.4 539.2],[320.1 247.6],[480 640]);
depthScaleFactor = 5000;
vslam = rgbdvslam(intrinsics,depthScaleFactor);
```

Process each pair of color and depth images, and visualize the camera poses and 3-D map points.



```
for i = 1:numel(imdsColor.Files)
    colorImage = readimage(imdsColor,i);
    depthImage = readimage(imdsDepth,i);
    addFrame(vslam,colorImage,depthImage);

    if hasNewKeyFrame(vslam)
        % Query 3-D map points and camera poses
        xyzPoints = mapPoints(vslam);
        [camPoses,viewIds] = poses(vslam);

        % Display 3-D map points and camera trajectory
        plot(vslam);
    end

    % Get current status of system
    status = checkStatus(vslam);

    % Stop adding frames when tracking is lost
    if status == uint8(0)
        break
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    plot(vslam);
end
```

```
reset(vslam);
```

Input Arguments

`vslam` — RGB-D visual SLAM object

`rgbdvslam` object

RGB-D visual SLAM object, specified as an `rgbdvslam` object.

Output Arguments

`camPoses` — Absolute camera poses of key frames

M-element array of `rigidtform3d` objects

Absolute camera poses of the key frames, returned as an *M*-element array of `rigidtform3d` objects.

`keyFrameIDs` — Key frame IDs for absolute camera poses

M-element array of integers

Key frame IDs for the absolute camera poses, returned as an *M*-element array of integers. Each element specifies the key frame ID for the camera pose in the corresponding element of `camPoses`. The IDs represent the order in which the image frames have been added to `vslam` by the `addFrame` object function.

plot

Plot 3-D map points and estimated camera trajectory in RGB-D visual SLAM

Syntax

```
plot(vslam)
plot(vslam,Name=Value)
ax = plot( ___ )
```

Description

`plot(vslam)` plots the 3-D map points and estimated camera trajectory from the RGB-D visual SLAM object `vslam`.

`plot(vslam,Name=Value)` specifies options using one or more name-value arguments. For example, `MarkerSize=10` sets the diameter of the marker size to 10 points.

`ax = plot( ___ )` returns the axes handle for the 3-D mapped points of the plot, using any combination of input arguments from previous syntaxes.

Examples

RGB-D Visual SLAM Using TUM RGB-D Data Set

Perform RGB-D visual simultaneous localization and mapping (vSLAM) using the data from the TUM RGB-D Benchmark. You can download the data to a temporary directory using a web browser or by running this code:

```
baseDownloadURL = "https://vision.in.tum.de/rgbd/dataset/freiburg3/rgbd_dataset_freiburg3_long_o

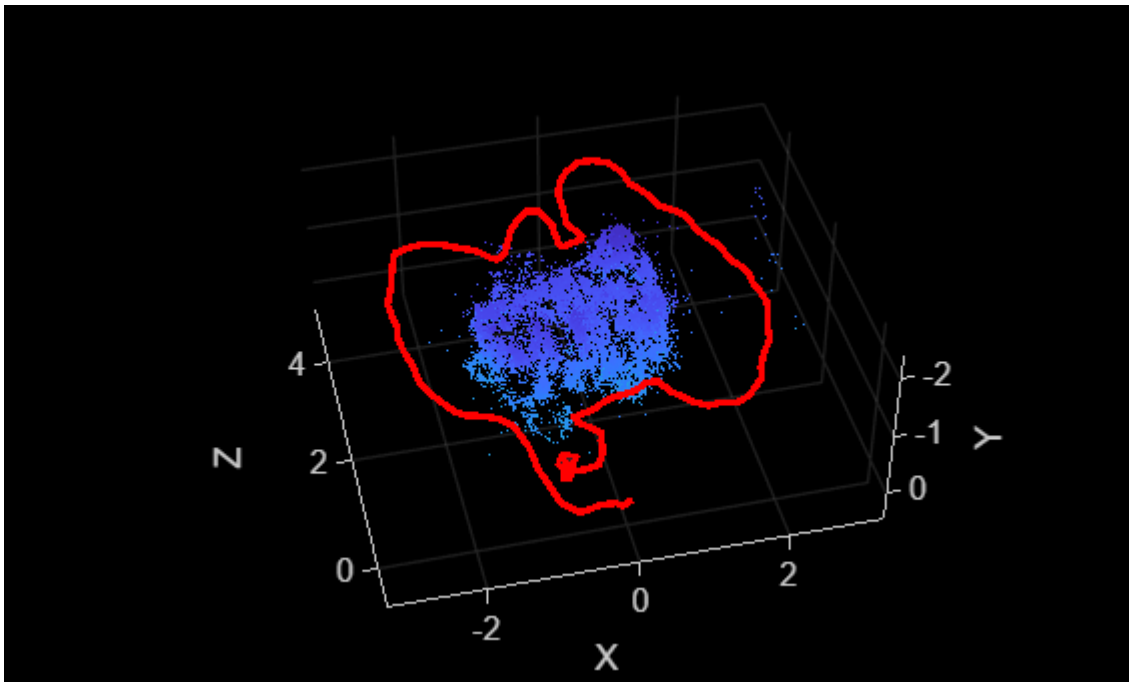
vslam = rgbdvslam(intrinsics,depthScaleFactor);
```

Process each pair of color and depth images, and visualize the camera poses and 3-D map points.



```
for i = 1:numel(imdsColor.Files)
    colorImage = readimage(imdsColor,i);
    depthImage = readimage(imdsDepth,i);
    addFrame(vslam,colorImage,depthImage);

    if hasNewKeyFrame(vslam)
        % Query 3-D map points and camera poses
        xyzPoints = mapPoints(vslam);
        [camPoses,viewIds] = poses(vslam);

        % Display 3-D map points and camera trajectory
        plot(vslam);
    end

    % Get current status of system
    status = checkStatus(vslam);

    % Stop adding frames when tracking is lost
    if status == uint8(0)
        break
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    plot(vslam);
end
```

```
reset(vslam);
```

RGB-D Visual-Inertial SLAM Using OpenLORIS-Scene Data Set

Perform RGB-D visual-inertial SLAM using the data from the OpenLORIS-Scene Dataset. Download the data to a temporary directory using a web browser or by running this code:

```
dataFolder  = fullfile(tempdir,"OpenLORIS-Scene",filesep);
downloadURL = "https://ssd.mathworks.com/supportfiles/shared_nav_vision/data/OpenLORIS-Scene_cor
zipFileName = dataFolder+"corridor1-4.zip";

if ~isfolder(dataFolder)
    mkdir(dataFolder);
    disp("Downloading corridor1-4.zip (1.13 GB). This download can take a few minutes.");
    options = weboptions('Timeout', Inf);
    websave(zipFileName, downloadURL, options);
    unzip(zipFileName, dataFolder);
end
```

Create two `imageDatastore` objects. One to store the color images and the other to store the depth images.

```
imageFolder = fullfile(dataFolder,"OpenLORIS-Scene_corridor1-4");
imdsColor = imageDatastore(fullfile(imageFolder,"color"));
imdsDepth = imageDatastore(fullfile(imageFolder,"aligned_depth"));
```

Load the IMU measurements data and the camera-to-IMU transform.

```
data    = load("corridor4_IMU_data.mat");
gyro    = data.gyroDataCell;
accel   = data.accelDataCell;
cam2IMU = data.cam2IMU;
```

Specify the camera intrinsics, the IMU parameters, and use them to create an RGB-D visual-inertial SLAM object.

```
% Camera intrinsic and IMU parameters can be found in the downloaded
% sensors.yaml file
intrinsics = cameraIntrinsics([6.1145098876953125e+02, 6.1148571777343750e+02],...
    [4.3320397949218750e+02, 2.4947302246093750e+02], [480, 848]);

imuParams = factorIMUParameters(AccelerometerBiasNoise=2.499999936844688e-05*eye(3),...
       AccelerometerNoise=0.00026780980988405645*eye(3),...
       GyroscopeNoise=1.0296060281689279e-05*eye(3),...
       GyroscopeBiasNoise=2.499999993688107e-07*eye(3),...
       SampleRate=250);

depthScaleFactor = 1000;
vslam = rgbdvslam(intrinsics, depthScaleFactor, imuParams, SkipMaxFrames=10,...
    CameraToIMUTransform=cam2IMU, TrackFeatureRange = [30, 150], DepthRange= [0.1, 6.5], ...
    NumPosesThreshold=20, MaxNumPoints=1.2e3);
```

Process image data and IMU data, and visualize the camera poses and 3-D map points. The abrupt changes observed in the camera poses demonstrate that the camera trajectories have been successfully aligned with the IMU predictions, which is an essential step in visual-inertial SLAM. This process transforms the camera poses into the IMU's coordinate system.

```
for i = 1:numel(imdsColor.Files)
    colorImage  = readimage(imdsColor,i);
```

```
    depthImage  = readimage(imdsDepth,i);
    addFrame(vslam, colorImage, depthImage, gyro{i}, accel{i});

    if hasNewKeyFrame(vslam)
        plot(vslam);
    end
end
```

Once all the frames have been processed, reset the system.

```
while ~isDone(vslam)
    if hasNewKeyFrame(vslam)
        ax = plot(vslam);
    end
end
view(ax, 0, 90)
```

```
reset(vslam);
```

Input Arguments

`vslam` — RGB-D visual SLAM object

`rgbdvslam` object

RGB-D visual SLAM object, specified as an `rgbdvslam` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `plot(vslam,MarkerSize=10)`, sets the diameter of the marker to 10 points.

`MarkerSize` — Diameter of markers for 3-D map points
`6` (default) | positive integer

Diameter of the markers for the 3-D map points, specified as a positive integer in points.

`MarkerColor` — Color of markers for 3-D map points
`[0 1 0]` (default) | RGB triplet | short or long color name

Color of the markers for the 3-D map points, specified as an RGB triplet or a short or long color name. Each value within an RGB triplet must be in the range `[0 1]`.

`ColorSource` — Colormap source for the markers
`"Y"` (default) | `"X"` | `"Z"` | `"MarkerColor"`

Colormap source for markers, specified as `"X"`, `"Y"`, `"Z"`, or `"MarkerColor"`.

`CameraSize` — Width of camera base
`0.1` (default) | positive scalar

Width of the camera base, specified as a positive scalar in the data units of the axes.

`CameraColor` — Color of camera
`[1 0 0]` (default) | RGB triplet | short or long color name

Color of the camera, specified as an RGB triplet or a short or long color name. Each value within an RGB triplet must be in the range `[0 1]`.

`Parent` — Axes for visualization
`Axes` object | `UIAxes` object

Axes for visualization, specified as an `Axes` graphics object or a `UIAxes` object. Use this name-value argument to visualize the plot in a UI for which you have specified `Figure` and `Axes` properties.

Output Arguments

`ax` — Axes handle
`Axes` graphics object

Axes handle, returned as an `axes` graphics object.

monovslam

Visual simultaneous localization and mapping (vSLAM) and visual-inertial sensor fusion with monocular camera

Description

Use the `monovslam` object to perform visual simultaneous localization and mapping (vSLAM) and visual inertial SLAM (viSLAM) with a monocular camera. The object extracts Oriented FAST and Rotated BRIEF (ORB) features from incrementally read images, and then tracks those features to estimate camera poses, identify key frames, and reconstruct a 3-D environment. The vSLAM algorithm also searches for loop closures using the bag-of-features algorithm, and then optimizes the camera poses using pose graph optimization. You can enhance the accuracy and robustness of the SLAM by integrating this object with IMU data to perform visual-inertial sensor fusion. To learn more about visual SLAM, see “Implement Visual SLAM in MATLAB”.

Note The `monovslam` object requires Navigation Toolbox.

Creation

Syntax

```
vslam = monovslam(intrinsics)
vslam = monovslam(intrinsics,imuParameters)
vslam = monovslam(intrinsics,PropertyName=Value)
```

Description

`vslam = monovslam(intrinsics)` creates a monocular visual SLAM object, `vslam`, by using the camera intrinsic parameters.

The `monovslam` object does not account for lens distortion. You can use the specified `undistortImage` function to undistort images before adding them to the object.

The object represents 3-D map points and camera poses in world coordinates. The object assumes the camera pose of the first key frame is an identity `rigidtform3d` transform.

Note The `monovslam` object runs on multiple threads internally, which can delay the processing of an image frame added by using the `addFrame` function. Additionally, the object running on multiple threads means the current frame the object is processing can be different than the recently added frame.

`vslam = monovslam(intrinsics,imuParameters)` creates a monocular visual SLAM object, `vslam`, by fusing the camera input intrinsics with inertial measurement unit (IMU) readings.

`vslam = monovslam(intrinsics,PropertyName=Value)` sets properties using one or more name-value arguments. For example, `MaxNumFeatures=850` sets the maximum number of ORB feature points to extract from each image to `850`.

Input Arguments

`intrinsics` — Camera intrinsic parameters

`cameraIntrinsics` object

Camera intrinsic parameters, specified as a `cameraIntrinsics` object.

This argument sets the `Intrinsics` property.

`imuParameters` — IMU parameters

`factorIMUParameters` object

IMU parameters, specified as a `factorIMUParameters` object. The object contains the noise, bias, and sample rate information about the inertial measurement unit (IMU).

Properties

Camera Parameters

`Intrinsics` — Camera intrinsic parameters

`cameraIntrinsics` object

This property is read-only.

Camera intrinsic parameters, stored as a `cameraIntrinsics` object.

Use the `intrinsics` argument to set this property.

Feature Extraction

`ScaleFactor` — Scale factor for image decomposition

`1.2` (default) | scalar greater than 1

This property is read-only after object creation.

Scale factor for image decomposition, stored as a scalar greater than 1. The scale factor is also referred to as the pyramid decimation ratio. Increasing the value of `ScaleFactor` reduces the number of pyramid levels, but reduce computation time. Decreasing this value (down to just over 1), increases the number of pyramid levels, which can improve tracking performance, at the cost of computation speed. The scale value at each level of decomposition is $\texttt{ScaleFactor}^{(level\text{-}1)}$, where *level* is any value in the range [0, `Numlevels`-1]. Given the input image of size *M*-by-*N*, the image size at each level of composition is M_{level}-by-N_{level}, where:

$$M_{level} = \frac{M}{ScaleFactor^{(level\ -\ 1)}}$$

$$N_{level} = \frac{N}{ScaleFactor^{(level\ -\ 1)}}$$

`NumLevels` — Number of decomposition levels

`8` (default) | integer greater than or equal to `1`

This property is read-only after object creation.

Number of decomposition levels, specified as an integer greater than or equal to `1`. Increase this value to extract keypoints from the image at more levels of decomposition. Along with the `ScaleFactor` value, `NumLevels` controls the number of pyramid levels on which the object evaluates feature points.

The image size at each decomposition level limits the number of levels at which you can extract keypoints. The image size at a level of decomposition must be at least 63-by-63 for keypoint detection. The maximum level of decomposition is calculated as

$$level_{\max} = \text{floor}\left(\frac{\log(\min(M,N)) - \log(63)}{\log(\text{ScaleFactor})}\right) + 1$$

If either the default value or the specified value of `NumLevels` is greater than $level_{max}$, the object modifies `NumLevels` to $level_{max}$ and returns a warning.

`MaxNumPoints` — Maximum number of ORB feature points uniformly extracted from each image

`1000` | positive integer

This property is read-only after object creation.

Maximum number of ORB feature points uniformly extracted from each image, specified as a positive integer. Values are typically in the range of [800, 2000], depending on the resolution of the image. When the number of extracted features is less than the value of `MaxNumPoints`, then the object uses all feature points.

Tracking

`TrackFeatureRange` — Range for the number of feature points to identify key frame

`[30 100]` | two-element vector of positive integers

This property is read-only after object creation.

Key frame feature point range, stored as a two-element vector of positive integers in the form [*lowerLimit upperLimit*]. This property specifies the minimum and maximum numbers of tracked features points a frame must contain for the object to identify it as a key frame. The `TrackFeatureRange` and the `SkipMaxFrames` properties enable you to control the frequency at which frames in the tracking process become key frames.

The success of tracking depends on the number of tracked points in the current frame, with one of these results:

- Tracking is lost — The number of tracked feature points in the current frame is less than the *lowerLimit* set by the `TrackFeatureRange` argument. This indicates that the image does not contain enough features, or that the camera is moving too fast. To improve the tracking, you can increase the *upperLimit* value of the `TrackFeatureRange` property and decrease the `SkipMaxFrames` property to add key frames more frequently.
- Tracking is successful — The object identifies the current frame as a key frame. The number of tracked feature points in the current frame is in the range set by `TrackFeatureRange`.
- Tracking adds key frames too frequently — The number of tracked feature points in the current frame is greater than the *upperLimit* set by the `TrackFeatureRange` property. This indicates that the camera is moving very slowly, which produces an unnecessary number of key frames. To

improve the tracking, you can reduce the frequency of adding key frames by increasing the value of the `SkipMaxFrames` property.

For more details, see the `addFrame` object function and “How to Improve Accuracy in Visual SLAM”.

`SkipMaxFrames` — Maximum number of skipped frames
`20` | positive integer

This property is read-only after object creation.

Maximum number of skipped frames, stored as a positive integer. When the number of tracked features is consistently greater than the *upperLimit* set by the `TrackFeatureRange` property, use the `SkipMaxFrames` property to control the frequency at which the object adds new key frames. The object identifies the current frame as a key frame when the number of skipped frames since the most recently added key frame equals the value of `SkipMaxFrames`. For more details, see “How to Improve Accuracy in Visual SLAM”.

`LoopClosureThreshold` — Minimum number of matched feature points between loop closure key frames
`60` | positive integer

This property is read-only after object creation.

Minimum number of matched feature points between loop closure key frames, stored as a positive integer.

`CustomBagOfFeatures` — Custom bag of features for loop detection
`[]` (default) | `bagOfFeaturesDBoW` object

This property is read-only after object creation.

Custom bag of features for loop detection, specified as a `bagOfFeaturesDBoW` object. The `bagOfFeaturesDBoW` enables you to create a custom bag of words (BoW) from feature descriptors, alongside options to utilize a built-in vocabulary or load a custom one from a specified file.

`Verbose` — Progress information display
`[]` (default) | `1` | `2` | `3`

This property is read-only after object creation.

Progress information display, specified as `[]`, `1`, `2`, or `3`. Paths to the location of log files, when they are created, is displayed on the command line. For more details, see “How to Improve Accuracy in Visual SLAM”.

Verbose value	Display description	Display location
`[]` or `false`	Display is turned off	—
`1` or `true`	Stages of vSLAM execution	Command window
`2`	Stages of vSLAM execution, with details on how the frame is processed, such as the artifacts used to initialize the map.	Log file in a temporary folder

Verbose value	Display description	Display location
3	Stages of vSLAM, artifacts used to initialize the map, poses and map points before and after bundle adjustment, and loop closure optimization data.	Log file in a temporary folder

IMU Fusion

`CameraToIMUTransform` — IMU sensor transformation
`rigidtform3d`

This property is read-only after object creation.

IMU sensor transformation, specified as a `rigidtform3d` object. The transformation describes the rotation and translation of the camera in the coordinate system of the IMU sensor.

`NumPosesThreshold` — Number of estimated camera poses to trigger camera-IMU alignment
`30` (default) | integer equal to or greater than 2

This property is read-only after object creation.

Number of estimated camera poses to trigger camera-IMU alignment, specified as an integer equal to or greater than 2. The process of aligning camera and IMU data is initiated after a specific number of camera poses have been estimated. This alignment serves two primary purposes: first, to estimate a scale factor that translates the up-to-scale results from a monocular camera into actual world units (meters), and second, to synchronize the IMU and camera frames, effectively eliminating the influence of gravity on accelerometer data. The timing for this alignment, determined by a threshold for the number of camera poses, is key to its success. A threshold set too low may not provide enough data for accurate calibration, while one set too high risks incorporating noise from measurement drift into the calibration. For a more in-depth understanding of this calibration technique, see the `estimateGravityRotationAndPoseScale` function.

`AlignmentFraction` — Subset of pose estimates
`0.8` (default) | scalar in the range (0,1]

This property is read-only after object creation.

Subset of pose estimates, specified as a scalar in the range of (0,1]. This value specifies a fraction of the number of recent pose estimates, calculated as `round(NumPosesThreshold*AlignmentFraction)`, for use in the camera-IMU alignment process. It effectively filters out initial, potentially noisy pose estimates, ensuring only the most relevant data contributes to the alignment for improved accuracy.

`IsIMUAligned` — Logical flag indicating IMU alignment completed successfully
`false` (default) | `true`

This property is read-only after object creation.

Logical flag indicating the IMU alignment completed successfully, specified as `true` or `false`. When IMU alignment completes successfully, the algorithm sets `IsIMUAligned` to `true`. Otherwise the value is `false`.

`GravityRotation` — Output rotation of IMU alignment process

`rigidtform3d` object (default)

This property is read-only after object creation.

Output rotation of IMU alignment process, specified as a `rigidtform3d` object. The rotation transforms the gravity vector from the IMU local navigation frame (NED or ENU) to the input pose reference frame.

The value of this property is automatically updated after the IMU alignment completes successfully and the `IsIMUAligned` property is `true`.

`IMUScale` — Scale of IMU alignment

1 object (default) | positive scalar

This property is read-only after object creation.

Scale of IMU alignment, specified as a positive scalar. The scale is applied as a multiplier to the input poses so that their units match the IMU measurements.

The value of this property is automatically updated after the IMU alignment completes successfully and the `isIMUAligned` property is `true`.

Object Functions

addFrame	Add image frame to visual SLAM object
hasNewKeyFrame	Check if new key frame added in visual SLAM object
checkStatus	Check status of visual SLAM object
isDone	End-of-processing status for visual SLAM object
mapPoints	Build 3-D map of world points
poses	Absolute camera poses of key frames
plot	Plot 3-D map points and estimated camera trajectory in visual SLAM
reset	Reset visual SLAM object

Examples

Monocular Visual SLAM Using TUM RGB-D Data Set

Perform monocular visual simultaneous localization and mapping (vSLAM) using the data from the TUM RGB-D Benchmark. You can download the data to a temporary directory using a web browser or by running this code:

```
baseDownloadURL = "https://cvg.cit.tum.de/rgbd/dataset/freiburg3/rgbd_dataset_freiburg3_long_off
dataFolder = fullfile(tempdir,"tum_rgbd_dataset",filesep);
options = weboptions(Timeout=Inf);
tgzFileName = dataFolder+"fr3_office.tgz";
folderExists = exist(dataFolder,"dir");

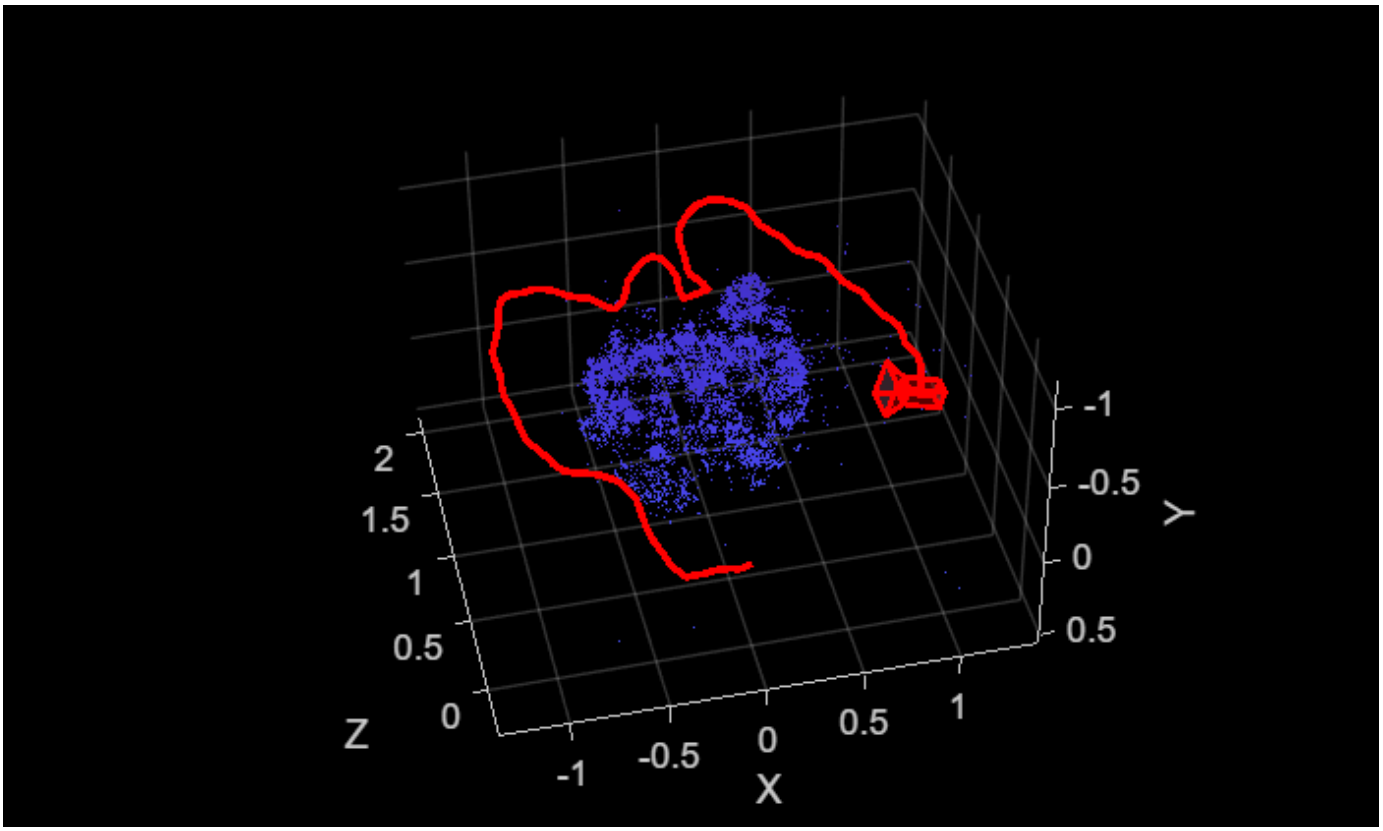
% Create a folder in a temporary directory to save the downloaded file
if ~folderExists
    mkdir(dataFolder)
    disp("Downloading fr3_office.tgz (1.38 GB). This download can take a few minutes.")
    websave(tgzFileName,baseDownloadURL,options);
```

```
    % Extract contents of the downloaded file
    disp("Extracting fr3_office.tgz (1.38 GB) ...")
    untar(tgzFileName,dataFolder);
end
```

Create an `imageDatastore` object to store all the RGB images.

```
imageFolder = dataFolder+"rgbd_dataset_freiburg3_long_office_household/rgb/";
imds = imageDatastore(imageFolder);
```

Specify your camera intrinsic parameters, and use them to create a monocular visual SLAM object.



```
intrinsics = cameraIntrinsics([535.4 539.2],[320.1 247.6],[480 640]);
vslam = monovslam(intrinsics,SkipMaxFrames=15);
```

Process each image frame, and visualize the camera poses and 3-D map points. Note that the `monovslam` object runs several algorithm parts on separate threads, which can introduce a latency in processing of an image frame added by using the `addFrame` function.

```
for i = 1:numel(imds.Files)
    addFrame(vslam,readimage(imds,i))

    if hasNewKeyFrame(vslam)
        % Display 3-D map points and camera trajectory
        plot(vslam);
    end

    % Get current status of system
    status = checkStatus(vslam);
end
```

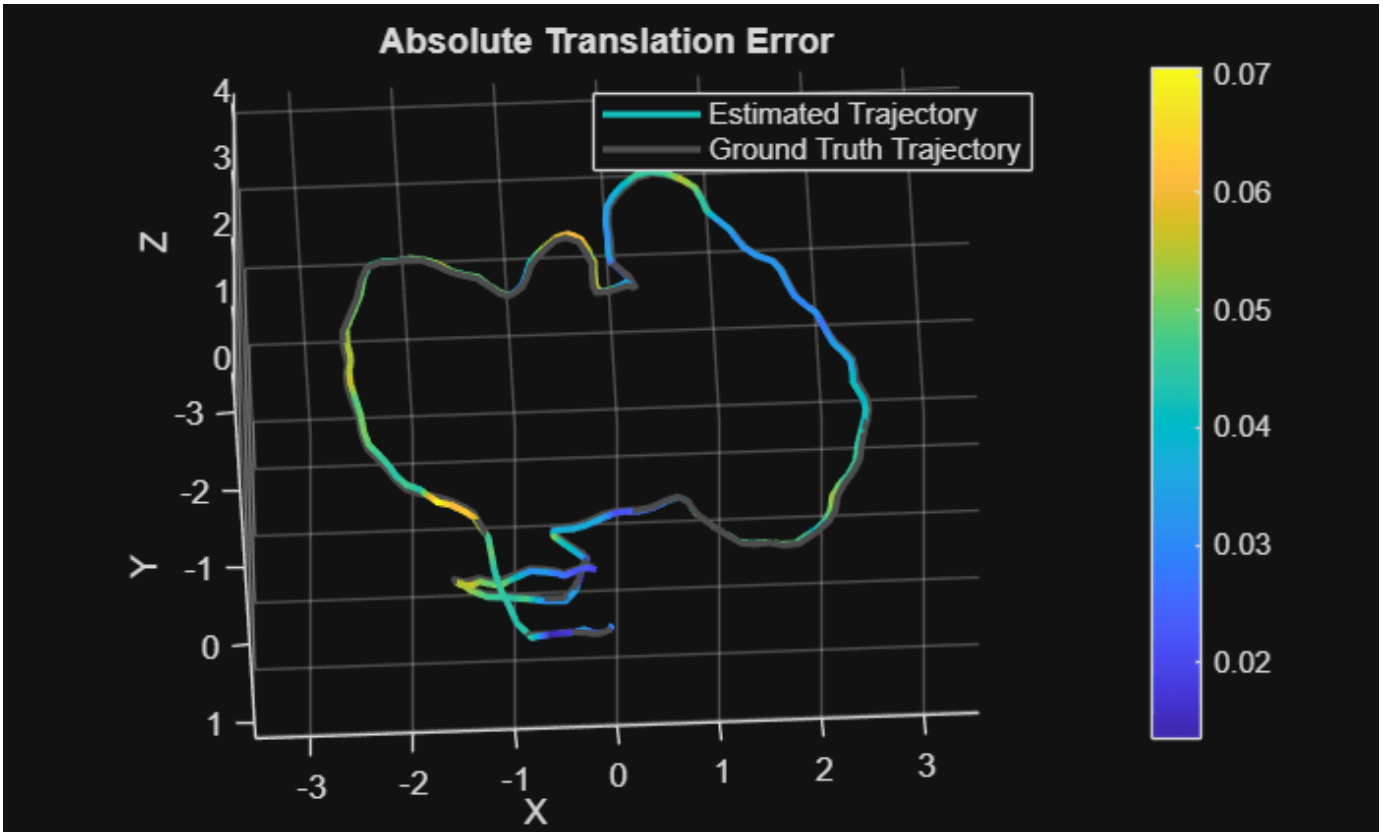
Plot intermediate results and wait until all images are processed.

```
while ~isDone(vslam)
    if hasNewKeyFrame(vslam)
        plot(vslam);
    end
end
```

After all the images are processed, you can collect the final 3-D map points and camera poses for further analysis.

```
xyzPoints = mapPoints(vslam);
[camPoses,addedFramesIdx] = poses(vslam);

% Reset the system
reset(vslam)
```



Compare the estimated camera trajectory with the ground truth to evaluate the accuracy.

```
% Load ground truth
gTruthData = load("orbslamGroundTruth.mat");
gTruth     = gTruthData.gTruth;

% Evaluate tracking accuracy
mtrics = compareTrajectories(camPoses, gTruth(addedFramesIdx), AlignmentType="similarity");
disp(['Absolute RMSE for key frame location (m): ', num2str(mtrics.AbsoluteRMSE(2))]);
```

```
Absolute RMSE for key frame location (m): 0.043641
```

```
% Plot the absolute translation error at each key frame
figure
ax = plot(mtrics, "absolute-translation");
view(ax, [2.70 -49.20]);
```

Monocular Visual-Inertial SLAM Using the BlackBird Data Set

Perform monocular visual-inertial SLAM using the data from the Blackbird data set (NYC Subway Winter). Download the MAT file which contains the images, camera intrinsics and IMU measurements.

```
uavDataTarFile =  matlab.internal.examples.downloadSupportFile('shared_nav_vision/data','Blackbi

% Extract the file.
outputFolder = fileparts(uavDataTarFile);
if (~exist(fullfile(outputFolder,"BlackbirdVIOData"),"dir"))
    untar(uavDataTarFile,outputFolder);
end

uavData = load(fullfile(outputFolder,"BlackbirdVIOData","data.mat"));

images     = uavData.images;
timeStamps = uavData.timeStamps;
```

Set up the IMU noise parameters, camera intrinsics and the camera-IMU extrinsics transform.

```
imuParams = factorIMUParameters(SampleRate=100,GyroscopeNoise=0.1, ...
            GyroscopeBiasNoise=3e-3,AccelerometerNoise=0.3, ...
            AccelerometerBiasNoise=1e-3,ReferenceFrame="ENU");
intrinsics = uavData.intrinsics;
camera2IMU = rigidtform3d(tform(uavData.camToIMUTransform));
```

Set up the monocular visual-inertial SLAM object.

```
vslam = monovslam(intrinsics,imuParams,MaxNumPoints=2000,SkipMaxFrames=2,TrackFeatureRange=[20,1(
        CameraToIMUTransform=camera2IMU,NumPosesThreshold=40,AlignmentFraction=0.9, ...
        CustomBagOfFeatures=bagOfFeaturesDBoW('BlackBirdBoW.bin.gz'),LoopClosureThreshold=100);
```

Process all the images frames and IMU measurements available, and visualize the camera poses and 3-D map points. The sequence does not contain any movement before the 150th frame.

```
startFrameIdx = 150;

for i = startFrameIdx:length(images)

    if(i>startFrameIdx)
        imuMesurements = helperExtractIMUMeasurements(uavData, i-1, i);
    else
        imuMesurements.gyro=[];
        imuMesurements.accel=[];
    end

    addFrame(vslam, images{i}, imuMesurements.gyro, imuMesurements.accel);

    if hasNewKeyFrame(vslam)
        plot(vslam);
    end
end
```

Note that the `monovslam` object runs several algorithm parts on separate threads, which can introduce a latency in processing of an image frame added by using the `addFrame` function.

```
% Plot intermediate results and wait until all images are processed
while ~isDone(vslam)
    if hasNewKeyFrame(vslam)
        plot(vslam);
    end
end
```

The helper function below is used to extract the IMU measurements, based on the camera timestamps.

```
function imuMesurements = helperExtractIMUMeasurements(data, startFrameIdx, currFrameIdx)

    timeStamps = data.timeStamps;

    startTimeStamp = timeStamps.imageTimeStamps(startFrameIdx);
    currTimeStamp  = timeStamps.imageTimeStamps(currFrameIdx);

    [~,startIMUIdx] = min(abs(timeStamps.imuTimeStamps - startTimeStamp));
    [~,currIMUIdx]  = min(abs(timeStamps.imuTimeStamps - currTimeStamp));

    imuMesurements.accel = data.accelReadings(startIMUIdx:(currIMUIdx-1),:);
    imuMesurements.gyro  = data.gyroReadings(startIMUIdx:(currIMUIdx-1),:);

end
```

Version History

Introduced in R2023b

R2025a: `monovslam` available in Navigation Toolbox with Computer Vision Toolbox license

You can use the `monovslam` object in Navigation Toolbox if you have a Computer Vision Toolbox license.

R2025a: MATLAB Coder support added for IMU sensor support

Added C/C++ support for visual-inertial sensor fusion using the `monovslam` object. Starting in R2025a, you can generate C/C++ code using the IMU parameters along with all other object parameters.

R2024b: Fusion support for IMU sensors

Use the `imuParameters` input argument as a `factorIMUParameters` object to specify information about IMU parameters. Use the `CameraToIMUTransform`, `NumPosesThreshold`, and `AlignmentFraction` properties to tune IMU parameters. The IMU-based features of the `monovslam` object do not support C/C++ code generation.

R2024b: Add ability to specify custom bag of words

Use the `CustomBagOfFeatures` name-value argument to specify a custom bag of words vocabulary as a `bagOfFeaturesDBoW` object.

R2024b: `Verbose` property enhanced to display progress information
Behavior changed in R2024b

The `Verbose` property added values of `1`, `2`, and `3` to display levels of progress information.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

To compile the generated code for non-host target, these dependencies must be installed:

- OpenCV 4.7.0
- Ceres-solver 2.2.0 library — Download the source and build it as a shared library, on your remote device.
- eigen3 Library

When generating portable C code with a C++ compiler, you must specify hierarchical packing with non-minimal headers. For more information on packaging options, see the `packNGo` function.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

addFrame

Add image frame to visual SLAM object

Syntax

```
addFrame(vslam,I)
addFrame( ___ ,gyro,accel)
```

Description

`addFrame(vslam,I)` adds a grayscale or RGB image `I`, to the visual SLAM object `vslam`.

Note The `monovslam` object runs on multiple threads internally, which can delay the processing of an image frame added by using the `addFrame` function. Additionally, the object running on multiple threads means the current frame the object is processing can be different than the recently added frame.

`addFrame( ___ ,gyro,accel)` adds IMU gyroscope `gyro`, and accelerometer `accel`, measurements to the visual SLAM object.

Examples

```

```
Absolute RMSE for key frame location (m): 0.043641
```

```
% Plot the absolute translation error at each key frame
figure
ax = plot(mtrics, "absolute-translation");
view(ax, [2.70 -49.20]);
```

Input Arguments

`vslam` — Visual SLAM object
`monovslam` object

Visual SLAM object, specified as a `monovslam` object.

`I` — Image
grayscale image | RGB image

Image, specified as a grayscale or RGB image.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

`gyro` — Gyroscope IMU measurement
N-by-3 matrices

Gyroscope IMU measurement, specified by *N*-by-3 matrices. *N* specifies the number of IMU measurements between the previous and current camera frames. Each row of the matrix specifies a gyroscope measurement of the form *[gx, gy, gz]*.

`accel` — Acceleration IMU measurement
N-by-3 matrices

Acceleration IMU measurement, specified by *N*-by-3 matrices. *N* specifies the number of IMU measurements between the previous and current camera frames. Each row of the matrix specifies an acceleration measurement of the form *[ax, ay, az]*.

Version History

Introduced in R2023b

R2024b: Input arguments added for IMU measurements

Specify IMU measurements, gyro and acceleration, for visual-inertial fusion.

hasNewKeyFrame

Check if new key frame added in visual SLAM object

Syntax

```
hasAdded = hasNewKeyFrame(vslam)
```

Description

`hasAdded = hasNewKeyFrame(vslam)` returns a logical value that indicates if a new key frame has been added within the visual simultaneous localization and mapping (vSLAM) object `vslam`.

Examples

Monocular Visual SLAM Using TUM RGB-D Data Set

Perform monocular visual simultaneous localization and mapping (vSLAM) using the data from the TUM RGB-D Benchmark. You can download the data to a temporary directory using a web browser or by running this code:

```
baseDownloadURL = "https://cvg.cit.tum.de/rgbd/dataset/freiburg3/rgbd_dataset_freiburg3_long_offi

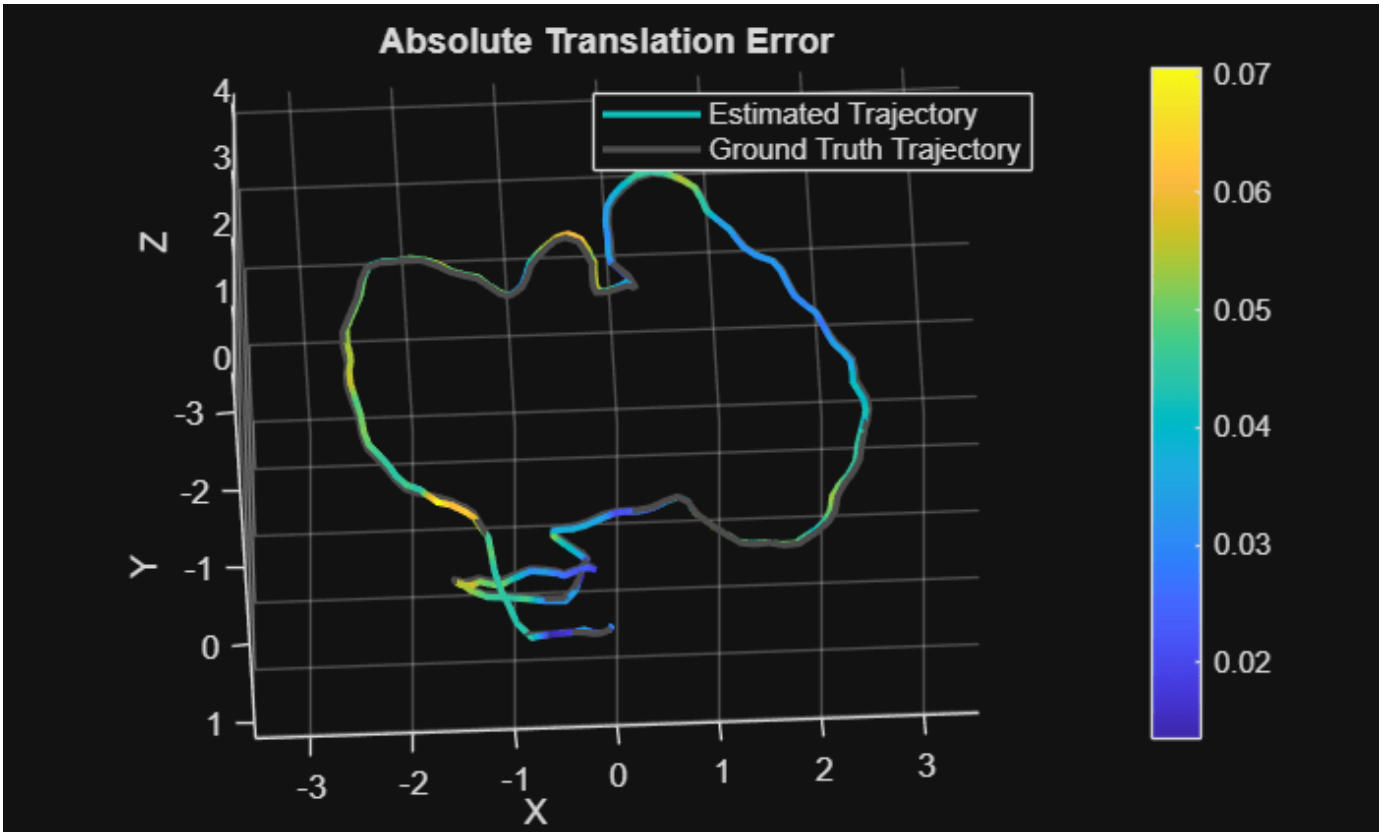
reset(vslam)
```



Compare the estimated camera trajectory with the ground truth to evaluate the accuracy.

```
% Load ground truth
gTruthData = load("orbslamGroundTruth.mat");
gTruth     = gTruthData.gTruth;

% Evaluate tracking accuracy
mtrics = compareTrajectories(camPoses, gTruth(addedFramesIdx), AlignmentType="similarity");
disp(['Absolute RMSE for key frame location (m): ', num2str(mtrics.AbsoluteRMSE(2))]);
```

```
Absolute RMSE for key frame location (m): 0.043641
```

```
% Plot the absolute translation error at each key frame
figure
ax = plot(mtrics, "absolute-translation");
view(ax, [2.70 -49.20]);
```

Input Arguments

`vslam` — Visual SLAM object
`monovslam` object

Visual SLAM object, specified as a `monovslam` object.

Output Arguments

`hasAdded` — New key frame status
`false` or `0` | `true` or `1`

New key frame status, returned as `0` (`false`) or `1` (`true`). A value of `true` indicates that a new key frame has been added within the visual SLAM object `vslam`. A value of `false` indicates that no new key frame has been added. The object considers an image frame to be a key frame if the number of tracked feature points in the current frame satisfies one of these conditions:

- The number of tracked feature points is within the limits specified by the `TrackFeatureRange` property of the `monovslam` object, `vslam`.
- The number of tracked feature points is greater than the upper limit specified by the `TrackFeatureRange` property of the `monovslam` object, `vslam`, and the number of skipped frames since adding the last key frame equals the value of the `SkipMaxFrames`.

The `hasNewKeyFrame` object function returns `true` once per new key frame added. For example, if the `monovslam` object adds only one key frame, then two consecutive calls to `hasNewKeyFrame` return `true` and `false`, respectively.

Functions
`addFrame` | `checkStatus` | `isDone` | `mapPoints` | `poses` | `plot` | `reset`

checkStatus

Check status of visual SLAM object

Syntax

```
status = checkStatus(vslam)
```

Description

`status = checkStatus(vslam)` returns the current status of the visual SLAM object. The frame the object is currently processing might be different than the most recently added frame.

Examples

Monocular Visual SLAM Using TUM RGB-D Data Set

Perform monocular visual simultaneous localization and mapping (vSLAM) using the data from the TUM RGB-D Benchmark. You can download the data to a temporary directory using a web browser or by running this code:

```
baseDownloadURL = "https://cvg.cit.tum.de/rgbd/dataset/freiburg3/rgbd_dataset_freiburg3_long_offi
dataFolder = fullfile(tempdir,"tum_rgbd_dataset",filesep);
options = weboptions(Timeout=Inf);
tgzFileName = dataFolder+"fr3_office.tgz";
folderExists = exist(dataFolder,"dir");

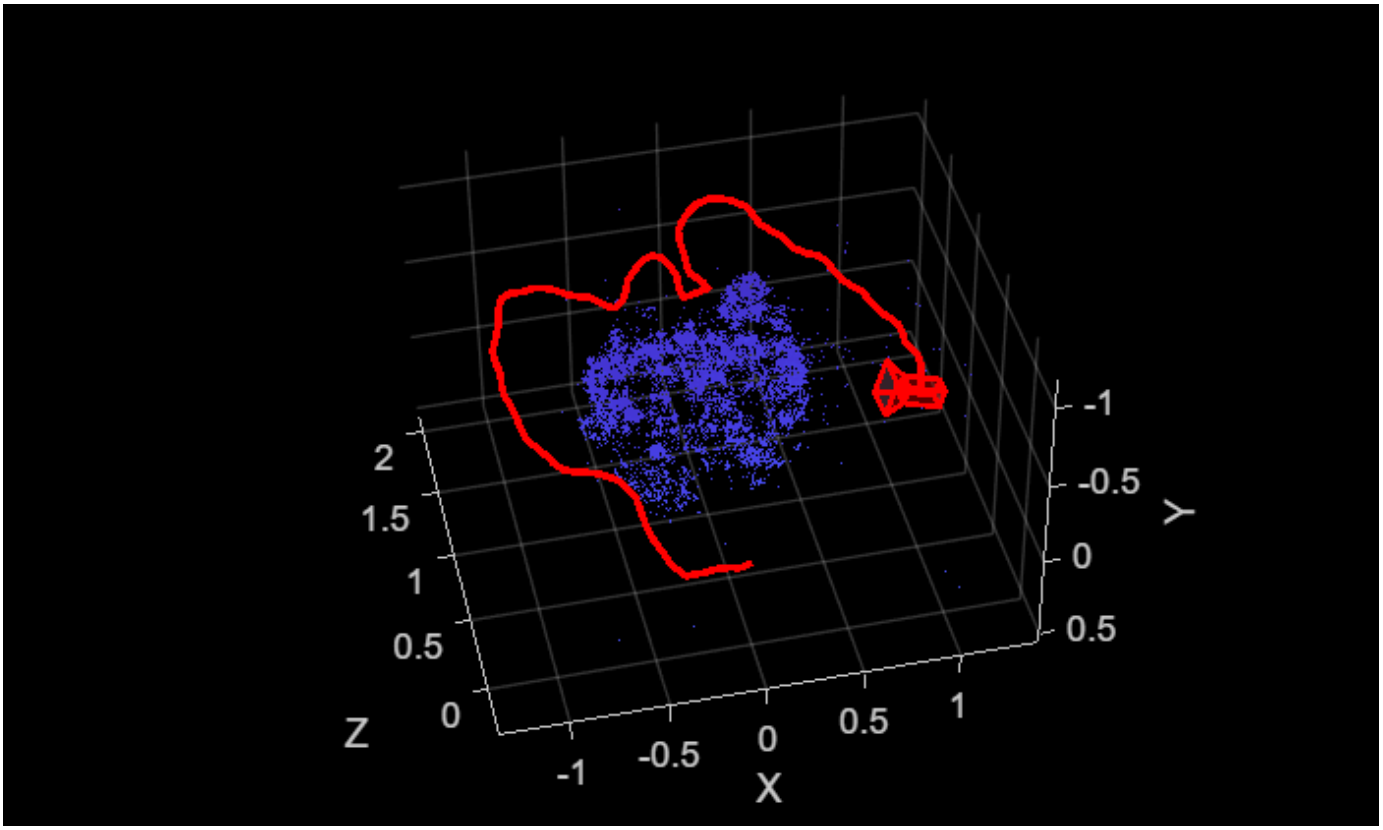
% Create a folder in a temporary directory to save the downloaded file
if ~folderExists
    mkdir(dataFolder)
    disp("Downloading fr3_office.tgz (1.38 GB). This download can take a few minutes.")
    websave(tgzFileName,baseDownloadURL,options);

    % Extract contents of the downloaded file
    disp("Extracting fr3_office.tgz (1.38 GB) ...")
    untar(tgzFileName,dataFolder);
end
```

Create an `imageDatastore` object to store all the RGB images.

```
imageFolder = dataFolder+"rgbd_dataset_freiburg3_long_office_household/rgb/";
imds = imageDatastore(imageFolder);
```

Specify your camera intrinsic parameters, and use them to create a monocular visual SLAM object.



```
intrinsics = cameraIntrinsics([535.4 539.2],[320.1 247.6],[480 640]);
vslam = monovslam(intrinsics,SkipMaxFrames=15);
```

Process each image frame, and visualize the camera poses and 3-D map points. Note that the `monovslam` object runs several algorithm parts on separate threads, which can introduce a latency in processing of an image frame added by using the `addFrame` function.

```
for i = 1:numel(imds.Files)
    addFrame(vslam,readimage(imds,i))

    if hasNewKeyFrame(vslam)
        % Display 3-D map points and camera trajectory
        plot(vslam);
    end

    % Get current status of system
    status = checkStatus(vslam);
end
```

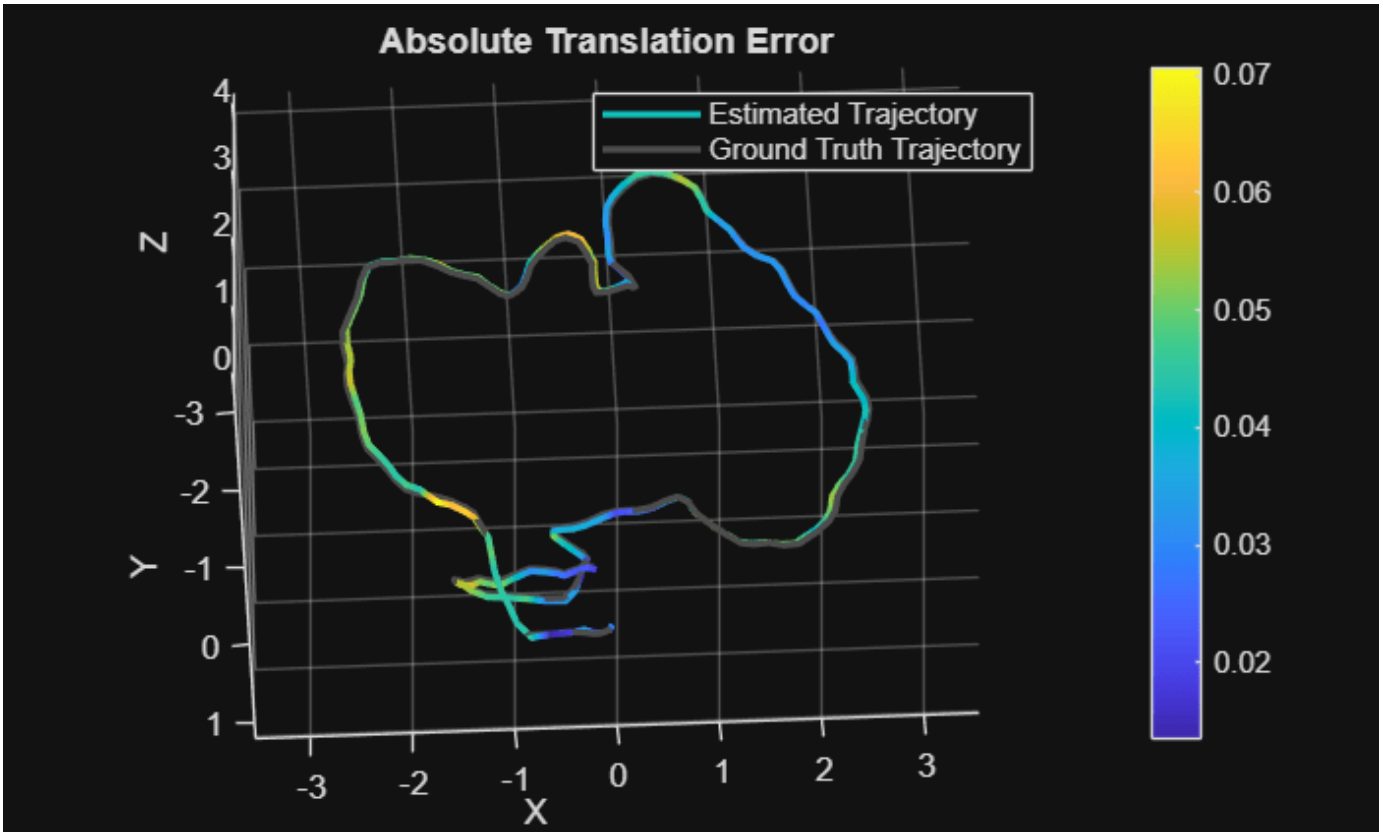
Plot intermediate results and wait until all images are processed.

```
while ~isDone(vslam)
    if hasNewKeyFrame(vslam)
        plot(vslam);
    end
end
```

After all the images are processed, you can collect the final 3-D map points and camera poses for further analysis.

```
xyzPoints = mapPoints(vslam);
[camPoses,addedFramesIdx] = poses(vslam);

% Reset the system
reset(vslam)
```



Compare the estimated camera trajectory with the ground truth to evaluate the accuracy.

```
% Load ground truth
gTruthData = load("orbslamGroundTruth.mat");
gTruth     = gTruthData.gTruth;

% Evaluate tracking accuracy
mtrics = compareTrajectories(camPoses, gTruth(addedFramesIdx), AlignmentType="similarity");
disp(['Absolute RMSE for key frame location (m): ', num2str(mtrics.AbsoluteRMSE(2))]);
```

```
Absolute RMSE for key frame location (m): 0.043641
```

```
% Plot the absolute translation error at each key frame
figure
ax = plot(mtrics, "absolute-translation");
view(ax, [2.70 -49.20]);
```

Input Arguments

`vslam` — Visual SLAM object

`monovslam` object

Visual SLAM object, specified as a `monovslam` object.

Output Arguments

`status` — Current status of visual SLAM object

`TrackingLost` enumeration | `TrackingSuccessful` enumeration | `FrequentKeyFrames` enumeration

Current status of the visual SLAM object, returned as a `TrackingLost`, `TrackingSuccessful`, or `FrequentKeyFrames` enumeration. This table describes these enumerations.

Enumeration Value	Numeric Value	Description
`TrackingLost`	`uint8(0)`	Tracking is lost. The number of tracked feature points in the frame currently being processed is less than the lower limit of the `TrackFeatureRange` property. This indicates the image does not contain enough features, or that the camera is moving too fast. To improve the tracking, you can increase the *upperLimit* value of the `TrackFeatureRange` argument and decrease the `SkipMaxFrames` argument to add key frames more frequently.
`TrackingSuccessful`	`uint8(1)`	Tracking is successful. The number of tracked feature points in the frame currently being processed is between the lower limit and upper limit values of the `TrackFeatureRange` property.
`FrequentKeyFrames`	`uint8(2)`	Tracking adds key frames too frequently. The number of tracked feature points in the frame currently being processed is greater than the upper limit of the `TrackFeatureRange` property.

Objects
`monovslam`

Functions
`addFrame` | `isDone` | `mapPoints` | `poses` | `plot` | `reset` | `hasNewKeyFrame`

isDone

End-of-processing status for visual SLAM object

Syntax

```
done = isDone(vslam)
```

Description

`done = isDone(vslam)` returns a logical value indicating whether the visual SLAM object has finished processing its frames. A value of `true` indicates the object is in an idle state. A value of `false` indicates the object is processing one or more frames.

Examples

Monocular Visual SLAM Using TUM RGB-D Data Set

mapPoints

Build 3-D map of world points

Syntax

```
xyzPoints = mapPoints(vslam)
```

Description

`xyzPoints = mapPoints(vslam)` builds a sparse 3-D map of world points, `xyzPoints`, from the input images in the visual simultaneous localization and mapping (vSLAM) object `vslam`.

Examples

Monocular Visual SLAM Using TUM RGB-D Data Set

Perform monocular visual simultaneous localization and mapping (vSLAM) using the data from the TUM RGB-D Benchmark. You can download the data to a temporary directory using a web browser or by running this code:

Absolute RMSE for key frame location (m): 0.043641
```

```
% Plot the absolute translation error at each key frame
figure
ax = plot(mtrics, "absolute-translation");
view(ax, [2.70 -49.20]);
```

Input Arguments

`vslam` — Visual SLAM object
`monovslam` object

Visual SLAM object, specified as a `monovslam` object.

Output Arguments

`xyzPoints` — 3-D map of world points
M-by-3 matrix

3-D map of world points, returned as an *M*-by-3 matrix. *M* is the number of points, and each point is specified in the form [*X Y Z*].

poses

Absolute camera poses of key frames

Syntax

```
camPoses = poses(vslam)
[camPoses,keyFrameIDs] = poses(vslam)
```

Description

`camPoses = poses(vslam)` returns the absolute camera poses `camPoses` of the key frames from the visual simultaneous localization and mapping (vSLAM) object `vslam`.

`[camPoses,keyFrameIDs] = poses(vslam)` returns the IDs `keyFrameIDs` of the key frames corresponding to the camera poses. The IDs represent the order in which the image frames have been added to the `vslam` object by the `addFrame` object function.

```

```
% Plot the absolute translation error at each key frame
figure
ax = plot(mtrics, "absolute-translation");
view(ax, [2.70 -49.20]);
```

Input Arguments

`vslam` — Visual SLAM object
`monovslam` object

Visual SLAM object, specified as a `monovslam` object.

Output Arguments

`camPoses` — Absolute camera poses of key frames
M-element array of `rigidtform3d` objects

Absolute camera poses of key frames, returned as an *M*-element array of `rigidtform3d` objects.

`keyFrameIDs` — Key frame IDs for absolute camera poses
M-element array of integers

Key frame IDs for the absolute camera poses, returned as an *M*-element array of integers. Each element specifies the key frame ID for the camera pose in the corresponding element of `camPoses`. The IDs represent the order in which the image frames have been added to the `vslam` object by the `addFrame` object function.

plot

Plot 3-D map points and estimated camera trajectory in visual SLAM

Syntax

```
plot(vslam)
plot(vslam,Name=Value)
ax = plot( ___ )
```

Description

`plot(vslam)` plots the 3-D map points and estimated camera trajectory from the visual SLAM object `vslam`.

`plot(vslam,Name=Value)` specifies options using one or more name-value arguments. For example, `MarkerSize=10` sets the diameter of the marker size to 10 points.

`ax = plot( ___ )` returns the axes handle for the 3-D mapped points of the plot, using any combination of input arguments from previous syntaxes.

Examples

Monocular Visual SLAM Using TUM RGB-D Data Set

Perform monocular visual simultaneous localization and mapping (vSLAM) using the data from the TUM RGB-D Benchmark. You can download the data to a temporary directory using a web browser or by running this code:

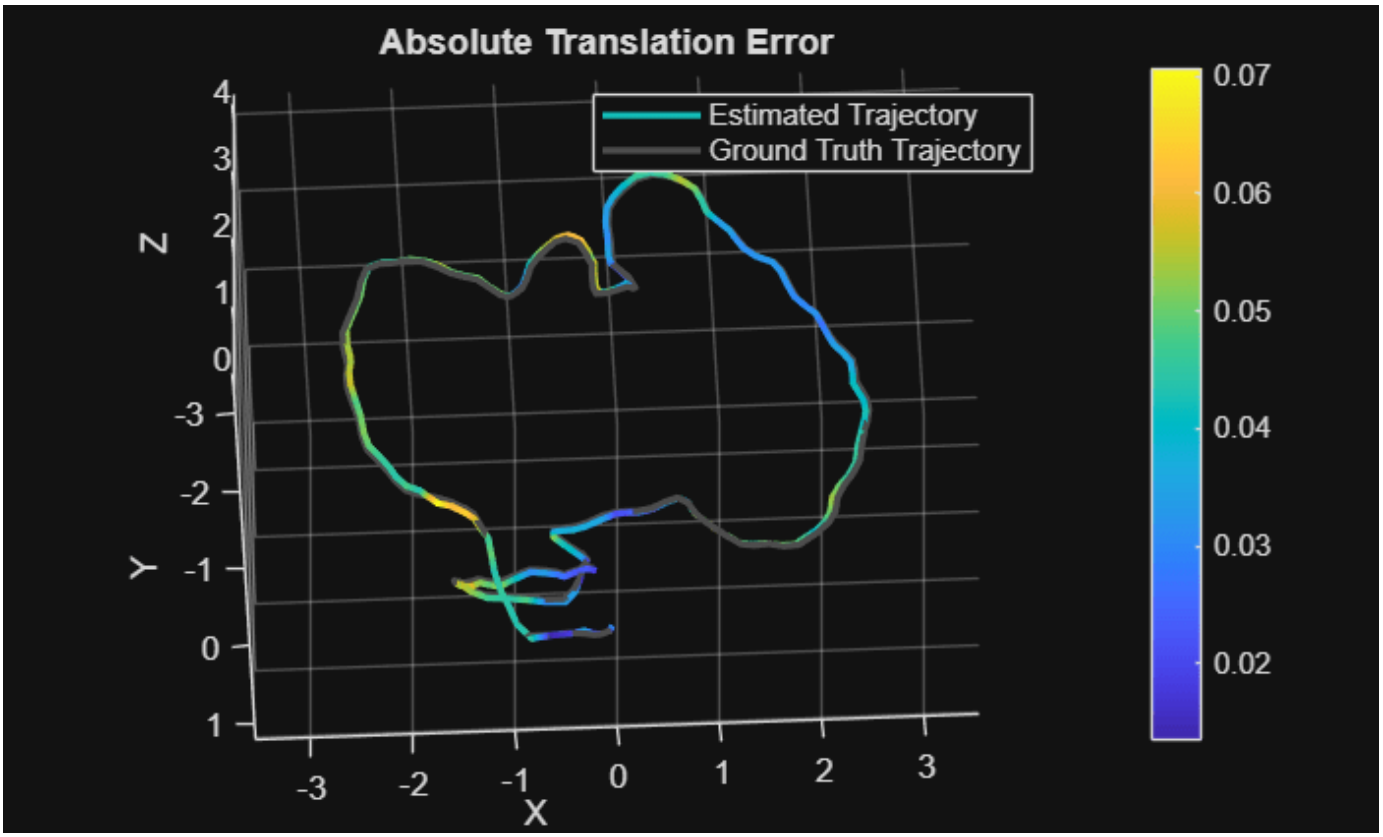
[camPoses,addedFramesIdx] = poses(vslam);

% Reset the system
reset(vslam)
```



Compare the estimated camera trajectory with the ground truth to evaluate the accuracy.

```
% Load ground truth
gTruthData = load("orbslamGroundTruth.mat");
gTruth     = gTruthData.gTruth;

% Evaluate tracking accuracy
mtrics = compareTrajectories(camPoses, gTruth(addedFramesIdx), AlignmentType="similarity");
disp(['Absolute RMSE for key frame location (m): ', num2str(mtrics.AbsoluteRMSE(2))]);
```

```
Absolute RMSE for key frame location (m): 0.043641
```

```
% Plot the absolute translation error at each key frame
figure
ax = plot(mtrics, "absolute-translation");
view(ax, [2.70 -49.20]);
```

Input Arguments

`vslam` — Visual SLAM object

`monovslam` object

Visual SLAM object, specified as a `monovslam` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `plot(vslam,MarkerSize=10)`, sets the diameter of the marker to 10 points.

`MarkerSize` — Diameter of markers for 3-D map points

`6` (default) | positive integer

Diameter of markers for 3-D map points, specified as a positive integer in points.

`MarkerColor` — Color of markers for 3-D map points

`[0,1,0]` (default) | RGB triplet | short or long color name

Color of markers for 3-D map points, specified as an RGB triplet or a short or long color name. Each value within an RGB triplet must be in the range `[0, 1]`

`ColorSource` — Colormap source for markers
`"Y"` (default) | `"X"` | `"Z"` | `"MarkerColor"`

Colormap source for markers, specified as `"X"`, `"Y"`, `"Z"`, or `"MarkerColor"`.

`CameraSize` — Width of camera base
`0.1` (default) | scalar

Width of the camera base, specified as a scalar in the data units of the axes.

`CameraColor` — Color of camera
`[1,0,0]` (default) | RGB triplet | short or long color name

Color of the camera, specified as an RGB triplet or a short or long color name. Each value within an RGB triplet must be in the range [`0`, `1`].

`Parent` — Axes for visualization
`Axes` object | `UIAxes` object

Axes for visualization, specified as an `Axes` object or a `UIAxes` object. Use this name-value argument to visualize the plot in a UI for which you have specified `Figure` and `Axes` properties.

Output Arguments

`ax` — Axes handle
`Axes` graphics object

Axes handle, returned as an `axes` graphics object

Reset visual SLAM object

Syntax

`reset(vslam)`

Description

`reset(vslam)` resets all internal processes and clears all data in the object.

Examples

Monocular Visual SLAM Using TUM RGB-D Data Set

Perform monocular visual simultaneous localization and mapping (vSLAM) using the data from the TUM RGB-D Benchmark. You can download the data to a temporary directory using a web browser or by running this code:

```
baseDownloadURL = "https://cvg.cit.tum.de/rgbd/dataset/freiburg3/rgbd_dataset_freiburg3_long_offi
dataFolder = fullfile(tempdir,"tum_rgbd_dataset",filesep);
options = weboptions(Timeout=Inf);
tgzFileName = dataFolder+"fr3_office.tgz";
folderExists = exist(dataFolder,"dir");

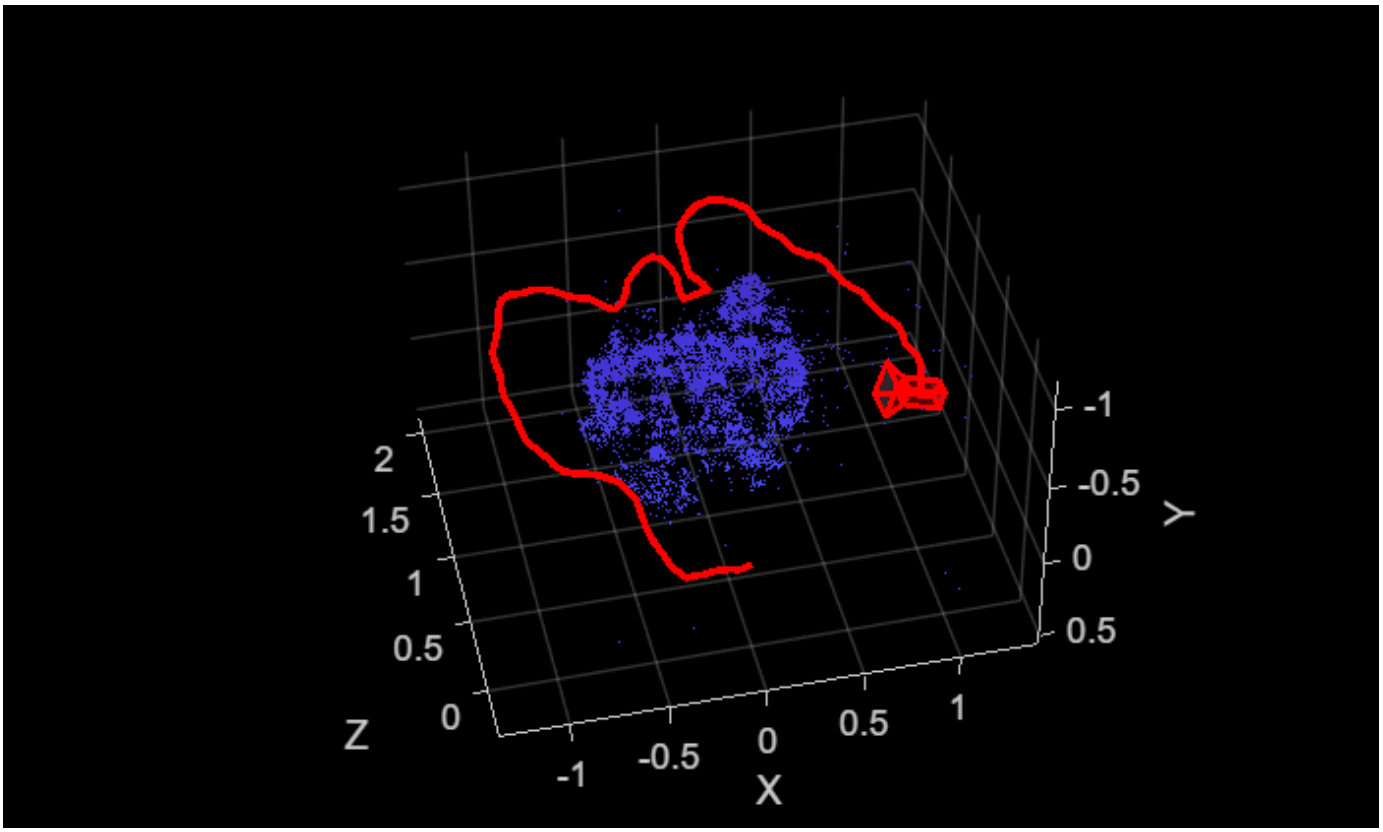
% Create a folder in a temporary directory to save the downloaded file
if ~folderExists
    mkdir(dataFolder)
    disp("Downloading fr3_office.tgz (1.38 GB). This download can take a few minutes.")
    websave(tgzFileName,baseDownloadURL,options);

    % Extract contents of the downloaded file
    disp("Extracting fr3_office.tgz (1.38 GB) ...")
    untar(tgzFileName,dataFolder);
end
```

Create an `imageDatastore` object to store all the RGB images.

```
imageFolder = dataFolder+"rgbd_dataset_freiburg3_long_office_household/rgb/";
imds = imageDatastore(imageFolder);
```

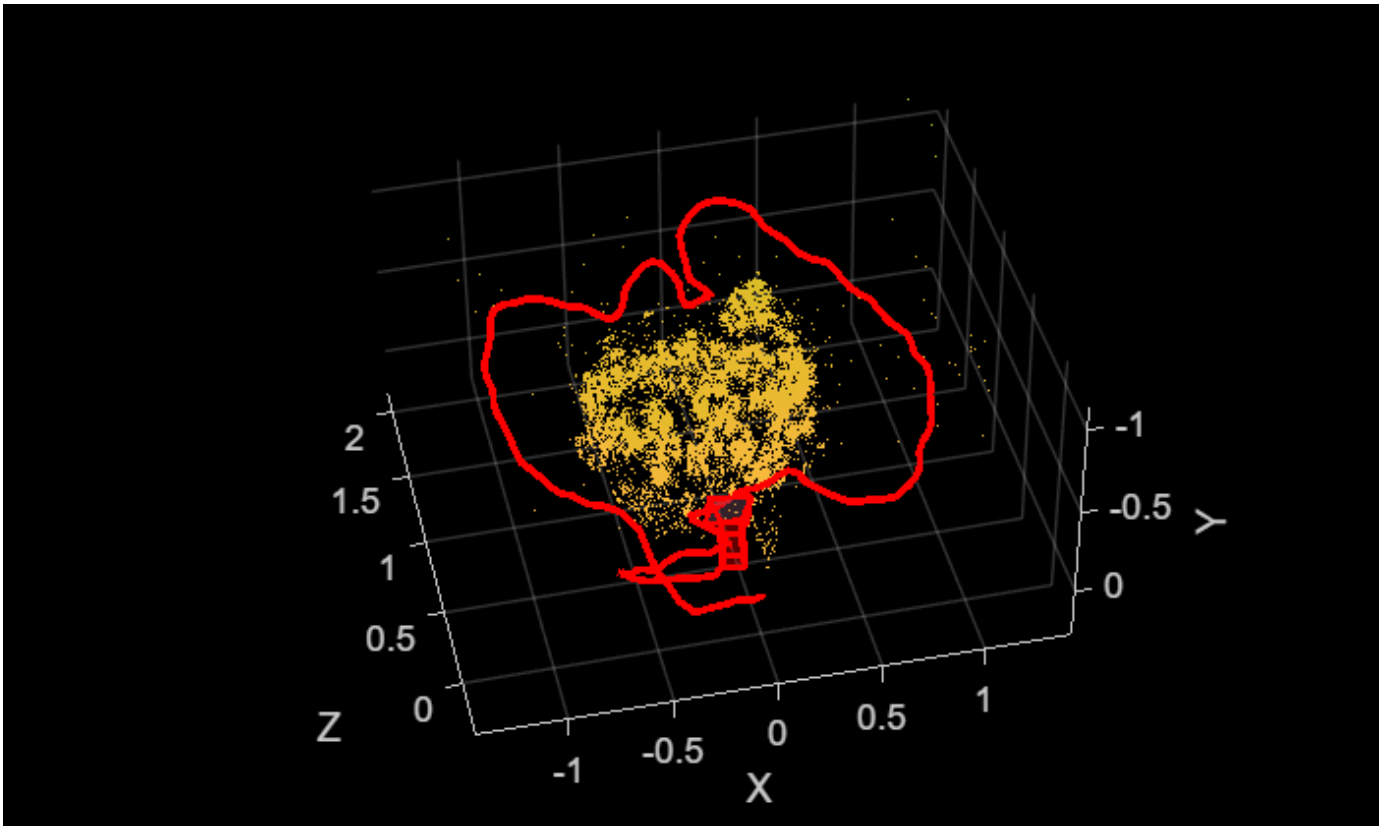
Specify your camera intrinsic parameters, and use them to create a monocular visual SLAM object.



```
intrinsics = cameraIntrinsics([535.4 539.2],[320.1 247.6],[480 640]);
vslam = monovslam(intrinsics,SkipMaxFrames=15);
```

Process each image frame, and visualize the camera poses and 3-D map points. Note that the `monovslam` object runs several algorithm parts on separate threads, which can introduce a latency in processing of an image frame added by using the `addFrame` function.

```
for i = 1:numel(imds.Files)
    addFrame(vslam,readimage(imds,i))
```



```
    if hasNewKeyFrame(vslam)
        % Display 3-D map points and camera trajectory
        plot(vslam);
    end

    % Get current status of system
    status = checkStatus(vslam);
end
```

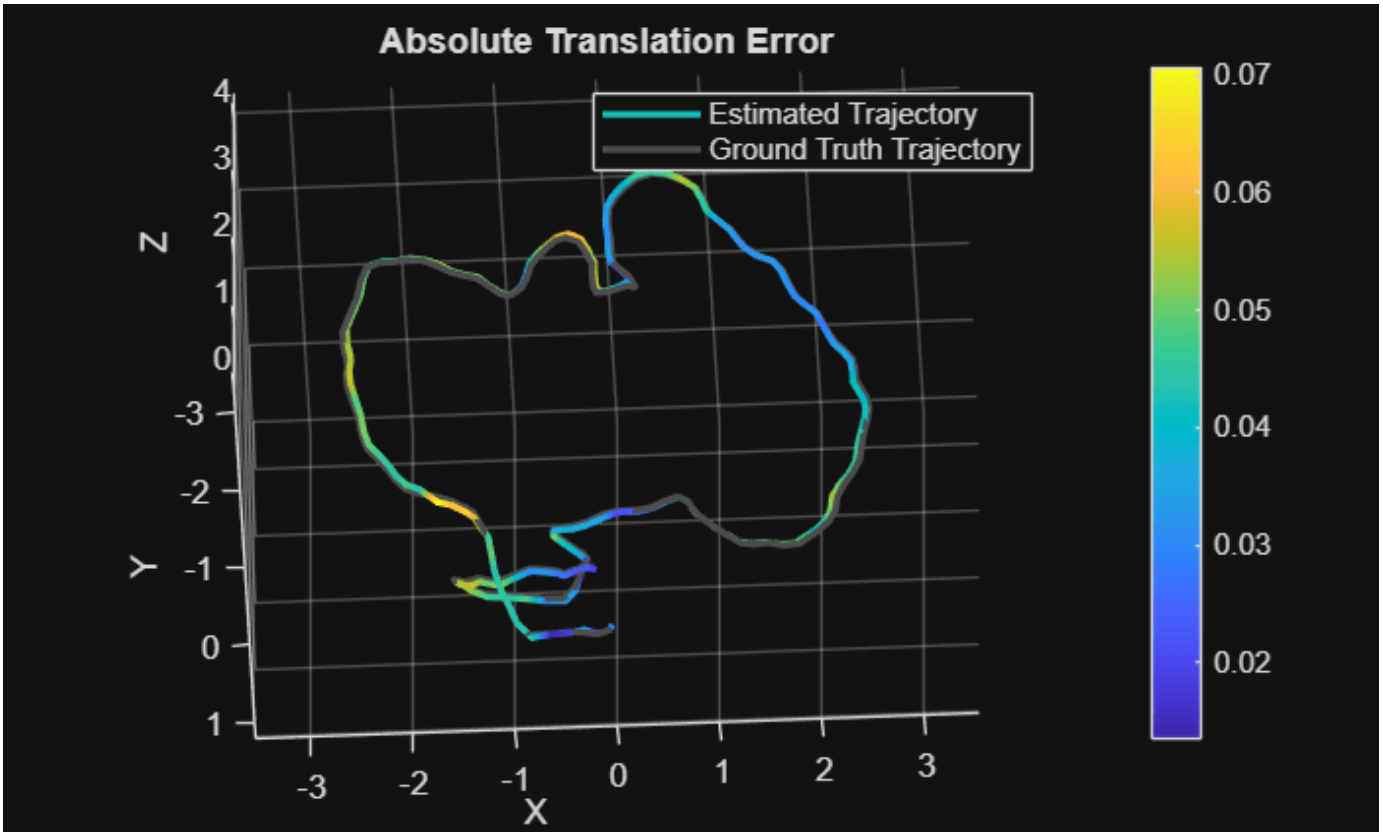
Plot intermediate results and wait until all images are processed.

```
while ~isDone(vslam)
    if hasNewKeyFrame(vslam)
        plot(vslam);
    end
end
```

After all the images are processed, you can collect the final 3-D map points and camera poses for further analysis.

```
xyzPoints = mapPoints(vslam);
[camPoses,addedFramesIdx] = poses(vslam);

% Reset the system
reset(vslam)
```



Compare the estimated camera trajectory with the ground truth to evaluate the accuracy.

```
% Load ground truth
gTruthData = load("orbslamGroundTruth.mat");
gTruth     = gTruthData.gTruth;

% Evaluate tracking accuracy
mtrics = compareTrajectories(camPoses, gTruth(addedFramesIdx), AlignmentType="similarity");
disp(['Absolute RMSE for key frame location (m): ', num2str(mtrics.AbsoluteRMSE(2))]);
```

```
Absolute RMSE for key frame location (m): 0.043641
```

```
% Plot the absolute translation error at each key frame
figure
ax = plot(mtrics, "absolute-translation");
view(ax, [2.70 -49.20]);
```

Input Arguments

`vslam` — Visual SLAM object
`monovslam` object

Visual SLAM object, specified as a `monovslam` object.

Version History

Introduced in R2023b

ocrTrainingOptions

Options for training OCR model

Description

The `ocrTrainingOptions` object specifies training options for an optical character recognition (OCR) model.

Creation

Syntax

```
ocrOptions = ocrTrainingOptions(Name=Value)
```

Description

`ocrOptions = ocrTrainingOptions(Name=Value)` creates an `ocrTrainingOptions` object. Specify one or more properties using name-value arguments to configure a set of training options, and then use them with the `trainOCR` function to train an OCR model. For example, `CharacterSetSource="base-model"` sets the source of the character set to use during OCR training to the base model.

Properties

`OutputLocation` — Folder in which to store the output model file
`pwd` (default) | string scalar | character vector

Folder in which to store the output model file, specified as a string scalar or character vector. If the folder already contains a file with the name specified by the `modelName` argument of the `trainOCR` function, then the `trainOCR` function overwrites it during training.

`CharacterSetSource` — Source of character set for text recognition training
`"auto"` (default) | `"base-model"` | `"ground-truth-data"`

Source of the character set for text recognition training, specified as `"auto"`, `"base-model"`, or `"ground-truth-data"`.

- `"auto"` — Training uses the character set of the base model when resuming from a checkpoint. Otherwise, training selects a character set as defined by the ground truth data.
- `"base-model"` — Training uses the character set of the base model specified in the `trainOCR` function. Use this option to fine-tune the base model used on the ground truth data.
- `"ground-truth-data"` — To use the character set defined by the ground truth data specified in the `trainOCR` function.

`MaxEpochs` — Maximum number of epochs used for training
5 (default) | positive integer

Maximum number of epochs used for training, specified as a positive integer.

`InitialLearnRate` — Initial learning rate used for training
1.0000e-03 (default) | numeric scalar

Initial learning rate used for training, specified as a numeric scalar. Decreasing the initial learning rate can increase training time. However, increasing the rate too much can result in the training being unable to converge.

`Verbose` — Progress information display
`true` or `1` (default) | `false` or `0`

Progress information display, specified as a numeric or logical `1` (`true`) or `0` (`false`).

`VerboseFrequency` — Number of iterations between progress displays
`50` (default) | positive integer

Number of iterations between progress displays, specified as a positive integer. This argument only applies when you set `Verbose` to `true`.

`CheckpointPath` — Path to save check point models
`""` (default) | character vector | string

Path to save check point models, specified as a character vector or a string. When you set `CheckpointPath` to `""`, the `trainOCR` function does not save checkpoints.

`CheckpointFrequency` — Frequency for saving check point models
`1` (default) | positive integer

Frequency for saving check point models, specified as a positive integer. This argument only applies when you specify a path by using `CheckpointPath`.

`CheckpointFrequencyUnit` — Unit of check point frequency
`"epoch"` (default)

Unit of check point frequency, specified as `"epoch"` or `"iteration"`. When you set this value to `"epoch"`, the `trainOCR` function saves a checkpoint every `CheckpointFrequecy` epochs. When you set this value to `"iteration"`, the `trainOCR` function saves a checkpoint every `CheckpointFrequecy` iterations.

`ValidationData` — Data to use for validation during training
`[]` (default) | datastore object

Data to use for validation during training, specified as a datastore object with the same format as the `trainingData` input argument of the `trainOCR` function.

`ValidationFrequency` — Number of iterations between evaluations of validation metrics
`50` (default) | positive integer

Number of iterations between evaluations of validation metrics, specified as a positive integer.

`ValidationPatience` — Validation loss tolerance
`Inf` (default) | positive integer

Validation loss tolerance, specified as `Inf` or a positive integer. This value specifies the consecutive number of iterations for which the validation loss can be greater than or equal to the previous smallest loss before the network stops training.

`OutputNetwork` — Network returned when training ends
`"auto"` (default) | `"best-training-loss"` | `"best-validation-loss"` | `"last-iteration"`

Network returned when training ends, specified as `"auto"`, `"best-training-loss"`, `"best-validation-loss"`, or `"last-iteration"`.

- `"auto"` — Returns `"best-validation-loss"` when you specify the `ValidationData` property. Otherwise, returns `"best-training-loss"`.
- `"best-training-loss"` — Returns the network at the iteration corresponding to the best training loss.
- `"best-validation-loss"` — Returns the network at the iteration corresponding to the best validation loss. To use this option, you must specify the `ValidationData` property.
- `"last-iteration"` — Returns the network corresponding to the last training iteration.

`SolverName` — Name of solver to use for training
`"adam"` (default) | `"sgdm"`

Name of the solver to use for training, specified as `"adam"` or `"sgdm"`.

`GradientDecayFactor` — Exponential decay rate for gradient moving average in the `adam` solver
`0.5` (default) | scalar in range `[0, 1)`

Exponential decay rate for the gradient moving average in the `adam` solver, specified as a scalar in the range `[0, 1)`.

The `GradientDecayFactor` corresponds to β_1, as defined by Kingma and Bar [1].

`SquareGradientDecayFactor` — Exponential decay rate for squared gradient moving average in `adam` solver
`0.999` (default) | scalar in the range `[0, 1)`

Exponential decay rate for the squared gradient moving average in the `adam` solver, specified by a scalar in the range `[0, 1)`.

The `GradientDecayFactor` corresponds to β_1, as defined by Kingma and Bar [1].

`Momentum` — Contribution of gradient step from previous iteration to current iteration of training
`0.5` (default) | scalar in range `[0, 1]`

Contribution of the gradient step from the previous iteration to the current iteration of training, specified as a scalar in the range `[0, 1]`. This argument applies only when using the `sgdm` solver.

`Shuffle` — Control shuffling of training data
`"once"` (default) | `"never"`

Control shuffling of training data, specified as `"once"` or `"never"`.

Examples

Specify Options For OCR Training

Create a directory to save the trained OCR model.

```
outputDir = "OCRModel";
if ~exist(outputDir, "dir")
    mkdir(outputDir);
end
```

Create a directory to save checkpoints.

```
checkpointsDir = "Checkpoints";
if ~exist(checkpointsDir, "dir")
    mkdir(checkpointsDir);
end
```

Create a set of options for training an OCR model.

- Set the gradient decay factor for ADAM optimization to 0.9.
- Use an initial learning rate of 20e-4.
- Set the maximum number of epochs for training to 15.
- Set the verbose frequency to 100 iterations.
- Specify the output directory.
- Specify the checkpoint path to enable saving checkpoints.

```
ocrOptions = ocrTrainingOptions(GradientDecayFactor=0.9,...
    InitialLearnRate=20e-4,...
    MaxEpochs=15,...
    VerboseFrequency=100,...
    OutputLocation=outputDir,...
    CheckpointPath=checkpointsDir)
```

```
ocrOptions =
  ocrTrainingOptions with properties:

               OutputLocation: "OCRModel"
                    MaxEpochs: 15
             InitialLearnRate: 0.0020
                      Verbose: 1
             VerboseFrequency: 100
               CheckpointPath: "Checkpoints"
          CheckpointFrequency: 1
      CheckpointFrequencyUnit: "epoch"
               ValidationData: []
          ValidationFrequency: 50
           ValidationPatience: Inf
                OutputNetwork: "auto"
                   SolverName: "adam"
          GradientDecayFactor: 0.9000
    SquareGradientDecayFactor: 0.9990
                     Momentum: 0.5000
                      Shuffle: "once"
```

```
CharacterSetSource: "auto"
```

Version History

Introduced in R2023a

ocrMetrics

Store OCR quality metrics

Description

The `ocrMetrics` object stores optical character recognition (OCR) quality metrics, consisting of the character and word error rates, for a set of images. The `evaluateOCR` function returns the `ocrMetrics` object.

Creation

Create an OCR quality metrics object by using the `evaluateOCR` function.

Properties

`DataSetMetrics` — Data set metrics
table

Data set metrics, specified as a table with one row. The table contains OCR metrics aggregated over the data set. The table contains one column for each metric specified by the `Metrics` name-value that correspond to the metrics of the `evaluateOCR` function.

`ImageMetrics` — OCR metrics
table with *N* rows

OCR metrics, specified as a table with *N* rows, where *N* is the number of images in the data set. The table contains one column for each metric specified by the `Metrics` name-value of the `evaluateOCR` function. Each image metric returns a vector with one element for each image in the data set. The order of the rows matches the order of the images in the data set.

Examples

Evaluate Accuracy of OCR Model

This example shows how to evaluate the accuracy of an OCR model that can recognize seven-segment numerals on a dataset. The evaluation dataset contain images of energy meter displays that have seven-segment numerals in them.

Download and extract dataset.

```
datasetURL = "https://ssd.mathworks.com/supportfiles/vision/data/7SegmentImages.zip";
datasetZip = "7SegmentImages.zip";
if ~exist(datasetZip,"file")
    disp("Downloading evaluation dataset (" + datasetZip + " - 96 MB) ...");
    websave(datasetZip,datasetURL);
end
```

```
datasetFiles = unzip(datasetZip);
```

Load the evaluation ground truth.

```
ld = load("7SegmentGtruth.mat");
gTruth = ld.gTruth;
```

Create datastores that contain images, bounding boxes and text labels from the `groundTruth` object using the `ocrTrainingData` function with the label and attribute names used during labeling.

```
labelName = "Text";
attributeName = "Digits";
[imds,boxds,txtds] = ocrTrainingData(gTruth,labelName,attributeName);
```

Combine the datastores.

```
cds = combine(imds,boxds,txtds);
```

Run OCR on the evaluation dataset.

```
results = ocr(cds, Model="seven-segment");
```

Evaluate the OCR results against the ground truth.

```
metrics = evaluateOCR(results,cds);
```

```
Evaluating ocr results
----------------------
* Selected metrics: character error rate, word error rate.
* Processed 119 images.
* Finalizing... Done.
* Data set metrics:

    CharacterErrorRate    WordErrorRate
    __________________    _____________

         0.082195             0.19958
```

Display accuracy of the OCR model.

```
modelAccuracy = 100*(1-metrics.DataSetMetrics.CharacterErrorRate);
disp("Accuracy of the OCR model= " + modelAccuracy + "%")
```

```
Accuracy of the OCR model= 91.7805%
```

Algorithms

- Error rates are a percentage of characters (words) in the input `groundTruthTxt` that have been incorrectly predicted in `resultTxt`.
- To compute the number of incorrect predictions to use in the error rate calculation, the function uses the Levenshtein distance, which is defined as the minimum number of edits (such as insertions, deletions, or substitutions) required to change one word (or sentence) into another one.

  Error rate = $(S + D + I)/N$ where,

- S — Number of substitutions
- D — Number of deletions
- I — Number of insertions
- N — Maximum number of characters (words) between `groundTruthTxt` or `resultTxt`

pcviewer

Visualize and inspect large 3-D point cloud

Description

Use the `pcviewer` object to view and inspect large 3-D point clouds. You can interact with the point cloud, and set camera and viewer properties. Point cloud interactions include navigating through the point cloud, modifying the size of points or enlarging their display, and selecting viewing planes. Camera and viewer properties enable you to select between first-person and orbital camera navigation, select a perspective or orthographic camera projection, and set camera location properties.

Creation

Syntax

```
viewer = pcviewer(ptCloud)
viewer = pcviewer(filename)
viewer = pcviewer( ___ ,color)
viewer = pcviewer( ___ ,Name=Value)
```

Description

`viewer = pcviewer(ptCloud)` creates a point cloud viewer that visualizes points stored in the object specified by `ptCloud`. You can access and modify point cloud viewer properties using the returned `pcviewer` object viewer.

`viewer = pcviewer(filename)` visualizes points stored in the file specified by `filename`. `filename` must be a PLY, PCD, LAS, or LAZ file type. LAS/LAZ files support requires the Lidar Toolbox™.

`viewer = pcviewer( ___ ,color)` specifies the colors with which to visualize the points of the point cloud, in addition to any combination of input arguments from previous syntaxes.

`viewer = pcviewer( ___ ,Name=Value)` specifies options using one or more name-value arguments. For example, `VerticalAxis="XUp"` sets the *x*-axis as the vertical axis in the viewer, with up as positive.

Input Arguments

`ptCloud` — Point cloud
`pointCloud` object

Point cloud, specified as a `pointCloud` object. The viewer uses the `Location` property of the input point cloud object to render the position of the points. By default, the viewer sets the colors of the points from the `Color` property of the input `pointCloud` object or by applying a colormap based on the *z*-values from the `Location` property of the object.

`filename` — Filename

string scalar | character vector

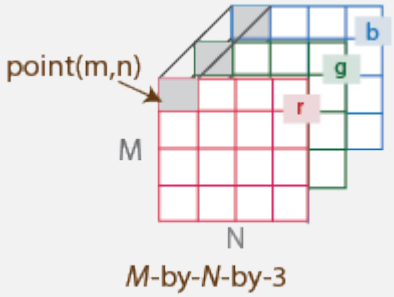
Filename, specified as a string scalar or a character vector. The file must be provided as a PLY, PCD, LAS, or LAZ file type. formatted file.

LAS/LAZ files support requires the Lidar Toolbox. LAZ files returned by the `lasFileWriter` object, which facilitates writing point cloud data to LAS/LAZ formats, are optimized for display. The viewer is also optimized for LAZ files stored in the Cloud Optimized Point Cloud (COPC) format. For more details, see the COPC website.

`color` — Color for points in point cloud

RGB triplet | short color name | long color name | *M*-by-3 matrix | *M*-by-*N*-by-3 array | string array | cell array of character vectors

Color for points in the point cloud, specified as an RGB triplet, an *M*-by-3 matrix, or an *M*-by-*N*-by-3 array for an organized point cloud, a short color name, a long color name, array of color names, or a cell array of color names. The `color` input sets the `Color` property. For details on color values, see Color Values on page 2-290 table.



- If the data type of the point cloud `Location` property is `single` or `double`, each `color` RGB value must be in the range [0, 1].
- If the data type of the point cloud `Location` property is `uint8`, each `color` RGB value must be in the range [0, 255].
- The `Color` property of the `pcviewer` object stores the `color` value as an RGB triplet, an *M*-by-3 matrix, or an *M*-by-*N*-by-3 array. If you specify the color one or more color names, the function converts them to their corresponding RGB triplets.

Color	Format	Example

Specify one color for all points	Short or long color name.	`"r"`
		
		`"red"`

	1-by-3 vector (RGB triplet).	 `[255 0 0]`
Specify a color for each point	String array, or cell array of character vectors.	`["red","yellow","blue"]`

	M-by-3 matrix for an unorganized point cloud, in which each row is an RGB triplet. *M* is the number of rows in the unorganized point cloud.	`255 0 0`
		`255 0 0`
		`0 255 255`
		

Color	Format	Example
	M-by-*N*-by-3 array for an organized point cloud, in which each page specifies the red, green, or blue value for the corresponding point in the point cloud. *M*-by-*N* is the size of the organized point cloud.	

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `viewer = pcviewer(ptCloud,ViewPlane="XY")` visualizes the point cloud from the *xy*-plane.

`CameraProjection` — Camera projection for 3-D views

`"perspective"` (default) | `"orthographic"`

Camera projection for 3-D views, specified as one of these values:

- `"perspective"` — Projects the viewing volume as the frustum of a pyramid (a pyramid whose apex has been cut off parallel to the base). Objects further from the camera appear smaller. Distance causes foreshortening, which enables you to perceive the depth of 3-D objects. This projection type is useful when you want to display realistic views of real objects. Perspective projection does not preserve the relative dimensions of objects. Instead, it displays a distant line segment smaller than a nearer line segment of the same length. Lines that are parallel in the data might not appear parallel in the scene.
- `"orthographic"` — This projection type maintains the correct relative dimensions of graphics objects regarding the distance of a given point from the viewer. Relative distance from the camera does not affect the size of objects. Lines that are parallel in the data parallel appear parallel on the screen. This projection type is useful when it is important to maintain the actual size of objects and the angles between objects.

`ViewPlane` — Axes plane to display of point cloud

`"auto"` (default) | `"XY"` | `"YX"` | `"XZ"` | `"ZX"` | `"YZ"` | `"ZY"`

Axes plane to display of point cloud, specified as `"auto"`, `"XY"`, `"YX"`, `"XZ"`, `"ZX"`, `"YZ"`, or `"ZY"`.

`VerticalAxis` — Vertical axis and direction

`"ZUp"` (default) | `"ZDown"` | `"XUp"` | `"XDown"` | `"YUp"` | `"YDown"`

Vertical axis and direction, specified as `"ZUp"`, `"ZDown"`, `"XUp"`, `"XDown"`, `"YUp"`, or `"YDown"`. This argument sets the selected axis of the point cloud as the vertical axis, positive in the specified direction..

`ColorSource` — Source of colormap data to use for the viewer

`"auto"` (default) | `"X"` | `"Y"` | `"Z"` | `"Intensity"` | `"Color"` | `"Row"` | `"Column"`

Source of colormap data to use for the viewer, specified as one of:

- `"X"` — Viewer maps the *x*-coordinates in the `Location` property of the input point cloud.
- `"Y"` — Viewer maps the *y*-coordinates in the `Location` property of the input point cloud.
- `"Z"` — Viewer maps the *z*-coordinates in the `Location` property of the input point cloud.
- `"Intensity"` — Viewer maps the `Intensity` property of the input point cloud.
- `"Color"` — Viewer maps the `Color` property of the input point cloud.
- `"Row"` — Viewer maps the row values of an organized point cloud.
- `"Column"` — Viewer maps the column values of an organized point cloud.
- `"auto""`— If the `Color` property of the input point cloud is available, the object uses those color values. Otherwise, the object assigns the colormap based on the *z*-coordinates in the `Location` property of the input point cloud.

If you provided the `color` input, the `ColorSource` name-value argument is not used.

`BackgroundColor` — Viewer background color
`[0 0 0]` (default) | RGB triplet | hexadecimal color code | short color name | long color name

Viewer background color, specified as an RGB triplet, hexadecimal color code, or a character vector for a short or long color name. For details on color values, see the Color Value on page 2-290 table.

`PointSize` — Size of point cloud points
2 (default) | positive scalar

Size of point cloud points, specified as a positive scalar, in pixels.

`AxesVisibility` — State of axes visibility
`"off"` (default) | `"on"` | `0` or `false` | `1` or `true`

State of axes visibility, specified as `"on"` or `"off"`, or as a numeric or logical `0` (`false`) or `1` (`true`). A value of `"on"` is equivalent to `true`, and `"off"` is equivalent to `false`. Thus, you can use the value of this property as a logical value. The value is stored as an on/off logical value of type `matlab.lang.OnOffSwitchState`.

- `"on"` — Display the axes and its children.
- `"off"` — Hide the axes without deleting it. You still can access the properties of an invisible axes object. (Child objects such as lines remain visible.)

`OptimizeForDisplay` — Logical to enable point cloud optimization for display performance
`1` (`true`) (default) | `0` (`false`)

Logical to enable point cloud optimization for display performance, specified as `1` (`true`) or `0` (`false`). When you set this argument to `true`, point clouds with more than 10 million points are converted into an octree structure. This structure renders a subset of points visible from the current viewpoint and adapts as the viewpoint changes. Enabling this optimization enhances interaction performance.

When you set this argument to `false`, all points are displayed. Displaying all points can decrease interaction performance, depending on your graphics hardware. For more details about graphics rendering in MATLAB, see “System Requirements for Graphics”

Creating an octree structure requires the Lidar Toolbox. If the Lidar Toolbox is not available, all points will be displayed, which can decrease interaction performance.

Properties

`PointSize` — Size of points
2 (default) | positive scalar

Sizes of points, specified as a positive scalar, in pixels.

`MagnifyPointDisplay` — Point display magnification
`"off"` (default) | `"on"` | `0` or `false` | `1` or `true`

Point display magnification, specified as `"on"` or `"off"`, or as a numeric or logical `0` (`false`) or `1` (`true`). A value of `"on"` is equivalent to `true` and shows the points magnified. A value of `"off"` is equivalent to `false` and shows points unmagnified, as they would appear from the position of the camera.

`CameraPosition` — Camera position viewpoint
`[1 1 1]` (default) | three-element vector

Camera position viewpoint, specified as a three-element vector of the form [*x y z*]. The camera is oriented along the view axis, which is a straight line that connects the camera position and the camera target. Changing the `CameraPosition` property changes the point from which you view the volume. For an illustration, see “Camera Graphics Terminology”.

`CameraTarget` — Camera target
`[0 0 0]` (default) | three-element vector

Camera target, specified as a three-element vector of the form [*x y z*]. The camera is oriented along the view axis, which is a straight line that connects the camera position and the camera target. For an illustration, see “Camera Graphics Terminology”.

`CameraUpVector` — Upwards direction
`[0 0 1]` (default) | three-element vector

Upwards direction for the camera, specified as a three-element vector of the form [*x y z*]. For example, the default orientation of the *z*-axis is the up direction (`[0 0 1]`). For an illustration, see “Camera Graphics Terminology”.

`CameraZoom` — Camera zoom level
`1` (default) | positive number

Camera zoom level, specified as a positive number.

`CameraProjection` — Type of camera view projection
`"projection"` | `"orthographic"`

Type of camera view projection, specified as a `"projection"` or `"orthographic"`.

`CameraViewAngle` — Vertical field of view
`60` (default) | positive scalar

Vertical field of view (FOV) for the perspective camera, specified as a positive scalar, in degrees. This property applies only when you set the `CameraProjection` property to `"perspective"`.

`BackgroundColor` — Viewer background color
`[0 0 0]` (default) | RGB triplet | hexadecimal color code | short color name | long color name

Viewer background color, specified as an RGB triplet, hexadecimal color code, or a short or long color name. For details on color values, see the Color Value on page 2-290 table.

`ShowOrientationAxes` — Orientation axes visibility
`"off"` (default) | `"on"` | `0` or `false` | `1` or `true`

Orientation axes visibility, specified as `"on"` or `"off"`, or as a numeric or logical `0` (`false`) or `1` (`true`). A value of `"on"` is equivalent to `true`, and `"off"` is equivalent to `false`. Thus, you can use the value of this property as a logical value.

`ShowPointCloudAxes` — Gridded axes visibility
`"off"` or `0` (`false`) (default) | `"on"` or `1` (`true`)

Gridded axes visibility, specified as `"on"` or `"off"`, or as a numeric or logical `0` (`false`) or `1` (`true`). A value of `"on"` is equivalent to `true`, and `"off"` is equivalent to `false`. Thus, you can use the value of this property as a logical value.

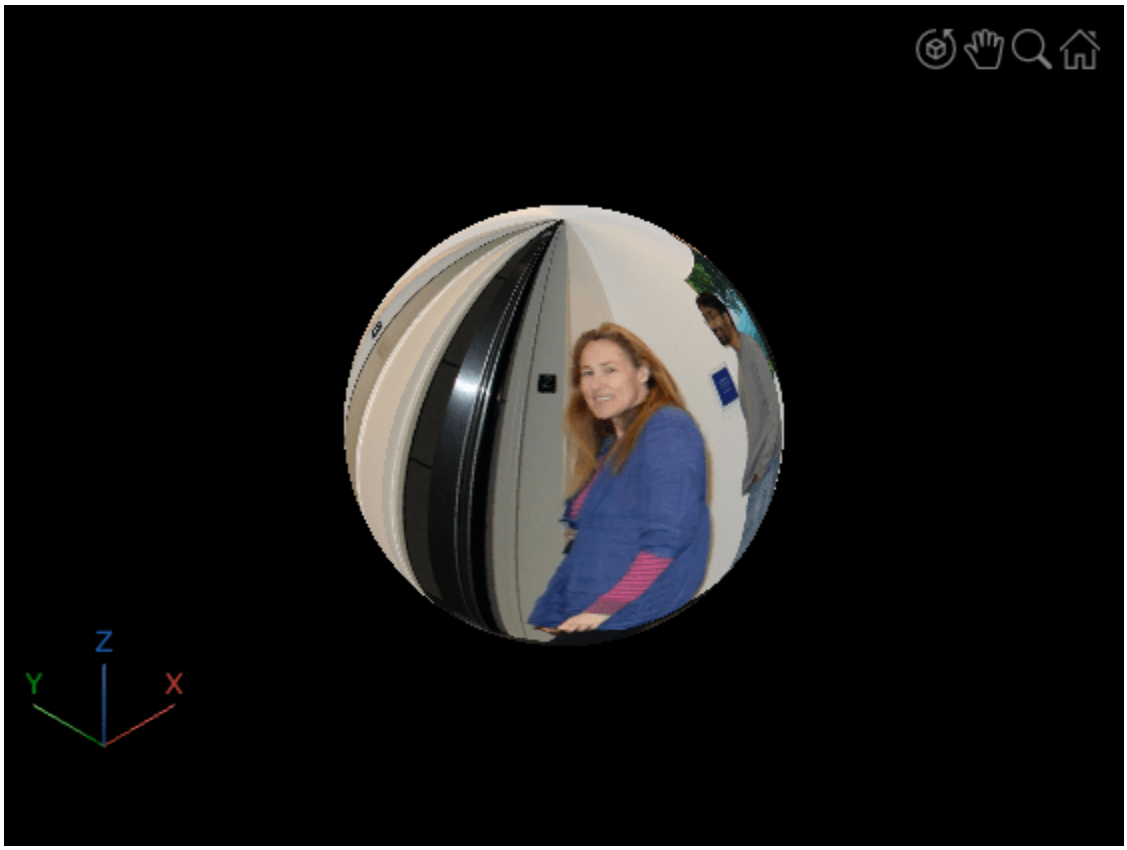
Examples

Plot Spherical Point Cloud with Texture Mapping

Create a sphere with 2500 faces. This generates a point cloud with approximately 6.25 million points.

```
numFaces = 2500;
[x,y,z] = sphere(numFaces);
```

Load an image into the workspace, then map it to the coordinates of the point cloud points.



```
I = imresize(imread("visionteam1.jpg"),size(x));
color = flipud(im2double(I));
color = reshape(color,[],3);
```

Create a point cloud object with the location of the sphere and the color from the image.

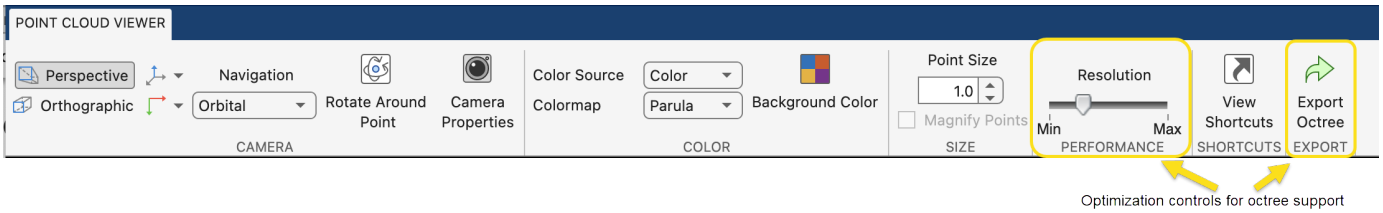
```
ptCloud = pointCloud([x(:) y(:) z(:)], Color=color);
```

Visualize the point cloud, and optionally interact with it using the viewer controls.

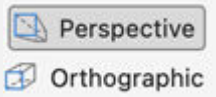
```
pcviewer(ptCloud);
```

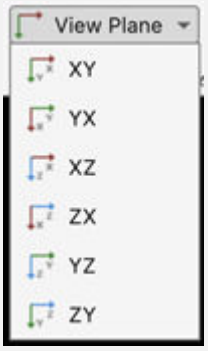
More About

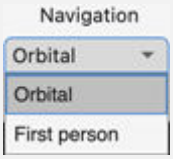
Color Values



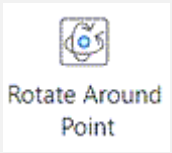
This table shows the valid long color names, their short name and RGB triplet equivalents, and how they appear in MATLAB.

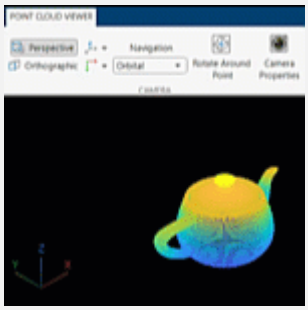


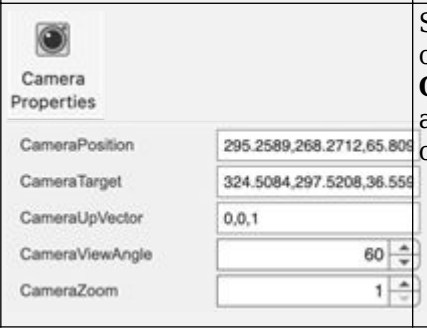




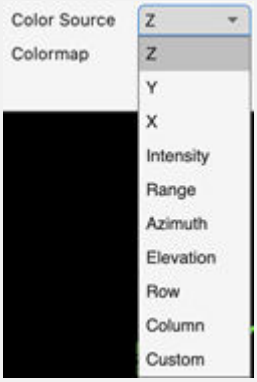
Color Name	Short Name	RGB Triplet	Appearance
"red"	"r"	[1 0 0]	
"green"	"g"	[0 1 0]	
"blue"	"b"	[0 0 1]	
"cyan"	"c"	[0 1 1]	
"magenta"	"m"	[1 0 1]	
"yellow"	"y"	[1 1 0]	
"black"	"k"	[0 0 0]	

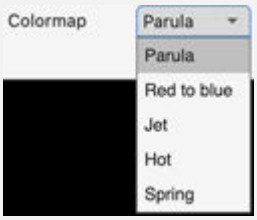




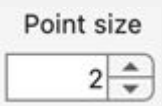


Color Name	Short Name	RGB Triplet	Appearance
"white"	"w"	[1 1 1]	





Point Cloud Viewer Toolstrip and Interactions



You can expand the viewer toolstrip by clicking the **Point Cloud Viewer** tab. By default, the toolstrip is collapsed.

Feature	Viewer Interaction	Description
Camera Projection		Projection style of the camera.
Vertical Axis		Vertical axis and direction, specified by `ZUp`, `ZDown`, `XUp`, `XDown`, `YUp`, or `YDown`. This value sets the selected axis of the point cloud as the vertical axis, positive in the direction specified.
View Plane		Axes plane to display point cloud, specified as `XY`, `YX`, `XZ`, `ZX`, `YZ`, or `ZY`.
Navigation		View projection used to display the 3-D point cloud, specified as `Orbital` or `First person`. For more details, see “Camera Navigation Controls” on page 2-295

Feature	Viewer Interaction	Description
Rotate Around Point		Select any point as the center of rotation. When the **Rotate Around Point** is disabled, the center of rotation is the axes center. The **Rotate Around Point** mode can only be used with the `Orbital` Navigation mode.
Camera Properties		Set camera location and orientation. The **CameraViewAngle** value applies only for the **Perspective** camera projection.

Feature	Viewer Interaction	Description
Color Source		Color source from which to render color values for the points. The available options depend on the data in the input point cloud. • `X`, `Y`, `Z` — Available for all point clouds • `Color` — Point cloud must have a non-empty color property. • `Intensity` — Point cloud must have non- empty `Intensity` property. • `Range`, `Azimuth`, and `Elevation` — Point cloud must come from a `velodyneFileReader` or a Pandar file reader. • `Row`, `Column` — Organized point clouds. • `Custom` — Color set when launching the `pcviewer` with the `color` argument, or by setting the `Color` property of the `pcviewer` object.
Colormap		Colormap used to render color.
Background Color		Viewer background color.

Feature	Viewer Interaction	Description
Point Size		Size of points, in pixels.
Magnify Points		Magnify the display of points. Enabling this option attenuates the size of the points based on the camera position. If the camera is positioned closer to the points, the points appear bigger than when the camera is far away. Magnify Points applies only for the perspective camera projection and the first person controls.
Resolution		Controls the number of points rendered in the viewer. This control is only visible if the point cloud data was optimized using an octree conversion. Increasing the resolution provides greater detail but can decrease interaction performance.
View Shortcuts		View the point cloud viewer keyboard shortcuts.
Export Octree		Export optimized point cloud. This file can be reused to visualize the point cloud without needing to regenerate the octree conversion.

Mouse interactions:

Behavior	Mouse Interaction
Rotate	Left-click and drag
Pan	Hold **Ctrl**, then left-click and drag
Zoom	Scroll the wheel

Axes toolbar:

Behavior	Mouse Interaction or Interaction after Selection
Rotate	Left-click and drag
Pan	Left-click and drag
Zoom buttons	Scroll wheel
Default	Return to view from launch of viewer instance

Camera Navigation Controls

The point cloud viewer provides orbital and first-person navigation controls. These controls describe the behavior of the observer or first person, represented as the camera, with respect to the object to visualize or orbital, represented as the target.

- `Orbital` — Camera target is fixed. Only the camera position can change.
- `First person` — Both the camera position and the target position can change. Enables first-person navigation for the perspective camera projection.

This table lists the mouse interactions for the `Orbital` and `First person` camera controls:

Interaction	Orbital	First person
Rotate	Rotate the object around the observer	Observer rotates. (Looks around the scene.)
Pan	Pan the object with respect to the observer	Observer moves or "walks" through the scene in the left, right, up, or down directions.
Zoom	Zoom object toward or away from observer. (Make the object appear larger or smaller).	Observer moves or "walks" in the forward or backward directions.

This table shows the orbital keyboard shortcuts:

Behavior	Keyboard shortcut
Rotate by *Z*-axis	Left and right arrows
Rotate by *X*-axis	Up and down arrows
Rotate by *Y*-axis	**Q** and **E**

This table shows the first-person keyboard shortcuts:

Behavior	Keyboard Shortcut
Move forward	**W** — Forward **S** — Backward
Move left or right	**A** — Left **D** — Right

Behavior	Keyboard Shortcut
Move up or down	**R** — Up **F** — Down
Look around the scene (Pitch/Yaw rotation of camera)	Up arrow — Pitch up Down arrow — Pitch down Left arrow — Yaw left Right arrow — Yaw right
Roll the scene (Roll rotation of camera)	**Q** — Clockwise roll **E** — Counter-clockwise roll

Version History

R2025a: Support for LAZ files

LAZ files can now store point clouds in an octree structure optimized for visualization. To enable this optimization, set the `LazVersion` name-value argument to `"1.4"` of the `lasFileWriter` object. This optimized storage format for LAZ files is based on the Cloud Optimized Point Cloud (COPC) format. For details, see the COPC website.

inflated3dVideoClassifier

Inflated-3D (I3D) video classifier. Requires Computer Vision Toolbox Model for Inflated-3D Video Classification

Description

Add-On Required: This feature requires the Computer Vision Toolbox Model for Inflated-3D Video Classification add-on.

The `inflated3dVideoClassifier` object is an Inflated-3D (I3D) video classifier pretrained on the Kinetics-400 data set. You can use the pretrained video classifier to classify 400 human actions, such as running, walking, and shaking hands. The I3D classifier model contains two subnetworks: the video network and the optical flow network. Both of these networks are trained on Kinetics-400 with RGB data and optical flow data respectively.

Creation

Syntax

```
i3d = inflated3dVideoClassifier
i3d = inflated3dVideoClassifier(classifierName,classes)
i3d = inflated3dVideoClassifier( ___ ,Name=Value)
```

Description

`i3d = inflated3dVideoClassifier` returns the I3D video classifier pretrained on the Kinetics-400 dataset.

`i3d = inflated3dVideoClassifier(classifierName,classes)` configures the pretrained Inflated 3D (I3D) video classifier for transfer learning on a new set of classes, `classes`, using one of two pretrained classifiers, specified by `classifierName`.

`i3d = inflated3dVideoClassifier( ___ ,Name=Value)` sets properties using name-value arguments in addition to the input arguments from the previous syntax. For example, `i3d = inflated3dVideoClassifier("googlenet-video","wavingHello","clapping",InputSize=[224,224,3,64])` sets the input size of the network to 64 frames of 224-by-224 pixels with 3 channels. You can specify multiple name-value arguments.

Note This object requires the Computer Vision Toolbox Model for Inflated-3D Video Classification. You can install the Computer Vision Toolbox Model for Inflated-3D Video Classification from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons. To use this object, you must have a license for the Deep Learning Toolbox.

Input Arguments

`classifierName` — Classifier name

`"googlenet-video"` | `"googlenet-video-flow"`

Classifier name, specified as `"googlenet-video"` or `"googlenet-video-flow"`.

Classifier	Description
`"googlenet-video"`	GoogLeNet-based I3D model pretrained on the Kinetics-400 video data for transfer learning.
`"googlenet-video-flow"`	GoogLeNet-based I3D model pretrained on the Kinetics-400 video and optical flow data for transfer learning. During training and inference, both video and optical flow data are used for classification.

Properties

Configure Classifier Properties

`InputSize` — Size of network

`[224,224,3,64]` (default) | four-element row vector

This property is read-only.

Size of the video classifier network, specified as a four-element row vector in the form [*H*,*W*,*C*,*T*], where *H* and *W* represent the height and width respectively, *C* represents the number of channels, and *T* represents the number of frames for the video subnetwork.

The input size of the flow subnetwork is equal in height, width, and number of frames, but the number of channels is fixed to 2.

Typical values for the number of frames are 8, 16, 32, or 64. Increase the number of frames to capture the temporal nature of activities when training the classifier. When you are using optical flow data, the number of channels must equal 2, which correspond to the *x*- and *y*-components of velocity.

`InputNormalizationStatistics` — Normalization statistics for the video and optical flow data

structure

This property is read-only.

Normalization statistics for the video and optical flow data, specified as a structure with field names `Video` and `OpticalFlow`, which are also structures with field names, `Min`, `Max`, `Mean`, and `StandardDeviation`. The `Min` and `Max` field values define the minimum and maximum values for rescaling the video and optical flow data. The `Mean`, and `StandardDeviation` values define the mean and standard deviation for input normalization. All field values must be specified as a row vector of size equal to the number of channels for the video input data. When you are using optical flow data, the number of channels must equal 2, which correspond to the *x*- and *y* components of velocity.

The default structure contains:

- A `Video` field, which contains the field `Min` set to `[0,0,0]`, and the field `Max` set to `[255,255,255]`.
- Empty `OpticalFlow`, `Mean`, and `StandardDeviation` field values.

For a video input, the data is rescaled between `-1` and `1` using the `Min` and `Max` field values. For an optical flow input, the data is rescaled between `-1` and `1` using computed minimum and maximum values from the input data.

Note When the `Min` and `Max` field values are not empty, the object first rescales the input data between `-1` and `1`. Then, if the `Mean`, and `StandardDeviation` field values are not empty, the object normalizes the rescaled values by subtracting the mean and dividing by the standard deviation.

An example using this property:

```
stats.Video = struct(Min=[0,0,0],Max=[255,255,255], ...
Mean=[],StandardDeviation=[]);
stats.OpticalFlow = struct(Min=[-20,-20],Max=[20,20] ,...
Mean=[],StandardDeviation=[]);
i3d = inflated3dVideoClassifier('googlenet-video-flow',["waving","clapping"],InputNormalizationS
```

`ModelName` — Name of trained video classifier

string scalar

Name of the trained video classifier, specified as a string scalar.

`Classes` — Classes that the video classifier is configured to train or classify

vector of strings | cell array of character vectors

This property is read-only.

Classes that the video classifier is configured to train or classify, specified as a vector of strings or a cell array of character vectors. For example:

```
classes = ['kiss','laugh','pick','pour','pushup'];
```

Training Properties

`VideoLearnables` — Learnable parameters for video subnetwork of I3D video classifier

table with three columns

Learnable parameters for the video subnetwork of the I3D video classifier, specified as a table with three columns.

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Parameter value, specified as a `dlarray` object.

The network learnable parameters contain the features learned by the network. For example, the weights of convolution and fully connected layers.

`VideoState` — State of the nonlearnable parameters for the video subnetwork of the I3D video classifier

table with three columns

State of the nonlearnable parameters for the video subnetwork of the I3D video classifier, specified as a table with three columns.

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Parameter value, specified as a `dlarray` object.

The network state contains information remembered by the network between iterations. For example, the state of LSTM and batch normalization layers. During training or inference, you can update the network state using the output of the forward and predict functions.

`OpticalLearnables` — Learnable parameters for the optical flow subnetwork of the I3D video classifier

table with three columns

Learnable parameters for the optical flow subnetwork of the I3D video classifier, specified as a table with three columns. Network learnable parameters, specified as a table with three columns:

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Parameter value, specified as a `dlarray` object.

The network learnable parameters contain the features learned by the network. For example, the weights of convolution and fully connected layers.

`OpticalFlowState` — State of the nonlearnable parameters for the optical flow subnetwork of the I3D video classifier

table with three columns

State of the nonlearnable parameters for the video subnetwork of the I3D video classifier, specified as a table with three columns. Network learnable parameters, specified as a table with three columns:

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Parameter value, specified as a `dlarray` object.

The network learnable parameters contain the features learned by the network. For example, the weights of convolution and fully connected layers.

Streaming Video Classification Properties

`VideoSequence` — Video sequence used for streaming classification

4-D numeric array

This property is read-only.

Video sequence used to update and classify sequences for streaming classification, specified as a 4-D numeric array. Each vector in the array is of the form [H,W,C,T], where H and W represent the height and width respectively, C represents the number of channels, and T represents the number of frames, for the video subnetwork. The `updateSequence` and `classifySequence` object functions use the video sequence specified by the `VideoSequence` property.

`OpticalFLowSequence` — Optical flow sequence used for streaming classification

4-D numeric array

This property is read-only.

Optical flow sequence used to update and classify sequences for streaming classification, specified as a 4-D numeric array. Each vector in the array is of the form (*H*,*W*,*C*,*T*), where *H* and *W* represent the height and width respectively, *C* represents the number of channels, and *T* represents the number of frames, for the optical flow subnetwork. The `updateSequence` and `classifySequence` object functions use the optical flow sequence specified by the `OpticalFlowSequence`.

Object Functions

Video Classification

classifyVideoFile	Classify a video file
resetSequence	Reset video and optical flow sequence properties for streaming video classification
updateSequence	Update video or optical flow sequence for classification
classifySequence	Classify video and optical flow sequence

Custom Training and Inference

forward	Compute video classifier outputs for training
predict	Compute video classifier predictions

Examples

Classify Video File Using Inflated 3D Video Classifier

This example shows how to use `classifyVideoFile` to classify a video using an Inflated 3D video classifier.

Load a pretrained Inflated-3D video network.

```
i3d = inflated3dVideoClassifier();
```

Specify the video file name to classify.

```
videoFilename = 'visiontraffic.avi';
```

Classify the video using the video classifier.

```
label = classifyVideoFile(i3d, videoFilename);
```

Note that the classifier is not fine-tuned to compute the correct predictions for visiontraffic.avi, therefore, the predicted label will not be correct. You must train the classifier for optimal performance on your video data.

slowFastVideoClassifier

SlowFast video classifier. Requires Computer Vision Toolbox Model for SlowFast Video Classification

Description

Add-On Required: This feature requires the Computer Vision Toolbox Model for SlowFast Video Classification add-on.

The `slowFastVideoClassifier` object is a SlowFast video classifier pretrained on the Kinetics-400 data set with a ResNet-50 3-D convolutional neural network (CNN). You can use the pretrained video classifier to classify 400 human actions such as running, walking, and shaking hands.

Creation

Syntax

```
sf = slowFastVideoClassifier
sf = slowFastVideoClassifier("resnet50-3d",classes)
sf = slowFastVideoClassifier( ___ ,Name=Value)
```

Description

`sf = slowFastVideoClassifier` returns a SlowFast video classifier pretrained on the Kinetics-400 data set.

`sf = slowFastVideoClassifier("resnet50-3d",classes)` configures the pretrained SlowFast video classifier for transfer learning on a new set of classes, `classes`.

`sf = slowFastVideoClassifier( ___ ,Name=Value)` sets properties using name-value arguments in addition to the input arguments from the previous syntax. For example, `sf = slowFastVideoClassifier("resnet50-3d",classes,InputSize=[256,256,3,32])` sets the input size of the network. You can specify multiple name-value arguments.

Note This function requires the Computer Vision Toolbox Model for SlowFast Video Classification. You can install Computer Vision Toolbox Model for SlowFast Video Classification from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons. To use this object, you must have a license for the Deep Learning Toolbox.

Properties

Configure Classifier Properties

`InputSize` — Size of the network
`[256,256,3,32]` (default) | four-element row vector

This property is read-only.

Size of the video classifier network, specified as a four-element row vector in the form [*H*,*W*,*C*,*T*], where *H* and *W* represent the height and width respectively, *C* represents the number of channels, and *T* represents the number of frames for the video subnetwork.

Typical values for the number of frames are 8, 16, 32, or 64. Increase the number of frames to capture the temporal nature of activities when training the classifier.

`InputNormalizationStatistics` — Normalization statistics for the video data
`structure` (default)

This property is read-only.

Normalization statistics for the video data, specified as a structure with field names `Min`, `Max`, `Mean`, and `StandardDeviation`. The `Min` and `Max` field values define the minimum and maximum values for rescaling the video data. The `Mean`, and `StandardDeviation` values define the mean and standard deviation for input normalization. All field values must be specified as a row vector of size equal to the number of channels for the video input data.

The default structure contains the fields, `Min`, `Max`, `Mean` and `StandardDeviation` with values `[0,0,0]`, `[255,255,255]`, `[0.45,0.45,0.45]`, and `[0.225,0.225,0.225]`, respectively. You must calculate the statistics values from the dataset for which you are training the video classifier. To rescale the data using minimum and maximum values precomputed from your dataset, specify both `Min` and `Max`. Otherwise, the minimum and maximum values are calculated from each input sequence when using `updateSequence` or `classifyVideoFile`.

Note The object normalizes the data by rescaling it between `0` and `1`, and then the rescaled data is standardized by subtracting the mean and dividing by the standard deviation. The rescaled data is standardized if the `Mean` and `StandardDeviation` fields are non-empty. The input is automatically normalized when using `updateSequence` or `classifyVideoFile` object functions. The data must be manually normalized when using the `forward` or `predict` object functions.

`ModelName` — Name of trained video classifier
string scalar

Name of the trained video classifier, specified as a string scalar.

`Classes` — Classes that the video classifier is configured to train or classify
vector of strings | cell array of character vectors

This property is read-only.

Classes that the video classifier is configured to train or classify, specified as a vector of strings or a cell array of character vectors. For example:

```
classes = ['kiss','laugh','pick','pour','pushup'];
```

Training Properties

`Learnables` — Learnable parameters for the SlowFast video classifier
table with three columns

Learnable parameters for the SlowFast video classifier, specified as a table with three columns.

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Parameter value, specified as a `dlarray` object.

The network state contains information remembered by the network between iterations. For example, the state of long short term networks (LSTM) and batch normalization layers. During training or inference, you can update the network state using the output of the `forward` and `predict` object functions.

`State` — State of the nonlearnable parameters of the SlowFast video classifier
table with three columns

State of the nonlearnable parameters of the SlowFast video classifier, specified as a table with three columns.

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Parameter value, specified as a `dlarray` object.

The network learnable parameters contain the features learned by the network. For example, the weights of convolution and fully connected layers.

Streaming Video Classification Properties

`VideoSequence` — Video sequence used for streaming classification
4-D numeric array

This property is read-only.

Video sequence used to update and classify sequences for streaming classification, specified as a 4-D numeric array. Each vector in the array is of the form [*H*,*W*,*C*,*T*], where *H* and *W* represent the height and width respectively, *C* represents the number of channels, and *T* represents the number of frames, for the video subnetwork. The `updateSequence` and `classifySequence` object functions use the video sequence specified by the `VideoSequence` property.

Object Functions

Video Classification

classifyVideoFile	Classify a video file
classifySequence	Classify video sequence
resetSequence	Reset video sequence properties for streaming video classification
updateSequence	Update video sequence for classification

Custom Training and Inference

forward	Compute video classifier outputs for training
predict	Compute video classifier predictions

Examples

Classify Video File Using Video Classifier

This example requires the Computer Vision Toolbox™ Model for SlowFast Video Classification. You can install the Computer Vision Toolbox Model for SlowFast Video Classification from Add-On Explorer. For more information about installing add-ons, see “Get and Manage Add-Ons”.

Load a slowfast video classifier pretrained on the Kinetics-400 data set.

```
sf = slowFastVideoClassifier;
```

Specify the file name of the video to classify.

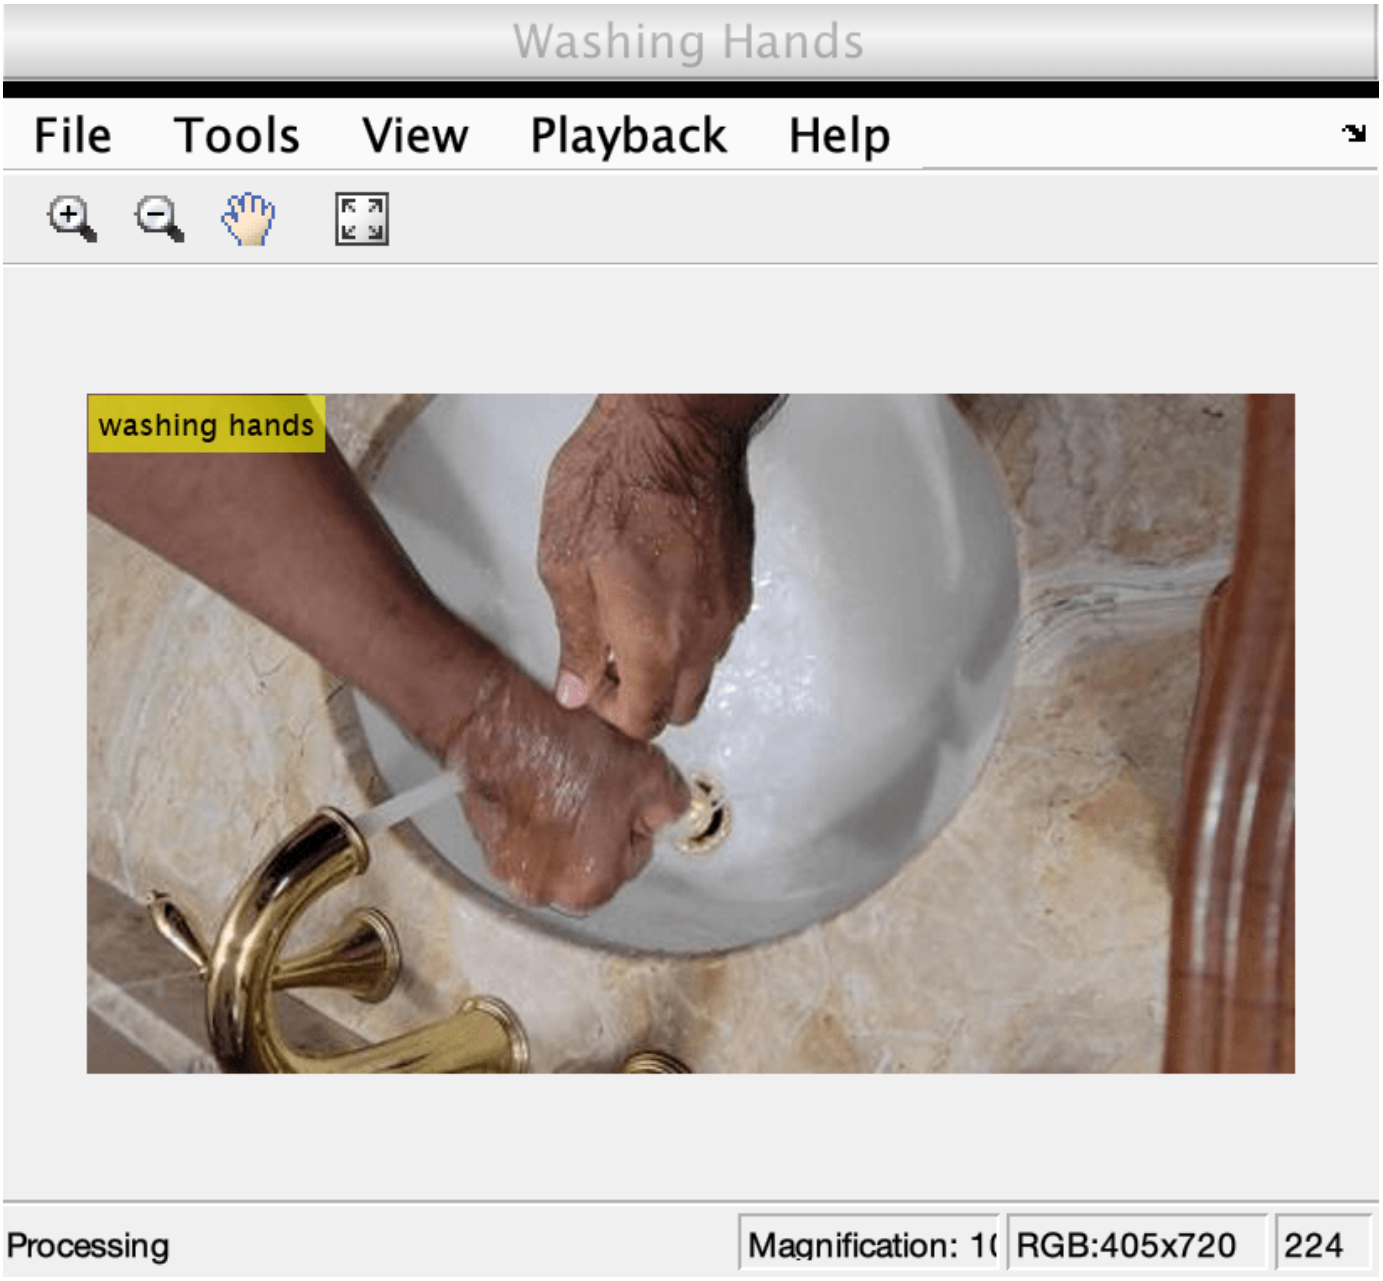
```
videoFilename = "washingHands.avi";
```

For video classification, set the number of randomly selected video sequences to 15.

```
numSequences = 15;
```

Classify the video using the `classifyVideoFile` function.

```
[label,score] = classifyVideoFile(sf,videoFilename,NumSequences=numSequences)
```



```
label = categorical
     washing hands

score = single

0.0034
```

Display the classified label using a `vision.VideoPlayer`.

```
player = vision.VideoPlayer('Name','Washing Hands');
reader = VideoReader(videoFilename);
while hasFrame(reader)
    frame = readFrame(reader);
    % Resize the frame by 1.5 times for display
    frame = imresize(frame,1.5);
    frame = insertText(frame,[2,2], string(label),'FontSize',18);
    step(player,frame);
end
```

r2plus1dVideoClassifier

R(2+1)D video classifier. Requires Computer Vision Toolbox Model for R(2+1)D Video Classification

Description

Add-On Required: This feature requires the Computer Vision Toolbox Model for R(2+1)D Video Classification add-on.

The `r2plus1dVideoClassifier` object returns an R(2+1)D video classifier pretrained on the Kinetics-400 data set. You can use the pretrained video classifier to classify 400 human actions, such as running, walking, and shaking hands.

Creation

Syntax

```
rd = r2plus1dVideoClassifier
rd = r2plus1dVideoClassifier("resnet-3d-18",classes)
rd = r2plus1dVideoClassifier( ___ ,Name=Value)
```

Description

`rd = r2plus1dVideoClassifier` returns a R(2+1)D video classifier pretrained on the Kinetics-400 dataset.

`rd = r2plus1dVideoClassifier("resnet-3d-18",classes)` configures the pretrained R(2+1)D video classifier for transfer learning on a new set of classes, `classes`. The video classifier is pretrained on the Kinetics-400 dataset with a ResNet3D convolutional neural network(CNN) with 18 spatio-temporal layers.

`rd = r2plus1dVideoClassifier( ___ ,Name=Value)` sets properties using name-value arguments in addition to the input arguments from the previous syntax. For example, `rd = r2plus1dVideoClassifier("resnet-3d-18",classes,InputSize=[112,112,3,32])` sets the input size of the network. You can specify multiple name-value arguments.

Note This function requires the Computer Vision Toolbox Model for R(2+1)D Video Classification. You can install the Computer Vision Toolbox Model for R(2+1)D Video Classification from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons. To use this object, you must have a license for the Deep Learning Toolbox.

Properties

Configure Classifier Properties

`InputSize` — Size of the network

`[112,112,3,32]` (default) | four-element row vector

This property is read-only.

Size of the video classifier network, specified as a four-element row vector in the form [*H*,*W*,*C*,*T*], where *H* and *W* represent the height and width respectively, *C* represents the number of channels, and *T* represents the number of frames for the video subnetwork.

Typical values for the number of frames are 8, 16, 32, or 64. Increase the number of frames to capture the temporal nature of activities when training the classifier.

`InputNormalizationStatistics` — Normalization statistics for the video data
`structure` (default)

This property is read-only.

Normalization statistics for the video data, specified as a structure with field names `Min`, `Max`, `Mean`, and `StandardDeviation`. The `Min` and `Max` field values define the minimum and maximum values for rescaling the video data. The `Mean`, and `StandardDeviation` values define the mean and standard deviation for input normalization. All field values must be specified as a row vector of size equal to the number of channels for the video input data.

The default structure contains the fields, `Min`, `Max`, `Mean` and `StandardDeviation` with values `[0,0,0]`, `[255,255,255]`, `[0.45,0.45,0.45]`, and `[0.225,0.225,0.225]`, respectively. You must calculate the statistics values from the dataset for which you are training the video classifier. To rescale the data using minimum and maximum values precomputed from your dataset, specify both `Min` and `Max`. Otherwise, the minimum and maximum values are calculated from each input sequence when using `updateSequence` or `classifyVideoFile`.

Note The object normalizes the data by rescaling it between `0` and `1`, and then the rescaled data is standardized by subtracting the mean and dividing by the standard deviation. The rescaled data is standardized if the `Mean` and `StandardDeviation` fields are non-empty. The input is automatically normalized when using `updateSequence` or `classifyVideoFile` object functions. The data must be manually normalized when using the `forward` or `predict` object functions.

`ModelName` — Name of trained video classifier
string scalar

Name of the trained video classifier, specified as a string scalar.

`Classes` — Classes that the video classifier is configured to train or classify
vector of strings | cell array of character vectors

This property is read-only.

Classes that the video classifier is configured to train or classify, specified as a vector of strings or a cell array of character vectors. For example:

```
classes = ['kiss','laugh','pick','pour','pushup'];
```

Training Properties

`Learnables` — Learnable parameters for the ResNet (2+1)D video classifier
table with three columns

Learnable parameters for the ResNet (2+1)D video classifier, specified as a table with three columns.

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Parameter value, specified as a `dlarray` object.

The network learnable parameters contain the features learned by the network. For example, the weights of convolution and fully connected layers.

`State` — State of the nonlearnable parameters of the R(2+1)D video classifier
table with three columns

State of the nonlearnable parameters for the ResNet (2+1)D video classifier, specified as a table with three columns.

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Parameter value, specified as a `dlarray` object.

The network state contains information remembered by the network between iterations. For example, the state of long short term networks (LSTM) and batch normalization layers. During training or inference, you can update the network state using the output of the `forward` and `predict` object functions.

Streaming Video Classification Properties

`VideoSequence` — Video sequence used for streaming classification
4-D numeric array

This property is read-only.

Video sequence used to update and classify sequences for streaming classification, specified as a 4-D numeric array. Each vector in the array is of the form [*H*,*W*,*C*,*T*], where *H* and *W* represent the height and width respectively, *C* represents the number of channels, and *T* represents the number of frames, for the video subnetwork. The `updateSequence` and `classifySequence` object functions use the video sequence specified by the `VideoSequence` property.

Object Functions

Video Classification

classifyVideoFile	Classify a video file
classifySequence	Classify video sequence
resetSequence	Reset video sequence properties for streaming video classification
updateSequence	Update video sequence for classification

Custom Training and Inference

forward	Compute video classifier outputs for training
predict	Compute video classifier predictions

Examples

Classify Video Stream Using R(2+1)D Video Classifier

This example shows how to classify a video stream using a pretrained R(2+1)D video classifier.

Load a pretrained R(2+1)D video classifier.

```
rd = r2plus1dVideoClassifier();
```

Create a VideoReader to read a video frame by frame.

```
videoFilename = "visiontraffic.avi";
reader = VideoReader(videoFilename);
```

Create a video player to visualize the video data and update the player position to match the size of the video.

```
player = vision.VideoPlayer;
player.Position(:,3:4) = [reader.Width reader.Height];
```

Specify the frequency at which the streaming video frames will be classified as 10. The classifier will be applied to a sequence of video frames every 10 frames to balance runtime performance against classification performance.

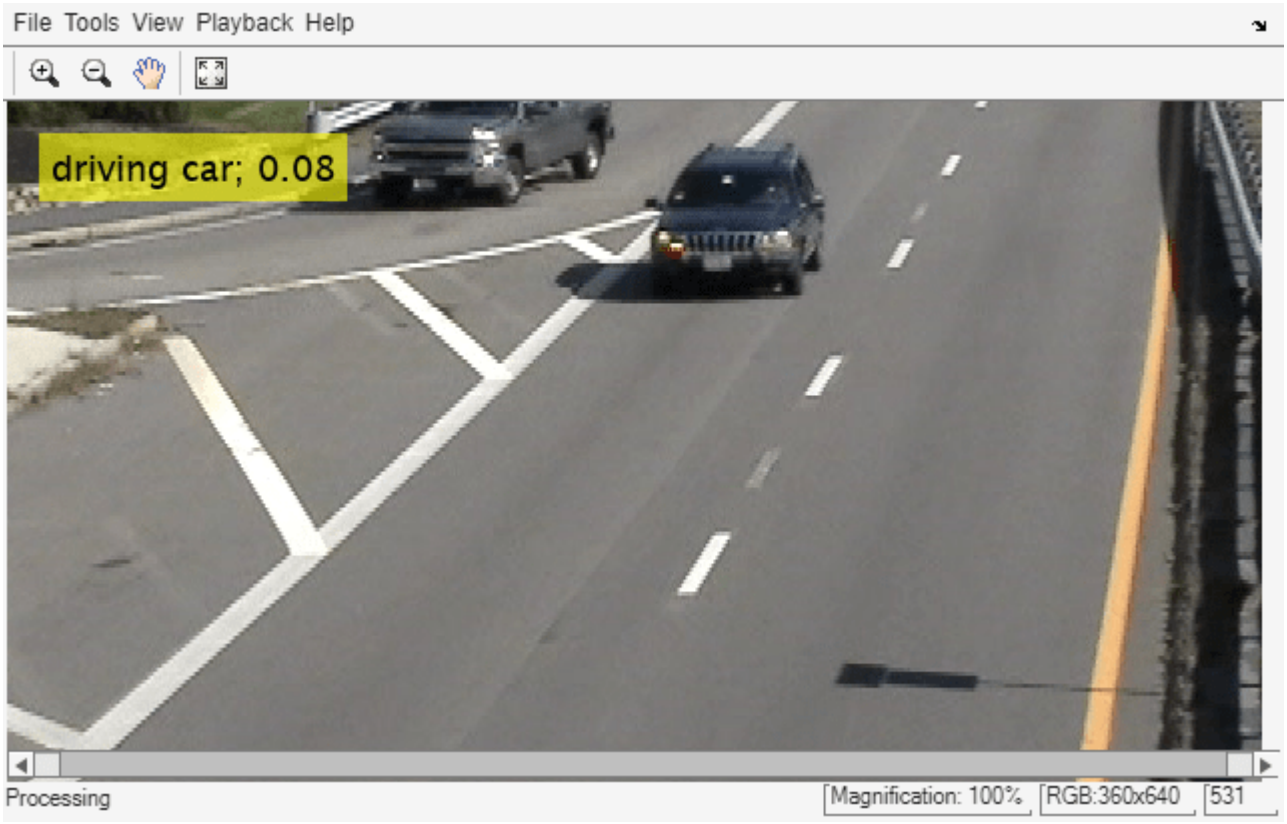
```
classificationFrequency = 10;
```

Specify the sequence length required by the classifier. This is based on the input size of the video classifier. You can begin to classify the sequence only after the sequence length reaches the required length.

```
sequenceLength = rd.InputSize(4);
```

Read through the video frame by frame, update the sequence with each new frame using `updateSequence`, and then classify the collected frames using `classifySequence`.

```
numFrames = 0;
text = "";



while hasFrame(reader)
    frame = readFrame(reader);
    numFrames = numFrames + 1;

    % Update the sequence with the next video frame.
    rd = updateSequence(rd,frame);

    % Classify the sequence based on the classificationFrequency.
    if mod(numFrames, classificationFrequency) == 0 && numFrames >= sequenceLength
        [label,score] = classifySequence(rd);
        text = string(label) + "; " + num2str(score, "%0.2f");
    end

    % Insert the predicted label into the video frame.
    frame = insertText(frame,[30,30],text,'FontSize',18);

    % Display the video and label.
    step(player,frame);
end
```

classifySequence

Classify video sequence

Syntax

```
label = classifySequence(classifier)
[label,score] = classifySequence(classifier)
[___] = classifySequence(classifier,ExecutionEnvironment=env)
```

Description

`label = classifySequence(classifier)` classifies a video sequence using the video classifier `classifier`. The function returns `label`, a scalar categorical that specifies the classification of the video or optical flow sequence. `label` is one of the values of the `Classes` property of the video classifier object.

`[label,score] = classifySequence(classifier)` additionally returns the classification score associated with the label. The score represents the confidence of the predicted class label, and contains values between `0` and `1`.

`[___] = classifySequence(classifier,ExecutionEnvironment=env)` specifies the hardware resources for running the classifier in addition to any combination of arguments from previous syntaxes, as one of these options:

- `"auto"` — Sets the execution environment to the GPU, if available. Otherwise the function sets it to the CPU.
- `"gpu"` — Sets the execution environment to the GPU. Usage of the GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Sets the execution environment to the CPU.

Examples

Classify Video Sequences in a Video File

This example shows how to classify video sequences in a video file using a SlowFast Video Classifier pretrained on the Kinetics-400 video activity recognition dataset. To learn more about how to train a video classifier network for your dataset, see “Gesture Recognition using Videos and Deep Learning”.

Load SlowFast Video Classifier

```
sf = slowFastVideoClassifier();
```

Set Up Video Player and Video Reader

Specify the video file name to stream video frames.

```
videoFilename = "pushup.mp4";
```

Create a VideoReader to read video.

```
reader = VideoReader(videoFilename);
```

Set up a video player.

```
player = vision.VideoPlayer;
```

Classify Video Sequences

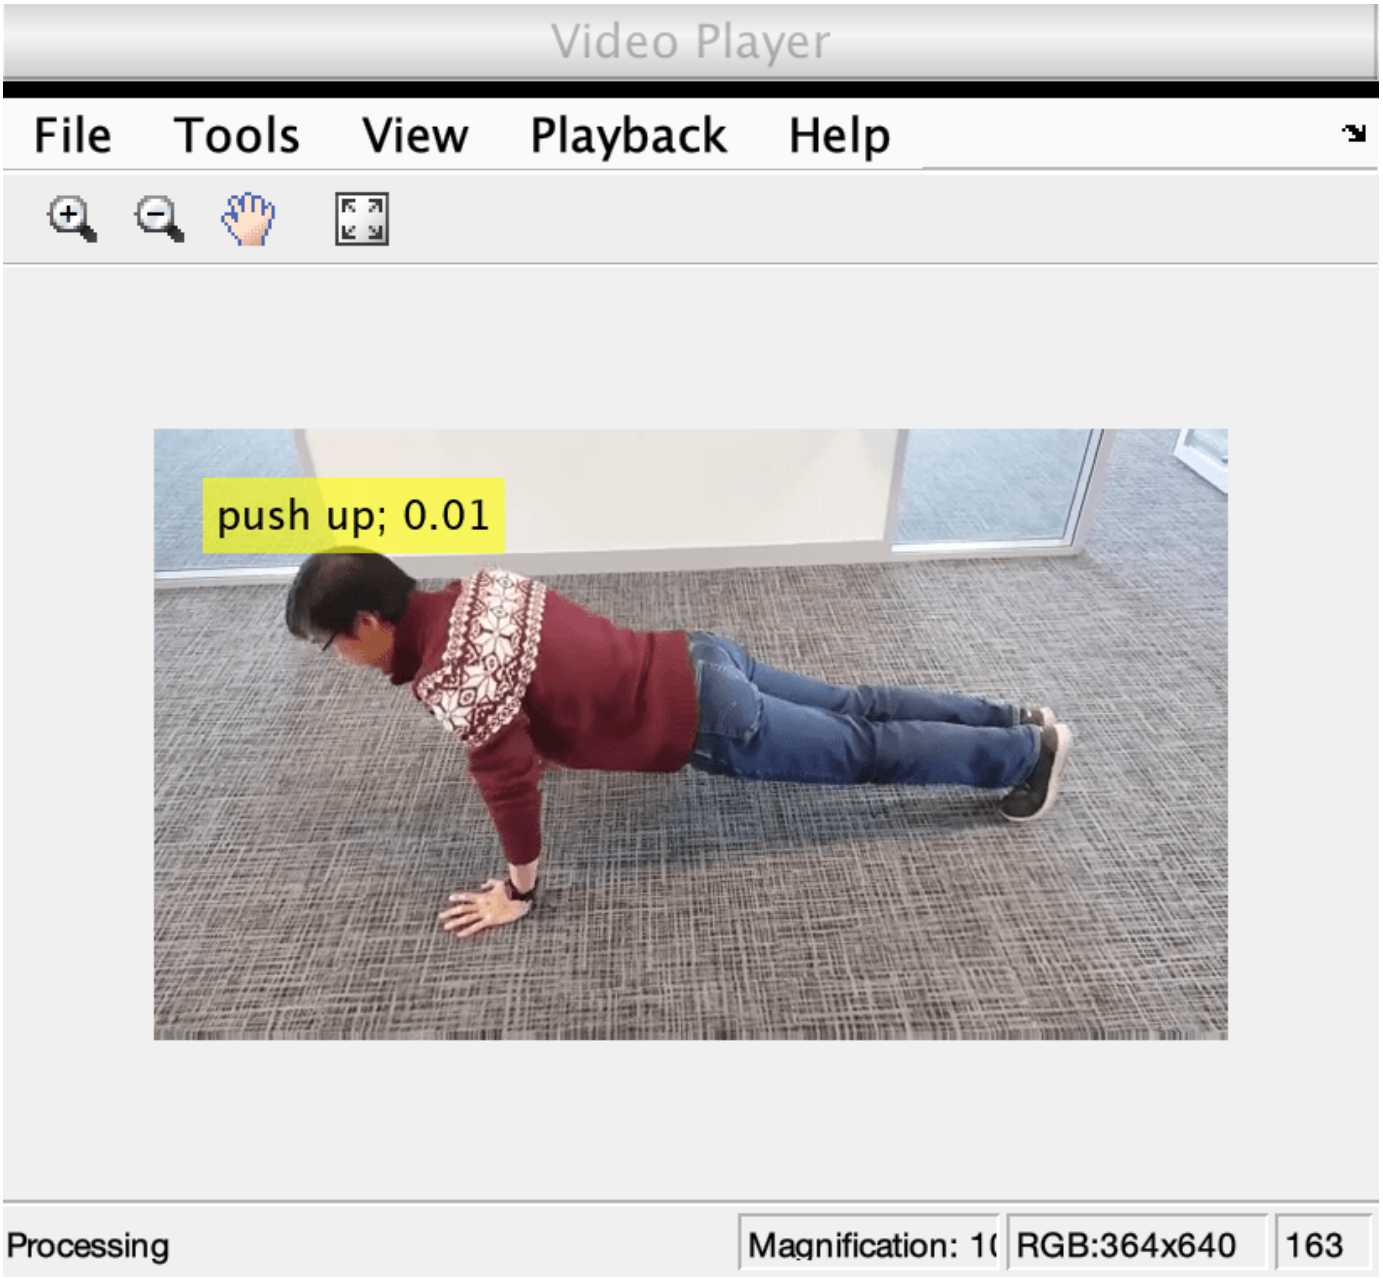
Specify how frequently the classifier should be applied to incoming video frames.

```
classifyInterval = 10;
```

A value of 10 balances runtime performance against classification performance. Increase this value to improve runtime performance at the cost of missing actions from the video file.

Obtain the sequence length of the SlowFast Video Classifier. Classify only after capturing at least `sequenceLength` number of frames from the video file.

```
sequenceLength = sf.InputSize(4);
```



Read video frames using the `hasFrame` and `readFrame` functions of the `VideoReader`. Using the `updateSequence` function update the video classifier's sequence. Using the `classifySequence` function classify the updated sequence.

```
numFrames = 0;
text = "";

while hasFrame(reader)
    frame = readFrame(reader);
    numFrames = numFrames + 1;

    % Update the sequence with the next video frame.
    sf = updateSequence(sf,frame);

    % Classify the sequence only at every classifyInterval number of frames.
    if mod(numFrames, classifyInterval) == 0 && numFrames >= sequenceLength
        [label,score] = classifySequence(sf);
        text = string(label) + "; " + num2str(score, "%0.2f");
    end
    frame = insertText(frame,[30,30],text,'FontSize',24);
    step(player,frame);
end
```

Classify Streaming Webcam Video Using SlowFast Video Classifier

This example shows how to classify a streaming video from a webcam using a pretrained SlowFast Video Classifier. To learn more about how to train a video classifier network for your dataset, see “Gesture Recognition using Videos and Deep Learning”.

Download Pretrained Video Classifier

Download the pretrained SlowFast video classifier.

```
downloadFolder = fullfile(tempdir,"gesture");
zipFile = "slowFastPretrained_fourClasses.zip";
if ~isfile(fullfile(downloadFolder,zipFile))
    disp("Downloading the pretrained network...");
    downloadURL = "https://ssd.mathworks.com/supportfiles/vision/data/" + zipFile;
    zipFile = fullfile(downloadFolder,zipFile);
    websave(zipFile,downloadURL);
    unzip(zipFile,downloadFolder);
end
```

Load the pretrained SlowFast video classifier.

```
pretrainedDataFile = fullfile(downloadFolder,"slowFastPretrained_fourClasses.mat");
pretrained = load(pretrainedDataFile);
slowFastClassifier = pretrained.data.slowFast;
```

Display the class label names of the pretrained video classifier. Any gesture such as "clapping" and "wavingHello" on to the webcam will be recognized by the SlowFast Video Classifier.

```
classes = slowFastClassifier.Classes
```

```
classes = 4×1 categorical array
    "clapping"
    "noAction"
    "somethingElse"
    "wavingHello"
```

Set Up the Webcam and the Video Player

In this example, a webcam object is used to capture streaming video. A Video Player is used to display the streaming video along with the predicted class.

Create a webcam object using the `webcam` function.

```
cam = webcam;
```

Create a Video Player using `vision.VideoPlayer` function. Make sure to place the Video Player in a position where you can clearly see the streaming video when running the classification.

```
player = vision.VideoPlayer;
```

Classify the Webcam Streaming Video

Specify how frequently the classifier should be applied to incoming video frames.

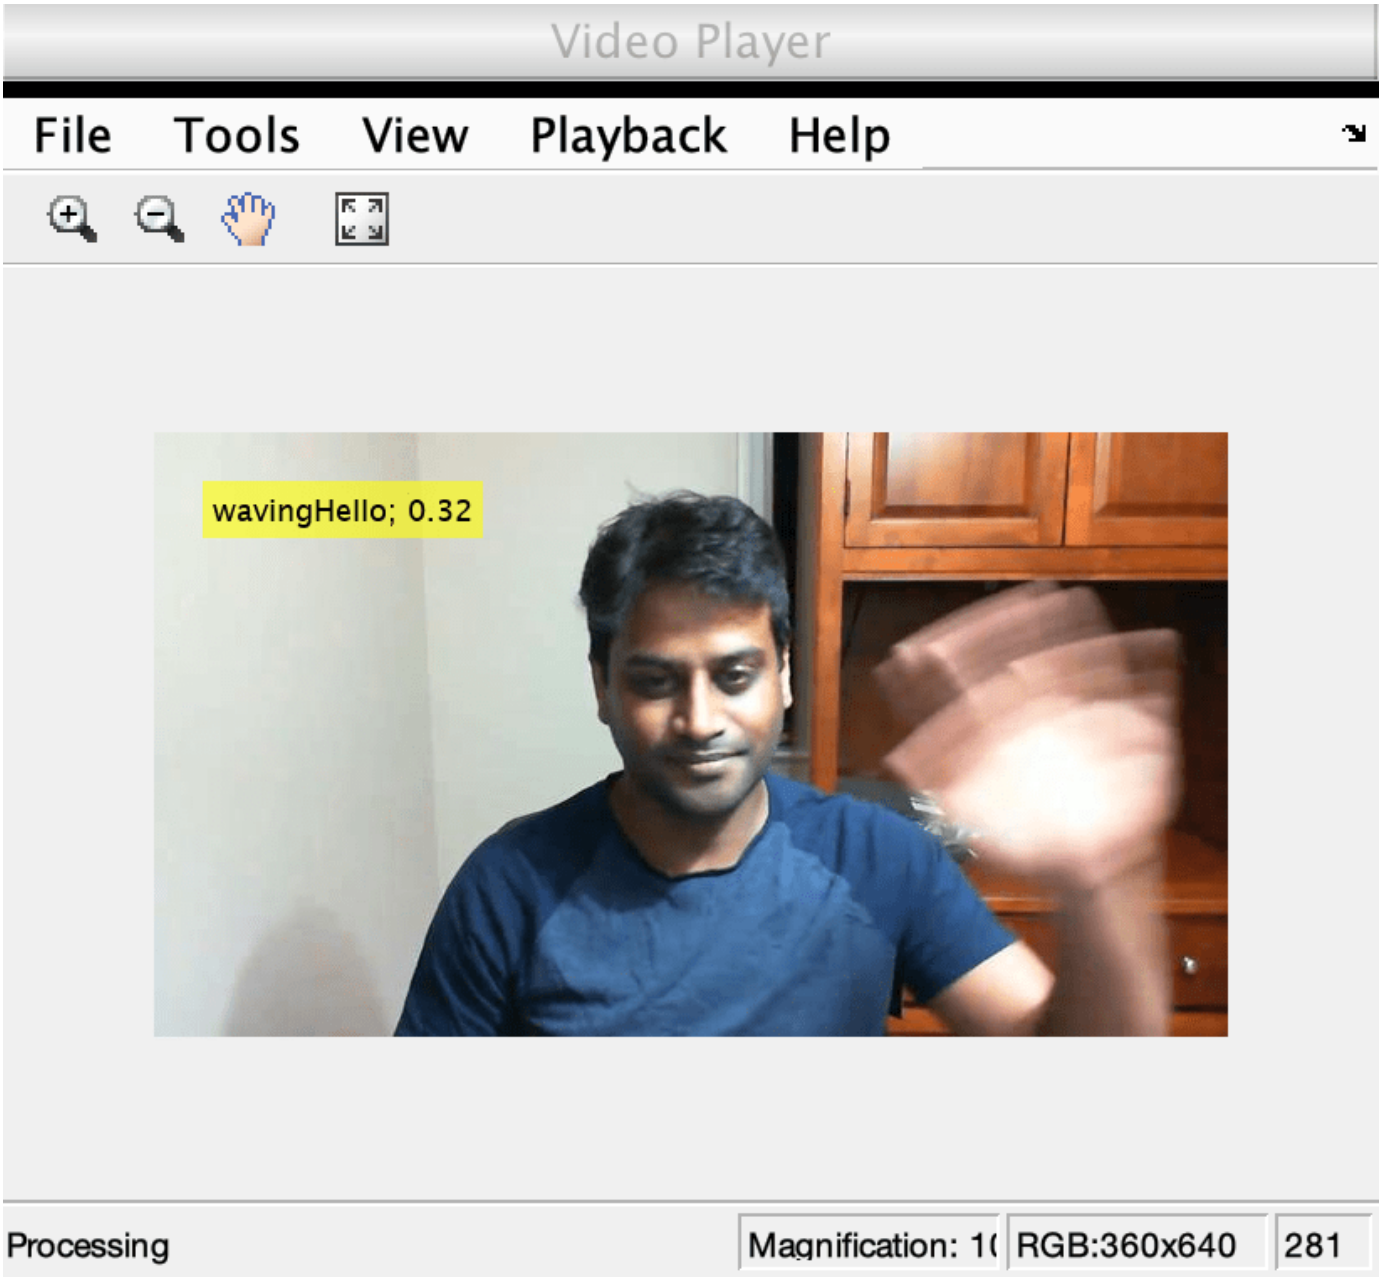
```
classifyInterval = 10;
```

A value of 10 balances runtime performance against classification performance. Increase this value to improve runtime performance at the cost of missing gestures from the live video stream.

Obtain the sequence length of the SlowFast Video Classifier. Classify only after capturing at least `sequenceLength` number of frames from the webcam.

```
sequenceLength = slowFastClassifier.InputSize(4);
```

Specify the maximum number of frames to capture in a loop using the `maxNumFrames` variable. Make sure you wave one of your hands to recognize `"wavingHello"` label, and clap using both your hands for the classifier to recognize `"clapping"` label.



```
maxNumFrames = 280;
```

Capture the webcam snapshot in a loop. Update the streaming video sequence of the classifier using the `updateSequence` method, and classify the streaming sequence using the `classifySequence` method.

```
numFrames = 0;
text = "";

while numFrames <= maxNumFrames
    frame = snapshot(cam);

    numFrames = numFrames + 1;
    slowFastClassifier = updateSequence(slowFastClassifier,frame);
    if mod(numFrames, classifyInterval) == 0 && numFrames >= sequenceLength
        [label,scores] = classifySequence(slowFastClassifier);
        if ~isempty(label)
            text = string(label) + "; " + num2str(max(scores), "%0.2f");
        end
    end
    frame = insertText(frame,[30,30],text,'FontSize',18);
    step(player,frame);
end
```

Input Arguments

`classifier` — Classifier

`r2plus1dVideoClassifier` object | `slowFastVideoClassifier` object

Classifier, specified as a `r2plus1dVideoClassifier` or `slowFastVideoClassifier` object.

Output Arguments

`label` — Classification of video or optical flow sequence

categorical scalar

Classification of the video or optical flow sequence, returned as a categorical scalar.

`score` — Classification score associated with the label
scalar value between `0` and `1`

Classification score associated with the label, returned as a scalar value between `0` and `1`. The score represents the confidence of the predicted class label.

Version History

Introduced in R2021b

classifySequence

Classify video and optical flow sequence

Syntax

```
label = classifySequence(i3d)
[label,score] = classifySequence(i3d)
[___] = classifySequence(i3d,ExecutionEnvironment=env)
```

Description

`label = classifySequence(i3d)` classifies a video and optical flow sequence using the Inflated-3D (I3D) video classifier `i3d`. The function returns `label`, a scalar categorical that specifies the classification of the video or optical flow sequence. `label` is one of the values of the `Classes` property of the video classifier object.

`[label,score] = classifySequence(i3d)` additionally returns the classification score associated with the label. The score represents the confidence of the predicted class label, and contains values between `0` and `1`.

`[___] = classifySequence(i3d,ExecutionEnvironment=env)` specifies the hardware resources for running the classifier in addition to any combination of arguments from previous syntaxes, as one of these options:

- `"auto"` — Sets the execution environment to the GPU, if available. Otherwise the function sets it to the CPU.
- `"gpu"` — Sets the execution environment to the GPU. Usage of the GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Sets the execution environment to the CPU.

Examples

Classify Video Sequences in a Video File

This example shows how to classify video sequences in a video file using a SlowFast Video Classifier pretrained on the Kinetics-400 video activity recognition dataset. To learn more about how to train a video classifier network for your dataset, see “Gesture Recognition using Videos and Deep Learning”.

Load SlowFast Video Classifier

```
sf = slowFastVideoClassifier();
```

Set Up Video Player and Video Reader

Specify the video file name to stream video frames.

```
videoFilename = "pushup.mp4";
```

Create a VideoReader to read video.

```
reader = VideoReader(videoFilename);
```

Set up a video player.

```
player = vision.VideoPlayer;
```

Classify Video Sequences

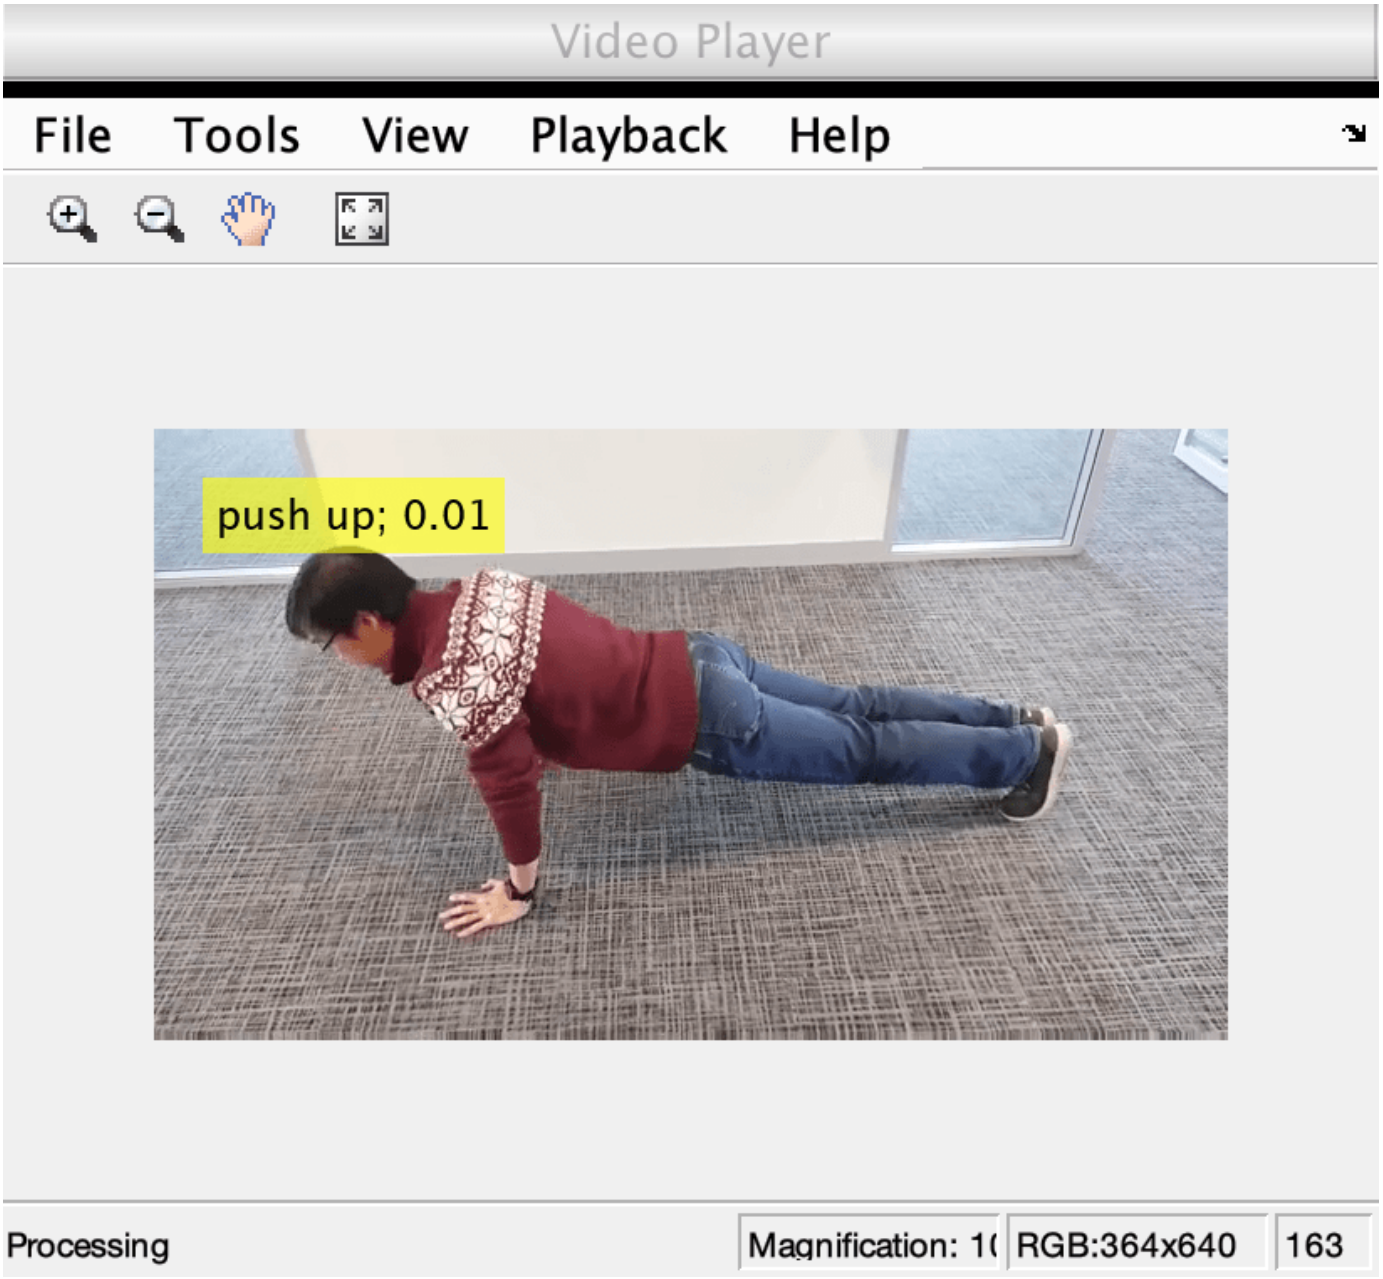
Specify how frequently the classifier should be applied to incoming video frames.

```
classifyInterval = 10;
```

A value of 10 balances runtime performance against classification performance. Increase this value to improve runtime performance at the cost of missing actions from the video file.

Obtain the sequence length of the SlowFast Video Classifier. Classify only after capturing at least `sequenceLength` number of frames from the video file.

```
sequenceLength = sf.InputSize(4);
```



Read video frames using the `hasFrame` and `readFrame` functions of the `VideoReader`. Using the `updateSequence` function update the video classifier's sequence. Using the `classifySequence` function classify the updated sequence.

```
numFrames = 0;
text = "";

while hasFrame(reader)
    frame = readFrame(reader);
    numFrames = numFrames + 1;

    % Update the sequence with the next video frame.
    sf = updateSequence(sf,frame);

    % Classify the sequence only at every classifyInterval number of frames.
    if mod(numFrames, classifyInterval) == 0 && numFrames >= sequenceLength
        [label,score] = classifySequence(sf);
        text = string(label) + "; " + num2str(score, "%0.2f");
    end
    frame = insertText(frame,[30,30],text,'FontSize',24);
    step(player,frame);
end
```

Input Arguments

`i3d` — Classifier
`inflated3dVideoClassifier` object

Classifier, specified as an `inflated3dVideoClassifier` object.

Output Arguments

`label` — Classification of video or optical flow sequence
categorical scalar

Classification of the video or optical flow sequence, returned as a categorical scalar.

`score` — Classification score associated with the label
scalar value between `0` and `1`

Classification score associated with the label, returned as a scalar value between `0` and `1`. The score represents the confidence of the predicted class label.

classifyVideoFile

Classify a video file

Syntax

```
label = classifyVideoFile(classifier,videoFilename)
[label,score] = classifyVideoFile( ___ )
[ ___ ] = classifySequence( ___ ,Name=Value)
```

Description

`label = classifyVideoFile(classifier,videoFilename)` predicts the class label for the video file, specified by `videoFilename` using the specified classifier `classifier`. The video file must be readable by the `VideoReader` object.

Use the `classifyVideoFile` object function for applications where the entire input video can be classified with one label. For example, you can use this object function to evaluate the performance of the classifier on a collection of ground truth video files. If the video contains sequences with different class labels, use the `classifySequence` object function.

This function selects sequences of frames from the video file using uniform random sampling to select the start of time of each sequence. The number of frames is set by the `InputSize` property of the classifier object. The function selects the most frequently occurring label in the video file as the classification label for the file. The video file must contain at least the number of frames set by the `InputSize` property.

`[label,score] = classifyVideoFile( ___ )` additionally returns the classification score associated with the label using the combination of input arguments from the previous syntax.. The score represents the confidence of the predicted class label and contains values between `0` and `1`.

`[ ___ ] = classifySequence( ___ ,Name=Value)` specifies options using name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `label = classifySequence(i3d,ExecutionEnvironment="cpu")` specifies for the classifier to run on the CPU.

Examples

Classify Video File Using Video Classifier

This example requires the Computer Vision Toolbox™ Model for SlowFast Video Classification. You can install the Computer Vision Toolbox Model for SlowFast Video Classification from Add-On Explorer. For more information about installing add-ons, see “Get and Manage Add-Ons”.

Load a slowfast video classifier pretrained on the Kinetics-400 data set.

```
sf = slowFastVideoClassifier;
```

Specify the file name of the video to classify.

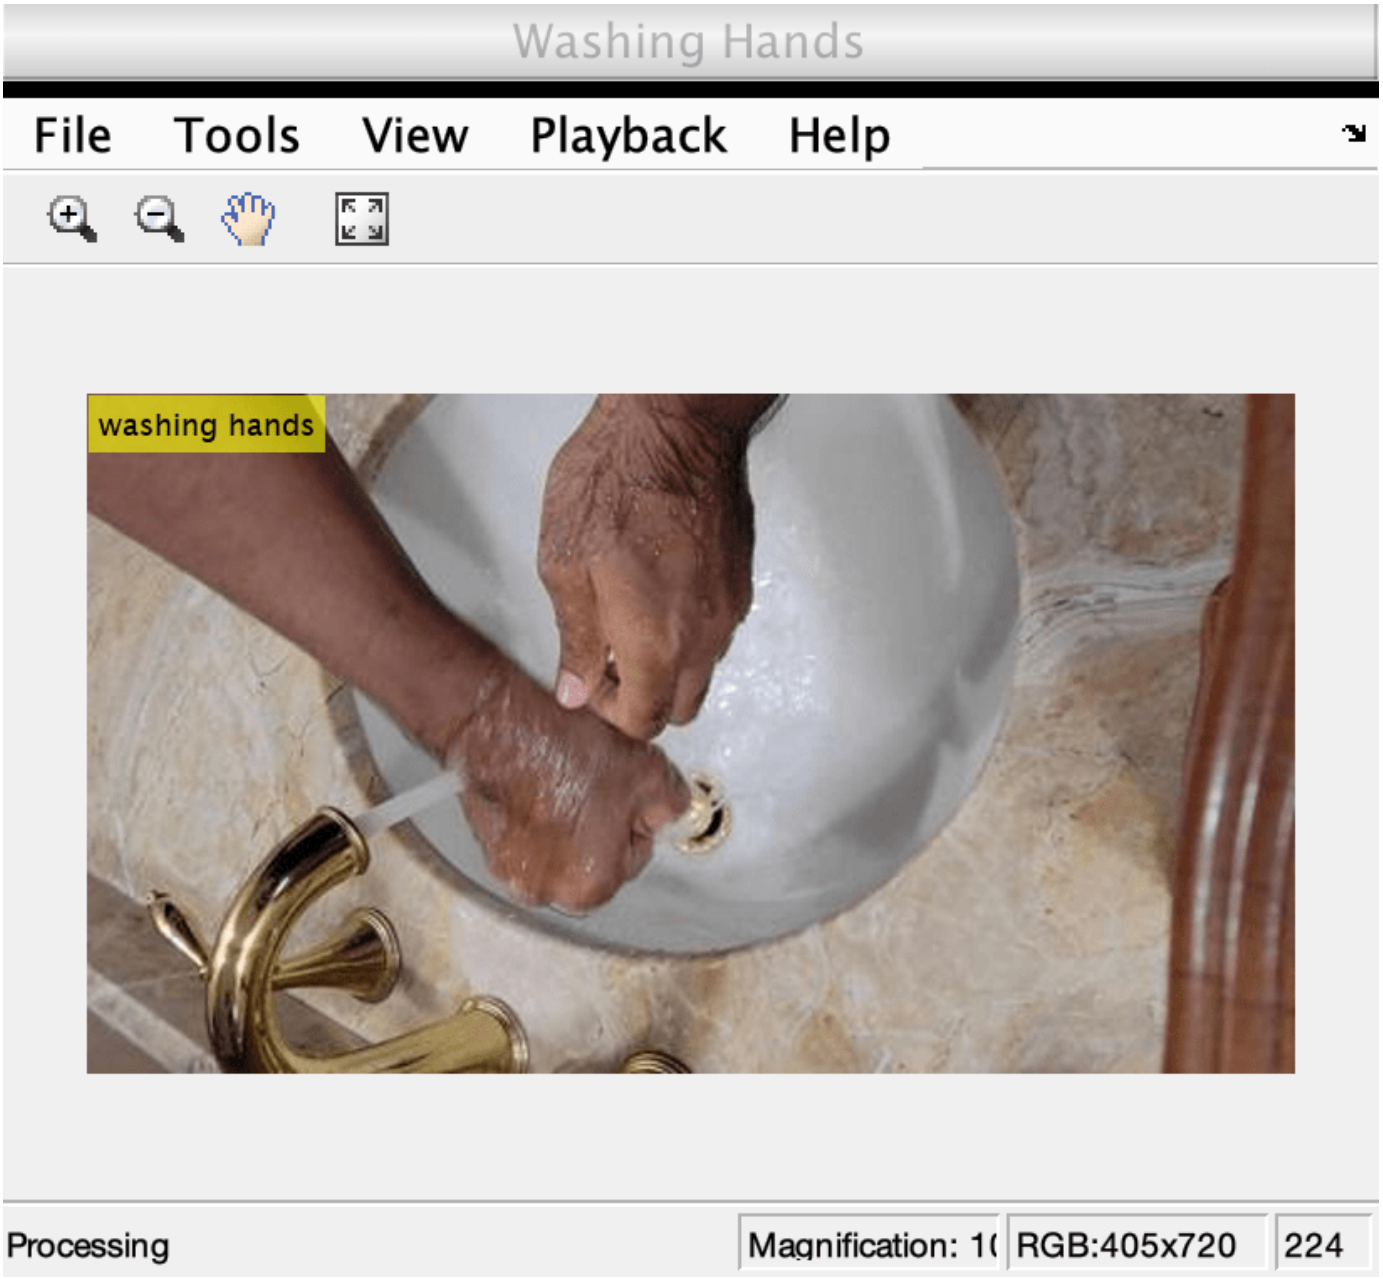
```
videoFilename = "washingHands.avi";
```

For video classification, set the number of randomly selected video sequences to 15.

```
numSequences = 15;
```

Classify the video using the `classifyVideoFile` function.

```
[label,score] = classifyVideoFile(sf,videoFilename,NumSequences=numSequences)
```



```
label = categorical
     washing hands

score = single

0.0034
```

Display the classified label using a `vision.VideoPlayer`.

```
player = vision.VideoPlayer('Name','Washing Hands');
reader = VideoReader(videoFilename);
while hasFrame(reader)
    frame = readFrame(reader);
    % Resize the frame by 1.5 times for display
    frame = imresize(frame,1.5);
    frame = insertText(frame,[2,2], string(label),'FontSize',18);
    step(player,frame);
end
```

Input Arguments

`classifier` — Classifier
`inflated3dVideoClassifier` object | `r2plus1dVideoClassifier` object | `slowFastVideoClassifier` object

Classifier, specified as an `inflated3dVideoClassifier`, `r2plus1dVideoClassifier`, or `slowFastVideoClassifier` object.

`videoFilename` — Video file name
character vector | string scalar

Video file name, specified as a character vector or a string scalar. The video file must be readable by the `VideoReader` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `label = classifySequence(i3d,ExecutionEnvironment="cpu")` specifies for the classifier to run on the CPU.

`ExecutionEnvironment` — Hardware execution environment

`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware execution environment on which to run the classifier, specified as `"auto"`, `"gpu"`, or `"cpu"`.

- `"auto"` — Sets the execution environment to the GPU, if available. Otherwise the function sets it to the CPU.
- `"gpu"` — Sets the execution environment to the GPU. Usage of the GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Sets the execution environment to the CPU.

`NumSequences` — Maximum number of sequences to sample from video file

`"auto"` (default) | positive integer

Maximum number of sequences to sample from the video file, specified as `"auto"` or a positive integer. When you set this value to `"auto"`, the function sets the number of sequences to twice the number of sequences that can be selected from the video file based on the number of frames available. The `"auto"` setting provides a uniform coverage of the entire video. Increasing the value of `NumSequences` increases the uniform coverage of the video.

`MiniBatchSize` — Mini-batch size for processing a large video

16 | positive integer

Mini-batch size used for processing a large video, specified as a positive integer. Video sequences are grouped and processed in mini-batches to improve computational efficiency. Increasing the value of `MiniBatchSize` increases processing speed, but uses more memory.

Output Arguments

`label` — Classification of video

categorical scalar

Classification of video, returned as a categorical scalar.

`score` — Classification score associated with the label

scalar value between `0` and `1`

Classification score associated with the label, returned as a scalar value between `0` and `1`. The score represents the confidence of the predicted class label.

forward

Compute video classifier outputs for training

Syntax

```
dLYVideo = forward(classifier,dlXVideo)
[dLYVideo,stateVideo] = forward(classifier,dlXVideo)
[dLYVideo,dlYFlow] = forward(classifier,dlXVideo,dlXFlow)
[dLYVideo,dlYFlow,stateVideo,stateFlow] = forward(classifier,dlXVideo,
dlXFlow)
```

Description

`dLYVideo = forward(classifier,dlXVideo)` computes the video classifier outputs for training. You can use this function with `dlfeval` to automatically compute gradients for updating the learnable parameters of the video classifier. `classifier` is specified as a `r2plus1dVideoClassifier` or `slowFastVideoClassifier` classifier object.

`[dLYVideo,stateVideo] = forward(classifier,dlXVideo)` also returns the updated video network state. The output, `stateVideo`, contains information maintained by the classifier between training iterations. For example, the state of batch normalization operation.

`[dLYVideo,dlYFlow] = forward(classifier,dlXVideo,dlXFlow)` also returns the optical flow outputs from the classifier for training. Use this syntax when you set the `OpticalFlowMethod` property of the classifier object to `"Farneback"`.

`[dLYVideo,dlYFlow,stateVideo,stateFlow] = forward(classifier,dlXVideo, dlXFlow)` also returns the updated video network and the optical flow network states.

Examples

Compute Video Classifier Outputs for Training

This example shows how to compute video classifier outputs for training. To learn more about how to train a video classifier network for your dataset, see “Gesture Recognition using Videos and Deep Learning”.

Load a video classifier pretrained on the Kinetics-400 data set.

```
sf = slowFastVideoClassifier;
```

Specify the video file name.

```
videoFilename = "washingHands.avi";
```

Create a `VideoReader` to read the video frames.

```
reader = VideoReader(videoFilename);
```

Read the required number of video frames corresponding to the video classifier network from the beginning of the video file. The required number of frames is defined by the value of the 4th element of the `InputSize` property of the video classifier.

```
sequenceLength = sf.InputSize(4);
sequenceRange = [1,sequenceLength];
videoFrames = read(reader,sequenceRange);
```

Resize the video frames for training. The required height and width are defined by the first two elements of the `InputSize` property of the video classifier.

```
heightWidth = sf.InputSize(1:2);
resized = imresize(videoFrames,heightWidth);
```

Convert the input to type `single`.

```
resized = single(resized);
```

Rescale the input between 0 and 1.

```
minValue = sf.InputNormalizationStatistics.Min;
maxValue = sf.InputNormalizationStatistics.Max;
minValue = reshape(minValue,1,1,3);
maxValue = reshape(maxValue,1,1,3);
resized = rescale(resized,0,1,InputMin=minValue,InputMax=maxValue);
```

Normalize the video data using the mean and standard deviation.

```
meanValue = sf.InputNormalizationStatistics.Mean;
stdValue = sf.InputNormalizationStatistics.StandardDeviation;
meanValue = reshape(meanValue,1,1,3);
stdValue = reshape(stdValue,1,1,3);
resized = resized - meanValue;
resized = resized./stdValue;
```

Convert the input to a `dlarray` object.

```
dlVideo = dlarray(resized,"SSCTB");
trainingActivations = forward(sf,dlVideo);
```

Find the class label corresponding to the maximum score.

```
[score,idx] = max(trainingActivations);
label = sf.Classes(idx)
```

```
label = categorical
     washing hands
```

```
score
```

```
score =
  1(S) × 1(S) × 1(S) × 1(C) × 1(B) single dlarray

    0.0026
```

Display the class label.

```
frame = videoFrames(:,:,:,end);
frame = insertText(frame,[2,2],string(label),FontSize=24);
imshow(frame)
```

Input Arguments

`classifier` — Classifier object

`r2plus1dVideoClassifier` object | `slowFastVideoClassifier` object

Classifier object, specified as a `r2plus1dVideoClassifier` or `slowFastVideoClassifier` object.

`dlXVideo` — Video input

H-by-*W*-by-*C*-by-*T*-by-*B* `SSCTB` formatted `dlarray` object

Video input, specified as an *H*-by-*W*-by-*C*-by-*T*-by-*B* `SSCTB` formatted `dlarray` object that corresponds to the video input of the classifier.

- *H* — Height.
- *W* — Width.
- *C* — Number of channels. The number of channels must be equal to the channels value of the `InputSize` property of the classifier object.
- *T* — Number of frames. The number of frames must be equal to the frames value of the `InputSize` property of the classifier object.
- *B* — Batch size.

`dlXFlow` — Video and optical flow input

`SSCTB` formatted `dlarray` object

Video and optical flow input, specified as an *H*-by-*W*-by-*C*-by-*T*-by-*B* `SSCTB` formatted `dlarray` object that corresponds to the video and optical flow input of the classifier.

- *H* — Height.
- *W* — Width.
- *C* — Number of channels. The number of channels must be equal to the channels value of the `InputSize` property of the classifier object.
- *T* — Number of frames. The number of frames must be equal to the frames value of the `InputSize` property of the classifier object.
- *B* — Batch size.

Output Arguments

`dLYVideo` — Activations of video network
`dlarray` object

Activations of the video network, returned as a formatted `dlarray` object.

`stateVideo` — Updated video network state
table

Updated video network state, returned as a table with three columns:

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Value of the parameter, specified as a `dlarray` object.

The network state contains information remembered by the network between iterations. For example, the state of the LSTM and batch normalization layers.

During training or inference, you can update the network state using the output of the `forward` and `predict` functions.

`dlYFlow` — Activations of optical flow network
`dlarray` object

Activations of the optical flow network, returned as a formatted `dlarray` object.

`stateFlow` — Updated optical flow network state
table

Updated optical flow network state, returned as a table with three columns:

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Value of the parameter, specified as a `dlarray` object.

The network state contains information remembered by the network between iterations. For example, the state of LSTM and batch normalization layers.

During training or inference, you can update the network state using the output of the `forward` and `predict` functions.

Input Arguments

`i3d` — Classifier

`inflated3dVideoClassifier` object

Classifier, specified as an `inflated3dVideoClassifier` object.

`dlXVideo` — Video input

H-by-*W*-by-*C*-by-*T*-by-*B* `SSCTB` formatted `dlarray` object

Video input, specified as an *H*-by-*W*-by-*C*-by-*T*-by-*B* `SSCTB` formatted `dlarray` object that corresponds to the video input of the classifier.

- *H* — Height.
- *W* — Width.
- *C* — Number of channels. The number of channels must be equal to the channels value of the `InputSize` property of the classifier object.
- *T* — Number of frames. The number of frames must be equal to the frames value of the `InputSize` property of the classifier object.
- *B* — Batch size.

`dlXFlow` — Video and optical flow input

`SSCTB` formatted `dlarray` object

Video and optical flow input, specified as an *H*-by-*W*-by-*C*-by-*T*-by-*B* `SSCTB` formatted `dlarray` object that corresponds to the video and optical flow input of the classifier.

- *H* — Height.
- *W* — Width.
- *C* — Number of channels. The number of channels must be equal to the channels value of the `InputSize` property of the classifier object.
- *T* — Number of frames. The number of frames must be equal to the frames value of the `InputSize` property of the classifier object.
- *B* — Batch size.

Output Arguments

`dLYVideo` — Activations of video network
`dlarray` object

Activations of the video network, returned as a formatted `dlarray` object.

`stateVideo` — Updated video network state
table

Updated video network state, returned as a table with three columns:

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Value of the parameter, specified as a `dlarray` object.

The network state contains information remembered by the network between iterations. For example, the state of the LSTM and batch normalization layers.

During training or inference, you can update the network state using the output of the `forward` and `predict` functions.

`dlYFlow` — Activations of optical flow network
`dlarray` object

Activations of the optical flow network, returned as a formatted `dlarray` object.

`stateFlow` — Updated optical flow network state
table

Updated optical flow network state, returned as a table with three columns:

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Value of the parameter, specified as a `dlarray` object.

The network state contains information remembered by the network between iterations. For example, the state of LSTM and batch normalization layers.

During training or inference, you can update the network state using the output of the `forward` and `predict` functions.

predict

Compute video classifier predictions

Syntax

```
dLYVideo = predict(classifier,dlXVideo)
[dLYVideo,stateVideo] = predict(classifier,dlXVideo)
[dLYVideo,dlYFlow] = predict(classifier,dlXVideo,dlXFlow)
[dLYVideo,dlYFlow,stateVideo,stateFlow] = predict(classifier,dlXVideo,
dlXFlow)
```

Description

`dLYVideo = predict(classifier,dlXVideo)` computes the predictions of the video classifier. `classifier` is specified as a `r2plus1dVideoClassifier` or `slowFastVideoClassifier` classifier object.

`[dLYVideo,stateVideo] = predict(classifier,dlXVideo)` also returns the updated video network state. The output, `stateVideo`, contains information between training iterations maintained by the classifier. For example, the state of batch normalization operation.

`[dLYVideo,dlYFlow] = predict(classifier,dlXVideo,dlXFlow)` also returns the optical flow predictions from the classifier for training. Use this syntax when you set the `OpticalFlowMethod` property of the classifier object to `"Farneback"`.

`[dLYVideo,dlYFlow,stateVideo,stateFlow] = predict(classifier,dlXVideo,dlXFlow)` also returns the updated video network and the optical flow network states.

Examples

Compute Predictions for Video Using Video Classifier

This example shows how to compute predictions for a video using a video classifier. To learn more about how to train a video classifier network for your dataset, see “Gesture Recognition using Videos and Deep Learning”.

Load a video classifier pretrained on the Kinetics-400 data set.

```
sf = slowFastVideoClassifier;
```

Specify the video file name.

```
videoFilename = "pushup.mp4";
```

Create a `VideoReader` to read the video frames.

```
reader = VideoReader(videoFilename);
```

Read the required number of video frames corresponding to the video classifier network, from the beginning of the video file. The required number of frames is defined by the value of the 4th element of the `InputSize` property of the video classifier.

```
sequenceLength = sf.InputSize(4);
sequenceRange = [1, sequenceLength];
videoFrames = read(reader,sequenceRange);
```

Resize video frames for prediction. The required height and width are defined by the first two elements of the `InputSize` property of the video classifier.

```
heightWidth = sf.InputSize(1:2);
resized = imresize(videoFrames,heightWidth);
```

Convert the input to type `single`.

```
resized = single(resized);
```

Rescale the input between 0 and 1.

```
minValue = sf.InputNormalizationStatistics.Min;
maxValue = sf.InputNormalizationStatistics.Max;
minValue = reshape(minValue,1,1,3);
maxValue = reshape(maxValue,1,1,3);
resized = rescale(resized,0,1,InputMin=minValue,InputMax=maxValue);
```

Normalize the video data using the mean and standard deviation.

```
meanValue = sf.InputNormalizationStatistics.Mean;
stdValue = sf.InputNormalizationStatistics.StandardDeviation;
meanValue = reshape(meanValue,1,1,3);
stdValue = reshape(stdValue,1,1,3);
resized = resized - meanValue;
resized = resized./stdValue;
```

Convert the input to dlarray object.

```
dlVideo = dlarray(resized,"SSCTB");
predictionScores = predict(sf,dlVideo);
```

Find the class label corresponding to the maximum score.

```
[score,idx] = max(predictionScores);
label = sf.Classes(idx)
```

```
label = categorical
     push up
```

Display the predicted class label and the score.

```
text = string(label) + "; " + num2str(score,"%0.2f");
frame = videoFrames(:,:,:,end);
frame = insertText(frame,[30,30],text,FontSize=24);

imshow(frame)
```

Input Arguments

`classifier` — Classifier object

`r2plus1dVideoClassifier` object | `slowFastVideoClassifier` object

Classifier object, specified as a `r2plus1dVideoClassifier` or `slowFastVideoClassifier` object.

`dlXVideo` — Video input

H-by-*W*-by-*C*-by-*T*-by-*B* `SSCTB` formatted `dlarray` object

Video input, specified as an *H*-by-*W*-by-*C*-by-*T*-by-*B* `SSCTB` formatted `dlarray` object that corresponds to the video input of the classifier.

- *H* — Height.
- *W* — Width.
- *C* — Number of channels. The number of channels must be equal to the channels value of the `InputSize` property of the classifier object.
- *T* — Number of frames. The number of frames must be equal to the frames value of the `InputSize` property of the classifier object.
- *B* — Batch size.

`dlXFlow` — Video and optical flow input

`SSCTB` formatted `dlarray` object

Video and optical flow input, specified as an *H*-by-*W*-by-*C*-by-*T*-by-*B* `SSCTB` formatted `dlarray` object that corresponds to the video and optical flow input of the classifier.

- *H* — Height.
- *W* — Width.
- *C* — Number of channels. The number of channels must be equal to the channels value of the `InputSize` property of the classifier object.
- *T* — Number of frames. The number of frames must be equal to the frames value of the `InputSize` property of the classifier object.
- *B* — Batch size.

Output Arguments

`dLYVideo` — Activations of video network
`dlarray` object

Activations of the video network, returned as a formatted `dlarray` object.

`stateVideo` — Updated video network state
table

Updated video network state, returned as a table with three columns:

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Value of the parameter, specified as a `dlarray` object.

The network state contains information remembered by the network between iterations. For example, the state of the LSTM and batch normalization layers.

During training or inference, you can update the network state using the output of the `forward` and `predict` functions.

`dlYFlow` — Activations of optical flow network
`dlarray` object

Activations of the optical flow network, returned as a formatted `dlarray` object.

`stateFlow` — Updated optical flow network state
table

Updated optical flow network state, returned as a table with three columns:

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Value of the parameter, specified as a `dlarray` object.

The network state contains information remembered by the network between iterations. For example, the state of LSTM and batch normalization layers.

During training or inference, you can update the network state using the output of the `forward` and `predict` functions.

predict

Compute video classifier predictions

Syntax

```
dLYVideo = predict(i3d,dlXVideo)
[dLYVideo,stateVideo] = predict(i3d,dlXVideo)
[dLYVideo,dlYFlow] = predict(i3d,dlXVideo,dlXFlow)
[dLYVideo,dlYFlow,stateVideo,stateFlow] = predict(i3d,dlXVideo,dlXFlow)
```

Description

`dLYVideo = predict(i3d,dlXVideo)` computes the predictions of the video classifier. `i3d` is specified as an `inflated3dVideoClassifier`, `r2plus1dVideoClassifier`, or `slowFastVideoClassifier` classifier object. Use this syntax when you set the `OpticalFlowMethod` property of the classifier object to `"none"`.

`[dLYVideo,stateVideo] = predict(i3d,dlXVideo)` also returns the updated video network state. The output, `stateVideo`, contains information between training iterations maintained by the classifier. For example, the state of batch normalization operation.

`[dLYVideo,dlYFlow] = predict(i3d,dlXVideo,dlXFlow)` also returns the optical flow predictions from the classifier for training. Use this syntax when you set the `OpticalFlowMethod` property of the classifier object to `"Farneback"`.

`[dLYVideo,dlYFlow,stateVideo,stateFlow] = predict(i3d,dlXVideo,dlXFlow)` also returns the updated video network and the optical flow network states.

frame = videoFrames(:,:,:,end);
frame = insertText(frame,[30,30],text,FontSize=24);

imshow(frame)
```

Input Arguments

`i3d` — Classifier

`inflated3dVideoClassifier` object

Classifier, specified as an `inflated3dVideoClassifier` object.

`dlXVideo` — Video input

H-by-*W*-by-*C*-by-*T*-by-*B* `SSCTB` formatted `dlarray` object

Video input, specified as an *H*-by-*W*-by-*C*-by-*T*-by-*B* `SSCTB` formatted `dlarray` object that corresponds to the video input of the classifier.

- *H* — Height.
- *W* — Width.
- *C* — Number of channels. The number of channels must be equal to the channels value of the `InputSize` property of the classifier object.
- *T* — Number of frames. The number of frames must be equal to the frames value of the `InputSize` property of the classifier object.
- *B* — Batch size.

`dlXFlow` — Video and optical flow input

`SSCTB` formatted `dlarray` object

Video and optical flow input, specified as an *H*-by-*W*-by-*C*-by-*T*-by-*B* `SSCTB` formatted `dlarray` object that corresponds to the video and optical flow input of the classifier.

- *H* — Height.

resetSequence

Reset video sequence properties for streaming video classification

Syntax

```
classifierReset = resetSequence(classifier)
```

Description

`classifierReset = resetSequence(classifier)` resets the video sequences for classification. `classifier` is the classifier, specified as a `r2plus1dVideoClassifier` or `slowFastVideoClassifier` object.

Examples

Classify Two Videos Using a Video Classifier

This example shows how to classify two different video sequences one after the other by reseting the video sequences of the video classifier using the `resetSequence` function. To learn more about how to train a video classifier network for your dataset, see “Gesture Recognition using Videos and Deep Learning”.

Load SlowFast Video Classifier

Load the SlowFast Video Classifier pretrained on the Kinetics-400 dataset.

```
sf = slowFastVideoClassifier();
```

Classify First Video Sequence

Specify the video file name.

```
videoFilename = "washingHands.avi";
```

Create a VideoReader to read the video frames.

```
reader = VideoReader(videoFilename);
```

Update the video classifier sequence with video frames before using `classifySequence`. The required number of frames is defined by the value of the 4th element of `InputSize` property of the video classifier.

```
sequenceLength = sf.InputSize(4);
```

Read a video sequence starting from the first frame.

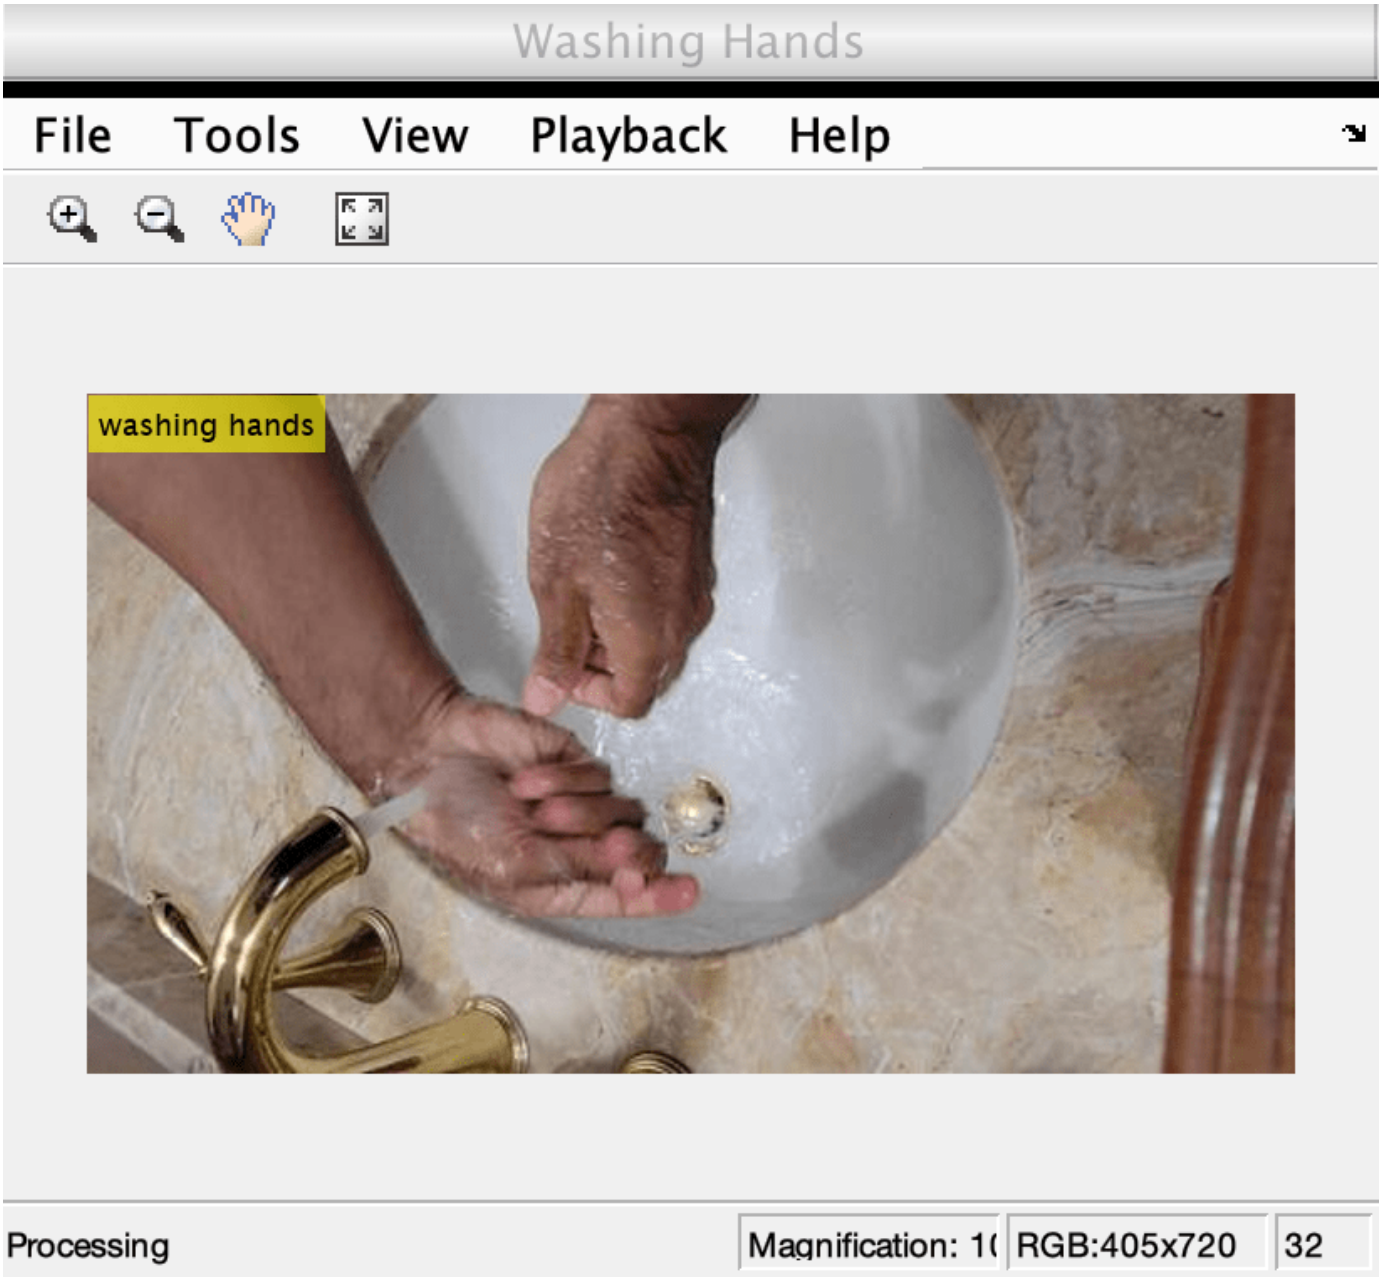
```
startSequenceIndex = 1;
sequenceRange = [startSequenceIndex, startSequenceIndex + sequenceLength - 1];
```

Update the video classifier sequence with video frames.

```
for ii = sequenceRange
    videoFrame = read(reader, ii);
    sf = updateSequence(sf,videoFrame);
end
```

Classify the video sequence updated so far.

```
[label1, score1] = classifySequence(sf)
```



```
label1 = categorical
     washing hands

score1 = single

0.0031
```

Display the classified label.

```
player = vision.VideoPlayer('Name','Washing Hands');
for ii = sequenceRange
    frame = read(reader,ii);
    % Resize the frame by 1.5 times for display
    frame = imresize(frame,1.5);
    frame = insertText(frame,[2,2], string(label1),'FontSize',18);
    step(player,frame);
end
```

Classify Second Video Sequence

Reset the video sequence of the video classifier without creating a new video classifier.

```
sf = resetSequence(sf);
```

Specify another video file to classify.

```
videoFilename = "vipmen.avi";
```

Create a VideoReader to read the video frames.

```
reader = VideoReader(videoFilename);
```

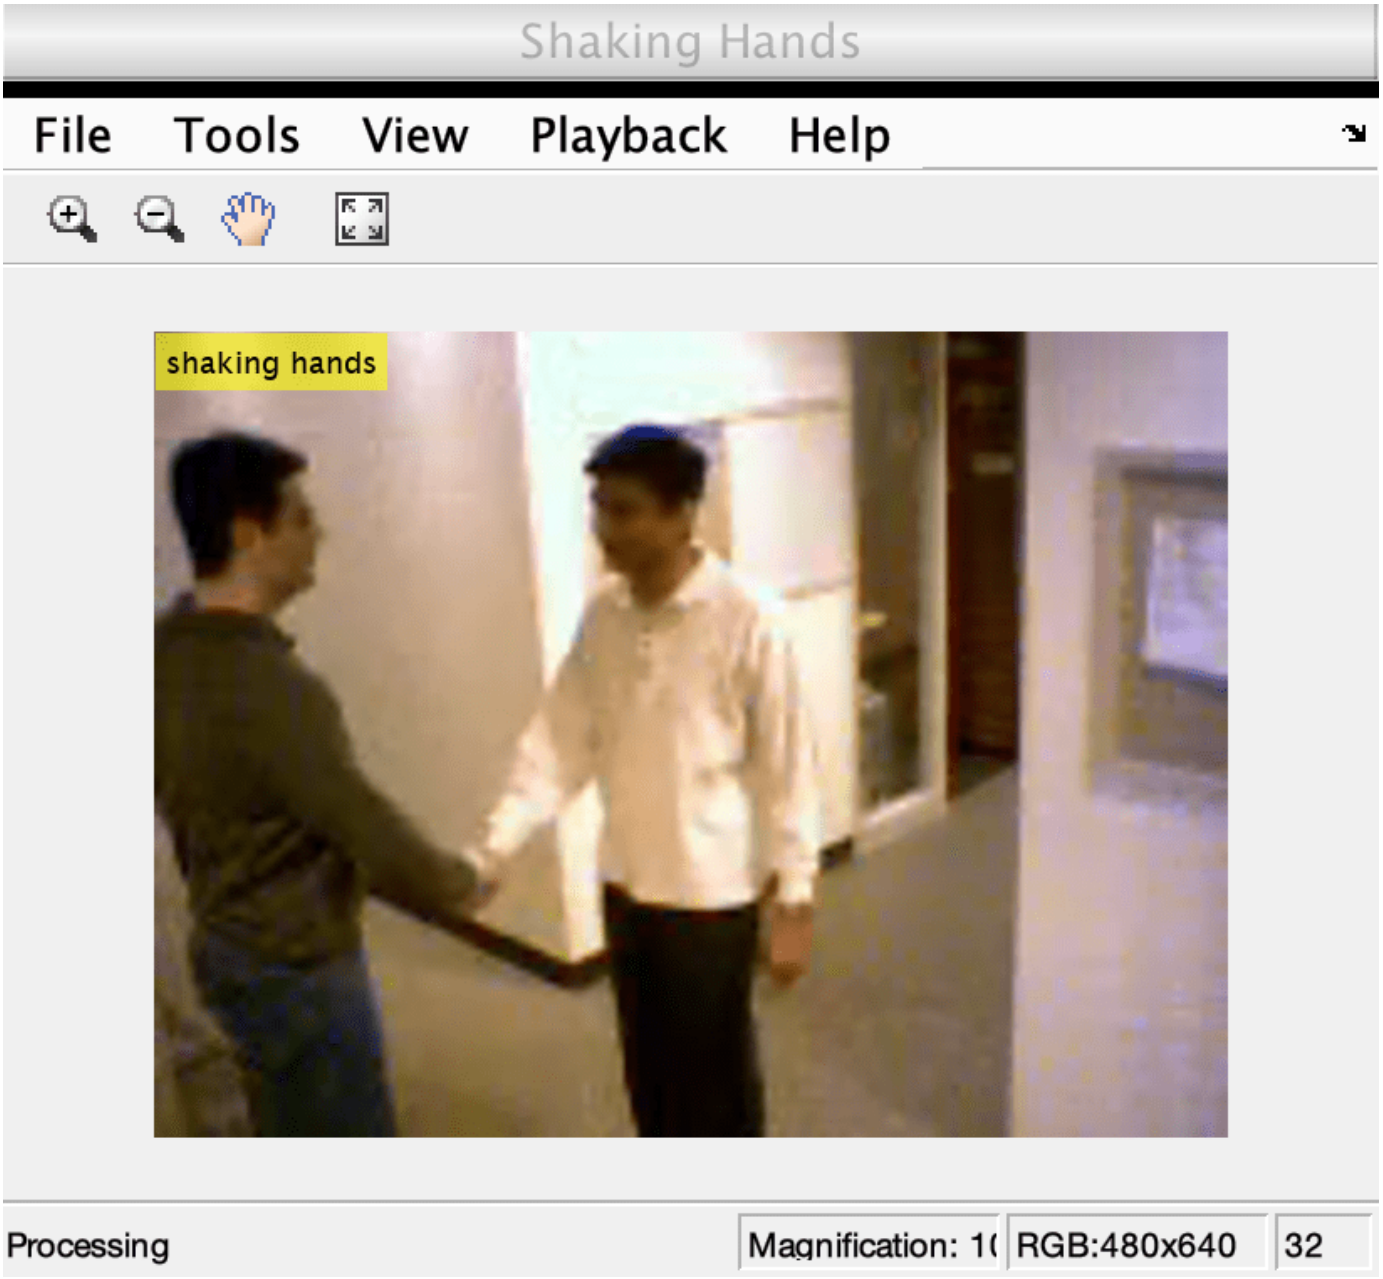
Read a video sequence starting from the 131st frame, where the `"shaking hands"` action begins.

```
startSequenceIndex = 131;
sequenceRange = [startSequenceIndex, startSequenceIndex + sequenceLength - 1];
```

Classify the second video sequence.

```
for ii = sequenceRange
    videoFrame = read(reader,ii);
    sf = updateSequence(sf,frame);
end

[label2, score2] = classifySequence(sf)
```



```
label2 = categorical
     shaking hands

score2 = single

0.0039
```

Display the classified label.

```
player = vision.VideoPlayer('Name','Shaking Hands');
for ii = sequenceRange
    frame = read(reader,ii);
    % Resize the frame by 4 times for display
    frame = imresize(frame, 4);
    frame = insertText(frame,[2,2], string(label2),'FontSize',18);
    step(player,frame);
end
```

Input Arguments

`classifier` — Classifier
`r2plus1dVideoClassifier` object | `slowFastVideoClassifier` object

Classifier, specified as a `r2plus1dVideoClassifier` or `slowFastVideoClassifier` object.

Output Arguments

`classifierReset` — Reset video classifier
`r2plus1dVideoClassifier` object | `slowFastVideoClassifier` object

Reset video classifier, returned as a `r2plus1dVideoClassifier` or `slowFastVideoClassifier` object.

updateSequence, updateSequence

Update video sequence for classification

Syntax

```
classifierUpdated = updateSequence(classifier,videoFrame)
classifierUpdated = updateSequence(classifier,
videoFrame,ExecutionEnvironment=env)
```

Description

`classifierUpdated = updateSequence(classifier,videoFrame)` updates the video sequence with the video frame `videoFrame`, and outputs an updated classifier. The output contains the updated classifier object.

To classify the updated sequence, use the `classifySequence` object function.

The video classifier object maintains the sequence as a first-in first-out (FIFO) queue. The `InputSize` property of the classifier object specifies the number of frames in the queue.

`classifierUpdated = updateSequence(classifier,
videoFrame,ExecutionEnvironment=env)` specifies the hardware resources for running the classifier in addition to any combination of arguments from previous syntaxes, as one of these options:

- `"auto"` — Sets the execution environment to the GPU, if available. Otherwise the function sets it to the CPU.
- `"gpu"` — Sets the execution environment to the GPU. Usage of the GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Sets the execution environment to the CPU.

Examples

Classify Video Sequences in a Video File

This example shows how to classify video sequences in a video file using a SlowFast Video Classifier pretrained on the Kinetics-400 video activity recognition dataset. To learn more about how to train a video classifier network for your dataset, see “Gesture Recognition using Videos and Deep Learning”.

Load SlowFast Video Classifier

```
sf = slowFastVideoClassifier();
```

Set Up Video Player and Video Reader

Specify the video file name to stream video frames.

```
videoFilename = "pushup.mp4";
```

Create a VideoReader to read video.

```
reader = VideoReader(videoFilename);
```

Set up a video player.

```
player = vision.VideoPlayer;
```

Classify Video Sequences

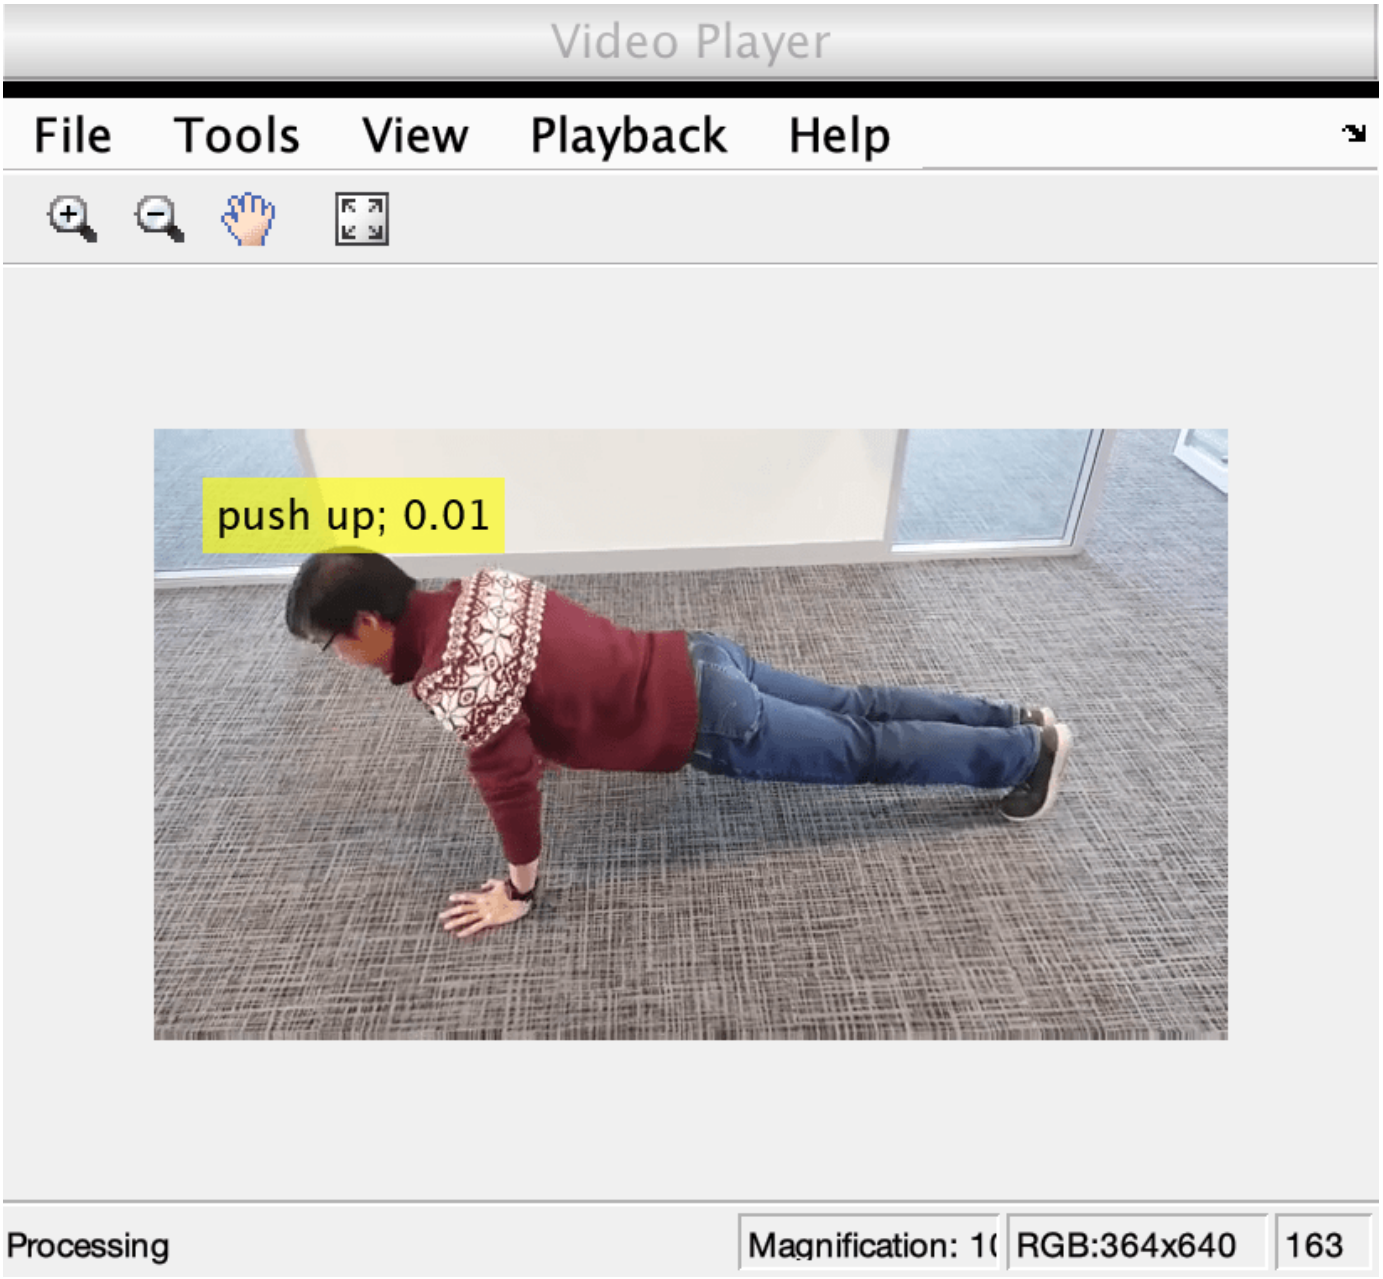
Specify how frequently the classifier should be applied to incoming video frames.

```
classifyInterval = 10;
```

A value of 10 balances runtime performance against classification performance. Increase this value to improve runtime performance at the cost of missing actions from the video file.

Obtain the sequence length of the SlowFast Video Classifier. Classify only after capturing at least `sequenceLength` number of frames from the video file.

```
sequenceLength = sf.InputSize(4);
```



Read video frames using the `hasFrame` and `readFrame` functions of the `VideoReader`. Using the `updateSequence` function update the video classifier's sequence. Using the `classifySequence` function classify the updated sequence.

```
numFrames = 0;
text = "";

while hasFrame(reader)
    frame = readFrame(reader);
    numFrames = numFrames + 1;

    % Update the sequence with the next video frame.
    sf = updateSequence(sf,frame);

    % Classify the sequence only at every classifyInterval number of frames.
    if mod(numFrames, classifyInterval) == 0 && numFrames >= sequenceLength
        [label,score] = classifySequence(sf);
        text = string(label) + "; " + num2str(score, "%0.2f");
    end
    frame = insertText(frame,[30,30],text,'FontSize',24);
    step(player,frame);
end
```

Input Arguments

`classifier` — Classifier object
`r2plus1dVideoClassifier` object | `slowFastVideoClassifier` object

Classifier object, specified as `r2plus1dVideoClassifier` or `slowFastVideoClassifier` object.

`videoFrame` — Video frame
numeric array

Video frame for updating the classifier, specified as an *H*-by-*W*-by-*C* numeric array. *H*, *W*, and *C* represent the height, width, and number of channels, respectively. The number of channels must match the number of channels set by the `InputSize` property of the classifier object.

Output Arguments

`classifierUpdated` — Updated video classifier
`r2plus1dVideoClassifier` object | `slowFastVideoClassifier` object

Updated video classifier, returned as a `r2plus1dVideoClassifier` or `slowFastVideoClassifier` object.

Version History

Introduced in R2021b

updateSequence

Update video or optical flow sequence for classification

Syntax

```
i3dUpdated = updateSequence(i3d,videoFrame)
i3dUpdated = udpateSequence(i3d,videoFrame,ExecutionEnvironment=env)
```

Description

`i3dUpdated = updateSequence(i3d,videoFrame)` updates the video or optical flow sequence with the video frame `videoFrame`, and outputs the updated Inflated-3D (I3D) video classifier `i3d` classifier. The output contains the updated classifier object.

To classify the updated sequence, use the `classifySequence` object function.

The video classifier object maintains the sequence as a first-in first-out (FIFO) queue. The `InputSize` property of the classifier object specifies the number of frames in the queue.

`i3dUpdated = udpateSequence(i3d,videoFrame,ExecutionEnvironment=env)` specifies the hardware resources for running the classifier in addition to any combination of arguments from previous syntaxes, as one of these options:

- `"auto"` — Sets the execution environment to the GPU, if available. Otherwise the function sets it to the CPU.
- `"gpu"` — Sets the execution environment to the GPU. Usage of the GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Sets the execution environment to the CPU.

Examples

Classify Video Sequences in a Video File

This example shows how to classify video sequences in a video file using a SlowFast Video Classifier pretrained on the Kinetics-400 video activity recognition dataset. To learn more about how to train a video classifier network for your dataset, see “Gesture Recognition using Videos and Deep Learning”.

Load SlowFast Video Classifier

```
sf = slowFastVideoClassifier();
```

Set Up Video Player and Video Reader

Specify the video file name to stream video frames.

```
videoFilename = "pushup.mp4";
```

Create a VideoReader to read video.

```
reader = VideoReader(videoFilename);
```

Set up a video player.

```
player = vision.VideoPlayer;
```

Classify Video Sequences

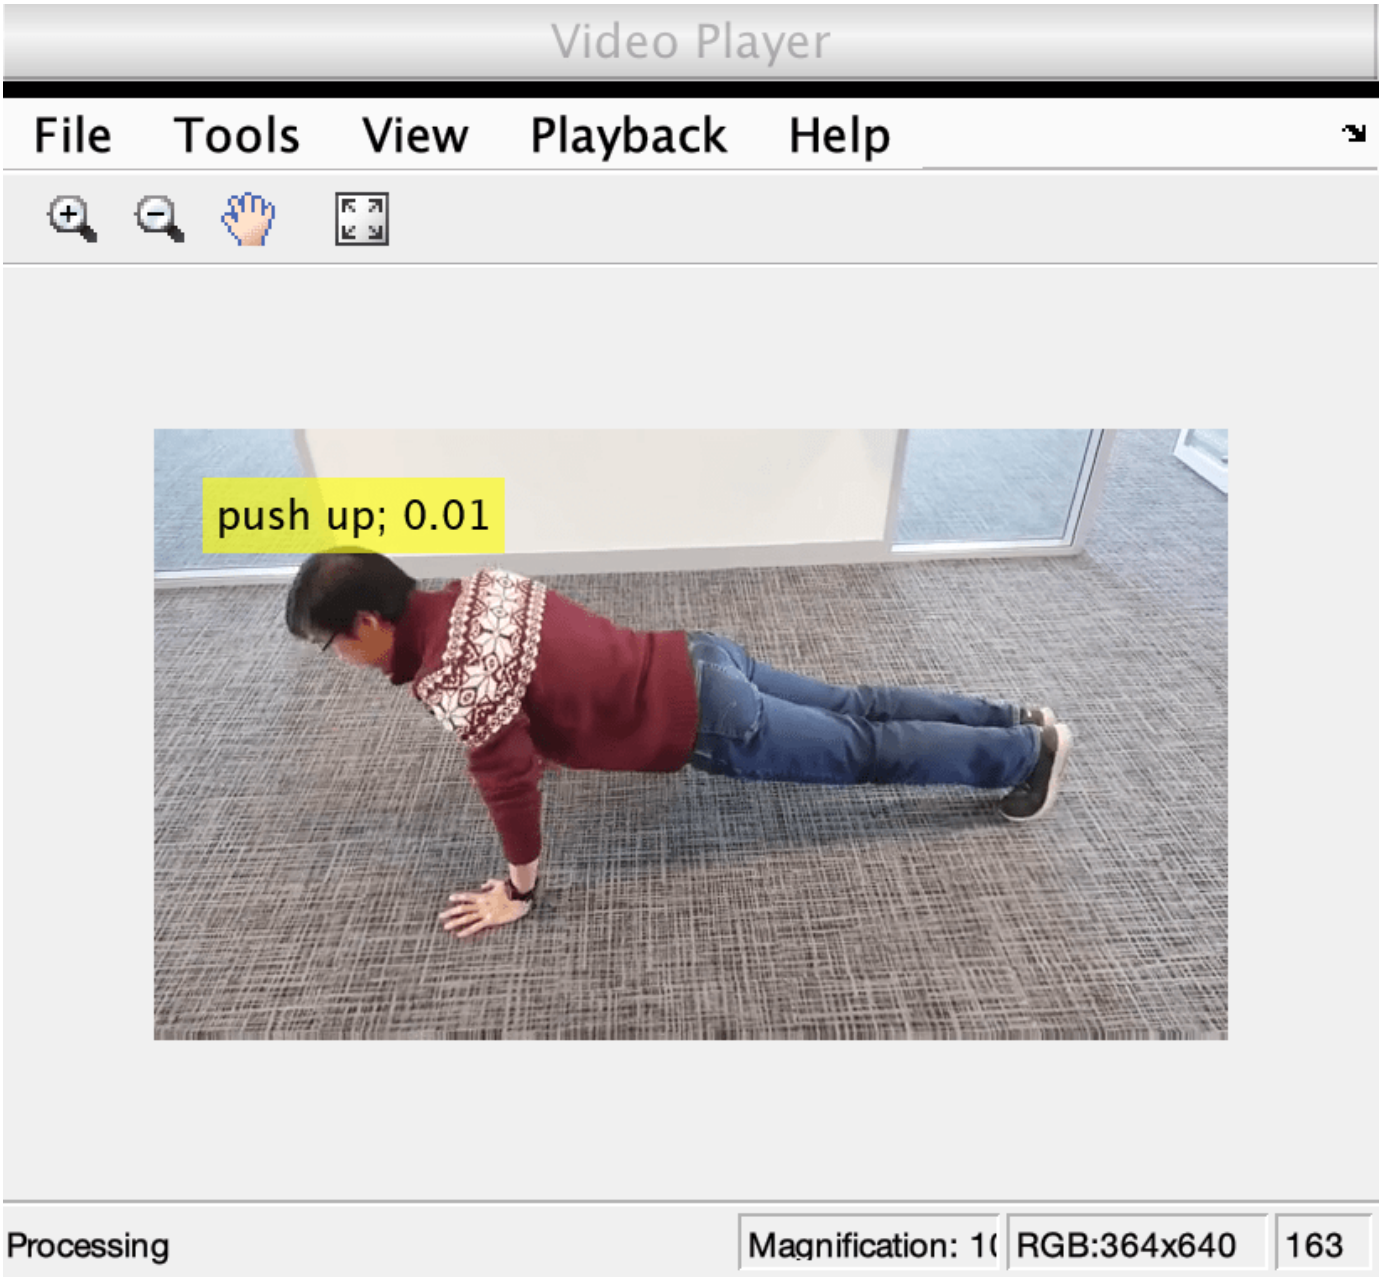
Specify how frequently the classifier should be applied to incoming video frames.

```
classifyInterval = 10;
```

A value of 10 balances runtime performance against classification performance. Increase this value to improve runtime performance at the cost of missing actions from the video file.

Obtain the sequence length of the SlowFast Video Classifier. Classify only after capturing at least `sequenceLength` number of frames from the video file.

```
sequenceLength = sf.InputSize(4);
```



Read video frames using the `hasFrame` and `readFrame` functions of the `VideoReader`. Using the `updateSequence` function update the video classifier's sequence. Using the `classifySequence` function classify the updated sequence.

```
numFrames = 0;
text = "";

while hasFrame(reader)
    frame = readFrame(reader);
    numFrames = numFrames + 1;

    % Update the sequence with the next video frame.
    sf = updateSequence(sf,frame);

    % Classify the sequence only at every classifyInterval number of frames.
    if mod(numFrames, classifyInterval) == 0 && numFrames >= sequenceLength
        [label,score] = classifySequence(sf);
        text = string(label) + "; " + num2str(score, "%0.2f");
    end
    frame = insertText(frame,[30,30],text,'FontSize',24);
    step(player,frame);
end
```

Input Arguments

`i3d` — Classifier
`inflated3dVideoClassifier` object

Classifier, specified as an `inflated3dVideoClassifier` object.

`videoFrame` — Video frame
numeric array

Video frame for updating the classifier, specified as an *H*-by-*W*-by-*C* numeric array. *H*, *W*, and *C* represent the height, width, and number of channels, respectively. The number of channels must match the number of channels set by the `InputSize` property of the classifier object.

Output Arguments

`i3dUpdated` — Updated video classifier
`inflated3dVideoClassifier` object

Updated video classifier, returned as an `inflated3dVideoClassifier` object.

vision.calibration.PatternDetector Class

Namespace: `vision.calibration`

Interface for defining custom planar pattern detectors

Description

The `vision.calibration.PatternDetector` class specifies the interface for defining custom planar pattern detectors for the Camera Calibrator and Stereo Camera Calibrator apps, as well as on the MATLAB command line.

To define a custom pattern detector, you must construct a class that inherits from the `vision.OpenPatternDetectorTemplate` class. This is an abstract class that defines the methods and properties for detecting calibration pattern keypoints in the images, invoked during the calibration process, and to generate corresponding points in the world coordinates.

You can define a custom pattern detector for single camera calibration, starting with a template, by typing this command at the MATLAB prompt:

```
vision.OpenPatternDetectorTemplate("monocular")
```

You can define a custom pattern detector for stereo camera calibration, starting with a template, by typing the following at the MATLAB prompt:

```
vision.OpenPatternDetectorTemplate("stereo")
```

The `vision.calibration.PatternDetector` class is a `handle` class.

Class Attributes

`Abstract`	`true`

For information on class attributes, see “Class Attributes”.

Properties

Clients of the `PatternDetector` class specify these predefined properties.

`Name` — Pattern detector name
character vector | string scalar

Pattern detector name, specified as a character vector or a string scalar.

`WorldUnits` — World point units
character vector | string scalar

World point units, specified as a character vector or a string scalar. `WorldUnits` specifies the unit of measure for the pattern keypoints in world coordinates.

`Panel` — Properties panel user-defined UI components
`uipanel` object

Properties panel user-defined UI components for displaying and specifying detector properties, specified as a `uipanel` object. To set this property, use the `propertiesPanel` function with a `uipanel` object, which the `PatternDetector` invokes.

Methods

Public Methods

Clients of a `PatternDetector` implement these user-defined functions to define execution of the algorithm. For more information on creating a custom detection pattern, see “Camera Calibration Using Custom Planar Calibration Patterns”.

generateWorldPoints	Generate world coordinates for keypoints of custom planar pattern
propertiesPanel	Define properties panel for custom pattern detector
drawImageAxesLabels	Display location and orientation of axes labels
detectPatternPoints	Detect calibration pattern keypoints in images containing custom patterns

Version History

Introduced in R2021b

propertiesPanel

Namespace: `vision.calibration`

Define properties panel for custom pattern detector

Syntax

```
propertiesPanel(detectorObj,panel)
```

Description

`propertiesPanel(detectorObj,panel)` displays properties contained in the detector object `detecterObj` in the parent user interface (UI) panel `panel`.

The Camera Calibrator or the Stereo Camera Calibrator app invokes the `propertiesPanel` object function when you select a custom pattern from one of the available patterns. Use this object function to define UI elements in the **Properties** section of the Image and Pattern Properties dialog box of the Camera Calibrator or the **Load Stereo Images** dialog box of the Stereo Camera Calibrator app.

Examples

Custom Pattern Properties Panel for Camera Calibrator

The `propertiesPanel` function enables you to customize the properties panel of a calibrator app by creating UI elements and defining their behavior. This `propertiesPanel` code snippet creates a properties panel related to a checkerboard detection:

```
function propertiesPanel(this,panel)
  %-------------------------------------------------------------
  % UI components for square size selector
  %-------------------------------------------------------------
  this.Panel = panel;

  % Label
      position = [90, 40, 185, 20];
      labelText = 'Square Size (in millimeters): ';
      uicontrol('Parent',this.Panel,'Style','text','FontUnits', ...
                'pixels',FontSize', 12,'Position',position, ...
                'HorizontalAlignment','left','String',labelText);

  % Editbox
      position = [275, 37, 50, 25];
      initSquareSize = 25;
      squareSizeEditBox = uicontrol('Parent',this.Panel, ...
                 'Style','edit','FontUnits','pixels','FontSize',15, ...
                 'String',initSquareSize,'Position', position, ...
                 'Callback',@(~, ~) doSquareSizeChanged(this));

  % Initialize property values
      this.SquareSize = str2double(get(squareSizeEditBox,'String'));
```

```
end

%-------------------------------------------------------------------------
function doSquareSizeChanged(this)
   this.SquareSize = str2double(get(this.SquareSizeEditBox,'String'));

   if this.SquareSize <= 0 || isnan(this.SquareSize)
      errordlg('Square size must be a numeric value greater than zero.');
   end
end
```

This function produces this UI pane:

Input Arguments

`detectorObj` — Detector object

`vision.calibration.PatternDetector` object

Detector object, specified as a single or stereo `vision.calibration.PatternDetector` object.

`panel` — User-defined UI components

`uipanel` object

User-defined UI components for displaying and specifying detector properties, specified as a `uipanel` object. When you invoke the `propertiesPanel` function with a `uipanel` object.

drawImageAxesLabels

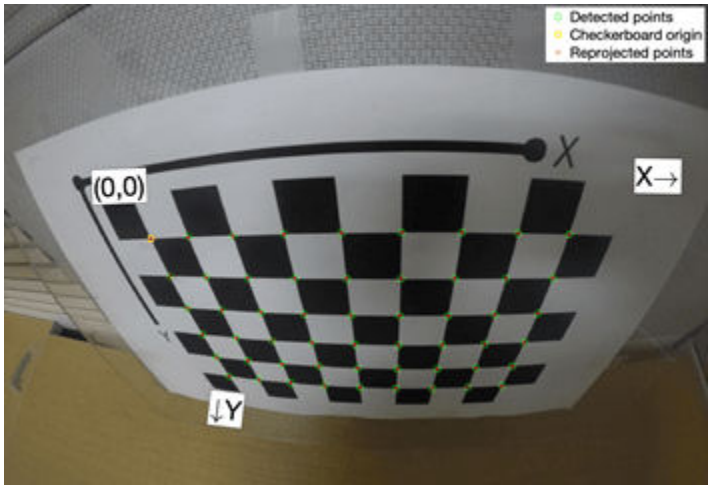
Namespace: `vision.calibration`

Display location and orientation of axes labels

Syntax

```
[originLabel,xLabel,yLabel] = drawImageAxesLabels(detectorObj,imagePoints)
```

Description



`[originLabel,xLabel,yLabel] = drawImageAxesLabels(detectorObj,imagePoints)` displays the orientation and location of the origin `originLabel` and the *X*- and *Y*-axis labels `xLabel` and `yLabel` of the circle grid pattern detected in the images rendered in the Camera Calibrator and Stereo Camera Calibrator apps.

If you do not implement this function, or if the returned values are empty, then the function does not render origin or axes labels in the image.

Examples

Label Image in Calibrator App

Use the `drawImageAxesLabels` function to identify and label the orientation and location for the origin and the *X*- and *Y*-axis labels of a detected pattern grid in an image. For example:

Calculate Orientation and Location for Pattern Origin

Use this function template, which includes the use of the `drawImageAxesLabels` object function, to calculate the orientation and location of the origin of the detected calibration pattern in an image.

The function omits the *X*- and *Y*-labels. The function includes both programmatic and app workflows for detecting the points.

```
function [originLabel,xLabel,yLabel] = drawImageAxesLabels(this,imagePoints)

    numBoardRows = this.BoardSize(1) - 1;
    numBoardCols = this.BoardSize(2) - 1;

    % Reshape checkerboard corners to boardSize-shaped array
    boardCoordsX = reshape(imagePoints(:,1),[numBoardRows numBoardCols]);
    boardCoordsY = reshape(imagePoints(:,2),[numBoardRows numBoardCols]);
    boardCoords = cat(3,boardCoordsX,boardCoordsY);

    % Origin label (check if the origin location is inside the image)
    if ~isnan(boardCoordsX(1,1))
        p1 = boardCoords(1,1,:);

        refPointIdx = find(~isnan(boardCoordsX(:,1)),2);
        p2 = boardCoords(refPointIdx(2),1,:);

        refPointIdx = find(~isnan(boardCoordsX(1,:)),2);
        p3 = boardCoords(1,refPointIdx(2),:);

        [loc, theta] = getAxesLabelPosition(p1,p2,p3);

        originLabel.Location = loc;
        originLabel.Orientation = theta;
    else
        originLabel = struct;
    end

    % X-axis and Y-axis labels
    xLabel = struct('Orientation',[],'Location',[]);
    yLabel = struct('Orientation',[],'Location',[]);

    %-------------------------------------------------------------
    % p1+v
    %  \
    %   \     v1
    %    p1 ------ p2
    %    |
    % v2 |
    %    |
    %    p3
    function [loc, theta] = getAxesLabelPosition(p1,p2,p3)
        v1 = p3 - p1;
        theta = -atan2d(v1(2),v1(1));

        v2 = p2 - p1;
        v = -v1 - v2;
        d = hypot(v(1),v(2));
        minDist = 40;
        if d < minDist
            v = (v/d) * minDist;
        end
        loc = p1 + v;
    end
end
```

Input Arguments

`detectorObj` — Detector object
`vision.calibration.PatternDetector` object

Detector object, specified as a single or stereo `vision.calibration.PatternDetector` object.

`imagePoints` — Image coordinates of detected circle grid
M-by-2 array

Image coordinates of the detected circle grid, returned as an *M*-by-2 array of *x*,*y* coordinates.

Output Arguments

`originLabel` — Orientation and location for pattern origin label
`structure`

Orientation and location of the pattern origin label, returned as a structure with two fields. The `Orientation` field contains the rotation of the origin label in the image frame, specified in degrees. The `Location` field contains the *x*,*y* location of the origin label in the image frame.

`xLabel` — Orientation and location of *X*-axis label
`structure`

Orientation and location of the *X*-axis label, returned as a structure with two fields. The `Orientation` field contains the rotation of the axis label in the image frame, specified in degrees. The `Location` field contains the *x*,*y* location of the axis label in the image frame.

`yLabel` — Orientation and location for *Y*- axis label
`structure`

Orientation and location of the *Y*-axis label, returned as a structure with two fields. The `Orientation` field contains the rotation of the axis label in the image frame, specified in degrees. The `Location` field contains the *x*,*y* location of the axis label in the image frame.

generateWorldPoints

Namespace: `vision.calibration`

Generate world coordinates for keypoints of custom planar pattern

Syntax

```
worldPoints = generateWorldPoints(detectorObj)
worldPoints = generateWorldPoints(detectorObj,varargin)
```

Description

`worldPoints = generateWorldPoints(detectorObj)` generates world coordinates for the detected keypoints of the custom planar calibration pattern.

`worldPoints = generateWorldPoints(detectorObj,varargin)` uses the `varargin` input to parse any additional parameters or options necessary to generate world points. For example, you can provide the parameters or options obtained from the properties pane of your calibrator app.

Examples

Generate World Points for Checkerboard Pattern

Use this function template, which includes the use of the `generateCheckerboardPoints` object function, to generate world points for a checkerboard pattern generator. The function includes both programmatic and app workflows for generating the world (image) points. The function uses name-value arguments for board and square size to set the corresponding fields in the **Properties** pane of the calibrator app.

```
function worldPoints = generateWorldPoints(this,varargin)

    if nargin > 1 % Command Line workflow
        parser = inputParser;
        parser.addParameter('SquareSize',25,@checkSquareSize);
        parser.addParameter('BoardSize',this.BoardSize,@checkBoardSize);
        parser.parse(varargin{:});

        boardSize = parser.Results.BoardSize;
        squareSize = parser.Results.SquareSize;
    else % Calibrator App workflow
        boardSize = this.BoardSize;
        squareSize = this.SquareSize;
    end

    worldPoints = generateCheckerboardPoints(boardSize,squareSize);

    %-----------------------------------------------------------------
    % Validation functions for command line workflow
    %-----------------------------------------------------------------
    function tf = checkSquareSize(squareSize)
```

```
            validateattributes(squareSize, {'numeric'}, ...
                {'scalar','positive','finite','nonsparse'},mfilename,'SquareSize');
            tf = true;
        end

        %-------------------------------------------------------------
        function tf = checkBoardSize(boardSize)
            validateattributes(boardSize,{'numeric'},...
                {'nonempty','vector','numel',2,'integer','positive','>=', 3},...
                mfilename,'BoardSize');
            tf = true;
        end
    end
```

Input Arguments

`detectorObj` — Pattern detector

`vision.calibration.PatternDetector` object.

Pattern detector, specified as a single or stereo `vision.calibration.PatternDetector` object.

`varargin` — Variable number of inputs

1-by-*N* cell array

Variable number of inputs, specified as a 1-by-*N* cell array, where *N* is the number of inputs to the function after `detectorObj`. For more details about using this input, see `varargin`.

Output Arguments

`worldPoints` — Image coordinates of detected key points

M-by-2 array

Image coordinates of detected keypoints in the calibration pattern, returned as an *M*-by-2 array of *x*,*y* coordinates. *M* is the number of pattern keypoints detected in the calibration images by using the `detectPatternPoints` function.

detectPatternPoints

Namespace: `vision.calibration`

Detect calibration pattern keypoints in images containing custom patterns

Syntax

```
[imagePoints,imagesUsed] = detectPatternPoints(detectorObj,imageFileNames)
[imagePoints,pairsUsed] = detectPatternPoints(detectorObj,imageFileNames1,
imageFileNames2)

[___] = detectPatternPoints(___,varargin)
```

Description

`[imagePoints,imagesUsed] = detectPatternPoints(detectorObj,imageFileNames)` detects the calibration pattern keypoints in the image files, specified by `imageFileNames`. The function also indicates in which of the images it detects the calibration pattern.

`[imagePoints,pairsUsed] = detectPatternPoints(detectorObj,imageFileNames1, imageFileNames2)` detects the calibration pattern keypoints in the stereo pairs of image files specified in `imageFileNames1` and `imageFileNames2`. The function also indicates in which of the image pairs it detects the calibration pattern.

`[___] = detectPatternPoints(___,varargin)` parses any parameters or options needed for detection. For example, you can provide the parameters or options obtained from the properties panel of your calibrator app while using it from the command line.

Examples

Detect Pattern Points for a Checkerboard Pattern

Use this function template, which includes the use of the `detectPatternPoints` object function, to detect the keypoints of a calibration pattern. The function includes both programmatic and app workflows for detecting the points.

```
function [imagePoints,imagesUsed] = detectPatternPoints(this,imageFileNames,varargin)
    parser = inputParser;
    parser.addParameter('HighDistortion',false,@checkHighDistortion);
    parser.parse(varargin{:});
    highDistortion = parser.Results.HighDistortion;

    % Use 'IsDistortionHigh' member value when the default value is
    % being used for HighDistortion
    if ismember('HighDistortion',parser.UsingDefaults)
       highDistortion = this.IsDistortionHigh;
    end

    [imagePoints,boardSize,imagesUsed] = detectCheckerboardPoints( ...
        imageFileNames,HighDistortion=highDistortion);
```

```
    this.BoardSize = boardSize;

    %-------------------------------------------------------------
    function tf = checkHighDistortion(highDistortion)
        validateattributes(highDistortion,{'logical','numeric'}, ...
            {'scalar','binary'},mfilename,'HighDistortion');
        tf = true;
    end
end
```

Input Arguments

`detectorObj` — Detector object

`vision.calibration.PatternDetector` object

Detector object, specified as a single or stereo `vision.calibration.PatternDetector` object.

`imageFileNames` — Image file names

cell array of character vectors | vector of strings

Image file names, specified as a cell array of character vectors or a vector of strings.

`imageFileNames1` — Stereo image file names for camera one

cell array of character vectors | array of string vectors

Stereo image file names for camera one, specified as a cell array of character vectors or an array of strings.

`imageFileNames2` — Stereo image file names for camera two

cell array of character vectors | array of string vectors

Stereo image file names for camera two, specified as a cell array of character vectors or an array of strings.

`varargin` — Variable number of inputs

1-by-*N* cell array

Variable number of inputs, specified as a 1-by-*N* cell array, where *N* is the number of inputs to the function receives after the explicitly declared inputs. For more details about using this input, see `varargin`.

Output Arguments

`imagePoints` — Image coordinates of detected pattern keypoints

M-by-2- by-*numImages* | *M*-by-2-by-*numPairs*-by-2 array

Image *x*-*y* coordinates of detected pattern keypoints, returned as an *M*-by-2-by-*numImages* array for single camera calibration or an *M*-by-2-by-*numPairs*-by-2 array for stereo camera calibration. *numImages* is the number of images in which a circle grid is detected. *numPairs* is the number of image pairs in which a circle grid is detected. For stereo images, `imagePoints(:,:,:,1)` returns the pattern keypoints from the first set of images, and `imagePoints(:,:,:,2)` returns the pattern keypoints from the second set of images. If the function cannot detect the complete pattern, then it returns a partially detected pattern with `[NaN,NaN]` for those *x*-*y* coordinates that could not be detected.

`imagesUsed` — Pattern detection flag
logical vector

Pattern detection flag, returned as a logical vector. A value of `true` for an element of the `imagesUsed` vector indicates that the function has detected the pattern in the corresponding image.

`pairsUsed` — Stereo pair pattern detection flag
logical vector

Stereo pair pattern detection flag, returned as a logical vector. A value of `true` for an element of the `pairsUsed` vector indicates that the function has detected the pattern in the corresponding image pair.

scanContextLoopDetector

Detect loop closures using scan context descriptors

Description

`scanContextLoopDetector` detects loop closures in point cloud data using global scan context descriptors. A scan context descriptor encodes a point cloud view into a 2-D descriptor. `scanContextLoopDetector` stores the descriptors with a corresponding view identifier to associate the detected loop closures to a view in a `pcviewset` for map building.

Creation

Syntax

```
loopDetector = scanContextLoopDetector()
```

Description

`loopDetector = scanContextLoopDetector()` creates a default `scanContextLoopDetector` object. Use the `addDescriptor` object function to add descriptors to the loop detector. Use the `detectLoop` object function to detect loop closures.

Properties

`ViewIds` — View identifiers
P-element vector

This property is read-only.

View identifiers, specified as a *P*-element vector of unique positive integers, where *P* is the number of descriptors added to the detector.

`Descriptors` — Scan context descriptors
M-by-*N*-by-*P* array

This property is read-only.

Scan context descriptors, specified as an *M*-by-*N*-by-*P* array. *M* is the number of radial bins and *N* is the number of azimuthal bins in the descriptor. *P* is the number of descriptors in the detector.

Object Functions

addDescriptor	Add descriptor to the loop closure detector
deleteDescriptor	Delete descriptors from the loop closure detector
detectLoop	Detect loop closures

Examples

Detect Loop Closure Against Recently Added Descriptor

Create a loop closure detector.

```
loopDetector = scanContextLoopDetector;
```

Create a Velodyne® PCAP file reader.

```
veloReader = velodyneFileReader('lidarData_ConstructionRoad.pcap','HDL32E');
```

Read the point clouds and extract the scan context descriptor from each point cloud scan. Add the descriptors to the detector.

```
for viewId = 1:10
    ptCloud = readFrame(veloReader,viewId);
    descriptor = scanContextDescriptor(ptCloud);
    addDescriptor(loopDetector,viewId,descriptor);
end
```

Check if the next point cloud can be classified as a loop closure detection without excluding any recently added descriptors.

```
viewId = viewId + 1;
ptCloud = readFrame(veloReader,viewId);
descriptor = scanContextDescriptor(ptCloud);
[loopViewId,dists] = detectLoop(loopDetector,descriptor,'NumExcludedDescriptors',0)
```

```
loopViewId = uint32

10

dists = single

0.0858
```

addDescriptor

Add descriptor to the loop closure detector

Syntax

```
addDescriptor(loopDetector,viewID,descriptor)
```

Description

`addDescriptor(loopDetector,viewID,descriptor)` adds the scan context descriptor `descriptor` that corresponds to the view identifier `viewID` to the loop closure detector `loopDetector`.

Compute descriptors to add to the loop closure detector over the same radial range, with the same number of radial and azimuthal bins. Use the `viewID` input to associate descriptors with a view in `pcviewset`.

Examples

Add Descriptor to Loop Closure Detector

Create a loop closure detector.

```
loopDetector = scanContextLoopDetector;
```

Load point cloud data into the workspace.

```
data = load("drivingLidarPoints.mat");
ptCloud = data.ptCloud;
```

Extract a scan context descriptor from the point cloud data.

```
descriptor = scanContextDescriptor(ptCloud);
```

Add the descriptor to the loop closure detector.

```
viewId = 1;
addDescriptor(loopDetector,viewId,descriptor);
```

Input Arguments

`loopDetector` — Loop closure detector
`scanContextLoopDetector` object

Loop closure detector, specified as a `scanContextLoopDetector` object.

`viewID` — View identifier
positive integer

View identifier, specified as a positive integer. You can use the same `viewID` to associate descriptors with a view in a `pcviewset`.

`descriptor` — Scan context descriptor
M-by-*N* matrix

Scan context descriptor, specified as an *M*-by-*N* matrix, where *M* is the number of radial bins and *N* is the number of azimuthal bins.

deleteDescriptor

Delete descriptors from the loop closure detector

Syntax

```
deleteDescriptor(loopDetector,viewIDs)
```

Description

`deleteDescriptor(loopDetector,viewIDs)` deletes the descriptors that correspond to the view identifiers `viewIDs` from the loop closure detector `loopDetector`. `viewIDs` is a vector of positive integers.

Examples

Delete Descriptor from Loop Closure Detector

Create a loop closure detector.

```
loopDetector = scanContextLoopDetector;
```

Create a Velodyne® PCAP file reader.

```
veloReader = velodyneFileReader('lidarData_ConstructionRoad.pcap','HDL32E');
```

Read the first and second point cloud scans.

```
ptCloud1 = readFrame(veloReader,1);
ptCloud2 = readFrame(veloReader,2);
```

Extract the descriptor for the first point cloud and add it to the loop closure detector.

```
viewId1 = 1;
descriptor1 = scanContextDescriptor(ptCloud1);
addDescriptor(loopDetector,viewId1,descriptor1);
```

Extract the second descriptor and add it to the loop closure detector.

```
viewId2 = 2;
descriptor2 = scanContextDescriptor(ptCloud2);
addDescriptor(loopDetector,viewId2,descriptor2);
```

Delete the descriptor that corresponds to view identifier `2`, from the detector.

```
deleteDescriptor(loopDetector,viewId2);
```

Input Arguments

`loopDetector` — Loop closure detector
`scanContextLoopDetector` object

Loop closure detector, specified as a `scanContextLoopDetector` object.

`viewIDs` — View identifiers
vector of integers

View identifiers, specified as a vector of positive integers.

detectLoop

Detect loop closures

Syntax

```
loopViewIds = detectLoop(loopDetector)
loopViewIds = detectLoop(loopDetector,descriptor)
[loopViewIds,dists] = detectLoop( ___ )
[ ___ ] = detectLoop( ___ ,Name=Value)
```

Description

`loopViewIds = detectLoop(loopDetector)` detects loop closures for the last added descriptor and returns the view identifiers `loopViewIds` that correspond to loop closures. If the function detects no loop closures, `loopViewIds` is empty. The loop closure detector ignores the number of most recently added descriptors, set by the `NumExcludedDescriptors` name-value argument, to avoid detecting loop closures against recent descriptors.

`loopViewIds = detectLoop(loopDetector,descriptor)` detects loop closures using the scan context descriptor `descriptor`.

`[loopViewIds,dists] = detectLoop( ___ )` returns the scan context distances `dists` between the loop descriptor and the query descriptors, using any combination of input arguments from previous syntaxes. The function computes distance between scan context descriptors, normalized to the range [0,1], using a modified cosine distance.

`[ ___ ] = detectLoop( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from the previous syntaxes. For example, `detectLoop(loopDetector,NumExcludedDescriptors=15)` detects loop closures for the last added descriptor while ignoring only the 15 most recently added loop descriptors.

Examples

Detect Loop Closure Against Recently Added Descriptor

Create a loop closure detector.

```
loopDetector = scanContextLoopDetector;
```

Create a Velodyne® PCAP file reader.

```
veloReader = velodyneFileReader('lidarData_ConstructionRoad.pcap','HDL32E');
```

Read the point clouds and extract the scan context descriptor from each point cloud scan. Add the descriptors to the detector.

```
for viewId = 1:10
    ptCloud = readFrame(veloReader,viewId);
    descriptor = scanContextDescriptor(ptCloud);
```

```
    addDescriptor(loopDetector,viewId,descriptor);
end
```

Check if the next point cloud can be classified as a loop closure detection without excluding any recently added descriptors.

```
viewId = viewId + 1;
ptCloud = readFrame(veloReader,viewId);
descriptor = scanContextDescriptor(ptCloud);
[loopViewId,dists] = detectLoop(loopDetector,descriptor,'NumExcludedDescriptors',0)
```

```
loopViewId = uint32

10

dists = single

0.0858
```

Input Arguments

`loopDetector` — Loop closure detector

`scanContextLoopDetector` object

Loop closure detector, specified as a `scanContextLoopDetector` object.

`descriptor` — Scan context descriptor

M-by-*N* matrix

Scan context descriptor, specified as an *M*-by-*N* matrix, where *M* is the number of radial bins and *N* is the number of azimuthal bins.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `detectLoop(loopDetector,NumExcludedDescriptors=15)` detects loop closures for the last added descriptor while ignoring only the 15 most recently added loop descriptors.

`DistanceThreshold` — Scan context distance threshold

`0.1` (default) | positive scalar

Scan distance threshold to classify a view as a loop closure, specified as a positive scalar. Increasing this value can return more loop closures, but this can also increase false positives.

`NumExcludedDescriptors` — Number of most recently added descriptors to exclude

`30` (default) | nonnegative integer

Number of most recently added descriptors to exclude as loop closure candidates, specified as a nonnegative integer. Exclude the most recently added descriptors to avoid detecting loop closures for the most recently added descriptor against recent descriptors. Increase `NumExcludedDescriptors` if many consecutive descriptors correspond to the same area.

`SearchRadius` — Search radius
`0.3` (default) | positive scalar

Search radius in a subdescriptor space, specified as a positive scalar. The function computes the scan context distance for only those descriptors within the search radius. Increasing this value can return more loop closures, but can also increase false positives. Typical values range between `0.2` and `0.4`.

`MaxDetections` — Maximum number of strongest loop closure detections returned
3 (default) | positive integer

Maximum number of strongest loop closure detections returned, specified as a positive integer. Increase this value to increase the potential number of loop closure detections returned. However, increasing this value can decrease computation speed. Set this value to `Inf` to return all loop closure detections.

Output Arguments

`loopViewIds` — Loop closure view identifiers
P-element vector

Loop closure view identifiers corresponding to loop closures, returned as a *P*-element vector of integer values. If the function finds no loop closures, it returns `loopViewIds` as an empty vector. The loop closure detector ignores the last “NumExcludedDescriptors” on page 2-0 descriptors to avoid detecting loop closures against recent descriptors.

`dists` — Scan context distance
P-element vector

Scan context distances, returned as a *P*-element vector of positive values. The distances represent the scan context distance between the loop descriptor and the corresponding query descriptor. The function computes the distance between scan context descriptors, normalized to the range [0,1], using a modified cosine distance.

Algorithms

The ring key descriptor is a subdescriptor extracted from a scan context descriptor. It is the occupancy ratio of each azimuthal bin that makes it rotation-invariant.

The scan context loop closure detector is a two-phase algorithm. It first uses the ring key descriptor for a nearest neighbor search to find candidate loop closures. Then, it computes the scan context distance using the scan context descriptors, and thresholds it to identify the best loop closure detections.

SIFTPoints

Object for storing SIFT interest points

Description

The `SIFTPoints` object enables you to pass data between the `detectSIFTFeatures` and `extractFeatures` functions. You can also use it to manipulate and plot the data returned by these functions. You can use the object to fill interest points interactively.

Creation

Syntax

```
points = SIFTPoints(location)
```

Description

`points = SIFTPoints(location)` constructs a `SIFTPoints` object from an *M*-by-2 matrix of [*x y*] point coordinates in `location`.

Input Arguments

`location` — Point coordinates
M-by-2 matrix of [*x y*] point coordinates.

Point coordinates, specified as an *M*-by-2 matrix of [*x y*] point coordinates. *M* is the number of points.

Properties

`Scale` — Scale
`1.6` (default) | scalar

Scale at which the interest points are detected, specified as a value greater than `0`.

`Metric` — Strength of detected feature
`0.0` (default) | numeric scalar

Strength of the detected feature, specified as a value in the range `[0 1]`. The SIFT algorithm uses the contrast threshold to determine strong features.

`Orientation` — Orientation
`0.0` (default) | angle in radians

Orientation of the detected feature, specified as an angle, in radians. The angle is measured counterclockwise from the *X*-axis with the origin specified by the `location` input. Do not set this property manually. Instead, use the call to `extractFeatures` to fill in this value. The `extractFeatures` function modifies the default value of `0.0`.The `Orientation` is mainly useful for visualization purposes.

`Octave` — Index of the Gaussian pyramid octave layer

`0` (default) | non-negative integer

Index of the Gaussian pyramid octave layer that the keypoint is extracted from, specified as an integer. An octave is a collection of difference-of-Gaussian pyramid layers, and is used for scale-space.

`Layer` — Layer within the octave

`0` (default) | integer

Layer within the octave from which the keypoint was extracted, specified as an integer.

Object Functions

plot	Plot detected feature points
isempty	Determine if points object is empty
length	Number of stored points
selectStrongest	Select points with strongest metrics
size	Return size of points object
selectUniform	Select uniformly distributed subset of point features
select	Select point or region features during code generation

Examples

Detect SIFT Features in Image

Read an image.

```
I = imread("cameraman.tif");
```

Detect SIFT features in the image.

```
points = detectSIFTFeatures(I)
```

```
points =
  245×1 SIFTPoints array with properties:

          Scale: [245×1 single]
    Orientation: [245×1 single]
         Octave: [245×1 int32]
          Layer: [245×1 int32]
       Location: [245×2 single]
         Metric: [245×1 single]
          Count: 245
```

Display the location and scale of the 10 strongest points in the image.

```
strongest = points.selectStrongest(10);
imshow(I)
hold on
plot(strongest)
```

Display the [*x* *y*] coordinates for the selected points.

```
strongest.Location
```

```
ans = 10×2 single matrix

  183.0139  205.4790
  112.5054  206.6145
  135.2954  125.0968
  101.1768  173.8070
  131.3702  113.8461
  167.1152   77.5036
  110.9539  155.9264
  135.0020   92.3701
  112.1106  173.5276
  156.8862   77.8692
```

Detect SIFT Features and Display Points

Read an image into the workspace.

```
I = imread("cameraman.tif");
```

Detect SIFT features in the image.

```
points = detectSIFTFeatures(I);
```

Display the last 5 detected points.

```
imshow(I)
hold on
plot(points(end-4:end))
```

Tips

- Although `SIFTPoints` may hold many points, it is a scalar object. Therefore, `numel(SIFTPoints)` always returns `1`. This value may differ from `length(SIFTPoints)`, which returns the true number of points held by the object.
- Properties can be specified as a scalar or a vector whose length matches the number of coordinates in `location`.

Version History

Introduced in R2021b

pcmapndt

Localization map based on normal distributions transform (NDT)

Description

The `pcmapndt` object creates a normal distributions transform (NDT) map from a prebuilt point cloud map of the environment. The NDT map is a compressed, memory-efficient representation suitable for localization. The object converts the point cloud map into a set of voxels (3-D boxes), each represented by a 3-D normal distribution. Use the `selectSubmap` object function to select a submap within the map from a coarse position estimate. Use the `findPose` object function to localize the pose of the sensor based on the assembled map.

Creation

Syntax

```
ndtMap = pcmapndt(ptCloudMap,voxelSize)
```

Description

`ndtMap = pcmapndt(ptCloudMap,voxelSize)` returns an NDT map from a point cloud map, `ptCloudMap`.

Input Arguments

`ptCloudMap` — Point cloud map
`pointCloud` object

Point cloud map, specified as a `pointCloud` object. The `pcmapndt` object creates a normal distributions transform (NDT) map from the prebuilt map of the environment, specified by `ptCloudMap`.

`voxelSize` — Size of voxels
scalar

This property is read-only.

Size of the voxels, specified as a scalar value in world units.

Properties

`SelectedSubmap` — Currently selected submap
entire map (default) | 6-element vector

This property is read-only.

Currently selected submap, specified as a 6-element vector of the form [*xmin*,*xmax ymin ymax zmin zmax*] that describes the range of the submap along each axis. The elements of the vector describe the region of interest represented by the submap.

`VoxelSize` — Size of voxels
scalar

This property is read-only.

Size of the voxels, specified as a scalar value in world units.

`XLimits` — Range of map along *x*-axis
2-element vector

This property is read-only.

Range of the map along the *x*-axis, specified as a 2-element vector of the form [*xmin xmax*].

`YLimits` — Range of map along the *Y*-axis
2-element vector

This property is read-only.

Range of the map along the *Y*-axis, specified as a 2-element vector of the form [*ymin ymax*].

`ZLimits` — Range of map along the *z*-axis
2-element vector

This property is read-only.

Range of the map along the *z*-axis, specified as a 2-element vector of the form [*zmin zmax*].

`VoxelMean` — Mean value of each voxel
M-by-3 matrix

This property is read-only.

Mean value of each voxel, specified as an *M*-by-3 matrix. Each row of the matrix contains the [*x y z*] values for a voxel. *M* is the number of voxels.

`VoxelCovariance` — Covariance of each voxel
3-by-3-by-*M* array

This property is read-only.

Covariance of each voxel, specified as a 3-by-3-by-*M* array for *M* voxels.

`VoxelNumPoints` — Number of points in each voxel
M-by-1 vector

This property is read-only.

Number of points in each voxel, specified as an *M*-by-1 vector for *M* voxels.

Object Functions

selectSubmap	Select submap within map
isInsideSubmap	Check if query position is inside selected submap
findPose	Localize point cloud within map using normal distributions transform (NDT) algorithm
show	Visualize normal distributions transform (NDT) map

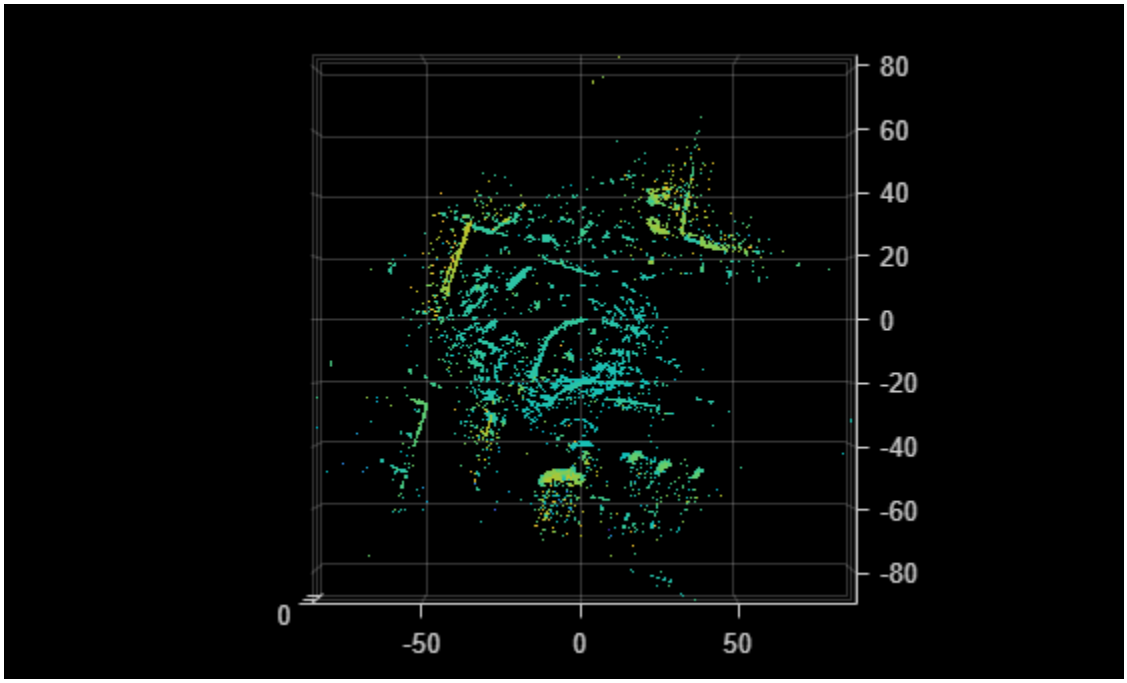
Examples

Create an NDT Map Representation

Load a point cloud view set, which was saved from a `pcviewset` object.

```
data = load('vSetPointClouds.mat');
vSet = data.vSet;
```

Extract point clouds and absolute poses to build a map.



```
ptClouds = vSet.Views.PointCloud;
tforms   = vSet.Views.AbsolutePose;
```

Create a point cloud map by aligning the point cloud scans using the absolute poses.

```
ptCloudMap = pcalign(ptClouds,tforms);
```

Create and visualize an NDT map from a point cloud map.

```
voxelSize = 1;
ndtMap = pcmapndt(ptCloudMap,voxelSize);
figure
show(ndtMap)
view(2)     % Change viewing angle to top-view
```

Lidar Localization Using NDT

Load a normal distributions transform (NDT) map from a MAT file.

```
data = load('ndtMapParkingLot.mat');
ndtMap = data.ndtMapParkingLot;
```

Load point cloud scans and pose estimates from a second MAT file.

```
data = load('parkingLotData.mat');
ptCloudScans = data.parkingLotData.ptCloudScans;
initPoseEsts = data.parkingLotData.initPoseEsts;
```

Display the NDT map.

```
show(ndtMap)
```

Change the viewing angle to top-view.

```
view(2)
```

Select the submap centered around the first estimate.

```
center = initPoseEsts(1).Translation;
sz = [70 50 20];
ndtMap = selectSubmap(ndtMap,center,sz);
```

Set the radius for visualization of the current location and the distance threshold to update the submap.

```
radius = 0.5;
distThresh = 15;
```

Loop over the point clouds, localize them in the map, and update the selected submap as needed.

```
numScans = numel(ptCloudScans);

for n = 1:numScans
    ptCloud = ptCloudScans(n);
    initPose = initPoseEsts(n);

    poseTranslation = initPose.Translation;
    [isInside,distToEdge] = isInsideSubmap(ndtMap,poseTranslation);
        submapNeedsUpdate = ~isInside ...       % Current pose is outside submap
        || any(distToEdge(1:2) < distThresh);   % Current pose is close to submap edge

if submapNeedsUpdate
    ndtMap = selectSubmap(ndtMap,poseTranslation,sz);
end

% Localize the point cloud scan in the map.
currPose = findPose(ndtMap,ptCloud,initPose);

% Display the position of the estimate as a circle.
pos = [currPose.Translation(1:2) radius];
showShape('circle',pos,'Color','r');
```

```
% Pause to view the change.
pause(0.05)
end
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- Because of architectural differences between the CPU and the GPU, there may be minor differences in results from simulation and code generation.
- In certain cases, there may be differences in the location of points in a voxel between simulation and code generation. However, the total number of points remains the same.

Functions

`selectSubmap` | `findPose` | `pcregisterndt` | `pcalign`

selectSubmap

Select submap within map

Syntax

```
ndtMapOut = selectSubmap(ndtMapIn,roi)
ndtMapOut = selectSubmap(ndtMapIn,center,sz)
```

Description

`ndtMapOut = selectSubmap(ndtMapIn,roi)` selects a submap within the NDT map `ndtMapIn` using the specified region of interest `roi`.

Use this function to confine the search space for localization when using coarse position estimates.

`ndtMapOut = selectSubmap(ndtMapIn,center,sz)` selects a submap specified by the center `center` and size `sz` of the submap.

Examples

Lidar Localization Using NDT

Load a normal distributions transform (NDT) map from a MAT file.

```
data = load('ndtMapParkingLot.mat');
ndtMap = data.ndtMapParkingLot;
```

Load point cloud scans and pose estimates from a second MAT file.

```
data = load('parkingLotData.mat');
ptCloudScans = data.parkingLotData.ptCloudScans;
initPoseEsts = data.parkingLotData.initPoseEsts;
```

Display the NDT map.

```
show(ndtMap)
```

Change the viewing angle to top-view.

```
view(2)
```

Select the submap centered around the first estimate.

```
center = initPoseEsts(1).Translation;
sz = [70 50 20];
ndtMap = selectSubmap(ndtMap,center,sz);
```

Set the radius for visualization of the current location and the distance threshold to update the submap.

```
radius = 0.5;
distThresh = 15;
```

Loop over the point clouds, localize them in the map, and update the selected submap as needed.

```
numScans = numel(ptCloudScans);

for n = 1:numScans
    ptCloud = ptCloudScans(n);
    initPose = initPoseEsts(n);

    poseTranslation = initPose.Translation;
    [isInside,distToEdge] = isInsideSubmap(ndtMap,poseTranslation);
        submapNeedsUpdate = ~isInside ...       % Current pose is outside submap
        || any(distToEdge(1:2) < distThresh);   % Current pose is close to submap edge

if submapNeedsUpdate
    ndtMap = selectSubmap(ndtMap,poseTranslation,sz);
end

% Localize the point cloud scan in the map.
currPose = findPose(ndtMap,ptCloud,initPose);

% Display the position of the estimate as a circle.
pos = [currPose.Translation(1:2) radius];
showShape('circle',pos,'Color','r');

% Pause to view the change.
pause(0.05)
end
```

Input Arguments

ndtMapIn — NDT map
`pcmapndt` object

NDT map, specified as a `pcmapndt` object.

`roi` — Region of interest
6-element vector

Region of interest, specified as a 6-element vector of the form [*xmin xmax ymin ymax zmin zmax*].

`center` — Center of submap
3-element vector

Center of the submap, specified as 3-element vector of the form [*xc yc zc*].

`sz` — Size of submap along each axis
3-element vector

Size of the submap along each axis, specified as 3-element vector of the form [*xsz ysz zsz*].

Output Arguments

`ndtMapOut` — NDT map
`pcmapndt` object

NDT map, returned as a `pcmapndt` object with an updated `SelectedSubmap` property.

If a region of the selected submap is outside of the limits of the map, the selected submap is constrained to the map limits as described by the `XLimits`, `YLimits`, and `ZLimits` properties of the `pcmapndt` object.

Tips

- Use a submap size large enough to include the uncertainty of the position estimates and the range of the sensor used with `findPose`. A larger submap can increase computation time during each call to the `findPose` function, but it can also reduce the frequency of submap updates.

isInsideSubmap

Check if query position is inside selected submap

Syntax

```
isInside = isInsideSubmap(ndtMap pos)
[isInside,distToEdge] = isInsideSubmap(ndtMap,pos)
```

Description

`isInside = isInsideSubmap(ndtMap pos)` check if the query position `pos`, is inside the selected submap of the NDT map `ndtMap`.

`[isInside,distToEdge] = isInsideSubmap(ndtMap,pos)` also returns the distance from the query position to the closest edge of the submap along the *X*-,*Y*-, and *Z*-axes respectively.

Examples

Check If Query Position Is in Submap

Load an NDT map from a MAT file.

```
data = load('ndtMapParkingLot.mat');
ndtMap = data.ndtMapParkingLot;
```

Select a submap with a specified center and set size.

```
center = [40 0 0];
sz = [50 50 20];
ndtMap = selectSubmap(ndtMap,center,sz);
```

Display the extent of the submap.

```
disp(ndtMap.SelectedSubmap)
```

```
   15.0000   65.0000  -25.0000   25.0000   -9.1840    5.4975
```

Check if a query position is inside the submap.

```
pos1 = [40 0 0]; % near center
[isInside1,distToEdge1] = isInsideSubmap(ndtMap,pos1)
```

```
isInside1 = logical
   1

distToEdge1 = 1×3

   25.0000   25.0000    5.4975
```

```
pos2 = [66 0 0]; % completely outside
[isInside2,distToEdge2] = isInsideSubmap(ndtMap,pos2)

isInside2 = logical
   0

distToEdge2 = 1×3

    1.0000   25.0000    5.4975

pos3 = [60 0 0]; % inside, 5 meters from edge in x direction
[isInside3,distToEdge3] = isInsideSubmap(ndtMap,pos3)

isInside3 = logical
   1

distToEdge3 = 1×3

    5.0000   25.0000    5.4975
```

Input Arguments

`ndtMap` — NDT map

`pcmapndt` object

NDT map, specified as a `pcmapndt` object.

`pos` — Query position

3-element vector

Query position, specified as a 3-element vector of the form [*x y z*].

Output Arguments

`isInside` — Indication of position inside submap

`true` | `false`

Indication of position inside submap, returned as a logical `true` or `false`.

`distToEdge` — Distance from the query position to closest edge of the submap

3-element vector

Distance from the query position to the closest edge of the submap in the *X*-, *Y*-, and *Z*-axes respectively, returned as a 3-element vector.

Functions

`selectSubmap` | `findPose`

Objects

`pcmapndt`

findPose

Localize point cloud within map using normal distributions transform (NDT) algorithm

Syntax

```
currPose = findPose(ndtMap,ptCloud,initPose)
currPose = findPose( ___ ,Name,Value)
```

Description

`currPose = findPose(ndtMap,ptCloud,initPose)` localizes the pose of the point cloud `ptCloud` within the NDT map `ndtMap` using the NDT algorithm. The function confines the search space to the submap, specified by the `SelectedSubmap` property of the `ndtMap` object.

`currPose = findPose( ___ ,Name,Value)` specifies options using one or more name-value arguments in addition to the input arguments in previous syntax. For example, `"MaxIterations",30` sets the maximum number of iterations before the function stops the NDT algorithm.

Examples

Lidar Localization Using NDT

Load a normal distributions transform (NDT) map from a MAT file.

```
data = load('ndtMapParkingLot.mat');
ndtMap = data.ndtMapParkingLot;
```

Load point cloud scans and pose estimates from a second MAT file.

```
data = load('parkingLotData.mat');
ptCloudScans = data.parkingLotData.ptCloudScans;
initPoseEsts = data.parkingLotData.initPoseEsts;
```

Display the NDT map.

```
show(ndtMap)
```

Change the viewing angle to top-view.

```
view(2)
```

Select the submap centered around the first estimate.

```
center = initPoseEsts(1).Translation;
sz = [70 50 20];
ndtMap = selectSubmap(ndtMap,center,sz);
```

Set the radius for visualization of the current location and the distance threshold to update the submap.

```
radius = 0.5;
distThresh = 15;
```

Loop over the point clouds, localize them in the map, and update the selected submap as needed.

```
numScans = numel(ptCloudScans);

for n = 1:numScans
    ptCloud = ptCloudScans(n);
    initPose = initPoseEsts(n);

    poseTranslation = initPose.Translation;
    [isInside,distToEdge] = isInsideSubmap(ndtMap,poseTranslation);
        submapNeedsUpdate = ~isInside ...       % Current pose is outside submap
        || any(distToEdge(1:2) < distThresh);   % Current pose is close to submap edge

if submapNeedsUpdate
    ndtMap = selectSubmap(ndtMap,poseTranslation,sz);
end

% Localize the point cloud scan in the map.
currPose = findPose(ndtMap,ptCloud,initPose);

% Display the position of the estimate as a circle.
pos = [currPose.Translation(1:2) radius];
showShape('circle',pos,'Color','r');

% Pause to view the change.
pause(0.05)
end
```

Input Arguments

`ndtMap` — NDT map
`pcmapndt` object

NDT map, specified as a `pcmapndt` object.

`ptCloud` — Point cloud
`pointCloud` object

Point cloud in the sensor coordinate system, specified as a `pointCloud` object.

`initPose` — Initial estimate for the pose of the sensor in the map
`rigidtform3d` object

Initial estimate for the pose of the sensor in the map, specified as a `rigidtform3d` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `"MaxIterations",30` stops the NDT algorithm after 30 iterations.

`OutlierRatio` — Expected percentage of outliers
`0.55` (default) | scalar in the range [0, 1)

Expected percentage of outliers with respect to a normal distribution, specified as a scalar in the range [0, 1). The NDT algorithm assumes a point is generated by the mixture of a normal distribution for inliers and a uniform distribution for outliers. A larger value of `OutlierRatio` reduces the influence of outliers.

Data Types: `single` | `double`

`MaxIterations` — Maximum number of iterations
`30` (default) | nonnegative integer

Maximum number of iterations before the NDT algorithm stops, specified as a nonnegative integer.

Data Types: `single` | `double`

`Tolerance` — Tolerance between consecutive NDT iterations
`[0.01 0.5]` (default) | 2-element vector

Tolerance between consecutive NDT iterations, specified as a 2-element vector with nonnegative values. The vector, [*Tdiff Rdiff*], represents the tolerance of absolute difference in translation and rotation, respectively, estimated in consecutive NDT iterations. *Tdiff* measures the Euclidean distance between two translation vectors. *Rdiff* measures the angular difference in degrees. The algorithm stops when the difference between estimated rigid transformations in the most recent consecutive iterations falls below the specified tolerance values.

Data Types: `single` | `double`

`Verbose` — Display progress information
`false` or `0` (default) | `true` or `1`

Display progress information, specified as a logical `0` (`false`) or `1` (`true`). Set `Verbose` to `true` to display progress information.

Data Types: `logical`

Output Arguments

`currPose` — Pose of sensor in map
`rigidtform3d` object

Pose of the sensor in the map, returned as a `rigidtform3d` object. The function confines the search space to the submap, specified by the `SelectedSubmap` property of `ndtMap`.

Tips

- To improve the accuracy and efficiency of localization, consider downsampling the point cloud using `pcdownsample` before using this function.

Version History

Introduced in R2021a

R2022b: Supports premultiply geometric transformation convention
Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, the `findpose` function now supports specifying `initPose` as a `rigidtform3d` object, which uses the premultiply convention. Although you can still specify `initPose` as a `rigid3d` object, this object is not recommended because it uses the postmultiply convention. The `findpose` function returns `currPose` as a geometric transformation object of the same type as `initPose`.

You can streamline your geometric transformation workflows by switching to the premultiply geometric transformation convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

Functions

`selectSubmap` | `show` | `pcregisterndt` | `isInsideSubmap` | `pcdownsample`

show

Visualize normal distributions transform (NDT) map

Syntax

```
show(ndtMap)
show(ndtMap,spatialExtent)
show(___,Name,Value)

ax = show(___)
```

Description

`show(ndtMap)` visualizes the NDT map as a point cloud. The function uses voxel means, covariances, and point counts to generate points for the display. These points are not the points used to build the map. The NDT map is a compressed representation of the point cloud map that stores the voxels and their 3-D normal distributions.

`show(ndtMap,spatialExtent)` displays points within the spatial map or submap specified by `spatialExtent`.

`show(___,Name,Value)` specifies options using one or more name-value arguments in addition to any combination of input arguments in previous syntaxes. For example, `'MarkerSize',6` sets the marker size to 6 points.

`ax = show(___)` returns the axes used to plot the NDT map.

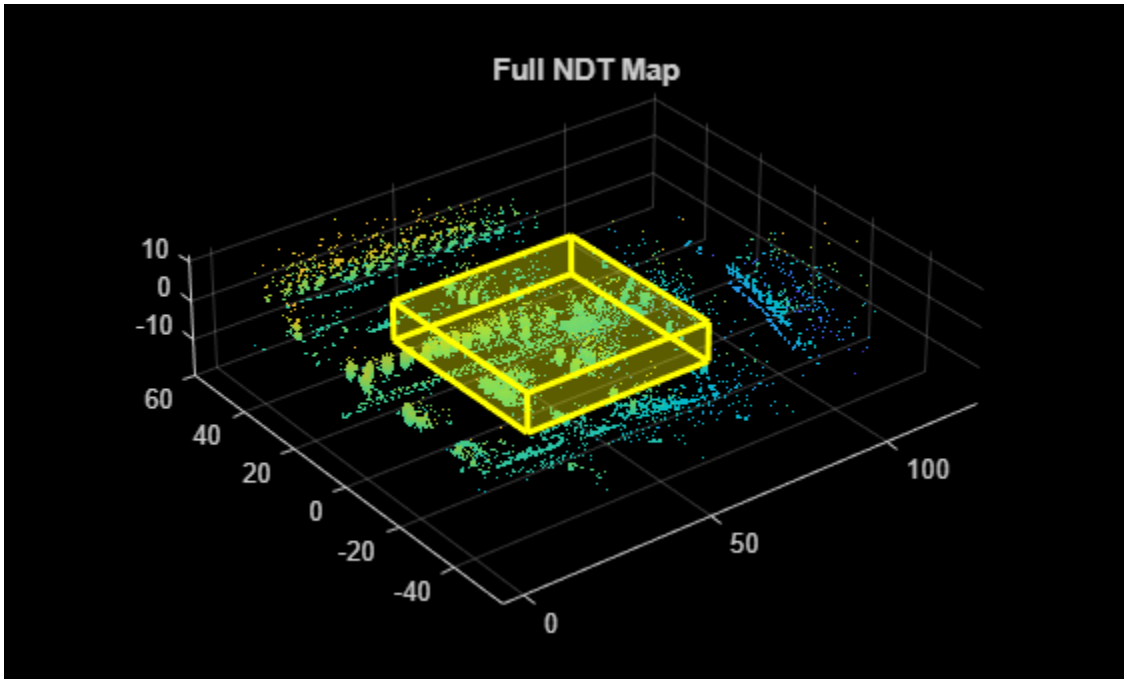
Examples

Select and Visualize Submap

Load an NDT map from a MAT file.

```
data = load('ndtMapParkingLot.mat');
ndtMap = data.ndtMapParkingLot;
```

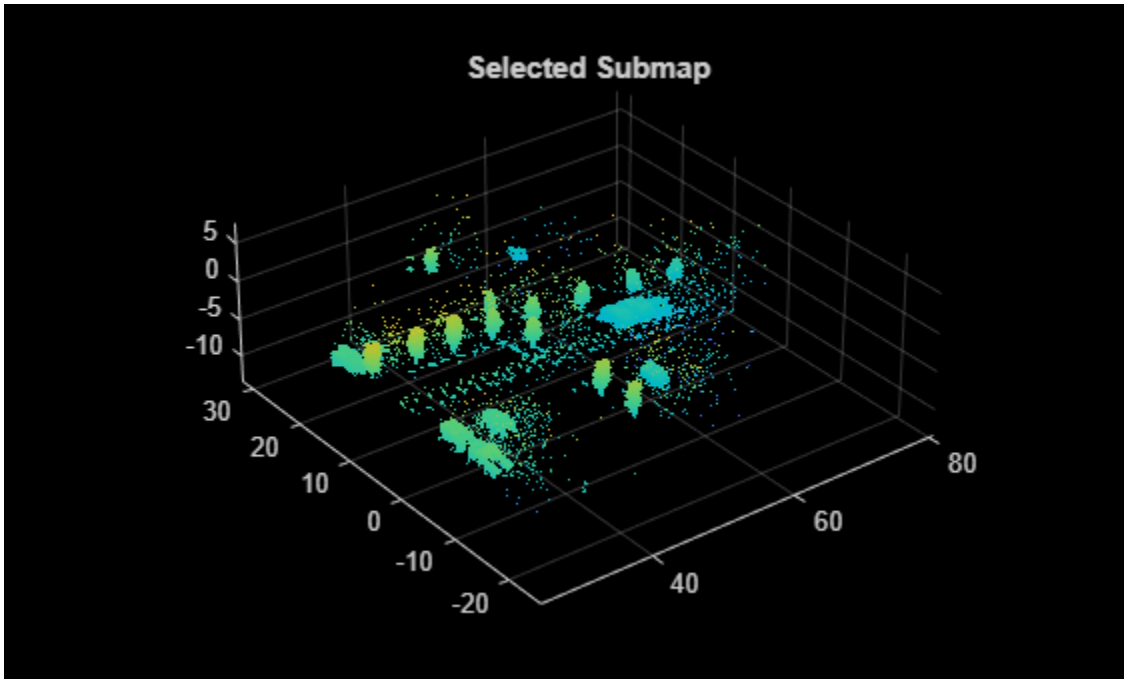
Select a submap from within the loaded NDT map at the specified location and size.



```
center  = [50  0  0];
sz      = [50 50 10];
ndtMap = selectSubmap(ndtMap,center,sz);
```

Visualize the full NDT map.

```
figure
show(ndtMap)
title('Full NDT Map')
```



Highlight the selected submap on the full NDT map.

```
pos = [center,sz,zeros(1, 3)];
showShape('cuboid',pos,'Color','y','Opacity',0.2);
```

Visualize the selected submap.

```
figure
show(ndtMap,'submap')
title('Selected Submap')
```

Input Arguments

`ndtMap` — NDT map

`pcmapndt` object

NDT map, specified as a `pcmapndt` object.

`spatialExtent` — Spatial extent

`'map'` | `'submap'`

Spatial extent, specified as `'map'` or `'submap'`. When you specify `'submap'`, only points within the current submap are displayed.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'MarkerSize',6` sets the marker size to 6 points.

`MarkerSize` — Diameter of marker

`6` (default) | positive scalar

Diameter of marker, specified as a positive scalar. This value specifies the approximate diameter of the point marker. Units are in points. A marker size larger than six can reduce rendering performance.

`Parent` — Axes on which to display visualization

`Axes` object

Axes on which to display the visualization, specified as an `Axes` object. To create an `Axes` object, use the `axes` function. To display the visualization in a new figure, leave `'Parent'` unspecified.

Output Arguments

`ax` — Plot axes

`Axes` object

Plot axes, returned as an `axes` graphics object.

worldpointset

Manage 3-D to 2-D point correspondences

Description

The `worldpointset` object stores correspondences between 3-D world points and 2-D image points across camera views. You can use a `worldpointset` object with an `imageviewset` object to manage image and map data for structure-from-motion, visual odometry, and visual simultaneous localization and mapping (SLAM).

Creation

Syntax

```
wpSet = worldpointset
```

Description

`wpSet = worldpointset` creates a worldpointset object with default properties. Use the object functions to perform actions such as adding, modifying or removing correspondences, finding points in a view, and finding views of points.

Properties

`WorldPoints` — 3-D world points
[ ] (default) | *M*-by-3 matrix

This property is read-only.

3-D world points, specified as an *M*-by-3 matrix with rows containing [*x y z*] world points. *M* is the number of 3-D world points.

`ViewIds` — Identifiers for views
[ ] (default) | *N*-element row vector of integers

This property is read-only.

Identifiers for views associated with world points, specified as an *N*-element row vector of integers.

`PointIds` — Identifiers for 3-D points
[ ] (default) | *M*-element row vector of integers

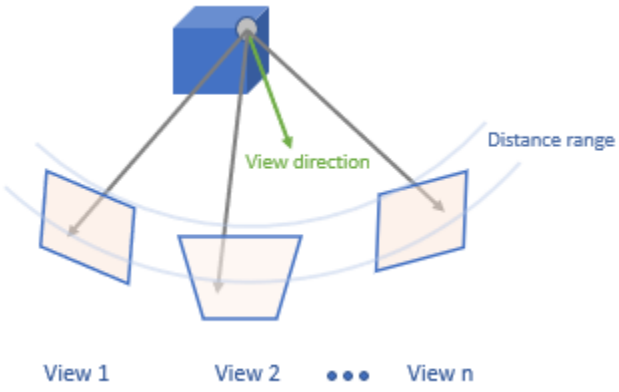
This property is read-only.

Identifiers for 3-D points in `WorldPoints`, specified as an *M*-element row vector of integers.

`Correspondences` — 3-D to 2-D point correspondences
empty three-column table (default) | three-column table

This property is read-only.

3-D to 2-D point correspondences, specified as a three-column table.



Column	Description
`PointIndex`	Each row contains the linear index of a world point.
`ViewId`	Each row contains a 1-by-*N* vector specifying the IDs of the views associated with the corresponding world points. *N* is the number of views associated with the world point.
`FeatureIndex`	Each row contains a 1-by-*N* vector specifying the indices of the feature points that correspond to the world point. Each element is the index of the feature point in the view specified by the corresponding element in the `ViewID` cell.

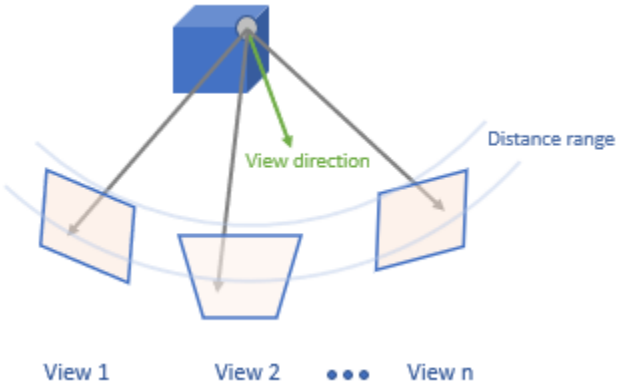
`ViewingDirection` — Mean viewing direction of each world point

empty matrix (default) | *M*-by-3 matrix

This property is read-only.

Mean viewing direction of each world point, specified as an *M*-by-3 matrix, where *M* is the number of points. The viewing direction provides an estimate for a view angle from which a 3-D point can be observed. The mean viewing direction is the average of all the unit vectors pointing from the world point to the camera centers of the associated views. When a new camera view is introduced into the system, the 3-D world points that can potentially be observed in this view can be predicted based on the range set by the distance limits and the `ViewingDirection`.

`DistanceLimits` — Distance limits for 3-D point observation



empty vector (default) | *M*-by-2 vector

This property is read-only.

An representing the minimum and maximum distances from which each world point is observed.

Distance limits for 3-D point observation, specified as an *M*-by-2 vector that represents the minimum and maximum distance, where *M* is the number of points. The range indicates how far the 3-D point

can be observed. When a new camera view is introduced into the system, the 3-D world points that can potentially be observed in this view can be predicted based on the range set by the distance limits and the `ViewingDirection`.

`RepresentativeViewId` — View IDs of the representative views
`empty vector` (default) | *M*-element column vector

This property is read-only.

View IDs of the representative views, specified as an *M*-element column vector, where *M* is the number of points. The representative view corresponds to the view that contains the representative feature in the representative view for each world point. A representative feature is the medoid of all the feature descriptors associated with the world point.

`RepresentativeFeatureIndex` — Representative feature descriptor index
`empty vector` (default) | *M*-element column vector

This property is read-only.

Representative feature descriptor index, specified as an *M*-element column vector, where *M* is the number of points. The index value corresponds to the view that contains the representative feature descriptor for each world point.

`Count` — Number of 3-D world points
`0` (default) | scalar

This property is read-only.

Number of 3-D world points, specified as a scalar.

Object Functions

addWorldPoints	Add world points to world point set
removeWorldPoints	Remove world points from world point set
updateWorldPoints	Update world points in world point set
selectWorldPoints	Select world points from world point set
addCorrespondences	Update world points in a world point set
removeCorrespondences	Remove 3-D to 2-D correspondences from world point set
updateCorrespondences	Update 3-D to 2-D correspondences in world point set

updateLimitsAndDirection	Update distance limits and viewing direction
updateRepresentativeView	Update representative view ID and corresponding feature index
findViewsOfWorldPoint	Find views that observe a world point
findWorldPointsInTracks	Find world points that correspond to point tracks
findWorldPointsInView	Find world points observed in view

Examples

Triangulate Stereo Images

Load a `MAT` file containing stereo parameters into the workspace.

```
load('webcamsSceneReconstruction.mat');
```

Read a stereo pair of images into the workspace.

```
I1 = imread('sceneReconstructionLeft.jpg');
I2 = imread('sceneReconstructionRight.jpg');
```

Undistort the images.

```
I1 = undistortImage(I1,stereoParams.CameraParameters1);
I2 = undistortImage(I2,stereoParams.CameraParameters2);
```

Define a rectangular region of interest (ROI), in the format [*x y width height*].

```
roi = [30 30 size(I1,2)-30 size(I1,1)-30];
```

Detect and extract SIFT features from both images using the ROI.

```
imagePoints1 = detectSIFTFeatures(im2gray(I1),ROI=roi);
imagePoints2 = detectSIFTFeatures(im2gray(I2),ROI=roi);

[feature1,validPoints1] = extractFeatures(im2gray(I1),imagePoints1);
[feature2,validPoints2] = extractFeatures(im2gray(I2),imagePoints2);
```

Match the extracted features to each other.

```
indexPairs = matchFeatures(feature1,feature2,MatchThreshold=10,Unique=true);
```

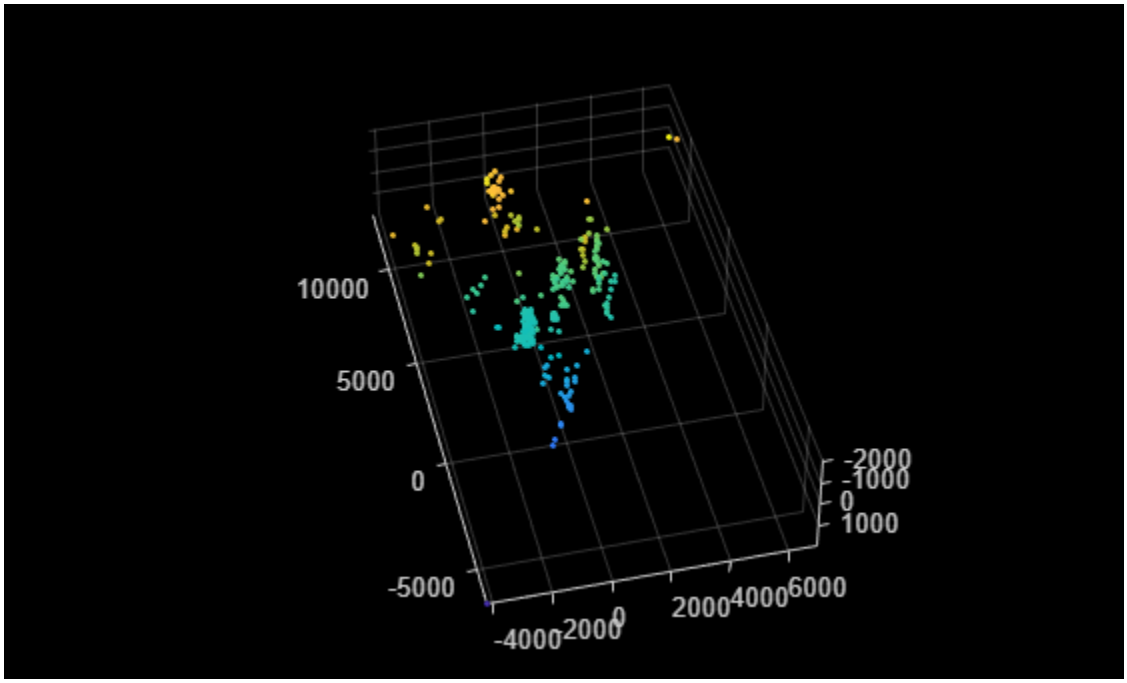
Compute the 3-D world points.

```
matchedPoints1 = validPoints1(indexPairs(:,1));
matchedPoints2 = validPoints2(indexPairs(:,2));
worldPoints    = triangulate(matchedPoints1,matchedPoints2,stereoParams);
```

Create a `worldpointset` object to manage correspondences.

```
wpSet = worldpointset;
```

Add the world points to the `worldpointset`.



```
[wpSet,newPointIndices] = addWorldPoints(wpSet,worldPoints);
```

Add the 3-D to 2-D point correspondences to the `worldpointset`.

```
wpSet = addCorrespondences(wpSet,1,newPointIndices,indexPairs(:,1));
wpSet = addCorrespondences(wpSet,2,newPointIndices,indexPairs(:,2));
```

Display the world points.

```
pcshow(wpSet.WorldPoints,VerticalAxis="y",VerticalAxisDir="down",MarkerSize=45)
```

Version History

Introduced in R2020b

R2022b: Visual SLAM: Track Visibility Relationship Between 3-D World Points and Camera Views

- Added `ViewingDirection`, `DistanceLimits`, `RepresentativeViewId`, and `RepresentativeFeatureIndex` properties.
- Added `updateLimitsAndDirection` and `updateRepresentativeView` object functions.

R2024a: Use unique point identifiers to specify world points

Use the new `selectWorldPoints` object function to select world points from a `worldpointset` object. Also, you can now specify unique point IDs to manage world points. In prior releases if you did not specify unique identifiers when points were added, then points were saved with sequential identifiers.

selectWorldPoints

Select world points from world point set

Syntax

```
wpSetSelected = selectWorldPoints(wpSet,pointIds)
```

Description

`wpSetSelected = selectWorldPoints(wpSet,pointIds)` selects world points from `wpSet` using the identifiers in `pointIds`. Use this syntax if you added points using the `addWorldPoints` function by specifying unique point identifiers `pointIds`.

Examples

Select World Points from World Point Set Using Point IDs

Generate 3-D world points.

```
worldPoints = rand(100,3);
```

Generate point IDs.

```
pointIds = randperm(100);
```

Create a `worldpointset` object.

```
wpSet = worldpointset
```

```
wpSet =
  worldpointset with properties:

                  WorldPoints: [0×3 single]
                      ViewIds: [1×0 uint32]
                     PointIds: [1×0 uint32]
             ViewingDirection: [0×3 single]
               DistanceLimits: [0×2 single]
         RepresentativeViewId: [0×1 double]
    RepresentativeFeatureIndex: [0×1 double]
                        Count: 0
              Correspondences: [0×3 table]
```

Add the world points to the world point set.

```
wpSet = addWorldPoints(wpSet,worldPoints,pointIds);
```

Select the first 50 points in the point set.

```
points = selectWorldPoints(wpSet,pointIds(1:50))
```

```
points = 50×3 single matrix
```

```
    0.1577    0.6827    0.6699
    0.1665    0.2842    0.4921

    0.8973    0.5022    0.7917
    0.9272    0.5898    0.0153
    0.2026    0.0748    0.2160
    0.1765    0.1055    0.2241
      ⋮
```

Input Arguments

`wpSet` — World point set
`worldpointset` object

World point set, specified as a `worldpointset` object.

`pointIds` — Identifiers for 3-D points
M-element row vector of integers

Identifiers for 3-D points in `wpSet`, specified as an *M*-element row vector of integers.

Output Arguments

`wpSetSelected` — Selected world point set
`worldpointset` object

Selected world point set, returned as a `worldpointset` object.

updateRepresentativeView

Update representative view ID and corresponding feature index

Syntax

```
wpSet = updateRepresentativeView(wpSet,pointIndices,viewTable)
wpSet = updateRepresentativeView(wpSet,pointIds,viewTable)
```

Description

`wpSet = updateRepresentativeView(wpSet,pointIndices,viewTable)` updates representative view ID and corresponding feature index of world points in the world point set object, `wpSet`. The representative view is based on a table of views, `viewTable`. `pointIndices` is the index to the world point related to the update. Use this syntax if you added points using the `addWorldPoints` function without specifying unique point identifiers `pointIds`.

`wpSet = updateRepresentativeView(wpSet,pointIds,viewTable)` updates representative view ID and corresponding feature point identifier of world points in the world point set object, `wpSet`. The representative view is based on a table of views, `viewTable`. `pointIds` is the point identifier to the world point related to the update. Use this syntax if you added points using the `addWorldPoints` function by specifying unique point identifiers `pointIds`.

Examples

Update Representative View of World Point Set

Create an `imageviewset` object.

```
vSet = imageviewset;
```

Add three views related to binary features.

```
viewId1 = 1;
features1 = binaryFeatures(randi(255,[10, 32],"uint8"));
vSet = addView(vSet,viewId1,Features=features1);
viewId2 = 2;
features2 = binaryFeatures(randi(255,[10, 32],"uint8"));
vSet = addView(vSet,viewId2,Features=features2);
viewId3 = 3;
features3 = binaryFeatures(randi(255,[10, 32],"uint8"));
vSet = addView(vSet,viewId3,Features=features3);
```

Create a `worldpointset` object and add world points

```
wpSet = worldpointset;
worldPoints = rand(10, 3); % Add world points
wpSet = addWorldPoints(wpSet, worldPoints);
```

Add correspondences for three views.

```
pointIndices= 1:10;
featureIndices1 = randperm(10);
wpSet  = addCorrespondences(wpSet,viewId1,pointIndices,featureIndices1);
featureIndices2 = randperm(10);
wpSet  = addCorrespondences(wpSet,viewId2,pointIndices,featureIndices2);
featureIndices3 = randperm(10);
wpSet  = addCorrespondences(wpSet,viewId3,pointIndices,featureIndices3);
```

Update representative view.

```
viewTable = findView(vSet, [viewId1,viewId2,viewId3]);
wpSet = updateRepresentativeView(wpSet,pointIndices,viewTable);
```

Check representative view ID and feature index.

```
wpSet.RepresentativeViewId
```

```
ans = 10×1

Input Arguments

`wpSet` — World point set

`worldpointset` object

World point set, specified as a `worldpointset` object.

`pointIndices` — Point index

M-element column vector of integers

Point index, specified as an *M*-element column vector of integers, where *M* is the number of world points. The function updates the representative view ID and corresponding feature index of the point that corresponds to the specified index.

`pointIds` — World point identifiers

M-element array vector of integers

World point identifiers, returned as an *M*-element vector of integers. *M* is the number of world points. The function updates the representative view ID and corresponding feature point identifier of the point that corresponds to the specified index. Use this input when points were added using `addWorldPoints`.

`viewTable` — One or more views

four-column table

One or more connected or indirectly connected views, specified as a four-column table. The table must contain the columns as described in this table.

Column	Description
`ViewId`	View identifier for the view, specified as a unique integer
`AbsolutePose`	Absolute pose of the view, specified as a `rigidtform3d` object.
`Features`	Feature vectors, specified as an *M*-by-*N* matrix of *M* feature vectors or as a `binaryFeatures`.
`Points`	Image points, specified as one of these options: • *M*-by-2 matrix of coordinates in the format [*x*,*y*] • *M*-element feature point array. For more details, see “Point Feature Types”.

Output Arguments

`wpSet` — World point set

`worldpointset` object

World point set, returned as a `worldpointset` object.

updateLimitsAndDirection

Update distance limits and viewing direction

Syntax

```
wpSet = updateLimitsAndDirection(wpSet,pointIndices,viewTable)
wpSet = updateLimitsAndDirection(wpSet,pointIds,viewTable)
```

Description

`wpSet = updateLimitsAndDirection(wpSet,pointIndices,viewTable)` updates the distance limits and viewing direction of world points in the world point set object, `wpSet`. The viewing direction is based on a table of views, `viewTable`. `pointIndices` is the index to the world point related to the update. Use this syntax if you added points using the `addWorldPoints` function without specifying unique point identifiers `pointIds`.

`wpSet = updateLimitsAndDirection(wpSet,pointIds,viewTable)` updates the distance limits and viewing direction of world points in the world point set object, `wpSet`. The viewing direction is based on a table of views, `viewTable`. `pointIds` is the point identifier to the world point related to the update. Use this syntax if you added points using the `addWorldPoints` function by specifying unique point identifiers `pointIds`.

Examples

Update Distance Limits and Viewing Direction of World Points

Create a `worldpointset` object and add world points and correspondences for view 1 and view 2.

```
wpSet = worldpointset;
worldPoints = rand(10,3);
wpSet = addWorldPoints(wpSet,worldPoints);
pointIndices = 1:10;
featureIndices = 1:10;
viewId1 = 1;
wpSet = addCorrespondences(wpSet,viewId1,pointIndices,featureIndices);
viewId2 = 2;
wpSet = addCorrespondences(wpSet,viewId1,pointIndices,featureIndices);
```

Create an `imageviewset` object and add views and poses to the set. Add a translation in the *x*-axis for pose 2.

```
vSet  = imageviewset;
pose1 = rigidtform3d;
vSet  = addView(vSet, viewId1, pose1);
pose2 = rigidtform3d([0 0 0],[1 0 0]);
vSet  = addView(vSet,viewId2,pose2);
```

Update the distance limit and viewing direction.

```
viewTable = findView(vSet,[viewId1,viewId2]);
wpSet = updateLimitsAndDirection(wpSet,pointIndices,viewTable);
```

Check distance limits and viewing direction.

```
wpSet.ViewingDirection
```

```
ans = 10×3 single matrix

```

Update Distance Limits and Viewing Direction of World Points

Create a `worldpointset` object and add world points and correspondences for view 1 and view 2.

```
wpSet = worldpointset;
worldPoints = rand(10,3);
pointIds = randperm(10);
wpSet = addWorldPoints(wpSet,worldPoints,pointIds);
featureIndices = 1:10;
viewId1 = 1;
wpSet = addCorrespondences(wpSet,viewId1,pointIds(1:10),featureIndices);
viewId2 = 2;
wpSet = addCorrespondences(wpSet,viewId1,pointIds(1:10),featureIndices);
```

Create an `imageviewset` object and add views and poses to the set. Add a translation in the *x*-axis for pose 2.

```
vSet  = imageviewset;
pose1 = rigidtform3d;
vSet  = addView(vSet, viewId1, pose1);
pose2 = rigidtform3d([0 0 0],[1 0 0]);
vSet  = addView(vSet,viewId2,pose2);
```

Update the distance limit and viewing direction.

```
viewTable = findView(vSet,[viewId1,viewId2]);
wpSet = updateLimitsAndDirection(wpSet,pointIds(1:10),viewTable);
```

Check distance limits and viewing direction.

```
wpSet.ViewingDirection
```

```
ans = 10×3 single matrix

```

Input Arguments

`wpSet` — World point set

`worldpointset` object

World point set, specified as a `worldpointset` object.

`pointIndices` — Point index

M-element column vector of integers

Point index, specified as an *M*-element column vector of integers, where *M* is the number of world points. The function updates the distance limits and viewing direction of the point that corresponds to the specified index. Use this input when sequential indices are used for the points in the `wpSet` object.

`pointIds` — World point identifiers

M-element array vector of integers

World point identifiers, returned as an *M*-element vector of integers. *M* is the number of world points. The function updates the distance limits and viewing direction of the point that corresponds to the specified point identifier. Use this input when points were added using `addWorldPoints`.

`viewTable` — One or more views
four-column table

One or more connected or indirectly connected views, specified as a four-column table. The table must contain the columns as described in this table.

Column	Description
`ViewId`	View identifier for the view, specified as a unique integer
`AbsolutePose`	Absolute pose of the view, specified as a `rigidtform3d` object.
`Features`	Feature vectors, specified as an *M*-by-*N* matrix of *M* feature vectors or as a `binaryFeatures`.
`Points`	Image points, specified as one of these options: • *M*-by-2 matrix of coordinates in the format [*x*,*y*] • *M*-element feature point array. For more details, see “Point Feature Types”.

Output Arguments

`wpSet` — World point set
`worldpointset` object

World point set, returned as a `worldpointset` object.

addCorrespondences

Update world points in a world point set

Syntax

```
wpSet = addCorrespondences(wpSet,viewId,pointIndices,featureIndices)
wpSet = addCorrespondences(wpSet,viewId,pointIds,featureIndices)
```

Description

`wpSet = addCorrespondences(wpSet,viewId,pointIndices,featureIndices)` adds correspondences between 3-D world points and 2-D feature points to the world point set `wpSet`, using the point indices `pointIndices` and the feature indices `featureIndices` for the specified view `viewId`. Use this syntax if you added points using the `addWorldPoints` function without specifying unique point identifiers `pointIds`.

`wpSet = addCorrespondences(wpSet,viewId,pointIds,featureIndices)` adds correspondences between 3-D world points and 2-D feature points to the world point set `wpSet`, using the point identifiers `pointIds` and the feature indices `featureIndices` for the specified view `viewId`. Use this syntax if you added points using the `addWorldPoints` function by specifying unique point identifiers `pointIds`.

Examples

Add 3-D to 2-D Correspondences to World Point Set

Generate 3-D world points.

```
worldPoints = rand(100,3);
```

Create a `worldpointset` object.

```
wpSet = worldpointset;
```

Add world points.

```
wpSet = addWorldPoints(wpSet,worldPoints);
```

Add correspondences to View 1 for the first 10 points.

```
viewId = 1;
pointIndices   = 1:10;
featureIndices = 1:10;
wpSet  = addCorrespondences(wpSet,viewId,pointIndices,featureIndices);
```

Add 3-D to 2-D Correspondences to World Point Set

Generate 3-D world points.

```
worldPoints = rand(100,3);
```

Generate pointIds.

```
pointIds = randperm(100);
```

Create a `worldpointset` object.

```
wpSet = worldpointset;
```

Add world points.

```
wpSet = addWorldPoints(wpSet,worldPoints,pointIds);
```

Add correspondences to View 1 for the first 10 points.

```
viewId = 1;
featureIndices = 1:10;
wpSet  = addCorrespondences(wpSet,viewId,pointIds(1:10),featureIndices);
```

Input Arguments

`wpSet` — World point set
`worldpointset` object

World point set, specified as a `worldpointset` object.

`viewId` — View identifier
scalar

View identifier, specified as a scalar.

`pointIds` — Identifiers for 3-D points
[ ] (default) | *M*-element row vector of integers

Identifiers for 3-D points in `wpSet`, specified as an *M*-element row vector of integers.

`pointIndices` — World point indices
M-element column vector of integers

World point indices, specified as an *M*-element column vector of integers. *M* is the number of world points for which you are adding correspondences.

`featureIndices` — 2-D feature point indices
M-element column vector of integers

Feature point indices, specified as an *M*-element column vector of integers. *M* is the number of world points for which you are adding correspondences.

Output Arguments

`wpSet` — World point set
`worldpointset` object

World point set, returned as a `worldpointset` object.

addWorldPoints

Add world points to world point set

Syntax

```
wpSet = addWorldPoints(wpSet,worldPoints)
wpSet = addWorldPoints(wpSet,worldPoints,pointIds)
[wpSet,newPointIndices] = addWorldPoints( ___ )
```

Description

`wpSet = addWorldPoints(wpSet,worldPoints)` adds world points to the world points set `wpSet`.

`wpSet = addWorldPoints(wpSet,worldPoints,pointIds)` also adds identifiers for 3-D points in `worldPoints` to `wpSet`.

`[wpSet,newPointIndices] = addWorldPoints( ___ )` additionally returns the indices in the world point set of the added world points.

Examples

Add World Points to World Point Set

Generate 3-D world points.

```
worldPoints = rand(100,3);
```

Create a `worldpointset` object.

```
wpSet = worldpointset
```

Add the world points to the world point set.

```
wpSet = addWorldPoints(wpSet,worldPoints)
```

Add World Points to World Point Set

Generate 3-D world points.

```
worldPoints = rand(100,3);
```

Generate pointIds.

```
pointIds = randperm(100);
```

Create a `worldpointset` object.

```
wpSet = worldpointset
```

```
wpSet =
  worldpointset with properties:

                   WorldPoints: [0×3 single]
                       ViewIds: [1×0 uint32]
                      PointIds: [1×0 uint32]
              ViewingDirection: [0×3 single]
                DistanceLimits: [0×2 single]
           RepresentativeViewId: [0×1 double]
     RepresentativeFeatureIndex: [0×1 double]
                         Count: 0
               Correspondences: [0×3 table]
```

Add the world points to the world point set.

```
wpSet = addWorldPoints(wpSet,worldPoints,pointIds)
```

```
wpSet =
  worldpointset with properties:

                   WorldPoints: [100×3 single]
                       ViewIds: [1×0 uint32]
                      PointIds: [33 96 61 3 43 1 25 4 19 6 36 90 76 58 20 10 69 99 35 60 21 57 10
              ViewingDirection: [100×3 single]
                DistanceLimits: [100×2 single]
           RepresentativeViewId: [100×1 double]
     RepresentativeFeatureIndex: [100×1 double]
                         Count: 100
               Correspondences: [100×3 table]
```

Input Arguments

`wpSet` — World point set

`worldpointset` object

World point set, specified as a `worldpointset` object.

`worldPoints` — World points coordinates

M-by-3 matrix

World points coordinates, specified as an *M*-by-3 matrix in the form [*x y z*].

`pointIds` — Identifiers for 3-D points

[ ] (default) | *M*-element row vector of integers

This property is read-only.

Identifiers for 3-D points in `WorldPoints`, specified as an *M*-element row vector of integers.

Output Arguments

`wpSet` — World point set

`worldpointset` object

World point set, returned as a `worldpointset` object.

`newPointIndices` — Added world point indices
M-element column vector of integers

Added world point indices, returned as an *M*-element column vector of integers. *M* is the number of world points added to the world point set.

findViewsOfWorldPoint

Find views that observe a world point

Syntax

```
viewIds = findViewsOfWorldPoint(wpSet,pointIndices)
[viewIds,featureIndices] = findViewsOfWorldPoint(wpSet,pointIndices)

viewIds = findViewsOfWorldPoint(wpSet,pointIds)
[viewIds,featureIndices] = findViewsOfWorldPoint(wpSet,pointIds)
```

Description

`viewIds = findViewsOfWorldPoint(wpSet,pointIndices)` finds the identifiers for views `viewIds` that observe the 3-D world points specified by `pointIndices` in a world point set `wpSet`. Use this syntax if you added points using the `addWorldPoints` function without specifying unique point identifiers `pointIds`. Use this syntax if you added points using the `addWorldPoints` function without specifying unique point identifiers `pointIds`.

`[viewIds,featureIndices] = findViewsOfWorldPoint(wpSet,pointIndices)` additionally returns the indices of the 2-D feature points that correspond to each 3-D world point for each associated view. Use this syntax if you added points using the `addWorldPoints` function without specifying unique point identifiers `pointIds`.

`viewIds = findViewsOfWorldPoint(wpSet,pointIds)` finds the identifiers for views `viewIds` that observe the 3-D world points specified by `pointIds` in a world point set `wpSet`. Use this syntax if you added points using the `addWorldPoints` function by specifying unique point identifiers `pointIds`.

`[viewIds,featureIndices] = findViewsOfWorldPoint(wpSet,pointIds)` additionally returns the indices of the 2-D feature points that correspond to each 3-D world point for each associated view. Use this syntax if you added points using the `addWorldPoints` function by specifying unique point identifiers `pointIds`.

Examples

Find Views of World Points

Generate 3-D world points.

```
worldPoints = rand(100,3);
```

Create a `worldpointset` object.

```
wpSet = worldpointset;
```

Add world points.

```
wpSet = addWorldPoints(wpSet,worldPoints);
```

Add 3-D to 2-D correspondences for view 1.

```
viewId1 = 1;
pointIndices1   = 1:10;
featureIndices1 = 1:10;
wpSet  = addCorrespondences(wpSet,viewId1,pointIndices1,featureIndices1);
```

Add 3-D to 2-D correspondences for view 2.

```
viewId2 = 2;
pointIndices2   = 6:10;
featureIndices2 = 1:5;
wpSet  = addCorrespondences(wpSet,viewId2,pointIndices2,featureIndices2);
```

Find views of world points.

```
pointIndex = 6:10;
viewIds = findViewsOfWorldPoint(wpSet,pointIndex);
```

Find Views of World Points

Generate 3-D world points and point Ids.

```
worldPoints = rand(100,3);
pointIds = randperm(100);
```

Create a `worldpointset` object.

```
wpSet = worldpointset;
```

Add world points.

```
wpSet = addWorldPoints(wpSet,worldPoints,pointIds);
```

Add 3-D to 2-D correspondences for view 1.

```
viewId1 = 1;
featureIndices1 = 1:10;
wpSet  = addCorrespondences(wpSet,viewId1,pointIds(1:10),featureIndices1);
```

Add 3-D to 2-D correspondences for view 2.

```
viewId2 = 2;
featureIndices2 = 1:5;
wpSet  = addCorrespondences(wpSet,viewId2,pointIds(6:10),featureIndices2);
```

Find views of world points.

```
viewIds = findViewsOfWorldPoint(wpSet,pointIds(6:10))
```

```
viewIds=5×1 cell array
    {2×1 uint32}
    {2×1 uint32}
    {2×1 uint32}
    {2×1 uint32}
    {2×1 uint32}
```

Input Arguments

`wpSet` — World point set

`worldpointset` object

World point set, specified as a `worldpointset` object.

`pointIndices` — World point indices

scalar | *N*-element vector of integers

World point indices, specified as a scalar or an *N*-element vector of integers. This input is valid when sequential indices are used for the points in the `wpSet` object.

`pointIds` — World point identifiers

M-element array vector of integers

World point identifiers, specified as an *M*-element vector of integers. *M* is the number of world points. This input is valid when points were added using `addWorldPoints`.

Output Arguments

`viewIds` — View identifiers

M-element column vector | *N*-element cell array

View identifiers, returned as an *M*-element column vector or *N*-element cell array. The function returns an *M*-element vector column, where *M* is the number of views that observe the world point, when `pointIndex` is a scalar. The function returns an *N*-element cell array when `pointIndex` is an *N*-element vector of integers. Each cell contains a column vector of the view identifiers for the associated world point.

`featureIndices` — 2-D feature point indices

M-element column vector | *N*-element cell array

2-D feature point indices, returned as an *M*-element column vector or *N*-element cell array. The function returns an *M*-element vector column, where *M* is the number of views that observe the world point, when `pointIndex` is a scalar. The function returns an *N*-element cell array when `pointIndex` is an *N*-element vector of integers. Each cell contains a column vector of the corresponding feature indices for the associated world point.

Version History

Introduced in R2020b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

If the input argument `pointIndex` is a scalar, the output arguments `viewIds` and `featureIndices` returned by the generated code are *M*-element cell arrays. *M* is the number of views that observe the world point.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

findWorldPointsInTracks

Find world points that correspond to point tracks

Syntax

```
pointIndices = findWorldPointsInTracks(wpSet,tracks)
[pointIndices,validIndex] = findWorldPointsInTracks(wpSet,tracks)

pointIds = findWorldPointsInTracks(wpSet,tracks)
[pointIds,validIndex] = findWorldPointsInTracks(wpSet,tracks)
```

Description

`pointIndices = findWorldPointsInTracks(wpSet,tracks)` finds the indices, `pointIndices`, of world points that correspond to the specified point tracks `tracks`.Use this syntax if you added points using the `addWorldPoints` function without specifying unique point identifiers `pointIds`.

`[pointIndices,validIndex] = findWorldPointsInTracks(wpSet,tracks)` additionally returns a vector that indicates whether each point track has a corresponding world point. Use this syntax if you added points using the `addWorldPoints` function without specifying unique point identifiers `pointIds`.

`pointIds = findWorldPointsInTracks(wpSet,tracks)` finds the point identifiers, `pointIds`, of world points that correspond to the specified point tracks `tracks`. Use this syntax if you added points using the `addWorldPoints` function by specifying unique point identifiers `pointIds`.

`[pointIds,validIndex] = findWorldPointsInTracks(wpSet,tracks)` additionally returns a vector that indicates whether each point track has a corresponding world point. Use this syntax if you added points using the `addWorldPoints` function by specifying unique point identifiers `pointIds`.

Examples

Find World Points in Tracks

Load precomputed world point set and image view set.

```
data = load(fullfile(toolboxdir('vision'),'visiondata','worldpointsetAndTracks.mat'));
```

Find point tracks across views.

```
tracks = findTracks(data.vSet);
```

Find 3-D world points corresponding to point tracks.

```
pointIndices = findWorldPointsInTracks(data.wpSet,tracks);
```

Input Arguments

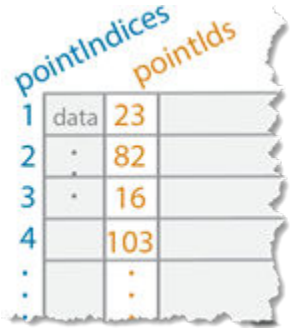
`wpSet` — World point set

`worldpointset` object

World point set, specified as a `worldpointset` object.

`tracks` — Point tracks

M-element row vector of `pointTrack` objects

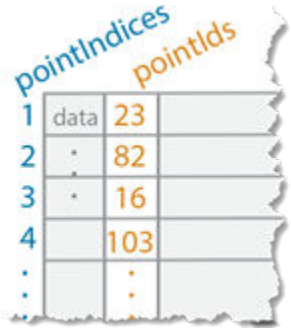


Point tracks, specified as an *M*-element row vector of `pointTrack` objects.

Output Arguments

`pointIndices` — World point indices

scalar | *N*-element vector of integers



World point indices, specified as a scalar or an *N*-element vector of integers. This input is valid when sequential indices are used for the points in the `wpSet` object.

`pointIds` — World point identifiers

M-element array vector of integers

World point identifiers, specified as an *M*-element vector of integers. *M* is the number of world points. This input is valid when points were added using `addWorldPoints`.

`validIndex` — Logical index

M-element logical vector

Logical index of point track correspondences, returned as an *M*-element logical vector. *M* is the number of point tracks in the `tracks` argument. A value of `1` (`true`) indicates that the associated point track has a corresponding world point, and a value of `0` (`false`) indicates that it does not.

Functions

`findTracks` | `findWorldPointsInView` | `findViewsOfWorldPoint`

Objects

`imageviewset` | `worldpointset`

findWorldPointsInView

Find world points observed in view

Syntax

```
pointIndices = findWorldPointsInView(wpSet,viewId)
pointIds = findWorldPointsInView(wpSet,viewId)
[___,featureIndices] = findWorldPointsInView(wpSet,viewId)
```

Description

`pointIndices = findWorldPointsInView(wpSet,viewId)` finds the indices of the 3-D world points `pointIndices` observed in the specified view `viewId`. Use this syntax if you added points using the `addWorldPoints` function without specifying unique point identifiers `pointIds`.

`pointIds = findWorldPointsInView(wpSet,viewId)` finds the point identifiers of the 3-D world points `pointIds` observed in the specified view `viewId`. Use this syntax if you added points using the `addWorldPoints` function by specifying unique point identifiers `pointIds`.

`[___,featureIndices] = findWorldPointsInView(wpSet,viewId)` additionally returns the indices of the corresponding 2-D feature points in the view.

Examples

Find World Points in World Points Set

Generate 3-D world points.

```
worldPoints = rand(100,3);
```

Create a `worldpointset` object.

```
wpSet = worldpointset;
```

Add world points.

```
wpSet = addWorldPoints(wpSet,worldPoints);
```

Add 3-D to 2-D correspondences for view 1.

```
viewId1 = 1;
pointIndices1   = 1:10;
featureIndices1 = 1:10;
wpSet  = addCorrespondences(wpSet,viewId1,pointIndices1,featureIndices1);
```

Add 3-D to 2-D correspondences for view 2.

```
viewId2 = 2;
pointIndices2   = 6:10;
featureIndices2 = 1:5;
wpSet  = addCorrespondences(wpSet,viewId2,pointIndices2,featureIndices2);
```

Find world points in view 2.

```
[pointIndices,featureIndices] = findWorldPointsInView(wpSet,viewId2)
```

```
pointIndices = 5×1

     6
     7
     8
     9
    10

featureIndices = 5×1

    1
    2
    3
    4
    5
```

Find World Points in World Points Set

Generate 3-D world points and point Ids.

```
worldPoints = rand(100,3);
pointIds = randperm(100);
```

Create a `worldpointset` object.

```
wpSet = worldpointset;
```

Add world points.

```
wpSet = addWorldPoints(wpSet,worldPoints,pointIds);
```

Add 3-D to 2-D correspondences for view 1.

```
viewId1 = 1;
featureIndices1 = 1:10;
wpSet  = addCorrespondences(wpSet,viewId1,pointIds(1:10),featureIndices1);
```

Add 3-D to 2-D correspondences for view 2.

```
viewId2 = 2;
featureIndices2 = 1:5;
wpSet  = addCorrespondences(wpSet,viewId2,pointIds(6:10),featureIndices2);
```

Find world points in view 2.

```
[pointIdsInView,featureIndices] = findWorldPointsInView(wpSet,viewId2);
```

Input Arguments

`wpSet` — World point set

`worldpointset` object

World point set, specified as a `worldpointset` object.

`viewId` — View identifier

scalar | *N*-element vector

View identifier, specified as a scalar or an *N*-element vector. *N* is the number of views specified. The dimensions of the `pointIndices` and `featureIndices` arguments depends on the value of the `viewId` argument.

`viewId`	`pointIndices`	`featureIndices`
scalar	*M*-element column vector	*M*-element column vector
N-element array	*N*-element cell array	*N*-element cell array

Output Arguments

`pointIndices` — 3-D world point indices

M-element column vector | *N*-element cell array

3-D world point indices, returned as an *M*-element column vector or an *N*-element cell array. *M* is the number of world points with corresponding feature points in the specified view. *N* is the number of views specified, and each element of the cell array contains a column vector of the world point indices with corresponding feature points in the associated view. This output is valid when sequential indices are used for the points in the `wpSet` object.

`pointIds` — World point identifiers

M-element array vector of integers

World point identifiers, returned as an *M*-element vector of integers. *M* is the number of world points found from the `wpSet` object. This output is valid when points were added using `addWorldPoints`.

`featureIndices` — 2-D feature point indices

M-element column vector | *N*-element cell array

2-D feature point indices, returned as an *M*-element column vector or an *N*-element cell array. *M* is the number of world points with corresponding feature points in the specified view. *N* is the number of views specified, and each element of the cell array contains a column vector of the feature point indices in the associated view with corresponding world points.

Version History

Introduced in R2020b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

If the input argument `viewId` is a scalar, the output arguments `pointIndices` and `featureIndices` returned by the generated code are *M*-element cell arrays. *M* is the number of world points with corresponding feature points in the specified view.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

removeCorrespondences

Remove 3-D to 2-D correspondences from world point set

Syntax

```
wpSet = removeCorrespondences(wpSet,viewId,pointIndices)
wpSet = removeCorrespondences(wpSet,viewId,pointIds)
```

Description

`wpSet = removeCorrespondences(wpSet,viewId,pointIndices)` removes the correspondences between the 3-D world points, specified by the point indices `pointIndices`, and 2-D feature points for the specified view `viewId` from a world point set. Use this syntax if you added points using the `addWorldPoints` function without specifying unique point identifiers `pointIds`.

`wpSet = removeCorrespondences(wpSet,viewId,pointIds)` removes the correspondences between the 3-D world points, specified by point identifiers `pointIds` and 2-D feature points for the specified view `viewId` from a world point set. Use this syntax if you added points using the `addWorldPoints` function by specifying unique point identifiers `pointIds`.

Examples

Remove Correspondences in World Point Set

Generate 3-D world points.

```
worldPoints = rand(100,3);
```

Create a `worldpointset` object.

```
wpSet = worldpointset;
```

Add world points.

```
wpSet = addWorldPoints(wpSet,worldPoints);
```

Add correspondences for a view.

```
viewId = 1;
pointIndices   = 1:10;
featureIndices = 1:10;
wpSet  = addCorrespondences(wpSet,viewId,pointIndices,featureIndices);
```

Remove the first 5 correspondences.

```
pointIndices = 1:5;
wpSet  = removeCorrespondences(wpSet,viewId,pointIndices);
```

Remove Correspondences in World Point Set

Generate 3-D world points.

```
worldPoints = rand(100,3);
```

Generate pointIds.

```
pointIds = randperm(100);
```

Create a `worldpointset` object.

```
wpSet = worldpointset;
```

Add world points.

```
wpSet = addWorldPoints(wpSet,worldPoints,pointIds);
```

Add correspondences for a view.

```
viewId = 1;
featureIndices = 1:10;
wpSet  = addCorrespondences(wpSet,viewId,pointIds(1:10),featureIndices);
```

Remove the first 5 correspondences.

```
wpSet  = removeCorrespondences(wpSet,viewId,pointIds(1:5));
```

Input Arguments

`wpSet` — World point set

`worldpointset` object

World point set, specified as a `worldpointset` object.

`viewId` — View identifier

scalar

View identifier, specified as a scalar.

`pointIndices` — World point indices

M-element column vector of integers

World point indices, specified as an *M*-element column vector of integers. *M* is the number of world points from which to remove correspondences. Use this input when sequential indices are used for the points in the `wpSet` object.

`pointIds` — World point identifiers

M-element array vector of integers

World point identifiers, returned as an *M*-element vector of integers. *M* is the number of world points from which to remove correspondences. Use this input when points were added using `addWorldPoints`.

Output Arguments

`wpSet` — World point set
`worldpointset` object

World point set, returned as a `worldpointset` object.

removeWorldPoints

Remove world points from world point set

Syntax

```
wpSet = removeWorldPoints(wpSet,pointIndices)
wpSet = removeWorldPoints(wpSet,pointIds)
```

Description

`wpSet = removeWorldPoints(wpSet,pointIndices)` removes the world points at the specified indices `pointIndices` from the world point set `wpSet`. Use this syntax if you added points using the `addWorldPoints` function without specifying unique point identifiers `pointIds`.

`wpSet = removeWorldPoints(wpSet,pointIds)` removes the world points specified by `pointIDs` from the world point set `wpSet`. Use this syntax if you added points using the `addWorldPoints` function by specifying unique point identifiers `pointIds`.

Examples

Remove Points from World Point Set

Generate 3-D world points.

```
worldPoints = rand(100,3);
```

Create a `worldpointset` object.

```
wpSet = worldpointset;
```

Add the world points to the world point set. Display the world point set.

```
[wpSet,newPointIndices] = addWorldPoints(wpSet,worldPoints);
wpSet
```

```
wpSet =
  worldpointset with properties:

                   WorldPoints: [100×3 single]
                       ViewIds: [1×0 uint32]
                      PointIds: [1×0 uint32]
              ViewingDirection: [100×3 single]
                DistanceLimits: [100×2 single]
          RepresentativeViewId: [100×1 double]
    RepresentativeFeatureIndex: [100×1 double]
                         Count: 100
               Correspondences: [100×3 table]
```

Remove the first 50 world points from the world point set.

```
wpSet = removeWorldPoints(wpSet,newPointIndices(1:50))

wpSet =
  worldpointset with properties:

                   WorldPoints: [50×3 single]
                       ViewIds: [1×0 uint32]
                      PointIds: [1×0 uint32]
              ViewingDirection: [50×3 single]
                DistanceLimits: [50×2 single]
           RepresentativeViewId: [50×1 double]
    RepresentativeFeatureIndex: [50×1 double]
                         Count: 50
               Correspondences: [50×3 table]
```

Remove Points from World Point Set

Generate 3-D world points.

```
worldPoints = rand(100,3);
```

Generate pointIds.

```
pointIds = randperm(100);
```

Create a `worldpointset` object.

```
wpSet = worldpointset;
```

Add the world points to the world point set. Display the world point set.

```
[wpSet,newPointIndices] = addWorldPoints(wpSet,worldPoints,pointIds);
```

```
wpSet
```

Remove the first 50 world points from the world point set.

```
wpSet = removeWorldPoints(wpSet,pointIds(1:50))

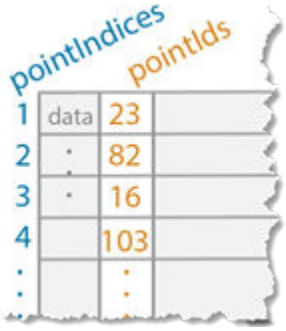
wpSet =
  worldpointset with properties:

                   WorldPoints: [50×3 single]
                       ViewIds: [1×0 uint32]
                      PointIds: [16 67 75 39 12 5 27 54 47 62 80 89 77 95 83 30 71 14 29 11 53 50
              ViewingDirection: [50×3 single]
                DistanceLimits: [50×2 single]
           RepresentativeViewId: [50×1 double]
    RepresentativeFeatureIndex: [50×1 double]
                         Count: 50
               Correspondences: [50×3 table]
```

Input Arguments

`wpSet` — World point set

`worldpointset` object



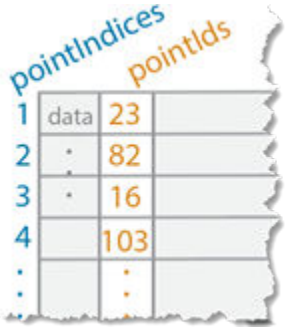
World point set, specified as a `worldpointset` object.

`pointIndices` — World point indices

M-element array vector of integers

World point indices, specified as an *M*-element vector of integers. *M* is the number of world points to remove from the `worldpointset` object. Use this input when sequential indices are used to identify points.

- `pointIds` — Unique identifiers assigned to points when using the `addWorldPoints` to add points.
- `pointIndices` — Sequential identifiers assigned to points.



`pointIds` — World point identifiers

M-element array vector of integers

World point identifiers, specified as an *M*-element vector of integers. *M* is the number of world points to remove from the `worldpointset` object. Use this input if you used the `addWorldPoints` function when points were added.

- `pointIds` — Unique identifiers assigned to points when using the `addWorldPoints` to add points.
- `pointIndices` — Sequential identifiers assigned to points.

Output Arguments

`wpSet` — World point set
`worldpointset` object

World point set, returned as a `worldpointset` object.

Version History

Introduced in R2020b

R2024a: Use unique point identifiers to specify world points

New for this release, you can use `pointIds` to specify unique point IDs to specify world points. In prior releases if you did not specify unique identifiers when points were added, then points were saved with sequential identifiers. World points can only be saved with one method, either using sequential `pointIndices` or with unique IDs `pointIDs`. The function will return an error if both types of IDs are passed into it.

updateCorrespondences

Update 3-D to 2-D correspondences in world point set

Syntax

```
wpSet = updateCorrespondences(wpSet,viewId,pointIndices,featureIndices)
wpSet = updateCorrespondences(wpSet,viewId,pointIds,featureIndices)
```

Description

`wpSet = updateCorrespondences(wpSet,viewId,pointIndices,featureIndices)` updates the correspondences between the 3-D world points specified by `pointIndices` and 2-D feature points `featureIndices` for the specified view `viewId` in a world point set `wpSet`. Use this syntax if you added points using the `addWorldPoints` function without specifying unique point identifiers `pointIds`.

`wpSet = updateCorrespondences(wpSet,viewId,pointIds,featureIndices)` updates the correspondences between the 3-D world points specified by the point identifiers `pointIds` and 2-D feature points `featureIndices` for the specified view `viewId` in a world point set `wpSet`. Use this syntax if you added points using the `addWorldPoints` function by specifying unique point identifiers `pointIds`.

Examples

Update Correspondences in World Point Set

Generate 3-D world points.

```
worldPoints = rand(100,3);
```

Create a `worldpointset` object.

```
wpSet = worldpointset;
```

Add world points.

```
wpSet = addWorldPoints(wpSet,worldPoints);
```

Add correspondences for a view.

```
viewId = 1;
pointIndices   = 1:10;
featureIndices = 1:10;
wpSet  = addCorrespondences(wpSet,viewId,pointIndices,featureIndices);
```

Update the feature indices.

```
newFeatureIndices = 11:20;
wpSet  = updateCorrespondences(wpSet,viewId,pointIndices,newFeatureIndices);
```

Update Correspondences in World Point Set

Generate 3-D world points.

```
worldPoints = rand(100,3);
```

Generate identifiers for 3-D world points.

```
pointIds = randperm(100);
```

Create a `worldpointset` object.

```
wpSet = worldpointset;
```

Add world points.

```
wpSet = addWorldPoints(wpSet,worldPoints,pointIds);
```

Add correspondences for a view.

```
viewId = 1;
featureIndices = 1:10;
wpSet  = addCorrespondences(wpSet,viewId,pointIds(1:10),featureIndices);
```

Update the feature indices.

```
newFeatureIndices = 11:20;
wpSet  = updateCorrespondences(wpSet,viewId,pointIds(1:10),newFeatureIndices);
```

Input Arguments

`wpSet` — World point set
`worldpointset` object

World point set, specified as a `worldpointset` object.

`viewId` — View identifier
scalar

View identifier, specified as a scalar.

`pointIndices` — World point indices
M-element column vector of integers

World point indices, specified as an *M*-element column vector of integers. *M* is the number of world points for which to update correspondences in the world point set. Use this input when sequential indices are used for the points in the `wpSet` object.

`pointIds` — World point identifiers
M-element array vector of integers

World point identifiers, returned as an *M*-element vector of integers. *M* is the number of world points from which to update correspondences. Use this input when points were added using `addWorldPoints`.

`featureIndices` — 2-D feature point indices
M-element column vector of integers

Feature point indices, specified as an *M*-element column vector of integers. *M* is the number of world points for which to update correspondences in the world point set.

Output Arguments

`wpSet` — World point set
`worldpointset` object

World point set, returned as a `worldpointset` object.

updateWorldPoints

Update world points in world point set

Syntax

```
wpSet = updateWorldPoints(wpSet,pointIndices,worldPoints)
wpSet = updateWorldPoints(wpSet,pointIds,worldPoints)
```

Description

`wpSet = updateWorldPoints(wpSet,pointIndices,worldPoints)` updates the locations of the world points at the specified indices `pointIndices` of the world point set `wpSet`. Use this syntax if you added points using the `addWorldPoints` function without specifying unique point identifiers `pointIds`.

`wpSet = updateWorldPoints(wpSet,pointIds,worldPoints)` updates the locations of the world points specified by the point identifiers `pointIds`, of the world point set `wpSet`.Use this syntax if you added points using the `addWorldPoints` function by specifying unique point identifiers `pointIds`.

Examples

Update World Point Set

Generate 3-D world points.

```
worldPoints = rand(100,3);
```

Create a `worldpointset` object.

```
wpSet = worldpointset;
```

Add the world points to the world point set.

```
wpSet = addWorldPoints(wpSet,worldPoints);
```

Update the first 50 world points with new locations.

```
pointIndices = 1:50;
newWorldPoints = worldPoints(pointIndices,:) + [0 0 5];
wpSet = updateWorldPoints(wpSet,pointIndices,newWorldPoints);
```

Update World Point Set

Generate 3-D world points.

```
worldPoints = rand(100,3);
```

Generate pointIds.

```
pointIds = randperm(100);
```

Create a `worldpointset` object.

```
wpSet = worldpointset;
```

Add the world points to the world point set.

```
wpSet = addWorldPoints(wpSet,worldPoints,pointIds);
```

Update the first 50 world points with new locations.

```
newWorldPoints = selectWorldPoints(wpSet,pointIds(1:50)) + [0 0 5];
wpSet = updateWorldPoints(wpSet,pointIds(1:50),newWorldPoints);
```

Input Arguments

`wpSet` — World point set
`worldpointset` object

World point set, specified as a `worldpointset` object.

`pointIndices` — World point indices
scalar | *N*-element vector of integers

World point indices, specified as a scalar or an *N*-element vector of integers. This input is valid when sequential indices are used for the points in the `wpSet` object.

`pointIds` — World point identifiers
M-element array vector of integers

World point identifiers, specified as an *M*-element vector of integers. *M* is the number of world points. This input is valid when points were added using `addWorldPoints`.

`worldPoints` — World points coordinates
M-by-3 matrix

World points coordinates, specified as an *M*-by-3 matrix in the form [*x y z*].

Output Arguments

`wpSet` — World point set
`worldpointset` object

World point set, returned as a `worldpointset` object.

pcviewset

Manage data for point cloud based odometry and SLAM

Description

The `pcviewset` object stores point cloud odometry and simultaneous localization and mapping (SLAM) data as a set of views and pairwise connections between views.

Creation

Syntax

```
vSet = pcviewset
```

Description

`vSet = pcviewset` creates a pcviewset object with default property names. Use object functions to perform actions such as adding, modifying, or removing views or connections.

Properties

`Views` — View attributes

empty three-column table (default) | three-column table

This property is read-only.

View attributes, specified as a three-column table. The table contains columns as described in this table.

Column	Description
`ViewID`	View identifier, specified as an integer. View identifiers are unique to a specific view.
`AbsolutePose`	Absolute pose of the view, specified as a `rigidtform3d` object.
`PointCloud`	Point cloud, specified as a `pointCloud` object.

`Connections` — Pairwise connections between views

empty four-column table (default) | four-column table

This property is read-only.

Pairwise connections between views, specified as a four-column table. The table contains columns as described in this table. Each row corresponds to one connection.

Column	Description
`ViewID1`	View identifier for the first view, specified as a unique integer.
`ViewID2`	View identifier for the second view, specified as a unique integer.
`RelativePose`	Relative pose of the second view with respect to the first view, specified as a `rigidtform3d` object.
`InformationMatrix`	Information matrix, specified as a 6-by-6 matrix. The information matrix represents the uncertainty of the measurement error and is the inverse of the covariance matrix.

`NumViews` — Number of views
`0` (default) | nonnegative integer

This property is read-only.

Number of views, specified as a nonnegative integer.

`NumConnections` — Number of connections
`0` (default) | nonnegative integer

This property is read-only.

Number of connections, specified as a nonnegative integer.

Object Functions

addView	Add views to view set
updateView	Update view in view set
deleteView	Delete view from view set
hasView	Check if view is in view set
addConnection	Add connection between views in view set
updateConnection	Update connection between views in a view set
deleteConnection	Delete a connection between views in view set
hasConnection	Check if connection between two views is in view set
findView	Find views associated with view identifiers
findConnection	Find connections associated with view identifiers
connectedViews	Connected views in view set
poses	Absolute poses associated with views in view set
createPoseGraph	Create pose graph
optimizePoses	Optimize absolute poses using relative pose constraints
plot	Plot point cloud view set views and connections

Examples

Perform Lidar Odometry Using Point Cloud Registration

Create a view set to hold odometry.

```
 vSet = pcviewset;
```

Create a Velodyne reader to read point clouds.

```
veloReader = velodyneFileReader('lidarData_ConstructionRoad.pcap','HDL32E');
ptCloud = readFrame(veloReader);
```

Preprocess one frame to remove the ground plane and to downsample point cloud.

```
elevationDelta = 25;
gridStep = 0.2;
groundPtsIdx = segmentGroundFromLidarData(ptCloud, ...
    ElevationAngleDelta=elevationDelta);
ptCloud = select(ptCloud,~groundPtsIdx,Output='full');
ptCloud = pcdownsample(ptCloud,'gridAverage',gridStep);
```

Initialize attributes for the first view.

```
absPose = rigidtform3d;
relPose = rigidtform3d;
```

Add the first view to the point cloud view set.

```
vSet = addView(vSet,1,absPose,PointCloud=ptCloud);
```

Initialize a point cloud map using the first view.

```
ptCloudMap = copy(ptCloud);

skipFrames = 5;
prevViewId = 1;
prevPtCloud = ptCloud;
```

Loop over frames to update odometry and the point cloud map.

```
for viewId = 6:skipFrames:40
    % Read point cloud.
    ptCloud = readFrame(veloReader,viewId);

    % Preprocess the frame.
    groundPtsIdx = segmentGroundFromLidarData(ptCloud, ...
        ElevationAngleDelta=elevationDelta);
    ptCloud = select(ptCloud,~groundPtsIdx,Output='full');
    ptCloud = pcdownsample(ptCloud,'gridAverage',gridStep);

    % Register new point cloud against the previous one.
    regGridStep = 5;
    relPose = pcregisterndt(ptCloud,prevPtCloud,regGridStep, ...
        InitialTransform=relPose);

    % Update the absolute pose.
    absPose = rigidtform3d(absPose.A * relPose.A);

    % Add new view and connection to the previous view.
    vSet = addView(vSet,viewId,absPose,PointCloud=ptCloud);
    vSet = addConnection(vSet,prevViewId,viewId,relPose);

    prevPtCloud = ptCloud;
```

```
    prevViewId = viewId;
end
```

Display the view set in a default 2-D view.

```
plot(vSet,ShowViewIds='on')
view(2)
```

Version History

Introduced in R2020a

R2022b: Supports premultiply geometric transformation convention

Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, the `pcviewset` object and its object functions are updated to use `rigidtform3d` objects, which support the premultiply convention. The `pcviewset` object now:

- Returns the `Views` property with the `AbsolutePose` column as a `rigidtform3d` object
- Returns the `Connections` property with the `RelativePose` column as a `rigidtform3d` object

Before, the properties returned `AbsolutePose` and `RelativePose` as `rigid3d` objects, which use the postmultiply convention.

For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

addView

Add views to view set

Syntax

```
vSet = addView(vSet,viewId)
vSet = addView(vSet,viewId,absPose)
vSet = addView( ___ ,"PointCloud",ptCloud)

vSet = addView(vSet,viewTable)
```

Description

`vSet = addView(vSet,viewId)` adds the view specified by `viewId` to the view set, `vSet`.

`vSet = addView(vSet,viewId,absPose)` specifies the absolute pose of the view.

`vSet = addView( ___ ,"PointCloud",ptCloud)` specifies the point cloud associated with the view in addition to any of the input argument combinations in previous syntaxes.

`vSet = addView(vSet,viewTable)` adds one or more views in the table specified by `viewTable`.

Examples

Update View in Point Cloud View Set

Create an empty point cloud view set.

```
vSet = pcviewset;
```

Add a view to the point cloud view set.

```
viewId  = 1;
ptCloud = pcread("teapot.ply");

vSet = addView(vSet,viewId,"PointCloud",ptCloud);
```

Update the absolute pose of the view.

```
rotationAngles = [0 0 0];
translation = [2 0 0];
absPose = rigidtform3d(rotationAngles,translation);
vSet = updateView(vSet,viewId,absPose);
```

Input Arguments

vSet — Point cloud view set

`pcviewset` object

Point cloud view set, specified as a `pcviewset` object.

`viewId` — View identifier
positive integer

View identifier, specified as a positive integer. View identifiers are unique to a specific view.

`absPose` — Absolute pose of the view
`rigidtform3d` object

Absolute pose of the view, specified as a `rigidtform3d` object.

`ptCloud` — Point cloud
`pointCloud` object

Point cloud, specified as a `pointCloud` object.

`viewTable` — One or more views
two-column table | three-column table

One or more views, specified as a two-column or three-column table. The table must contain the columns `ViewId` and `AbsolutePose`. The `Points` column is optional.

Column	Description
`ViewID`	View identifier, specified as an integer. View identifiers are unique to a specific view.
`AbsolutePose`	Absolute pose of the view, specified as a `rigidtform3d` object.
`Points`	Point cloud for the view, specified as a `pointCloud` object.

Output Arguments

`vSet` — View set with added views
`pcviewset` object

View set with added views, returned as a `pcviewset` object.

Version History

Introduced in R2020a

R2022b: Supports premultiply geometric transformation convention

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, you can now specify poses (the `absPose` argument and the `AbsolutePose` column of the `viewTable` argument) as `rigidtform3d` objects, which use the premultiply convention.

Although you can still specify poses as `rigid3d` objects, these objects are not recommended because they use the postmultiply convention. The `addView` function automatically converts the poses to the premultiply convention and returns a `pcviewset` object that represents the poses as `rigidtform3d` objects.

For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

When you specify table as an input argument, then code generation has limitations. For information about the limitations, see “Code Generation for Tables” (MATLAB Coder) and “Table Limitations for Code Generation” (MATLAB Coder).

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

Objects

`pcviewset`

updateView

Update view in view set

Syntax

```
vSet = updateView(vSet,viewId,absPose)
vSet = updateView( ___ ,"PointCloud",ptCloud)

vSet = updateView(vSet,viewTable)
```

Description

`vSet = updateView(vSet,viewId,absPose)` updates the view specified by `viewId` with the absolute pose `absPose`.

`vSet = updateView( ___ ,"PointCloud",ptCloud)` specifies the point cloud associated with the view.

`vSet = updateView(vSet,viewTable)` updates the views specified in the table `viewTable`.

Examples

Update View in Point Cloud View Set

Create an empty point cloud view set.

```
vSet = pcviewset;
```

Add a view to the point cloud view set.

```
viewId  = 1;
ptCloud = pcread("teapot.ply");

vSet = addView(vSet,viewId,"PointCloud",ptCloud);
```

Update the absolute pose of the view.

```
rotationAngles = [0 0 0];
translation = [2 0 0];
absPose = rigidtform3d(rotationAngles,translation);
vSet = updateView(vSet,viewId,absPose);
```

Input Arguments

vSet — Point cloud view set

`pcviewset` object

View set, specified as an `pcviewset` object.

`viewId` — View identifier
integer

Point cloud view identifier, specified as a unique integer.

`absPose` — Absolute pose
`rigidtform3d` object

Absolute pose, specified as a `rigidtform3d` object.

`ptCloud` — Point cloud
`pointCloud` object

Point cloud, specified as a `pointCloud` object.

`viewTable` — New view or set of views
two-column table | three-column table

New view or set of views, specified as a two- or three- column table. The table must contain the columns `ViewId` and `AbsolutePose`, and an optional column, `Points`.

Column	Description
`ViewID`	View identifier for the view, specified as a unique integer
`AbsolutePose`	Absolute pose of the view, specified as a `rigidtform3d` object.
`Points`	A `pointCloud`.

Output Arguments

`vSet` — View set with updated view
`pcviewset` object

View set with updated view, returned as a `pcviewset` object.

Version History

Introduced in R2020a

R2022b: Supports premultiply geometric transformation convention

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, you can now specify poses (the `absPose` argument and the `AbsolutePose` column of the `viewTable` argument) as `rigidtform3d` objects, which use the premultiply convention.

Although you can still specify poses as `rigid3d` objects, these objects are not recommended because they use the postmultiply convention. The `updateView` function automatically converts the poses to the premultiply convention and returns a `pcviewset` object that represents the poses as `rigidtform3d` objects.

deleteView

Delete view from view set

Syntax

```
vSet = deleteView(vSet,viewId)
```

Description

`vSet = deleteView(vSet,viewId)` deletes the view specified by `viewId` from the view set, `vSet`.

Examples

Delete View from Point Cloud View Set

Create an empty point cloud view set.

```
vSet = pcviewset;
```

Add two views to the point cloud view set.

```
viewId1 = 1;
viewId2 = 2;
ptCloud1 = pcread('teapot.ply');
ptCloud2 = pctransform(ptCloud1,rigidtform3d([0 0 0],[2 0 0]));

vSet = addView(vSet,viewId1,'PointCloud',ptCloud1);
vSet = addView(vSet,viewId2,'PointCloud',ptCloud2);
```

Delete the first view.

```
vSet = deleteView(vSet,viewId1);
```

Input Arguments

`vSet` — Point cloud view set

`pcviewset` object

Point cloud view set, specified as a `pcviewset` object.

`viewId` — View identifier

positive integer

View identifier, specified as an integer. View identifiers are unique to a specific view.

Output Arguments

vSet — View set with deleted views

`pcviewset` object

View set with deleted views, returned as a `pcviewset` object.

Version History

Introduced in R2020a

`pcviewset`

hasView

Check if view is in view set

Syntax

```
tf = hasView(vSet,viewId)
```

Description

`tf = hasView(vSet,viewId)` returns `1` (true), if the view specified by `viewId` is in the view set, `vSet`. The function returns `0` (false), if the view is not in `vSet`.

Examples

Check If View Is in Point Cloud View Set

Create an empty point cloud view set.

```
vSet = pcviewset;
```

Add a view with ID `1` to the point cloud view set.

```
ptCloud = pcread('teapot.ply');
vSet = addView(vSet,1,'PointCloud',ptCloud);
```

Check if a view with ID `1` is in the view set.

```
hasView(vSet,1)
```

```
ans = logical
   1
```

Check if a view with ID `2` is in the view set.

```
hasView(vSet,2)
```

```
ans = logical
   0
```

Input Arguments

`vSet` — Point cloud view set

`pcviewset` object

Point cloud view set, specified as a `pcviewset` object.

`viewId` — View identifier

positive integer

View identifier, specified as an integer. View identifiers are unique to a specific view.

Output Arguments

`tf` — True or false result

`1 | 0`

True or false result indicating if view is in view set `vSet`, returned as a `1` or `0` data type `logical`.

Version History

addConnection

Add connection between views in view set

Syntax

```
vSet = addConnection(vSet,viewId1,viewId2)
vSet = addConnection(vSet,viewId1,viewId2,relPose)
vSet = addConnection(vSet,viewId1,viewId2,relPose,infoMat)
```

Description

`vSet = addConnection(vSet,viewId1,viewId2)` adds a connection between views `viewId1` and `viewId2` to the view set, `vSet`.

`vSet = addConnection(vSet,viewId1,viewId2,relPose)` specifies the relative pose of `viewId2` with respect to `viewId1`.

`vSet = addConnection(vSet,viewId1,viewId2,relPose,infoMat)` specifies the information matrix associated with the connection.

Examples

Add Connection to Point Cloud View Set

Create an empty point cloud view set.

```
vSet = pcviewset;
```

Load point cloud data.

```
data = load('livingRoom.mat');
ptCloud1 = data.livingRoomData{1};
ptCloud2 = data.livingRoomData{2};
```

Add `ptCloud1` to the point cloud view set. Specify a `rigidtform3d` object as the origin.

```
absPose1 = rigidtform3d;
vSet = addView(vSet,1,absPose1,'PointCloud',ptCloud1);
```

Add `ptCloud2` to the point cloud view set. Specify a `rigidtform3d` object as the origin.

```
vSet = addView(vSet,2,absPose1,'PointCloud',ptCloud2);
```

Estimate the rigid transformation between the two point clouds.

```
ptCloud2Downsampled = pcdownsample(ptCloud2,'gridAverage',0.1);
gridStep = 0.5;
relPose = pcregisterndt(ptCloud2Downsampled,ptCloud1,gridStep);
```

Add a connection between the views.

```
vSet = addConnection(vSet,1,2,relPose);
```

Compute the accumulated absolute pose.

```
absPose2 = rigidtform3d(absPose1.A * relPose.A);
```

Update the absolute pose of second view.

```
vSet = updateView(vSet,2,absPose2);
```

Input Arguments

`vSet` — Point cloud view set

`pcviewset` object

Point cloud view set, specified as a `pcviewset` object.

`viewId1` — View identifier 1

positive integer

View identifier 1, specified as an integer. View identifiers are unique to a specific view.

`viewId2` — View identifier 2

positive integer

View identifier 2, specified as an integer. View identifiers are unique to a specific view.

`relPose` — Relative pose

`rigidtform3d` object

Relative pose of `viewId2` with respect to `viewId1`, specified as a `rigidtform3d` object.

`infoMat` — Information matrix

6-by-6 numeric matrix

Information matrix associated with the connection, specified as a 6-by-6 numeric matrix.

Output Arguments

`vSet` — View set with added connections

`pcviewset` object

View set with added connections between views, returned as a `pcviewset` object.

Version History

Introduced in R2020a

R2022b: Supports premultiply geometric transformation convention

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, you can now specify the `relPose` argument as a `rigidtform3d` object, which uses the premultiply convention.

Although you can still specify `relPose` as a `rigid3d` object, this object is not recommended because it uses the postmultiply convention. The `addConnection` function automatically converts the relative pose to the premultiply convention and returns a `pcviewset` object that represents the pose as a `rigidtform3d` object.

updateConnection

Update connection between views in a view set

Syntax

```
vSet = updateConnection(vSet,viewId1,viewId2,relPose)
vSet = updateConnection(vSet,viewId1,viewId2,relPose,infoMat)
```

Description

`vSet = updateConnection(vSet,viewId1,viewId2,relPose)` updates the connection between views `viewId1` and `viewId2` with the relative pose specified by `relPose`.

`vSet = updateConnection(vSet,viewId1,viewId2,relPose,infoMat)` specifies the information matrix associated with the connection.

Examples

Update Connection in Point Cloud View Set

Create an empty point cloud view set.

```
vSet = pcviewset;
```

Load point cloud data.

```
data = load('livingRoom.mat');
ptCloud1 = data.livingRoomData{1};
ptCloud2 = data.livingRoomData{2};
```

Add two views to the point cloud view set.

```
vSet = addView(vSet,1,'PointCloud',ptCloud1);
vSet = addView(vSet,2,'PointCloud',ptCloud2);
```

Add a connection between the two views.

```
vSet = addConnection(vSet,1,2);
```

Estimate the rigid transformation between the two point clouds.

```
ptCloud2Downsampled = pcdownsample(ptCloud2,'gridAverage',0.1);

gridStep = 0.5;
relPose = pcregisterndt(ptCloud2Downsampled,ptCloud1,gridStep);
```

Compute the accumulated absolute pose for each view.

```
absPose1 = rigidtform3d;
absPose2 = rigidtform3d(absPose1.A * relPose.A);
```

Update the connection with relative pose between views.

```
vSet = updateConnection(vSet,1,2,relPose);
```

Update the views with the absolute poses.

```
vSet = updateView(vSet,1,absPose1);
vSet = updateView(vSet,2,absPose2);
```

Input Arguments

`vSet` — Point cloud view set

`pcviewset` object

Point cloud view set, specified as a `pcviewset` object.

`viewId1` — View identifier 1

positive integer

View identifier 1, specified as an integer. View identifiers are unique to a specific view.

`viewId2` — View identifier 2

positive integer

View identifier 2, specified as an integer. View identifiers are unique to a specific view.

`relPose` — Relative pose

`rigidtform3d` object

Relative pose of `viewId2` with respect to `viewId1`, specified as a `rigidtform3d` object.

`infoMat` — Information matrix

6-by-6 numeric matrix

Information matrix associated with the connection, specified as a 6-by-6 numeric matrix.

Output Arguments

`vSet` — View set with updated connections

`pcviewset` object

View set with updated connections between views, returned as a `pcviewset` object.

Version History

Introduced in R2020a

R2022b: Supports premultiply geometric transformation convention

deleteConnection

Delete a connection between views in view set

Syntax

```
vSet = deleteConnection(vSet,viewId1,viewId2)
```

Description

`vSet = deleteConnection(vSet,viewId1,viewId2)` deletes the connection between views `viewId1` and `viewId2` in the view set, `vSet`.

Examples

Delete Connection Between Views in Point Cloud View Set

Create an empty point cloud view set.

```
vSet = pcviewset;
```

Add two views and one connection to the view set.

```
vSet = addView(vSet,1);
vSet = addView(vSet,2);
vSet = addConnection(vSet,1,2);
```

Delete the connection between the two views.

```
vSet = deleteConnection(vSet,1,2);
```

Input Arguments

`vSet` — Point cloud view set
`pcviewset` object

Point cloud view set, specified as a `pcviewset` object.

`viewId1` — View identifier 1
positive integer

View identifier 1, specified as an integer. View identifiers are unique to a specific view.

`viewId2` — View identifier 2
positive integer

View identifier 2, specified as an integer. View identifiers are unique to a specific view.

Output Arguments

vSet — View set with deleted connections
`pcviewset` object

View set with deleted connections between views, returned as a `pcviewset` object.

hasConnection

Check if connection between two views is in view set

Syntax

```
tf = hasConnection(vSet,viewId1,viewId2)
```

Description

`tf = hasConnection(vSet,viewId1,viewId2)` returns `1` (true), if the connection between views `viewId1` and `viewId2` is in the view set, `vSet`. The function returns `0` (false), if the connection does not exist in `vSet`.

Examples

Check for Connection Between Views in Point Cloud View Set

Create an empty point cloud view set.

```
vSet = pcviewset;
```

Add two views to the point cloud view set.

```
vSet = addView(vSet,1);
vSet = addView(vSet,2);
```

Add a connection to the point cloud view set.

```
vSet = addConnection(vSet,1,2);
```

Check if the connection is between views is in the point cloud view set.

```
tf = hasConnection(vSet,1,2)
```

```
tf = logical
   1
```

Input Arguments

vSet — Point cloud view set

`pcviewset` object

Point cloud view set, specified as a `pcviewset` object.

viewId1 — View identifier 1

positive integer

View identifier 1, specified as an integer. View identifiers are unique to a specific view.

`viewId2` — View identifier 2
positive integer

View identifier 2, specified as an integer. View identifiers are unique to a specific view.

Output Arguments

`tf` — True or false result
`1` | `0`

True or false result indicating if the connection between views `viewId1` and `viewId2` exists in view set `vSet`, returned as a `1` or `0` data type `logical`.

connectedViews

Connected views in view set

Syntax

```
viewTable = connectedViews(vSet,viewId)
```

Description

`viewTable = connectedViews(vSet,viewId)` returns a table of views from `vSet` that are connected to the view specified by `viewId`.

Examples

Get Connected Views in View Set

Create an empty point cloud view set object.

```
vSet = pcviewset;
```

Add views to the point cloud view set.

```
vSet = addView(vSet,1);
vSet = addView(vSet,2);
vSet = addView(vSet,3);
vSet = addView(vSet,4);
```

Connect views in the point cloud view set.

```
vSet = addConnection(vSet,1,2);
vSet = addConnection(vSet,2,3);
vSet = addConnection(vSet,2,4);
```

Get the connected views for the view with ID 2.

```
viewTable = connectedViews(vSet,2)
```

```
viewTable=3×3 table
    ViewId      AbsolutePose        PointCloud
    ______    _________________    _____________

      1       1×1 rigidtform3d    1×1 pointCloud
      3       1×1 rigidtform3d    1×1 pointCloud
      4       1×1 rigidtform3d    1×1 pointCloud
```

Input Arguments

vSet — Point cloud view set

`pcviewset` object

Point cloud view set, specified as a `pcviewset` object.

`viewId` — View identifier
positive integer

View identifier, specified as an integer. View identifiers are unique to a specific view.

Output Arguments

`viewTable` — One or more views
two-column table | three-column table

One or more views, returned as a three-column table. The table must contain the columns as described in this table.

Column	Description
`ViewId`	View identifier, specified as an integer. View identifiers are unique to a specific view.
`AbsolutePose`	Absolute pose of the view, specified as a `rigidtform3d` object.
`Points`	Point cloud for the view, specified as a `pointCloud` object.

Version History

Introduced in R2020a

R2022b: Supports premultiply geometric transformation convention
Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, the `connectedViews` function now returns the `AbsolutePose` value in the `viewTable` argument as a `rigidtform3d` object, which uses the premultiply convention. Before, the function returned `AbsolutePose` as a `rigid3d` object, which uses the postmultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

poses

Absolute poses associated with views in view set

Syntax

```
sensorPoses = poses(vSet)
```

Description

`sensorPoses = poses(vSet)` returns a table of absolute poses associated with the views contained in the view set, `vSet`.

Examples

Get Absolute Poses from Point Cloud View Set

Create an empty point cloud view set.

```
vSet = pcviewset;
```

Load point cloud data.

```
data = load('livingRoom.mat');
ptCloud1 = data.livingRoomData{1};
ptCloud2 = data.livingRoomData{2};
```

Add `ptCloud1` to the view set.

```
absPose1 = rigidtform3d;
vSet = addView(vSet,1,absPose1,'PointCloud',ptCloud1);
```

Add `ptCloud2` to the view set.

```
vSet = addView(vSet,2,'PointCloud',ptCloud2);
```

Estimate the rigid transformation between the two point clouds.

```
ptCloud2Downsampled = pcdownsample(ptCloud2,'gridAverage',0.1);

gridStep = 0.5;
relPose = pcregisterndt(ptCloud2Downsampled,ptCloud1,gridStep);
```

Add a connection between the two views.

```
vSet = addConnection(vSet,1,2,relPose);
```

Compute the accumulated absolute pose.

```
absPose2 = rigidtform3d(absPose1.A * relPose.A);
```

Update the absolute pose of second view.

```
vSet = updateView(vSet,2,absPose2);
```

Get absolute poses.

```
sensorPoses = poses(vSet)
```

```
sensorPoses=2×2 table
    ViewId      AbsolutePose
    ______    _________________

      1       1×1 rigidtform3d
      2       1×1 rigidtform3d
```

Input Arguments

vSet — Point cloud view set

`pcviewset` object

Point cloud view set, specified as a `pcviewset` object.

Output Arguments

sensorPoses — Absolute poses

two-column table

Absolute poses, returned as a two-column table. The table contains columns as described in this table.

Column	Description
`ViewID`	View identifier, returned as a positive integer. View identifiers are unique to a specific view.
`AbsolutePose`	Absolute pose of the view, returned as a `rigidtform3d` object.

Version History

Introduced in R2020a

R2022b: Supports premultiply geometric transformation convention

Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, the `poses` function now returns the `AbsolutePose` value in the `sensorPoses` argument as a `rigidtform3d` object, which uses the premultiply convention. Before, the function returned `AbsolutePose` as a `rigid3d` object, which uses the postmultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

When generating code, the output argument `sensorPoses` is returned as a structure with fields *ViewID* and *AbsolutePose*.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

optimizePoses

Optimize absolute poses using relative pose constraints

Syntax

```
vSetOptim = optimizePoses(vSet)
vSetOptim = optimizePoses(vSet,Name,Value)
```

Description

`vSetOptim = optimizePoses(vSet)` returns a point cloud view set whose absolute poses are optimized. `vSetOptim` and `vSet` are `pcviewset` objects.

The `optimizePoses` function performs pose graph optimization on the absolute poses for the `Views` in the view set using the relative pose constraints established by the `Connections` property. You can use `optimizePoses` to correct drift in odometry after detecting loop closures.

`vSetOptim = optimizePoses(vSet,Name,Value)` specifies options using one or more name-value pair arguments. For example, `'Tolerance',0.2` sets the tolerance of the optimization cost function to `0.2`.

Examples

Create and Optimize Poses Using Point Cloud View Set

Create a view set.

```
vSet = pcviewset;
```

Add four nodes and specify absolute poses.

```
absPoses = repelem(rigidtform3d,4,1);

absPoses(1).Translation = [0 0 0];
absPoses(2).Translation = [1 0 0];
absPoses(3).Translation = [2 0 0];
absPoses(4).Translation = [0.1 0 0];

vSet = addView(vSet,1,absPoses(1));
vSet = addView(vSet,2,absPoses(2));
vSet = addView(vSet,3,absPoses(3));
vSet = addView(vSet,4,absPoses(4));
```

Define 4 edges, 3 odometry and 1 loop closure.

```
relPoses = repelem(rigidtform3d,4,1);

relPoses(1).Translation = [1 0 0];
relPoses(2).Translation = [1 0 0];
relPoses(3).Translation = [-1.9 0 0];
relPoses(4).Translation = [0.2 0 0];
```

```
vSet = addConnection(vSet,1,2,relPoses(1)); % odometry
vSet = addConnection(vSet,2,3,relPoses(2)); % odometry
vSet = addConnection(vSet,3,4,relPoses(3)); % odometry
vSet = addConnection(vSet,4,1,relPoses(4)); % loop closure
```

Optimize view set.

```
vSetOptim = optimizePoses(vSet);
```

DIsplay original and optimized locations.

```
disp('Original absolute translations:')
```

```
Original absolute translations:
```

```
disp(vertcat(vSet.Views.AbsolutePose.Translation))
```

```
         0         0         0
    1.0000         0         0
    2.0000         0         0
    0.1000         0         0
```

```
disp('Optimized absolute translations:')
```

```
Optimized absolute translations:
```

```
disp(vertcat(vSetOptim.Views.AbsolutePose.Translation))
```

```
         0         0         0
    0.9250         0         0
    1.8500         0         0
   -0.1250         0         0
```

Input Arguments

vSet — Point cloud view set

`pcviewset` object

Point cloud view set, specified as a `pcviewset` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'MaxIterations',300` sets the maximum number of iterations to `300`.

MaxIterations — Maximum number of iterations

`300` (default) | positive integer

Maximum number of iterations before the function terminates optimization, specified as the comma-separated pair consisting of `'MaxIterations'` and a positive integer. Increase this value for greater accuracy in the results. Decrease this value for faster results.

`Tolerance` — Tolerance of optimization cost function
`1e-8` (default) | positive scalar

Tolerance of the optimization cost function between two consecutive iterations, specified as the comma-separated pair consisting of '`Tolerance`' and a positive scalar. If the cost function changes by less than the '`Tolerance`' value between two consecutive iterations, the function terminates optimization.

`Verbose` — Display progress information
`false` or `0` (default) | `true` or `1`

Display progress information, specified as the comma-separated pair consisting of `Verbose` and a numeric or logical `0` (`false`) or `1` (`true`). To display the progress information, set '`Verbose`' to `true`.

Output Arguments

`vSetOptim` — Optimized absolute poses
`pcviewset` object

Point cloud view set that contains optimized absolute poses, specified as a `pcviewset` object.

Tips

- To update a view set with optimized poses, use the `updateView` object function.
- The `optimizePoses` object function holds the first view fixed.

Algorithms

The `optimizePoses` function uses the Levenberg-Marquardt optimization algorithm with sparse Cholesky decomposition from the general (hyper) graph optimization (G2o) library, [1 on page 2-503].

Version History

Introduced in R2020a

R2024a: Added code generation support for non-host target platforms

Supports code generation for host and non-host target platforms.

Functions

`createPoseGraph`

Objects

`imageviewset` | `pcviewset`

createPoseGraph

Create pose graph

Syntax

```
G = createPoseGraph(vSet)
```

Description

`G = createPoseGraph(vSet)` returns a pose graph derived from the views and connections in the view set, `vSet`.

Examples

Create Pose Graph from Point Cloud View Set

Create an empty point cloud view set.

```
vSet = pcviewset;
```

Define three relative poses.

```
relPoses = repelem(rigidtform3d,3,1);
relPoses(1).Translation = [3 0 0];
relPoses(2).Translation = [5 0 0];
relPoses(3).Translation = [2 0 0];
```

Accumulate absolute poses.

```
absPoses = repelem(rigidtform3d,4,1);
absPoses(2).A = absPoses(1).A * relPoses(1).A;
absPoses(3).A = absPoses(2).A * relPoses(2).A;
absPoses(4).A = absPoses(3).A * relPoses(3).A;
```

Add four views to the point cloud view set.

```
vSet = addView(vSet,1,absPoses(1));
vSet = addView(vSet,2,absPoses(2));
vSet = addView(vSet,3,absPoses(3));
vSet = addView(vSet,4,absPoses(4));
```

Add three connections to the point cloud view set.

```
vSet = addConnection(vSet,1,2,relPoses(1));
vSet = addConnection(vSet,2,3,relPoses(2));
vSet = addConnection(vSet,3,4,relPoses(3));
```

Add a loop closure connection to the point cloud view set.

```
relPoses(4).Translation = [9 0 0];
vSet = addConnection(vSet,4,1,relPoses(4));
```

Create a pose graph.

```
G = createPoseGraph(vSet);
```

Input Arguments

vSet — View set

`pcviewset` object

View set, specified as a `pcviewset` object.

Output Arguments

G — Pose graph

`digraph` object

Pose graph, returned as a `digraph` object. The nodes in the object correspond to views, and the edges in the object correspond to connections.

The `EndNodes` of the `Edges` in the `G` digraph correspond to indices into the `Views` table, (not `ViewIds`).

Tips

- The `EndNodes` of the `Edges` in the `G` digraph correspond to indices into the `Views` table, (not `ViewIds`).
- Use “Directed and Undirected Graphs” to inspect, modify, or visualize the pose graph.
- Use the `optimizePoseGraph` function to optimize the pose graph. Use of this function requires the Navigation Toolbox.

Functions

`digraph` | `optimizePoses` | `optimizePoseGraph`

Objects

`pcviewset`

findView

Find views associated with view identifiers

Syntax

```
views = findView(vSet,viewIds)
```

Description

`views = findView(vSet,viewIds)` returns a table containing view attributes that correspond to the view identifiers in `viewIds`.

Examples

Find View Corresponding to View ID

Create an empty point cloud view set.

```
vSet = pcviewset;
```

Add two views to the view set.

```
viewId1 = 10;
viewId2 = 5;
ptCloud1 = pcread("teapot.ply");
ptCloud2 = pctransform(ptCloud1,rigidtform3d([0 0 0],[2 0 0]));
vSet = addView(vSet,viewId1,PointCloud=ptCloud1);
vSet = addView(vSet,viewId2,PointCloud=ptCloud2);
```

Find the view associated with the view identifier `5,` and then display the view table.

```
view = findView(vSet,5);
disp(view)
```

```
    ViewId      AbsolutePose         PointCloud
    ______    _________________    _______________

      5       1×1 rigidtform3d    1×1 pointCloud
```

Get the point cloud that corresponds to view identifier `5`.

```
ptCloud = view.PointCloud;
```

Get the absolute pose associated with view identifier `5`.

```
absPose = view.AbsolutePose;
```

Input Arguments

`vSet` — Point cloud view set

`pcviewset` object

Point cloud view set, specified as a `pcviewset` object.

`viewIds` — View identifier

M-element vector

View identifiers, specified as an *M*-element vector of integers. View identifiers are unique to a specific view.

Output Arguments

`views` — Table containing view attributes

three-column table

Table containing view attributes, specified as a three-column table. The table contains the columns `ViewId`, `AbsolutePose`, and `pointCloud` attribute descriptions.

Version History

Introduced in R2021b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Objects

`pcviewset`

findConnection

Find connections associated with view identifiers

Syntax

```
conn = findConnection(vSet,viewIds1,viewIds2)
```

Description

`conn = findConnection(vSet,viewIds1,viewIds2)` returns a table containing connection attributes for connections between `viewIds1` and `viewIds2`. `viewIds1` and `viewIds2` are *M*-element vectors of view identifiers.

Examples

Find Connection and Relative Pose Between Two Views

Create an empty point cloud view set.

```
vSet = pcviewset;
```

Add two views to the view set.

```
viewId1 = 10;
viewId2 = 5;
vSet = addView(vSet,viewId1);
vSet = addView(vSet,viewId2);
```

Add a connection between `viewId1` and `viewId2`.

```
vSet = addConnection(vSet,viewId1,viewId2);
```

Find and display the connection between `viewId1` and `viewId2`.

```
conn = findConnection(vSet,viewId1,viewId2);
disp(conn)
```

```
    ViewId1    ViewId2      RelativePose      InformationMatrix
    _______    _______    _________________    _________________

      10           5       1×1 rigidtform3d      {6×6 double}
```

Get the relative pose between `viewId1` and `viewId2`.

```
relPose = conn.RelativePose;
```

Input Arguments

vSet — Point cloud view set

`pcviewset` object

Point cloud view set, specified as a `pcviewset` object.

`viewIds1` — View identifiers
M-element vector

View identifiers, specified as an *M*-element vector of integers. View identifiers are unique to a specific view.

`viewIds2` — View identifiers
M-element vector

View identifiers, specified as an *M*-element vector of integers. View identifiers are unique to a specific view.

Output Arguments

`conn` — Table containing connection attributes
four-column table

Table containing view attributes, specified as a four-column table. The table contains the columns `ViewId1`, `ViewId2`, `RelativePose`, and `InformationMatrix` attribute descriptions.

Version History

Objects
`pcviewset`

plot

Plot point cloud view set views and connections

Syntax

```
plot(vSet)
h = plot(vSet)
plot(vSet,Name=Value)
```

Description

`plot(vSet)` plots the views and connections in the point cloud view set, `vSet`.

`h = plot(vSet)` returns a graph plot, `h`

`plot(vSet,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `plot(vSet,ShowViewIds="on")` turns on the ID display.

Examples

Plot Point Cloud View with View Identifiers

Create an empty point cloud view set.

```
vSet = pcviewset;
```

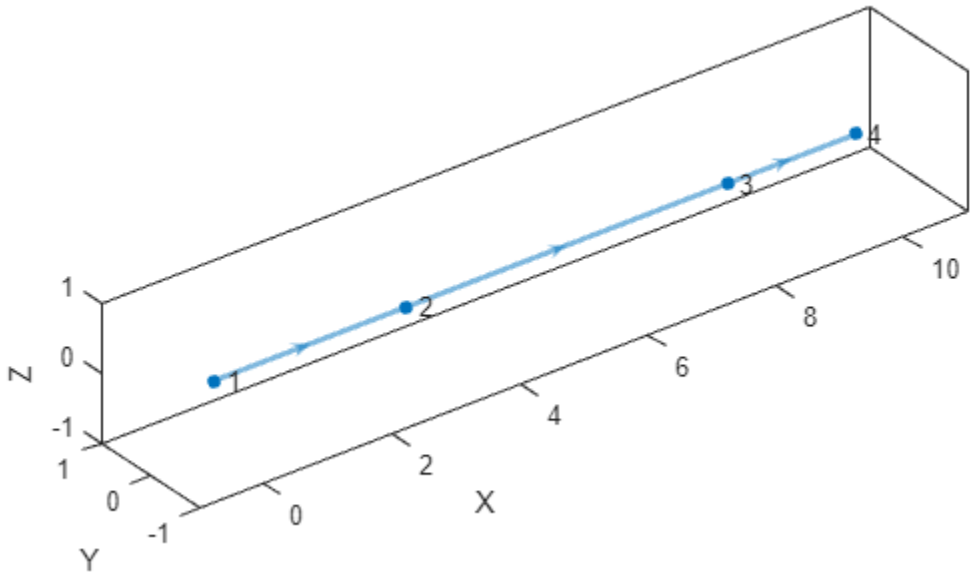
Define 3 relative poses.

```
relPoses = repelem(rigidtform3d,3,1);
relPoses(1).Translation = [3 0 0];
relPoses(2).Translation = [5 0 0];
relPoses(3).Translation = [2 0 0];
```

Accumulate the absolute poses.

```
absPoses = repelem(rigidtform3d,4,1);
absPoses(2).A = absPoses(1).A * relPoses(1).A;
absPoses(3).A = absPoses(2).A * relPoses(2).A;
absPoses(4).A = absPoses(3).A * relPoses(3).A;
```

Add 4 views to the point cloud view set.



```
vSet = addView(vSet,1,absPoses(1));
vSet = addView(vSet,2,absPoses(2));
vSet = addView(vSet,3,absPoses(3));
vSet = addView(vSet,4,absPoses(4));
```

Add 3 connections to the view set.

```
vSet = addConnection(vSet,1,2,relPoses(1));
vSet = addConnection(vSet,2,3,relPoses(2));
vSet = addConnection(vSet,3,4,relPoses(3));
```

Display the point cloud view set with view IDs.

```
plot(vSet,ShowViewIds="on")
```

Input Arguments

vSet — Point cloud view set

`pcviewset` object

Point cloud view set, specified as a `pcviewset` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `ShowViewId="on"` turns on the ID display.

Parent — Axes on which to plot view set

`Axes` object (default)

Axes on which to plot view set, specified as an `Axes` object. To create an `Axes` object, use the `axes` function.

`ShowViewIds` — Display of view identifiers
`"off"` (default) | `"on"`

Display of view identifiers, specified as `"on"` or `"off"`.

Output Arguments

`h` — Graph plot
`GraphPlot` object

Graph plot, returned as a `GraphPlot` object. You can use the `GraphPlot` object functions and properties to inspect and adjust the plotted graph.

Version History

Introduced in R2020a

Functions
`axes` | `GraphPlot`

Objects
`pcviewset`

imageviewset

Manage data for structure-from-motion, visual odometry, and visual SLAM

Description

The `imageviewset` object manages view attributes and pairwise connections between views of data used in structure-from-motion, visual odometry, and simultaneous localization and mapping (SLAM) data. View attributes can be feature descriptors, feature points, or absolute camera poses. Pairwise connections between views can be point matches, relative camera poses, or an information matrix. You can also use this object to find point tracks used by `triangulateMultiview` and `bundleAdjustment` functions.

Creation

Syntax

```
vSet = imageviewset()
```

Description

`vSet = imageviewset()` returns an `imageviewset` object. You can add views and connections using the `addView` and `addConnection` object functions.

Properties

`Views` — View attributes

empty three-column table (default) | three-column table

This property is read-only.

View attributes, specified as a three-column table. The table contains columns as described in this table.

Column	Description
`ViewId`	View identifier for the view, specified as a unique integer
`AbsolutePose`	Absolute pose of the view, specified as a `rigidtform3d` or `se3` object.
`Features`	Feature vectors, specified as an *M*-by-*N* matrix of *M* feature vectors or as a `binaryFeatures`.

Column	Description
`Points`	Image points, specified as one of these options: • *M*-by-2 matrix of coordinates in the format [*x*,*y*] • *M*-element feature point array. For more details, see “Point Feature Types”.

`Connections` — Pairwise connections between views
empty four-column table (default) | four-column table

This property is read-only.

Pairwise connections between views, specified as a four-column table. The table contains columns as described in this table. Each row corresponds to one connection.

Column	Description
`ViewId1`	View identifier for the first view, specified as a unique integer.
`ViewId2`	View identifier for the second view, specified as a unique integer.
`RelativePose`	Relative pose of the second view with respect to the first view, specified as a `rigidtform3d` or `simtform3d` object.
`InformationMatrix`	Information matrix, specified as a 6-by-6 matrix (when you specify `RelativePose` as a `rigidtform3d` object) or 7-by-7 matrix (when you specify `RelativePose` as a `simtform3d` object). The information matrix represents the uncertainty of the measurement error and is the inverse of the covariance matrix.
`Matches`	Indices of matched feature points between two views, specified as *M*-by-2 matrix.

`NumViews` — Number of views
`0` (default) | nonnegative integer

This property is read-only.

Number of views, specified as a nonnegative integer.

`NumConnections` — Number of connections
`0` (default) | nonnegative integer

This property is read-only.

Number of connections, specified as a nonnegative integer.

`ViewsSE3` — View attributes
empty three-column table (default) | three-column table

View attributes, specified as a three-column table. This property applies only when adding views with `se3` objects. The table contains these columns:

Column	Description
`ViewID`	View identifier, specified as an integer. View identifiers are unique to a specific view.
`AbsolutePose`	Absolute pose of the view, specified as an `se3` object.
`Features`	Feature vectors, specified as an *M*-by-*N* matrix of *M* feature vectors or as a `binaryFeatures` object.
`Points`	Image points, specified as an *M*-by-2 matrix of coordinates of the form [*x*,*y*] or an *M*-element feature point array.

Object Functions

addView	Add views to view set
updateView	Update view in view set
deleteView	Delete view from view set
hasView	Check if view is in view set
addConnection	Add connection between views in view set
updateConnection	Update connection between views in a view set
deleteConnection	Delete a connection between views in view set
hasConnection	Check if connection between two views is in view set
findView	Find views associated with view identifiers
findConnection	Find connections associated with view identifiers
connectedViews	Returns directly and indirectly connected views
poses	Absolute poses associated with views in view set
posesSe3	Absolute Se3 poses associated with views in view set
createPoseGraph	Create pose graph
findTracks	Find matched points across multiple views
optimizePoses	Optimize absolute poses using relative pose constraints
plot	Plot image view set views and connections

Examples

Find Point Tracks Across Sequence of Images

Load images in the workspace.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata','structureFromMotion');
images = imageDatastore(imageDir);
```

Compute features for the first image.

```
I = im2gray(readimage(images,1));
pointsPrev = detectSURFFeatures(I);
[featuresPrev,pointsPrev] = extractFeatures(I,pointsPrev);
```

Create an image view set and add one view to the set.

```
vSet = imageviewset;
vSet = addView(vSet,1,'Features',featuresPrev,'Points',pointsPrev);
```

Compute features and matches for the rest of the images.

```
for i = 2:numel(images.Files)
  I = im2gray(readimage(images, i));
  points = detectSURFFeatures(I);
  [features, points] = extractFeatures(I,points);
  vSet = addView(vSet,i,'Features',features,'Points',points);
  pairsIdx = matchFeatures(featuresPrev,features);
  vSet = addConnection(vSet,i-1,i,'Matches',pairsIdx);
  featuresPrev = features;
end
```

Find point tracks across views in the image view set.

```
tracks = findTracks(vSet);
```

Version History

Introduced in R2020a

R2022b: Supports premultiply geometric transformation convention
Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, the `imageviewset` object and its object functions are updated to use `rigidtform3d` and `simtform3d` objects, which support the premultiply convention. The `imageviewset` object now:

- Returns the `Views` property with the `AbsolutePose` column as a `rigidtform3d` object
- Returns the `Connections` property with the `RelativePose` column as a `rigidtform3d` or `simtform3d` object

Before, the properties returned `AbsolutePose` and `RelativePose` as `rigid3d` and `affine3d` objects, which use the postmultiply convention.

For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

R2022b: Visual SLAM: Improve accuracy of pose estimation

The `imageviewset` adds the `connectedViews` object function.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

The `plot` method of `imageviewset` object is not supported for code generation.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

addView

Add views to view set

Syntax

```
vSet = addView(vSet,viewId)
vSet = addView(vSet,viewId,absPose)
vSet = addView( ___ ,Name=Value)

vSet = addView(vSet,viewTable)
```

Description

`vSet = addView(vSet,viewId)` adds the view specified by `viewId` to the view set, `vSet`.

`vSet = addView(vSet,viewId,absPose)` specifies the absolute pose of the view.

`vSet = addView( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any of the input argument combinations in previous syntaxes.

`vSet = addView(vSet,viewTable)` adds one or more views in the table specified by `viewTable`.

Examples

Add View to Image View Set

Create an empty image view set.

```
vSet = imageviewset;
```

Detect interest points in the image.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata','structureFromMotion');
I = imread(fullfile(imageDir,'image1.jpg'));
points = detectSURFFeatures(im2gray(I));
```

Add the interest points as a view to the image view set.

```
vSet = addView(vSet,1,'Points',points);
```

Input Arguments

vSet — Image view set

`imageviewset` object

Image view set, specified as an `imageviewset` object.

viewId — View identifier

positive integer

View identifier, specified as an integer. View identifiers are unique to a specific view.

absPose — Absolute pose of the view
`rigidtform3d` object | `se3` object

Absolute pose of the view, specified as a `rigidtform3d` or an `se3` object.

`viewTable` — One or more views
two-column table | three-column table

One or more views, specified as a two-column or three-column table. The table must contain the columns `ViewId` and `AbsolutePose`. The `Points` column is optional.

Column	Description
`ViewID`	View identifier, specified as an integer. View identifiers are unique to a specific view.
`AbsolutePose`	Absolute pose of the view, specified as a `rigidtform3d` or an `se3` object.
`Points`	Image points, specified as an *M*-by-2 matrix of coordinates of the form [*x*,*y*] or an *M*-element feature point array.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `"Points",detectSURFFeatures(im2gray(I))`

`Features` — Feature vectors
M-by-*N* matrix | `binaryFeatures` object

Feature vectors, specified as an *M*-by-*N* matrix of *M* feature vectors or as a `binaryFeatures` object.

`Points` — Image points
M-by-2 matrix | *M*-element feature point array

Image points, specified as an *M*-by-2 matrix of coordinates in the format [*x*,*y*] or an *M*-element feature point array. For more details, see “Point Feature Types”.

Output Arguments

`vSet` — View set with added views
`imageviewset` object

View set with added views, returned as an `imageviewset` object.

Version History

Introduced in R2020a

R2022b: Supports premultiply geometric transformation convention

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, you can now specify poses (the `absPose` argument and the `AbsolutePose` column of the `viewTable` argument) as `rigidtform3d` objects, which use the premultiply convention.

Although you can still specify poses as `rigid3d` objects, these objects are not recommended because they use the postmultiply convention. The `addView` function automatically converts the poses to the premultiply convention and returns an `imageviewset` object that represents the poses as `rigidtform3d` objects.

For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

When you specify table as an input argument, then code generation has limitations. For information about the limitations, see “Code Generation for Tables” (MATLAB Coder) and “Table Limitations for Code Generation” (MATLAB Coder).

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

updateView

Update view in view set

Syntax

```
vSet = updateView(vSet,viewId,absPose)
vSet = updateView( ___ ,"PointCloud",ptCloud)

vSet = updateView(vSet,viewTable)
```

Description

`vSet = updateView(vSet,viewId,absPose)` updates the view specified by `viewId` with the absolute pose `absPose`.

`vSet = updateView( ___ ,"PointCloud",ptCloud)` specifies the point cloud associated with the view.

`vSet = updateView(vSet,viewTable)` updates the views specified in the table `viewTable`.

Examples

Update View in Image View Set

Create an empty image view set.

```
vSet = imageviewset;
```

Detect interest points in an image.

```
imageDir= fullfile(toolboxdir("vision"),"visiondata","structureFromMotion");
I = imread(fullfile(imageDir,"image1.jpg"));
points = detectSURFFeatures(im2gray(I));
```

Add a view to the image view set.

```
vSet = addView(vSet,1,Points=points);
```

Update the absolute pose of the view.

```
absPose = rigidtform3d(eye(3),[0 0 1]);
vSet = updateView(vSet,1,absPose);
```

Input Arguments

vSet — Image view set

`imageviewset` object

Image view set, specified as an `imageviewset` object.

`viewId` — View identifier
integer

Point cloud view identifier, specified as a unique integer.

`absPose` — Absolute pose
`rigidtform3d` object | `se3` object

Absolute pose, specified as a `rigidtform3d` or an `se3` object.

`ptCloud` — Point cloud
`pointCloud` object

Point cloud, specified as a `pointCloud` object.

`viewTable` — New view or set of views
two-column table | three-column table

New view or set of views, specified as a two- or three- column table. The table must contain the columns `ViewId` and `AbsolutePose`, and an optional column, `Points`.

Column	Description
`ViewID`	View identifier for the view, specified as a unique integer
`AbsolutePose`	Absolute pose of the view, specified as a `rigidtform3d` or an `se3` object.
`Points`	A `pointCloud`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `"Points",detectSURFFeatures(im2gray(I))`

`Features` — Feature vectors
M-by-*N* matrix | `binaryFeatures` object

Feature vectors, specified as an *M*-by-*N* matrix of *M* feature vectors or as a `binaryFeatures` object.

`Points` — Image points
M-by-2 matrix | *M*-element feature point array

Image points, specified as an *M*-by-2 matrix of coordinates in the format [*x*,*y*] or an *M*-element feature point array. For more details, see “Point Feature Types”.

Output Arguments

`vSet` — View set with updated view
`imageviewset` object

View set with updated view, returned as an `imageviewset` object.

Version History

Introduced in R2020a

R2022b: Supports premultiply geometric transformation convention

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, you can now specify poses (the `absPose` argument and the `AbsolutePose` column of the `viewTable` argument) as `rigidtform3d` objects, which use the premultiply convention.

Although you can still specify poses as `rigid3d` objects, these objects are not recommended because they use the postmultiply convention. The `updateView` function automatically converts the poses to the premultiply convention and returns an `imageviewset` object that represents the poses as `rigidtform3d` objects.

For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

When you specify table as an input argument, then code generation has limitations. For information about the limitations, see “Code Generation for Tables” (MATLAB Coder) and “Table Limitations for Code Generation” (MATLAB Coder).

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

deleteView

Delete view from view set

Syntax

```
vSet = deleteView(vSet,viewId)
```

Description

`vSet = deleteView(vSet,viewId)` deletes the view specified by `viewId` from the view set, `vSet`.

Examples

Delete View from Image View Set

Create an empty image view set.

```
vSet = imageviewset;
```

Detect interest points in an image.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata','structureFromMotion');
I = imread(fullfile(imageDir,'image1.jpg'));
points = detectSURFFeatures(im2gray(I));
```

Add a view to the image view set.

```
vSet = addView(vSet,1,'Points',points);
```

Delete the view.

```
vSet = deleteView(vSet,1);
```

Input Arguments

`vSet` — Image view set

`imageviewset` object

Image view set, specified as an `imageviewset` object.

`viewId` — View identifier

positive integer

View identifier, specified as an integer. View identifiers are unique to a specific view.

Output Arguments

vSet — View set with deleted views
`imageviewset` object

View set with deleted views, returned as an `imageviewset` object.

Version History

Introduced in R2020a

hasView

Check if view is in view set

Syntax

```
tf = hasView(vSet,viewId)
```

Description

`tf = hasView(vSet,viewId)` returns `1` (true), if the view specified by `viewId` is in the view set, `vSet`. The function returns `0` (false), if the view is not in `vSet`.

Examples

Check If View Is in Image View Set

Create an empty image view set.

```
vSet = imageviewset;
```

Detect interest points in an image.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata','structureFromMotion');
I = imread(fullfile(imageDir, 'image1.jpg'));
points = detectSURFFeatures(im2gray(I));
```

Add a view with ID `1` to the image view set.

```
vSet = addView(vSet,1,'Points',points);
```

Check if a view with ID `1` is in the view set.

```
hasView(vSet,1)
```

```
ans = logical
   1
```

Check if a view with ID `2` is in the view set.

```
hasView(vSet,2)
```

```
ans = logical
   0
```

Input Arguments

vSet — Image view set

`imageviewset` object

Image view set, specified as an `imageviewset` object.

`viewId` — View identifier
positive integer

View identifier, specified as an integer. View identifiers are unique to a specific view.

Output Arguments

`tf` — True or false result
`1` | `0`

True or false result indicating if view is in view set `vSet`, returned as a `1` or `0` data type `logical`.

Version History

Introduced in R2020a

addConnection

Add connection between views in view set

Syntax

```
vSet = addConnection(vSet,viewId1,viewId2)
vSet = addConnection(vSet,viewId1,viewId2,relPose)
vSet = addConnection(vSet,viewId1,viewId2,relPose,infoMat)
vSet = addConnection(___,"Matches",featureMatches)
```

Description

`vSet = addConnection(vSet,viewId1,viewId2)` adds a connection between views `viewId1` and `viewId2` to the view set, `vSet`.

`vSet = addConnection(vSet,viewId1,viewId2,relPose)` specifies the relative pose of `viewId2` with respect to `viewId1`.

`vSet = addConnection(vSet,viewId1,viewId2,relPose,infoMat)` specifies the information matrix associated with the connection.

`vSet = addConnection(___,"Matches",featureMatches)` specifies the indices of matched points between two views in addition to any of the input argument combinations in previous syntaxes.

Examples

Add Connection to Image View Set

Create an empty image view set.

```
vSet = imageviewset;
```

Read two images into the workspace.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata', ...
  'structureFromMotion');
I1 = im2gray(imread(fullfile(imageDir,'image1.jpg')));
I2 = im2gray(imread(fullfile(imageDir,'image2.jpg')));
```

Detect interest points in each image.

```
points1 = detectSURFFeatures(I1);
points2 = detectSURFFeatures(I2);
```

Extract feature descriptors from the interest points.

```
[features1,validPoints1] = extractFeatures(I1,points1);
[features2,validPoints2] = extractFeatures(I2,points2);
```

Add the features and points for the two images to the image view set.

```
vSet = addView(vSet,1,'Features',features1,'Points',validPoints1);
vSet = addView(vSet,2,'Features',features2,'Points',validPoints2);
```

Match the features between the two images.

```
indexPairs = matchFeatures(features1,features2);
```

Store the matched features as a connection in the image view set.

```
vSet = addConnection(vSet,1,2,'Matches',indexPairs);
```

Input Arguments

`vSet` — Image view set

`imageviewset` object

Image view set, specified as an `imageviewset` object.

`viewId1` — View identifier 1

positive integer

View identifier 1, specified as an integer. View identifiers are unique to a specific view.

`viewId2` — View identifier 2

positive integer

View identifier 2, specified as an integer. View identifiers are unique to a specific view.

`relPose` — Relative pose

`rigidtform3d` object | `simtform3d` object | `se3` object

Relative pose of `viewId2` with respect to `viewId1`, specified as a `rigidtform3d`, `simtform3d`, or `se3` object.

`infoMat` — Information matrix

6-by-6 numeric matrix

Information matrix associated with the connection, specified as a 6-by-6 numeric matrix.

`featureMatches` — Indices of matched points between two views

M-b-2 matrix

Indices of matched points between two views, specified as an *M*-b-2 matrix.

Output Arguments

`vSet` — View set with added connections

`imageviewset` object

View set with added connections between views, returned as an `imageviewset` object.

Version History

Introduced in R2020a

R2022b: Supports premultiply geometric transformation convention

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, you can now specify `relPose` as a `rigidtform3d` or `simtform3d` object, which use the premultiply convention.

Although you can still specify `relPose` as a `rigid3d` or `affine3d` object, these objects are not recommended because they use the postmultiply convention. The `addConnection` function automatically converts the pose to the premultiply convention and returns an `imageviewset` object that represents the pose as a `rigidtform3d` or `simtform3d` object.

For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

Extended Capabilities

Objects
`rigidtform3d` | `simtform3d` | `imageviewset` | `se3`

updateConnection

Update connection between views in a view set

Syntax

```
vSet = updateConnection(vSet,viewId1,viewId2,relPose)
vSet = updateConnection(vSet,viewId1,viewId2,relPose,infoMat)
vSet = updateConnection(___,"Matches",featureMatches)
```

Description

`vSet = updateConnection(vSet,viewId1,viewId2,relPose)` updates the connection between views `viewId1` and `viewId2` with the relative pose specified by `relPose`.

`vSet = updateConnection(vSet,viewId1,viewId2,relPose,infoMat)` specifies the information matrix associated with the connection.

`vSet = updateConnection(___,"Matches",featureMatches)` specifies the indices of matched points between two views in addition to any of the input argument combinations in previous syntaxes.

Examples

Update Connection in Image View Set

Create an empty image view set.

```
vSet = imageviewset;
```

Read two images into the workspace.

```
imageDir= fullfile(toolboxdir("vision"),"visiondata","structureFromMotion");
I1 = im2gray(imread(fullfile(imageDir,"image1.jpg")));
I2 = im2gray(imread(fullfile(imageDir,"image2.jpg")));
```

Detect interest points in each image.

```
points1 = detectSURFFeatures(I1);
points2 = detectSURFFeatures(I2);
```

Extract feature descriptors from the interest points.

```
[features1,validPoints1] = extractFeatures(I1,points1);
[features2,validPoints2] = extractFeatures(I2,points2);
```

Add features and the points for the two images to the image view set.

```
vSet = addView(vSet,1,Features=features1,Points=validPoints1);
vSet = addView(vSet,2,Features=features2,Points=validPoints2);
```

Match the features between the two images. Then, store the matched features as a connection in the image view set.

```
indexPairs = matchFeatures(features1,features2);
vSet = addConnection(vSet,1,2,Matches=indexPairs);
```

Create a relative pose between the views. Then,update the connection in the image view set.

```
theta = 30; % degrees
rot = [ cosd(theta) -sind(theta) 0; ...
        sind(theta) cosd(theta) 0; ...
        0           0  1];

trans = [2 3 4];
tform = rigidtform3d(rot,trans);
vSet = updateConnection(vSet,1,2,tform);
```

Input Arguments

`vSet` — Image view set

`imageviewset` object

Image view set, specified as an `imageviewset` object.

`viewId1` — View identifier 1

positive integer

View identifier 1, specified as an integer. View identifiers are unique to a specific view.

`viewId2` — View identifier 2

positive integer

View identifier 2, specified as an integer. View identifiers are unique to a specific view.

`relPose` — Relative pose

`rigidtform3d` object | `simtform3d` object | `se3` object

Relative pose of `viewId2` with respect to `viewId1`, specified as a `rigidtform3d`, `simtform3d`, or `se3` object.

`infoMat` — Information matrix

6-by-6 numeric matrix

Information matrix associated with the connection, specified as a 6-by-6 numeric matrix.

`featureMatches` — Indices of matched points between two views

M-b-2 matrix

Indices of matched points between two views, specified as an *M*-b-2 matrix.

Output Arguments

`vSet` — View set with updated connections

`imageviewset` object

View set with updated connections, returned as an `imageviewset` object.

Version History

Introduced in R2020a

R2022b: Supports premultiply geometric transformation convention

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, you can now specify the `relPose` argument as a `rigidtform3d` or `simtform3d` object, which use the premultiply convention.

Although you can still specify `relPose` as a `rigid3d` or `affine3d` object, these objects are not recommended because they use the postmultiply convention. deleteConnection

Delete a connection between views in view set

Syntax

```
vSet = deleteConnection(vSet,viewId1,viewId2)
```

Description

`vSet = deleteConnection(vSet,viewId1,viewId2)` deletes the connection between views `viewId1` and `viewId2` in the view set, `vSet`.

Examples

Delete Connection Between Views in Image View Set

Create an empty image view set.

```
vSet = imageviewset;
```

Read two images into the workspace.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata','structureFromMotion');
I1 = im2gray(imread(fullfile(imageDir,'image1.jpg')));
I2 = im2gray(imread(fullfile(imageDir,'image2.jpg')));
```

Detect interest points in each image.

```
points1 = detectSURFFeatures(I1);
points2 = detectSURFFeatures(I2);
```

Extract feature descriptors from the interest points.

```
[features1,validPoints1] = extractFeatures(I1,points1);
[features2,validPoints2] = extractFeatures(I2,points2);
```

Add the features and points for the two images to the image view set.

```
vSet = addView(vSet,1,'Features',features1,'Points',validPoints1);
vSet = addView(vSet,2,'Features',features2,'Points',validPoints2);
```

Match the features between the two images. Then, store the matches features as a connection in the image view set.

```
indexPairs = matchFeatures(features1,features2);
vSet = addConnection(vSet,1,2,'Matches',indexPairs);
```

Delete the connection between the two views.

```
vSet = deleteConnection(vSet,1,2);
```

Input Arguments

`vSet` — Image view set
`imageviewset` object

Image view set, specified as an `imageviewset` object.

`viewId1` — View identifier 1
positive integer

View identifier 1, specified as an integer. View identifiers are unique to a specific view.

`viewId2` — View identifier 2
positive integer

View identifier 2, specified as an integer. View identifiers are unique to a specific view.

Output Arguments

`vSet` — View set with deleted connections
`imageviewset` object

View set with deleted connections, returned as an `imageviewset` object.

Version History

hasConnection

Check if connection between two views is in view set

Syntax

```
tf = hasConnection(vSet,viewId1,viewId2)
```

Description

`tf = hasConnection(vSet,viewId1,viewId2)` returns `1` (true), if the connection between views `viewId1` and `viewId2` is in the view set, `vSet`. The function returns `0` (false), if the connection does not exist in `vSet`.

Examples

Check for Connection Between Views in View Set

Create an empty image view set.

```
vSet = imageviewset;
```

Add two views to the image view set.

```
vSet = addView(vSet,1);
vSet = addView(vSet,2);
```

Add a connection to the image view set.

```
vSet = addConnection(vSet,1,2);
```

Check if the connection between views is in the view set.

```
tf = hasConnection(vSet,1,2)
```

```
tf = logical
   1
```

Input Arguments

vSet — Image view set

`imageviewset` object

Image view set, specified as an `imageviewset` object.

viewId1 — View identifier 1

positive integer

View identifier 1, specified as an integer. View identifiers are unique to a specific view.

`viewId2` — View identifier 2
positive integer

View identifier 2, specified as an integer. View identifiers are unique to a specific view.

Output Arguments

`tf` — True or false result
`1` | `0`

True or false result indicating if view is in view set `vSet`, returned as a `1` or `0` data type `logical`.

Version History

Introduced in R2020a

Extended Capabilities

`imageviewset`

connectedViews

Returns directly and indirectly connected views

Syntax

```
viewTable = connectedViews(vSet,viewId)
[viewTable,dist] = connectedViews( ___ )
viewTable = connectedViews(vSet,viewId,Name=Value)
```

Description

`viewTable = connectedViews(vSet,viewId)` returns a table of views from `vSet` that are connected and indirectly connected to the view specified by `viewId`.

`[viewTable,dist] = connectedViews( ___ )` also returns the distances between the `viewId` view and each view in `viewTable`.

`viewTable = connectedViews(vSet,viewId,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes For example, `MaxDistance=1` additionally sets the distance between two connected views.

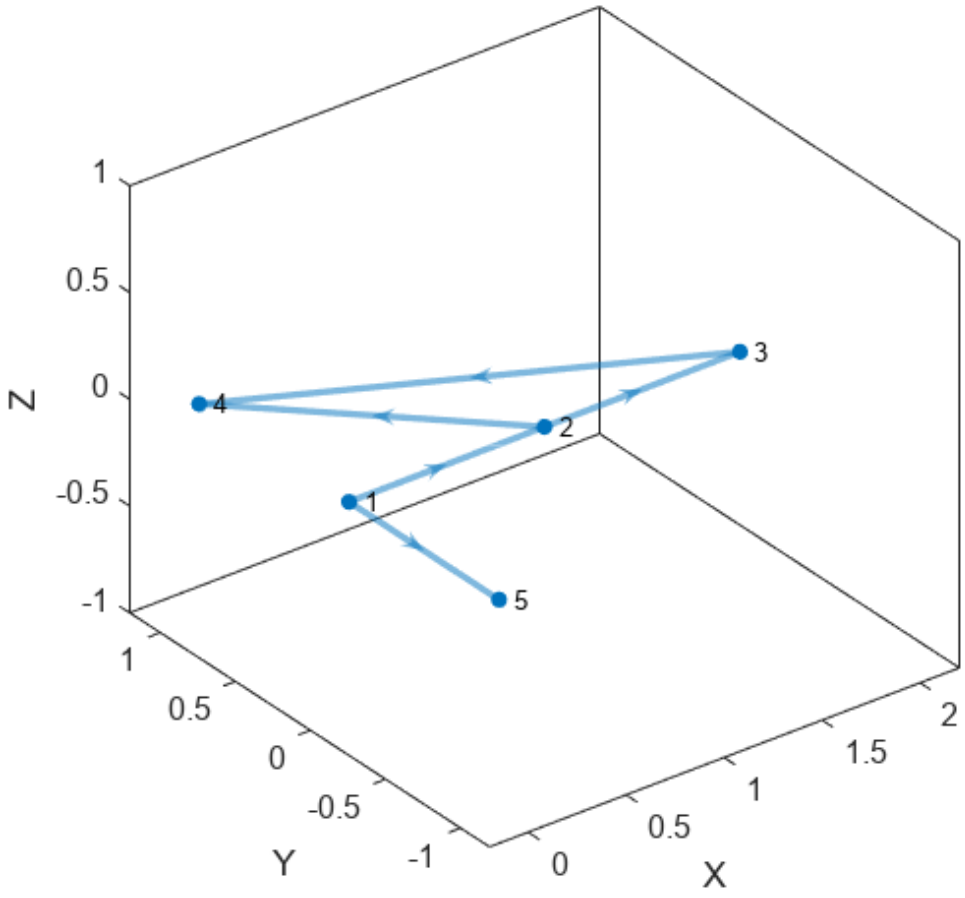
Examples

Get Connected Views in View Set

Create an empty `imageviewset` object.

```
vSet = imageviewset;
```

Add views to the image view set.



```
pose1 = rigidtform3d;
vSet = addView(vSet,1,pose1,Features=rand(10,3),Points=rand(10,2));
pose2 = rigidtform3d([0 0 0],[1 0 0]);
vSet = addView(vSet,2,pose2,Features=rand(10,3),Points=rand(10,2));
pose3 = rigidtform3d([0 0 0],[2 0 0]);
vSet = addView(vSet,3,pose3,Features=rand(10,3),Points=rand(10,2));
pose4 = rigidtform3d([0 0 0],[0 1 0]);
vSet = addView(vSet,4,pose4,Features=rand(10,3),Points=rand(10,2));
pose5 = rigidtform3d([0 0 0],[0 -1 0]);
vSet = addView(vSet,5,pose5,Features=rand(10,3),Points=rand(10 ,2));
```

Connect views in the image view set.

```
vSet = addConnection(vSet,1,2,Matches=[1 2; 2 3; 3 4; 4 5]);
vSet = addConnection(vSet,2,3,Matches=[1 2; 2 3; 3 4]);
vSet = addConnection(vSet,2,4,Matches=[4 1]);
vSet = addConnection(vSet,3,4,Matches=[4 1]);
vSet = addConnection(vSet,1,5,Matches=[1 2; 4 1]);
```

Display the view set with view IDs.

```
plot(vSet,ShowViewIds="on");
```

Get the strongly connected views of view 2 with the at least 3 matched feature points.

```
viewTableStrong = connectedViews(vSet,2,MinNumMatches=3)
```

```
viewTableStrong=2×4 table
    1    1×1 rigidtform3d    10×3 double    10×2 double
    3    1×1 rigidtform3d    10×3 double    10×2 double
```

Get views with maximum distance of 2, within view 3.

```
[viewTableNeaby,dist] = connectedViews(vSet,3,MaxDistance=2)
```

```
viewTableNeaby=3×4 table
    2    1×1 rigidtform3d    10×3 double    10×2 double
    4    1×1 rigidtform3d    10×3 double    10×2 double
    1    1×1 rigidtform3d    10×3 double    10×2 double
```

```
dist = 3×1

    1
    1
    2
```

Input Arguments

`vSet` — Image view set

`imageviewset` object

Image view set, specified as an `imageviewset` object.

`viewId` — View identifier

positive integer

View identifier, specified as an integer. View identifiers are unique to a specific view.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `MaxDistance=2` sets the distance between two connected views to 2.

`MaxDistance` — Maximum distance between connected views and `viewId` view

`1` (default) | positive integer

Maximum distance between connected views and the view that corresponds to `viewId`, specified as a positive integer. The distance between any two connected views must be equal to `1`. To find indirectly connected views, set `MaxDistance` to a value greater than `1`.

`MinNumMatches` — Minimum number of matched feature points

`0` (default) | nonnegative integer

Minimum number of matched feature points in a connection for the view to be counted as a connected view, specified as a nonnegative integer.

Output Arguments

`viewTable` — One or more views

three-column table

View attributes, specified as a three-column table. The table contains columns as described in this table.

Column	Description
`ViewId`	View identifier for the view, specified as a unique integer
`AbsolutePose`	Absolute pose of the view, specified as a `rigidtform3d` object.
`Features`	Feature vectors, specified as an *M*-by-*N* matrix of *M* feature vectors or as a `binaryFeatures`.
`Points`	Image points, specified as one of these options: • *M*-by-2 matrix of coordinates in the format [*x*,*y*] • *M*-element feature point array. For more details, see “Point Feature Types”.

`dist` — Distance between identified view and each view in the view table
positive integers

Distance between the view identified in `viewId` and each view in the view table `viewTable`, specified as an *M*-by-1 vector of positive integers.

Version History

Introduced in R2020a

R2022b: Supports premultiply geometric transformation convention
Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, the `connectedViews` function now returns the `AbsolutePose` value in the `viewTable` argument as a `rigidtform3d` object, which uses the premultiply convention. Before, the function returned `AbsolutePose` as a `rigid3d` object, which uses the postmultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

Added a new Name-Value argument, `MaxDistance`. Use `MaxDistance` to find indirectly-connected views by setting it to a value greater than `1`.

poses

Absolute poses associated with views in view set

Syntax

```
sensorPoses = poses(vSet)
```

Description

`sensorPoses = poses(vSet)` returns a table of absolute poses associated with the views contained in the view set, `vSet`.

Examples

Retrieve Absolute Poses from Image View Set

Load images into the workspace.

```
imageDir = fullfile(toolboxdir("vision"),"visiondata","structureFromMotion");
images = imageDatastore(imageDir);
```

Compute features for the first image.

```
I = im2gray(readimage(images,1));
pointsPrev = detectSURFFeatures(I);
[featuresPrev,pointsPrev] = extractFeatures(I,pointsPrev);
```

Create an image view set and add the extracted feature points to the image view set.

```
vSet = imageviewset;
vSet = addView(vSet,1,Points=pointsPrev);
```

Compute features and matches for the rest of the images.

```
for i = 2:numel(images.Files)
 I = im2gray(readimage(images,i));
 points = detectSURFFeatures(I);
 [features,points] = extractFeatures(I,points);
 vSet = addView(vSet,i,Features=features,Points=points);
 pairsIdx = matchFeatures(featuresPrev,features);
 vSet = addConnection(vSet,i-1,i,Matches=pairsIdx);
 featuresPrev = features;
end
```

Get the absolute poses.

```
sensorPoses = poses(vSet)
```

```
sensorPoses=5×2 table
    ViewId      AbsolutePose
    ______    _________________
```

```
1       1×1 rigidtform3d
2       1×1 rigidtform3d
3       1×1 rigidtform3d
4       1×1 rigidtform3d
5       1×1 rigidtform3d
```

Input Arguments

vSet — Image view set

`imageviewset` object

Image view set, specified as an `imageviewset` object.

Output Arguments

sensorPoses — Absolute poses

two-column table

Absolute poses, returned as a two-column table. The table contains columns as described in this table.

Column	Description
`ViewID`	View identifier, returned as a positive integer. View identifiers are unique to a specific view.
`AbsolutePose`	Absolute pose of the view, returned as a `rigidtform3d` or `se3` object.

Version History

Introduced in R2020a

R2022b: Supports premultiply geometric transformation convention

Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, the `poses` function now returns the `AbsolutePose` value in the `sensorPoses` argument as a `rigidtform3d` object, which uses the premultiply convention. Before, the function returned `AbsolutePose` as a `rigid3d` object, which uses the postmultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

When generating code, the output argument `sensorPoses` is returned as a structure with fields *ViewID* and *AbsolutePose*.

Use posesSe3 instead of poses for code generation if you're using se3 poses as input to `vset`

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Objects
`imageviewset` | `rigidtform3d` | `se3`

posesSe3

Absolute Se3 poses associated with views in view set

Syntax

```
sensorPoses = posesSe3(vSet)
```

Description

`sensorPoses = posesSe3(vSet)` returns a table of absolute Se3 poses associated with the views contained in the view set, `vSet`. Use this function when you need to perform code generation using Se3 poses.

Examples

Retrieve Absolute Poses from Image View Set

Load images into the workspace.

```
imageDir = fullfile(toolboxdir("vision"),"visiondata","structureFromMotion");
images = imageDatastore(imageDir);
```

Compute features for the first image.

```
I = im2gray(readimage(images,1));
pointsPrev = detectSURFFeatures(I);
[featuresPrev,pointsPrev] = extractFeatures(I,pointsPrev);
```

Create an image view set and add the extracted feature points to the image view set.

```
vSet = imageviewset;
vSet = addView(vSet,1,Points=pointsPrev);
```

Compute features and matches for the rest of the images.

```
for i = 2:numel(images.Files)
 I = im2gray(readimage(images,i));
 points = detectSURFFeatures(I);
 [features,points] = extractFeatures(I,points);
 vSet = addView(vSet,i,Features=features,Points=points);
 pairsIdx = matchFeatures(featuresPrev,features);
 vSet = addConnection(vSet,i-1,i,Matches=pairsIdx);
 featuresPrev = features;
end
```

Get the absolute poses.

```
sensorPoses = poses(vSet)
```

```
sensorPoses=5×2 table
    ViewId      AbsolutePose
    ______    _________________
```

```
1       1×1 rigidtform3d
2       1×1 rigidtform3d
3       1×1 rigidtform3d
4       1×1 rigidtform3d
5       1×1 rigidtform3d
```

Input Arguments

vSet — Image view set

`imageviewset` object

Image view set, specified as an `imageviewset` object.

Output Arguments

case when

sensorPoses — Absolute poses

two-column table

Absolute poses, returned as a two-column table. The table contains columns as described in this table.

Column	Description
`ViewID`	View identifier, returned as a positive integer. View identifiers are unique to a specific view.
`AbsolutePose`	Absolute pose of the view, returned as an `se3` object.

Version History

Introduced in R2026a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

When generating code, the output argument `sensorPoses` is returned as a structure with fields *ViewID* and *AbsolutePose*.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Objects
`imageviewset` | `rigidtform3d` | `se3`

optimizePoses

Optimize absolute poses using relative pose constraints

Syntax

```
vSetOptim = optimizePoses(vSet)
[vSetOptim,poseScale] = optimizePoses(vSet)
vSetOptim = optimizePoses(vSet, minNumMatches)
vSetOptim = optimizePoses( ___ ,Name,Value)
```

Description

`vSetOptim = optimizePoses(vSet)` returns an image view set whose absolute poses are optimized. `vSetOptim` and `vSet` are `imageviewset` objects.

The `optimizePoses` function performs pose graph optimization on the absolute poses for the `Views` in the view set using the relative pose constraints established by the `Connections` property. You can use `optimizePoses` to correct drift in odometry after detecting loop closures.

`[vSetOptim,poseScale] = optimizePoses(vSet)` also returns the scales associated with the optimized absolute poses. This output applies only when the `RelativePose` of at least one connection is represented as a `simtform3d` object.

`vSetOptim = optimizePoses(vSet, minNumMatches)` additionally specifies the minimum number of matched feature points in a connection in order for the connection to be included in optimization.

`vSetOptim = optimizePoses( ___ ,Name,Value)` uses additional options specified by one or more name-value arguments.

Examples

Create and Optimize Poses Using Image View Set

Create a view set.

```
vSet = imageviewset;
```

Add four nodes and specify absolute poses.

```
absPoses = repelem(rigidtform3d, 4, 1);

absPoses(1).Translation = [ 0   0 0];
absPoses(2).Translation = [ 1   0 0];
absPoses(3).Translation = [ 2   0 0];
absPoses(4).Translation = [ 0.1 0 0];

vSet = addView(vSet, 1, absPoses(1));
vSet = addView(vSet, 2, absPoses(2));
```

```
vSet = addView(vSet, 3, absPoses(3));
vSet = addView(vSet, 4, absPoses(4));
```

Define 4 edges, 3 odometry and 1 loop closure.

```
relPoses = repelem(rigidtform3d, 4, 1);

relPoses(1).Translation = [ 1   0 0];
relPoses(2).Translation = [ 1   0 0];
relPoses(3).Translation = [-1.9 0 0];
relPoses(4).Translation = [ 0.2 0 0];

vSet = addConnection(vSet, 1, 2, relPoses(1)); % odometry
vSet = addConnection(vSet, 2, 3, relPoses(2)); % odometry
vSet = addConnection(vSet, 3, 4, relPoses(3)); % odometry
vSet = addConnection(vSet, 4, 1, relPoses(4)); % loop closure
```

Optimize view set.

```
vSetOptim = optimizePoses(vSet);
```

DIsplay original and optimized locations.

```
disp('Original absolute translations:')
```

```
Original absolute translations:
```

```
disp(vertcat(vSet.Views.AbsolutePose.Translation))
```

```
         0         0         0
    1.0000         0         0
    2.0000         0         0
    0.1000         0         0
```

```
disp('Optimized absolute translations:')
```

```
Optimized absolute translations:
```

```
disp(vertcat(vSetOptim.Views.AbsolutePose.Translation))
```

```
         0         0         0
    0.9250         0         0
    1.8500         0         0
   -0.1250         0         0
```

Input Arguments

vSet — Image view set

`imageviewset` object

Image view set, specified as an `imageviewset` object.

minNumMatches — Minimum number of connections

positive integer

Minimum number of connections, specified as a positive integer. Set `minNumMatches` to the minimum number of matched feature points in a connection for the connection to be included in optimization.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `"MaxIterations",300`

`MaxIterations` — Maximum number of iterations
`300` (default) | positive integer

Maximum number of iterations before optimization is terminated, specified as a positive integer. Increase this value for more accurate results. Decrease this value for faster results.

`Tolerance` — Tolerance of the optimization cost function
`1e-8` (default) | positive scalar

Tolerance of the optimization cost function between two iterations, specified as a positive scalar. Optimization is terminated when the cost function changes by less than the `Tolerance` value between two iterations.

`Verbose` — Display progress information
`false` (default) | `true`

Display progress information, specified as a logical `true` or `false`. Set `Verbose` to `true` to display progress information.

Output Arguments

`vSetOptim` — Optimized absolute poses
`imageviewset` object

Image view set that contains optimized absolute poses, returned as an `imageviewset` object.

`poseScale` — Scales of optimized absolute poses
vector of positive values

Scales of optimized absolute poses, returned as a vector of positive values. This output applies only when the `RelativePose` of the pairwise “Connections” on page 2-0 property, of at least one connection is represented as a `simtform3d` object.

Tips

- To update a view set with optimized poses, use the `updateView` object function.
- The optimizePoses object function holds the first view fixed.

Algorithms

The `optimizePoses` function uses the Levenberg Marquardt optimization algorithm with sparse Cholesky factorization from the general (hyper) graph optimization (g2o) library, (1 on page 2-553).

Version History

Introduced in R2020a

R2024a: Added code generation support for non-host target platforms

Supports code generation for host and non-host target platforms.

R2022b: Supports premultiply geometric transformation convention
Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, the `optimizePoses` function now supports image view sets that represent poses as `rigidtform3d` or `simtform3d` objects, which use the premultiply convention.

For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

Functions
`createPoseGraph`

Objects
`imageviewset`

createPoseGraph

Create pose graph

Syntax

```
G = createPoseGraph(vSet)
```

Description

`G = createPoseGraph(vSet)` returns a pose graph derived from the views and connections in the view set, `vSet`.

You can use the pose graph for inspection, modification, visualization, and pose graph optimization.

Examples

Create Pose Graph from Image View Set

Create an empty image view set.

```
vSet = imageviewset;
```

Define three relative poses.

```
relPoses = repelem(rigidtform3d,3,1);
relPoses(1).Translation = [3 0 0];
relPoses(2).Translation = [5 0 0];
relPoses(3).Translation = [2 0 0];
```

Accumulate absolute poses.

```
absPoses = repelem(rigidtform3d,4,1);
absPoses(2).A = absPoses(1).A*relPoses(1).A;
absPoses(3).A = absPoses(2).A*relPoses(2).A;
absPoses(4).A = absPoses(3).A*relPoses(3).A;
```

Add four views to the image view set.

```
vSet = addView(vSet,1,absPoses(1));
vSet = addView(vSet,2,absPoses(2));
vSet = addView(vSet,3,absPoses(3));
vSet = addView(vSet,4,absPoses(4));
```

Add three connections to the image view set.

```
vSet = addConnection(vSet,1,2,relPoses(1));
vSet = addConnection(vSet,2,3,relPoses(2));
vSet = addConnection(vSet,3,4,relPoses(3));
```

Add a loop closure connection to the image view set.

```
relPoses(4).Translation = [9 0 0];
vSet = addConnection(vSet,4,1,relPoses(4));
```

Create a pose graph.

```
G = createPoseGraph(vSet)
```

```
G =
  digraph with properties:

    Edges: [4×4 table]
    Nodes: [4×2 table]
```

Input Arguments

vSet — View set

`imageviewset` object

View set, specified as an `imageviewset` object.

Output Arguments

G — Pose graph

`digraph` object

Pose graph, returned as a `digraph` object. The nodes in the object correspond to views, and the edges in the object correspond to connections.

The `EndNodes` of the `Edges` in the `G` digraph correspond to indices into the `Views` table, (not `ViewIds`).

Tips

- The `EndNodes` of the `Edges` in the `G` digraph correspond to indices into the `Views` table, (not `ViewIds`).
- Use “Directed and Undirected Graphs” to inspect, modify, or visualize the pose graph.
- Use the `optimizePoseGraph` function to optimize the pose graph. Use of this function requires the Navigation Toolbox.

Objects
`imageviewset`

findView

Find views associated with view identifiers

Syntax

```
views = findView(vSet,viewIds)
```

Description

`views = findView(vSet,viewIds)` finds the views associated with the specified view `viewIds` and returns the view attributes.

Examples

Find View Corresponding to View ID

Create an empty image view set.

```
vSet = imageviewset;
```

Add two images.

```
imageDir = fullfile(toolboxdir("vision"),"visiondata","structureFromMotion");
I1 = im2gray(imread(fullfile(imageDir,"image1.jpg")));
I2 = im2gray(imread(fullfile(imageDir,"image2.jpg")));
```

Detect interest points in the two images.

```
points1 = detectSURFFeatures(I1);
points2 = detectSURFFeatures(I2);
```

Extract features descriptors from the detected points.

```
[features1,validPoints1] = extractFeatures(I1,points1);
[features2,validPoints2] = extractFeatures(I2,points2);
```

Add the points to the imageviewset object.

```
vSet = addView(vSet,1,Features=features1,Points=validPoints1);
vSet = addView(vSet,2,Features=features2,Points=validPoints2);
```

Find the view that corresponds to `viewID` equal to 1.

```
view = findView(vSet,1)
```

```
view=1×4 table
    ViewId      AbsolutePose         Features              Points
    ______    _________________    _______________    ____________________

      1       1×1 rigidtform3d    {574×64 single}    {574×1 SURFPoints}
```

Check the feature points that correspond to `viewID` equal to 1.

```
view.Points{:}
```

```
ans =
  574×1 SURFPoints array with properties:

              Scale: [574×1 single]
    SignOfLaplacian: [574×1 int8]
        Orientation: [574×1 single]
           Location: [574×2 single]
             Metric: [574×1 single]
              Count: 574
```

Input Arguments

`vSet` — Image view set

`imageviewset` object

Image view set, specified as an `imageviewset` object.

`viewIds` — View identifier

M-element vector

View identifiers, specified as an *M*-element vector of integers. Each view identifier is unique to a specific view.

Output Arguments

`views` — View attributes

four-column table

View attributes, returned as a four-column table. The table contains the columns `ViewId`, `AbsolutePose`, `Features`, and `Points` attribute descriptions.

findConnection

Find connections associated with view identifiers

Syntax

```
conn = findConnection(vSet,viewIds1,viewIds2)
```

Description

`conn = findConnection(vSet,viewIds1,viewIds2)` finds the connections between the specified view identifiers `viewIds1` and `viewIds2` and returns the connection attributes `conn`.

Examples

Find Connection Between Two Image View Sets

Create an empty imageviewset object.

```
vSet = imageviewset;
```

Add three views to the view set.

```
viewId1 = 10;
viewId2 = 5;
viewId3 = 2;
vSet = addView(vSet,viewId1);
vSet = addView(vSet,viewId2);
vSet = addView(vSet,viewId3);
```

Add a connection between viewId1 and viewId2.

```
relPose1 = rigidtform3d(eye(3),[0 0 1]);
vSet = addConnection(vSet,viewId1,viewId2,relPose1);
```

Add a connection between viewId2 and viewId3.

```
relPose2 = rigidtform3d(eye(3),[0 0 2]);
vSet = addConnection(vSet,viewId2,viewId3,relPose2);
```

Find the connection between viewId1 and viewId2.

```
conn = findConnection(vSet,viewId1,viewId2)
```

```
conn=1×5 table
    ViewId1    ViewId2       RelativePose       InformationMatrix      Matches
    _______    _______    __________________    _________________    ___________

      10          5       {1×1 rigidtform3d}      {6×6 double}       {0×2 uint32}
```

Check the relative pose between viewId1 and viewId2.

```
conn.RelativePose{:}

ans =
  rigidtform3d with properties:

    Dimensionality: 3
       Translation: [0 0 1]
                 R: [3×3 double]

                 A: [1     0     0     0
                     0     1     0     0
                     0     0     1     1
                     0     0     0     1]
```

Input Arguments

`vSet` — Image view set

`imageviewset` object

Image view set, specified as an `imageviewset` object.

`viewIds1` — Initial view identifiers

M-element vector

Initial view identifiers, specified as an *M*-element vector of integers. Each view identifier is unique to a specific view.

`viewIds2` — Connected view identifiers

M-element vector

Connected view identifiers, specified as an *M*-element vector of integers. Each view identifier is unique to a specific view.

Output Arguments

`conn` — Connection attributes

four-column table

Pairwise connections between views, returned as a four-column table. The table contains columns as described in this table. Each row corresponds to one connection.

Column	Description
`ViewId1`	View identifier for the first view, specified as a unique integer.
`ViewId2`	View identifier for the second view, specified as a unique integer.
`RelativePose`	Relative pose of the second view with respect to the first view, specified as a `rigidtform3d` or `simtform3d` object.

Column	Description
`InformationMatrix`	Information matrix, specified as a 6-by-6 matrix (when you specify `RelativePose` as a `rigidtform3d` object) or 7-by-7 matrix (when you specify `RelativePose` as a `simtform3d` object). The information matrix represents the uncertainty of the measurement error and is the inverse of the covariance matrix.
`Matches`	Indices of matched feature points between two views, specified as *M*-by-2 matrix.

findTracks

Find matched points across multiple views

Syntax

```
tracks = findTracks(vSet)
tracks = findTracks(vSet,viewIds)
tracks = findTracks( ___ ,'MinTrackLength',trackLength)
```

Description

`tracks = findTracks(vSet)` finds and returns point tracks across multiple views in the view set, `vSet`. Each track contains 2-D projections of the same 3-D world point.

`tracks = findTracks(vSet,viewIds)` finds point tracks across a subset of views specified by `viewIds`.

`tracks = findTracks( ___ ,'MinTrackLength',trackLength)` specifies the minimum length of the tracks.

Examples

Find Point Tracks Across Sequence of Images

Load images in the workspace.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata','structureFromMotion');
images = imageDatastore(imageDir);
```

Compute features for the first image.

```
I = im2gray(readimage(images,1));
pointsPrev = detectSURFFeatures(I);
[featuresPrev,pointsPrev] = extractFeatures(I,pointsPrev);
```

Create an image view set and add one view to the set.

```
vSet = imageviewset;
vSet = addView(vSet,1,'Features',featuresPrev,'Points',pointsPrev);
```

Compute features and matches for the rest of the images.

```
for i = 2:numel(images.Files)
  I = im2gray(readimage(images, i));
  points = detectSURFFeatures(I);
  [features, points] = extractFeatures(I,points);
  vSet = addView(vSet,i,'Features',features,'Points',points);
  pairsIdx = matchFeatures(featuresPrev,features);
  vSet = addConnection(vSet,i-1,i,'Matches',pairsIdx);
  featuresPrev = features;
end
```

Find point tracks across views in the image view set.

```
tracks = findTracks(vSet);
```

Input Arguments

`vSet` — Image view set

`imageviewset` object

Image view set, specified as an `imageviewset` object.

`viewIds` — View identifiers

vector of integers

View identifiers, specified as a vector of positive integers. View identifiers are unique to a specific view.

`trackLength` — Minimum length of the tracks

positive integer equal to or greater than 2

Minimum length of the tracks, specified as a positive integer equal to or greater than 2.

Output Arguments

`tracks` — Point tracks

`pointTrack` object

Point tracks across multiple views, returned as a `pointTrack` object.

Version History

Introduced in R2020a

plot

Plot image view set views and connections

Syntax

```
plot(vSet)
h = plot(vSet)
plot(vSet,Name=Value)
```

Description

`plot(vSet)` plots the views and connections in the view set, `vSet`.

`h = plot(vSet)` returns a graph plot, `h`

`plot(vSet,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `plot(vSet,ShowViewIds="off")` turns off the ID display.

Examples

Plot View Set View Identifiers

Create an empty image view set.

```
vSet = imageviewset;
```

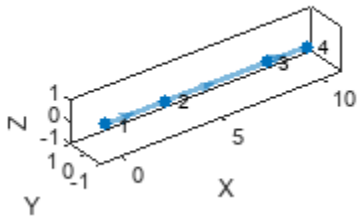
Define three relative poses.

```
relPoses = repelem(rigidtform3d,3,1);
relPoses(1).Translation = [3 0 0];
relPoses(2).Translation = [5 0 0];
relPoses(3).Translation = [2 0 0];
```

Calculate and add absolute poses.

```
absPoses = repelem(rigidtform3d,4,1);
absPoses(2).A = absPoses(1).A*relPoses(1).A;
absPoses(3).A = absPoses(2).A*relPoses(2).A;
absPoses(4).A = absPoses(3).A*relPoses(3).A;
```

Add four views to the image view set.



```
vSet = addView(vSet,1,absPoses(1));
vSet = addView(vSet,2,absPoses(2));
vSet = addView(vSet,3,absPoses(3));
vSet = addView(vSet,4,absPoses(4));
```

Add connections between the added views.

```
vSet = addConnection(vSet,1,2,relPoses(1));
vSet = addConnection(vSet,2,3,relPoses(2));
vSet = addConnection(vSet,3,4,relPoses(3));
```

Plot the view set with view identifers.

```
plot(vSet,ShowViewIds="on")
```

Input Arguments

vSet — Image view set

`imageviewset` object

Image view set, specified as a `imageviewset` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `ShowViewId="off"` turns off the ID display.

Parent — Axes on which to plot view set

`Axes` object (default)

Axes on which to plot view set, specified as an `Axes` object. To create an `Axes` object, use the `axes` function.

ShowViewIds — Display of view identifiers

`"off"` (default) | `"on"`

Display of view identifiers, specified as `"on"` or `"off"`.

Output Arguments

h — Graph plot

`GraphPlot` object

Graph plot, returned as a `GraphPlot` object. You can use the `GraphPlot` object functions and properties to inspect and adjust the plotted graph.

ssdObjectDetector

Detect objects using SSD deep learning detector

Description

The `ssdObjectDetector` detects objects from an image, using a single shot detector (SSD) object detector. To detect objects in an image, pass the trained detector to the `detect` function. You can also use the trained detector for multiclass object detection. For information about SSD object detection, see “Getting Started with SSD Multibox Detection”.

Creation

Syntax

```
detector = ssdObjectDetector(net,classes,aboxes)
detector = ssdObjectDetector(baseNet,classes,aboxes,DetectionNetworkSource=
layer)
detector = ssdObjectDetector( ___ ,Name=Value)
```

Description

`detector = ssdObjectDetector(net,classes,aboxes)` creates an object detector using the SSD deep learning network `net`.

If `net` is a pretrained SSD deep learning network, the function creates a pretrained SSD object detector. The `classes` and `aboxes` are the classes and anchor boxes used when the network was trained.

If `net` is an untrained SSD deep learning network, the function creates a SSD object detector to use for training and inference. `classes` and `aboxes` specify the object classes and the anchor boxes, respectively, for training the SSD network. Use the `trainSSDObjectDetector` function to train the network before performing object detection.

`detector = ssdObjectDetector(baseNet,classes,aboxes,DetectionNetworkSource=layer)` creates a SSD object detector by adding detection heads to specified feature extraction layers within a base network, `baseNet`.

If `baseNet` is a pretrained deep learning network, then the function creates a SSD object detector and configures it to perform transfer learning with the specified object classes and anchor boxes.

If `baseNet` is an untrained deep learning network, then the function creates a SSD object detector and configures it for object detection. `classes` and `aboxes` specify the object classes and the anchor boxes, respectively, for training the SSD network.

You must train the detector on a training dataset before performing object detection. Use the `trainSSDObjectDetector` function to train the detector.

Before R2021a, use the equivalent syntax `detector = ssdObjectDetector(baseNet,classes,aboxes,"DetectionNetworkSource",layer)`.

`detector = ssdObjectDetector( ___ ,Name=Value)` specifies properties using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `InputSize=[224 224 3]` sets the *height*, *width*, and number of *channels* for the image size used for training.

Input Arguments

`net` — SSD deep learning network

`dlnetwork` object

SSD deep learning network, specified as a `dlnetwork` object. The input network can be either an untrained or a pretrained deep learning network. The input network must not have loss layers.

`baseNet` — Base network

`dlnetwork` object

Base network for creating the SSD deep learning network, specified as a `dlnetwork` object. The network can be either an untrained or a pretrained deep learning network. When you specify this argument, you must also specify the feature extraction layers by using the `layer` input argument.

`classes` — Names of object classes

string vector | cell array of character vectors | categorical vector

Names of object classes for training the detector, specified as a string vector, cell array of character vectors, or categorical vector. This argument sets the `ClassNames on page 2-0` property of the `ssdObjectDetector` object.

Data Types: `char` | `string` | `categorical`

`aboxes` — Anchor boxes

N-by-1 cell array

Anchor boxes for training the detector, specified as an *N*-by-1 cell array. *N* is the number of output layers in the SSD deep learning network. Each cell contains an *M*-by-2 matrix, where *M* is the number of anchor boxes in that layer. Each row in the *M*-by-2 matrix denotes the size of an anchor box in the form [*height width*].

The first element in the cell array specifies the anchor boxes to associate with the first output layer, the second element in the cell array specifies the anchor boxes to associate with the second output layer, and so on. For accurate detection results, specify large anchor boxes for the first output layer and small anchor boxes for the last output layer. That is, the anchor box sizes must decrease for each output layer in the order in which the layers appear in the SSD deep learning network.

This argument sets the `AnchorBoxes on page 2-0` property of the `ssdObjectDetector` object.

Data Types: `cell`

`layer` — Names of feature extraction layers

cell array of character vectors | string array

Names of the feature extraction layers in the base network, specified as a cell array of character vectors or a string array.

Example: `layer = {'conv10','fire9-concat'}`

Example: `layer = ["conv10","fire9-concat"]`

Data Types: `char` | `string` | `cell`

Properties

`InputSize` — Image size used for training

vector

This property is read-only.

Image size used for training, stored as a vector of form [*height width*] or [*height width channels*]. To set this property, specify it at object creation. The size of the training images must be a multiple of 32.

`ModelName` — Name of classification model

character vector | string scalar

This property is read-only.

Name of the classification model, specified as a character vector or string scalar. By default, the name is set to the heading of the second column of the `trainingData` table specified in the `trainSSDObjectDetector` function. You can modify this name after creating your `ssdObjectDetector` object.

`Network` — Trained SSD multibox object detection network

`dlnetwork` object

This property is read-only.

Trained SSD multibox object detection network, specified as a `dlnetwork` object. The `dlnetwork` object stores the layers that define the convolutional neural network used within the SSD detector.

`AnchorBoxes` — Size of anchor boxes

P-by-1 cell array

This property is read-only.

Size of anchor boxes, specified as a *P*-by-1 cell array for *P* number of feature extraction layers used for object detection in the SSD network. Each element of the array contains an *M*-by-2 matrix of anchor box sizes, in the format [*height width*]. Each cell can contain a different number of anchor boxes.

You can set this property by using the input argument `aboxes`.

`ClassNames` — Names of object classes

cell array

This property is read-only.

Names of the object classes that the SSD detector is trained to find, specified as a cell array. You can set this property by using the input argument `classes`.

Object Functions

detect Detect objects using SSD multibox object detector

Examples

Create Custom SSD Object Detector

This example shows how to create a SSD object detection network by using a pretrained ResNet-50 convolutional neural network as the base network.

Load a pretrained deep learning network to use as the base network. This example uses a ResNet-50 pretrained network as the base network. For information about other available pretrained networks, see “Pretrained Deep Neural Networks” (Deep Learning Toolbox).

```
baseNet = imagePretrainedNetwork("resnet50");
```

Use `analyzeNetwork` to display the architecture of the base network.

```
analyzeNetwork(baseNet)
```

Specify the class names and anchor boxes to use for training the SSD deep learning network created using ResNet-50 as the base network.

```
classNames = ["person" "car" "dog"];
anchorBoxes = {[30 60;60 30;50 50;100 100], ...
               [40 70;70 40;60 60;120 120], ...
               [50 80;80 60;70 70;140 140]};
```

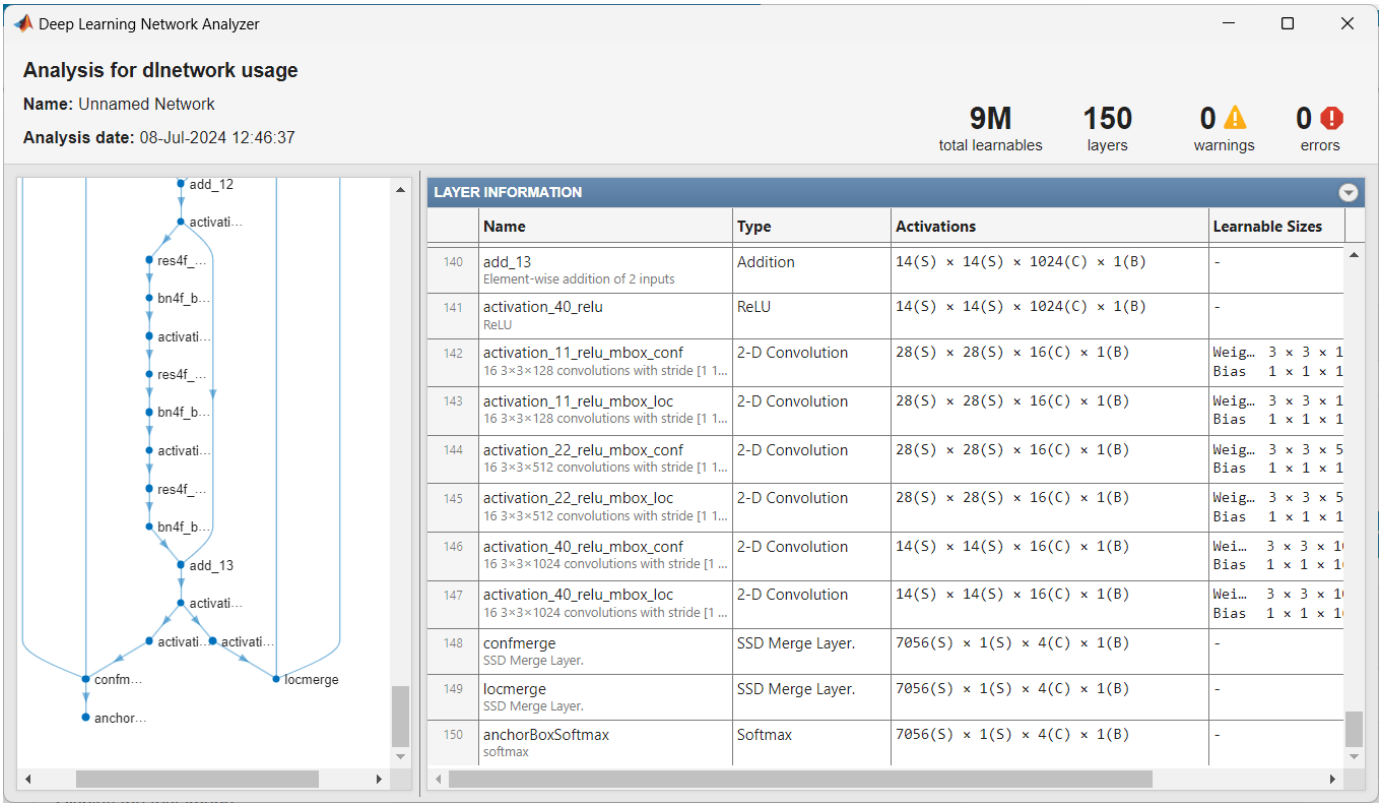
Specify the names of the feature extraction layers in the base network to use as the detection heads.

```
featureExtractionLayers = ["activation_11_relu" "activation_22_relu" "activation_40_relu"];
```

Create an SSD object detector by using the specified base network and the detection heads.

```
detector = ssdObjectDetector(baseNet,classNames,anchorBoxes,DetectionNetworkSource=featureExtrac
```

Display and inspect the properties of the SSD object detector.



```
disp(detector)
```

```
  ssdObjectDetector with properties:

       Network: [1×1 dlnetwork]
    AnchorBoxes: {3×1 cell}
     ClassNames: [3×1 string]
      InputSize: [224 224 3]
      ModelName: ''
```

Use `analyzeNetwork` to display the SSD network architecture and get information about the network layers.

```
analyzeNetwork(detector.Network)
```

Detect Vehicles Using SSD Object Detector

Load a pretrained single shot detector (SSD) object to detect vehicles in an image. The detector is trained with images of cars on a highway scene.

```
vehicleDetector = load("ssdVehicleDetector.mat","detector");
detector = vehicleDetector.detector;
```

Read a test image into the workspace.

```
I = imread("highway.png");
```

Display the test image.

```
imshow(I)
```

Run the pretrained SSD object detector by using the `detect` function. The output contains the bounding boxes, scores, and the labels for vehicles detected in the image. The labels are derived from the `ClassNames` property of the detector.

```
[bboxes,scores,labels] = detect(detector,I)
```

```
bboxes = 2×4

   139    78    96    81
    99    67   165   146

scores = 2×1 single column vector

    0.8349
    0.6302

labels = 2×1 categorical
     vehicle
     vehicle
```

Annotate the image with the detection results.

```
if ~isempty(bboxes)
    detectedI = insertObjectAnnotation(I,"rectangle",bboxes,cellstr(labels));
else
   detectedI = insertText(I,[10 10],"No Detections");
end

imshow(detectedI)
```

Version History

Introduced in R2020a

R2024b: Returns `Network` property as `dlnetwork` object
Behavior changed in R2024b

The `Network` property now returns a `dlnetwork` object instead of a `DAGNetwork` object.

R2024b: `LayerGraph` objects are not recommended
Not recommended starting in R2024b

Starting in R2024b, `LayerGraph` objects are not recommended. If you want to use a pretrained SSD network or a base feature extraction network, specify `net` or `baseNet` as a `dlnetwork` object instead.

There are no plans to remove support for `LayerGraph` objects. However, `dlnetwork` objects have these advantages and are recommended instead:

- `dlnetwork` objects are a unified data type that supports network building, prediction, built-in training, visualization, compression, verification, and custom training loops.
- `dlnetwork` objects support a wider range of network architectures that you can create or import from external platforms.
- Training and prediction with `dlnetwork` objects is typically faster than with `LayerGraph` objects.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `detect` method of the `ssdObjectDetector` is supported for code generation.
- The `roi` argument to the `detect` method must be a codegen constant (`coder.const()`) and a 1-by-4 vector.
- Only the `Threshold`, `SelectStrongest`, `MinSize`, `MaxSize`, and `MiniBatchSize` name-value arguments are supported. All name-value arguments must be compile-time constants.
- The channel and batch size of the input image must be fixed size.
- The `labels` output is returned as a categorical array.
- In the generated code, the input is rescaled to the size of the input layer of the network. But the bounding box that the `detect` method returns is in reference to the original input size.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

For code generation,

- Only the `detect` method of the `ssdObjectDetector` is supported for code generation.
- The `roi` argument to the `detect` method must be a codegen constant (`coder.const()`) and a 1-by-4 vector.
- Only the `Threshold`, `SelectStrongest`, `MinSize`, `MaxSize`, and `MiniBatchSize` name-value arguments are supported.
- The channel and batch size of the input image must be fixed size.
- The `labels` output is returned as a categorical array.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

detect

Detect objects using SSD multibox object detector

Syntax

```
bboxes = detect(detector,I)
[bboxes,scores] = detect(detector,I)
[___,labels] = detect(detector,I)
[___] = detect(___,roi)

detectionResults = detect(detector,ds)

[___] = detect(___,Name,Value)
```

Description

`bboxes = detect(detector,I)` detects objects within a single image or an array of images, `I`, using an single shot multibox detector (SSD). The locations of objects detected are returned as a set of bounding boxes.

When using this function, use of a CUDA enabled NVIDIA GPU is highly recommended. The GPU reduces computation time significantly. Usage of the GPU requires Parallel Computing Toolbox. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

`[bboxes,scores] = detect(detector,I)` also returns the detection scores for each bounding box.

`[___,labels] = detect(detector,I)` also returns a categorical array of labels assigned to the bounding boxes, using either of the preceding syntaxes. The labels used for object classes are defined during training using the `trainSSDObjectDetector` function.

`[___] = detect(___,roi)` detects objects within the rectangular search region specified by `roi`.

`detectionResults = detect(detector,ds)` detects objects within the series of images returned by the `read` function of the input datastore.

`[___] = detect(___,Name,Value)` specifies options using one or more `Name,Value` pair arguments. For example, `detect(detector,I,"Threshold",0.75)` sets the detection score threshold to `0.75`. Any detections with a lower score are removed.

Examples

Detect Vehicles Using SSD Object Detector

Load a pretrained single shot detector (SSD) object to detect vehicles in an image. The detector is trained with images of cars on a highway scene.

```
vehicleDetector = load("ssdVehicleDetector.mat","detector");
detector = vehicleDetector.detector;
```

Read a test image into the workspace.

```
I = imread("highway.png");
```

Display the test image.

```
imshow(I)
```

Run the pretrained SSD object detector by using the `detect` function. The output contains the bounding boxes, scores, and the labels for vehicles detected in the image. The labels are derived from the `ClassNames` property of the detector.

```
[bboxes,scores,labels] = detect(detector,I)
```

```
bboxes = 2×4

   139    78    96    81
    99    67   165   146

scores = 2×1 single column vector

    0.8349
    0.6302

labels = 2×1 categorical
     vehicle
     vehicle
```

Annotate the image with the detection results.

```
if ~isempty(bboxes)
    detectedI = insertObjectAnnotation(I,"rectangle",bboxes,cellstr(labels));
else
   detectedI = insertText(I,[10 10],"No Detections");
end

imshow(detectedI)
```

Input Arguments

`detector` — SSD object detector

`ssdObjectDetector` object

SSD object detector, specified as an `ssdObjectDetector` object. To create this object, call the `trainSSDObjectDetector` function with training data as input.

`I` — Input image

H-by-*W*-by-*C*-by-*B* numeric array of images

Input image, specified as an *H*-by-*W*-by-*C*-by-*B* numeric array of images. Images must be real, nonsparse, grayscale or RGB image.

- *H* — Height in pixels.
- *W* — Width in pixels
- *C* — The channel size in each image must be equal to the network's input channel size. For example, for grayscale images, *C* must be equal to `1`. For RGB color images, it must be equal to `3`.
- *B* — Number of images in the array.

The detector is sensitive to the range of the input image. Therefore, ensure that the input image range is similar to the range of the images used to train the detector. For example, if the detector was

trained on `uint8` images, rescale this input image to the range [0, 255] by using the `im2uint8` or `rescale` function. The size of this input image should be comparable to the sizes of the images used in training. If these sizes are very different, the detector has difficulty detecting objects because the scale of the objects in the input image differs from the scale of the objects the detector was trained to identify. Consider whether you used the `SmallestImageDimension` property during training to modify the size of training images.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single` | `logical`

`ds` — Datastore
`datastore` object

Datastore, specified as a `datastore` object containing a collection of images. Each image must be a grayscale, RGB, or multichannel image. The function processes only the first column of the datastore, which must contain images and must be cell arrays or tables with multiple columns.

`roi` — Search region of interest
[*x y width height*] vector

Search region of interest, specified as a four-element vector of the form [*x y width height*]. The vector specifies the upper left corner and size of a region in pixels.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `"SelectStrongest",true`

`Threshold` — Detection threshold
`0.5` (default) | scalar

Detection threshold, specified as a scalar in the range [0, 1]. Detections that have scores less than this threshold value are removed. To reduce false positives, increase this value.

`SelectStrongest` — Select strongest bounding box
`true` (default) | `false`

Select the strongest bounding box for each detected object, specified as `true` or `false`.

- `true` — Return the strongest bounding box per object. To select these boxes, `detect` calls the `selectStrongestBboxMulticlass` function, which uses nonmaximal suppression to eliminate overlapping bounding boxes based on their confidence scores.

  For example:

  ```
  selectStrongestBboxMulticlass(bboxes,scores,labels, ...
                                RatioType="Union", ...
                                OverlapThreshold=0.5);
  ```

- `false` — Return all detected bounding boxes. You can then create your own custom operation to eliminate overlapping bounding boxes.

`MaxSize` — Maximum region size
`size(I)` (default) | [*height width*] vector

Maximum region size that contains a detected object, specified as a [*height width*] vector. Units are in pixels.

To reduce computation time, set this value to the known maximum region size for the objects being detected in the image. By default, `MaxSize` is set to the height and width of the input image, `I`.

`MinSize` — Minimum region size
`[1 1]` (default) | [*height width*] vector

Minimum region size that contains a detected object, specified as a [*height width*] vector. Units are in pixels.

To reduce computation time, set this value to the known minimum region size for the objects being detected in the image. By default, `MinSize` is set to `[1 1]`.

`MiniBatchSize` — Minimum batch size
`128` (default) | scalar

Minimum batch size, specified as a scalar value. Use the `MiniBatchSize` to process a large collection of images. Images are grouped into minibatches and processed as a batch, which can improve computation efficiency at the cost of increased memory demand. Decrease the size to use less memory.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as `"auto"`, `"gpu"`, or `"cpu"`.

- `"auto"` — Use a GPU if it is available. Otherwise, use the CPU.
- `"gpu"` — Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Use the CPU.

`Acceleration` — Performance optimization
`"auto"` (default) | `"mex"` | `"none"`

Performance optimization, specified as one of the following:

- `"auto"` — Automatically apply a number of optimizations suitable for the input network and hardware resource.
- `"mex"` — Compile and execute a MEX function. This option is available when using a GPU only. Using a GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If Parallel Computing Toolbox or a suitable GPU is not available, then the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"none"` — Disable all acceleration.

The default option is `"auto"`. If `"auto"` is specified, MATLAB applies a number of compatible optimizations. If you use the `"auto"` option, MATLAB does not ever generate a MEX function.

Using the `Acceleration` options `"auto"` and `"mex"` can offer performance benefits, but at the expense of an increased initial run time. Subsequent calls with compatible parameters are faster. Use performance optimization when you plan to call the function multiple times using new input data.

The `"mex"` option generates and executes a MEX function based on the network and parameters used in the function call. You can have several MEX functions associated with a single network at one time. Clearing the network variable also clears any MEX functions associated with that network.

The `"mex"` option is only available for input data specified as a numeric array, cell array of numeric arrays, table, or image datastore. No other types of datastore support the `"mex"` option.

The `"mex"` option is only available when you are using a GPU. You must also have a C/C++ compiler installed. For setup instructions, see “Set Up Compiler” (GPU Coder).

`"mex"` acceleration does not support all layers. For a list of supported layers, see “Supported Layers” (GPU Coder).

Output Arguments

`bboxes` — Location of objects detected

M-by-4 matrix | *B*-by-1 cell array

Location of objects detected within the input image or images, returned as an *M*-by-4 matrix or a *B*-by-1 cell array. *M* is the number of bounding boxes in an image, and *B* is the number of *M*-by-4 matrices when the input contains an array of images.

Each row of `bboxes` contains a four-element vector of the form [*x y width height*]. This vector specifies the upper left corner and size of that corresponding bounding box in pixels.

`scores` — Detection scores

M-by-1 vector | *B*-by-1 cell array

Detection confidence scores, returned as an *M*-by-1 vector or a *B*-by-1 cell array. *M* is the number of bounding boxes in an image, and *B* is the number of *M*-by-1 vectors when the input contains an array of images. A higher score indicates higher confidence in the detection.

`labels` — Labels for bounding boxes

M-by-1 categorical array | *B*-by-1 cell array

Labels for bounding boxes, returned as an *M*-by-1 categorical array or a *B*-by-1 cell array. *M* is the number of labels in an image, and *B* is the number of *M*-by-1 categorical arrays when the input contains an array of images. You define the class names used to label the objects when you train the input `detector`.

`detectionResults` — Detection results

3-column table

Detection results, returned as a 3-column table with variable names, *Boxes*, *Scores*, and *Labels*. The *Boxes* column contains *M*-by-4 matrices, of *M* bounding boxes for the objects found in the image. Each row contains a bounding box as a 4-element vector in the format [*x*,*y*,*width*,*height*]. The format specifies the upper-left corner location and size in pixels of the bounding box in the corresponding image.

boxLabelDatastore

Datastore for bounding box label data

Description

The `boxLabelDatastore` object creates a datastore for bounding box label data. Use this object to read labeled bounding box data for object detection.

To read bounding box label data from a `boxLabelDatastore` object, use the `read` function. This object function returns a cell array with either two or three columns. You can create a datastore that combines the `boxLabelDatastore` object with an `ImageDatastore` object using the `combine` object function. Use the combined datastore to train object detectors using the training functions such as `trainYOLOv4ObjectDetector` and `trainSSDObjectDetector`. To modify the `ReadSize` property, you can use dot notation.

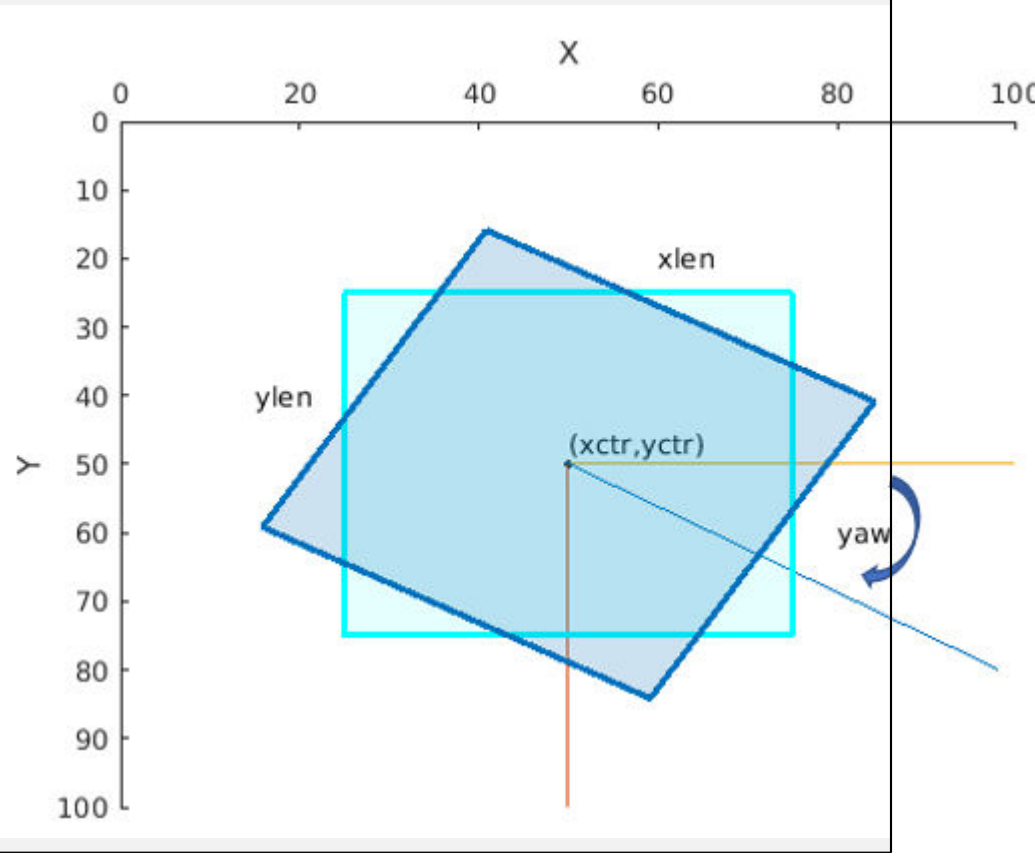
Creation

Syntax

```
blds = boxLabelDatastore(tbl1,...,tbln)
blds = boxLabelDatastore(tbl1,...,tbln,bSet)
```

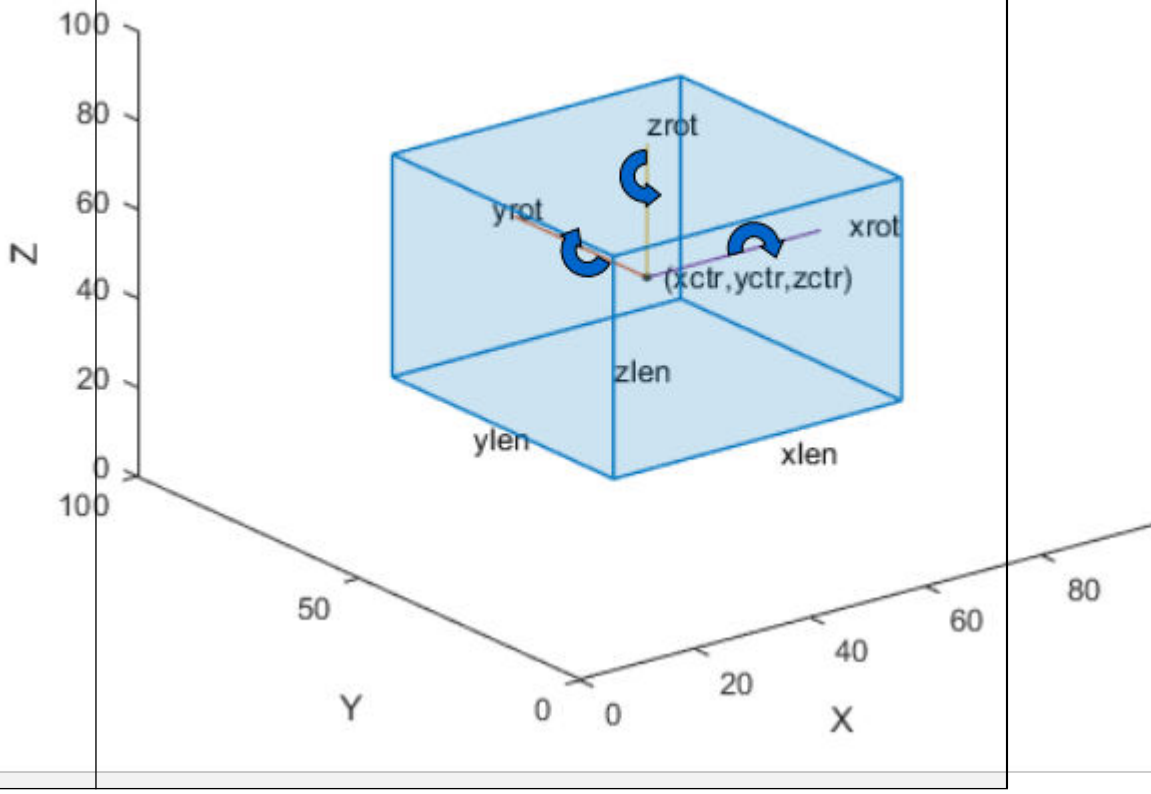
Description

`blds = boxLabelDatastore(tbl1,...,tbln)` creates a `boxLabelDatastore` object from one or more tables containing labeled bounding box data.



`blds = boxLabelDatastore(tbl1,...,tbln,bSet)` creates a `boxLabelDatastore` object for block-based labeled bounding box data. The blocks have resolution level, block size, and block positions specified by the block locations in `bSet`.

Input Arguments



`tbl1,...,tbln` — Labeled bounding box data (as separate arguments)

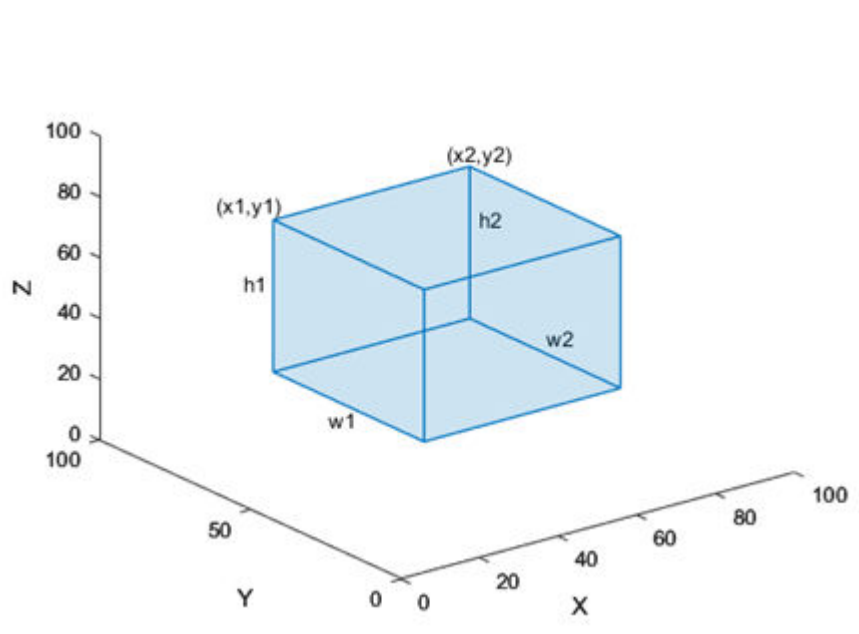


table with one or more columns

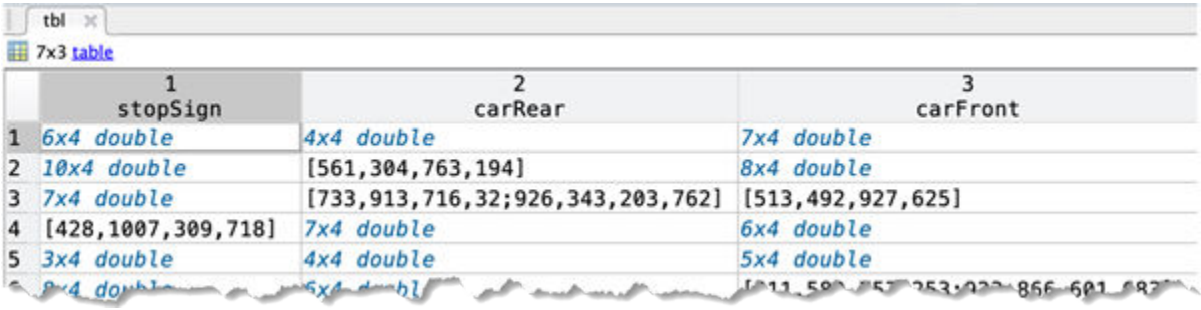
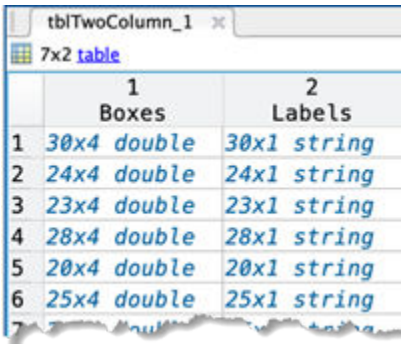
Labeled bounding box data, specified as a table with one or more columns. Each table corresponds to a set of labels. The bounding boxes can be axis-aligned rectangles, rotated rectangles, or cuboids. The table below describes the format of the bounding boxes.

Bounding Box	Description
Axis-aligned rectangle	Defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and y specify the upper-left corner of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis. • *h* specifies the height of the rectangle, which is its length along the *y*-axis.
Rotated rectangle	Defined in spatial coordinates as an *M*-by-5 numeric matrix with rows of the form [*xctr yctr xlen ylen yaw*], where: • *M* is the number of rotated rectangles. • *xctr* and *yctr* specify the center of the rectangle. • *xlen* specifies the width of the rectangle, which is its length along the *x*-axis before rotation. • *ylen* specifies the height of the rectangle, which is its length along the *y*-axis before rotation. • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the bounding box. 



Bounding Box	Description
Cuboid	Defined in spatial coordinates as an *M*-by-9 numeric matrix with rows of the form [*xctr yctr zctr xlen ylen zlen xrot yrot zrot*], where: • *M* is the number of cuboids. • *xctr*, *yctr*, and *zctr* specify the center of the cuboid. • *xlen*, *ylen*, and *zlen* specify the length of the cuboid along the *x*-axis, *y*-axis, and *z*-axis, respectively, before rotation. • *xrot*, *yrot*, and *zrot* specify the rotation angles of the cuboid around the *x*-axis, *y*-axis, and *z*-axis, respectively. The *xrot*, *yrot*, and *zrot* rotation angles are in degrees about the cuboid center. Each rotation is clockwise-positive with respect to the positive direction of the associated spatial axis. The function computes rotation matrices assuming ZYX order Euler angles [*xrot yrot zrot*]. The figure shows how these values determine the position of a cuboid.

Bounding Box	Description
Projected Cuboid	M-by-8 vector of the form `[x1, y1, w1, h1, x2, y2, w2, h2]`, where: • `M` is the number of labels in the frame. • `x1, y1` specifies the *x*,*y* coordinates for the upper-left location of the front-face of the projected cuboid • `w1` specifies the width for the front-face of the projected cuboid. • `h1` specifies the height for the front-face of the projected cuboid. • `x2, y2` specifies the *x*,*y* coordinates for the upper-left location of the back-face of the projected cuboid. • `w2` specifies the width for the back-face of the projected cuboid. • `h2` specifies the height for the back-face of the projected cuboid. The figure shows how these values determine the position of a cuboid. 



- A table with one or more columns:

  All columns contain bounding boxes. Each column must be a cell vector containing *M*-by-*N* matrices. *M* is the number of images and *N* represents a single object class, such as *stopSign*, *carRear*, or *carFront*.

- A table with two columns.

  The first column contains bounding boxes. The second column must be a cell vector that contains the label names corresponding to each bounding box. Each element in the cell vector must be an *M*-by-1 categorical or string vector, where *M* represents the number of labels.

To create a ground truth table, use the Image Labeler or Video Labeler app. To create a table of training data from the generated ground truth, use the `objectDetectorTrainingData` function.

Data Types: `table`

bSet — Block locations

`blockLocationSet` object

Block locations, specified as a `blockLocationSet` object. You can create this object by using the `balanceBoxLabels` function or the `blockLocationsWithROI` function.

Properties

LabelData — Labeled bounding box data

N-by-2 cell array

This property is read-only.

Labeled bounding box data, specified as an *N*-by-2 cell matrix of *N* images. The first column must be a cell vector that contains bounding boxes. Each element in the cell contains a vector representing either an axis-aligned rectangle, rotated rectangle, or a cuboid. The second column must be a cell vector that contains the label names corresponding to each bounding box. An *M*-by-1 categorical vector represents each label name.

Bounding Box Descriptions

Bounding Box	Cell Vector	Format
Axis-aligned rectangle	*M*-by-4 for *M* bounding boxes	[*x*,*y*,*width*,*height*]
Rotated rectangle	*M*-by-5 for *M* bounding boxes	[*xcenter*,*ycenter*,*width*,*height*,*yaw*]
Cuboid	*M*-by-9 for *M* bounding boxes	[*xcenter*,*ycenter*,*zcenter*,*width*,*height*,*depth*,*rx*,*ry*,*rz*]
Projected cuboid	*M*-by-8 vector for *M* bounding boxes	[*x1*,*y1*,*w1*,*h1*,*x2*,*y2*,*w2*,*h2*]

`ReadSize` — Maximum number of rows of label data

1 (default) | positive integer

Maximum number of rows of label data to read in each call to the `read` function, specified as a positive integer.

Object Functions

combine	Combine data from multiple datastores
countEachLabel	Count occurrence of pixel or box labels
hasdata	Determine if data is available to read from label datastore
numpartitions	Number of partitions for label datastore
partition	Partition label datastore
preview	Read first row of data in datastore
progress	Percentage of data read from a datastore
read	Read data from label datastore
readall	Read all data in label datastore
reset	Reset label datastore to initial state
shuffle	Return shuffled version of label datastore
subset	Create subset of datastore or FileSet
transform	Transform datastore
isPartitionable	Determine whether datastore is partitionable
isShuffleable	Determine whether datastore is shuffleable

Examples

Estimate Anchor Boxes for YOLO v2 Object Detection Network

This example shows how to estimate anchor boxes using a table containing the training data. The first column contains the training images and the remaining columns contain the labeled bounding boxes.

```
data = load("vehicleTrainingData.mat");
trainingData = data.vehicleTrainingData;
```

Create a `boxLabelDatastore` object using the labeled bounding boxes from the training data.

```
blds = boxLabelDatastore(trainingData(:,2:end));
```

Specify the class names using the labels from the training data.

```
classes = trainingData.Properties.VariableNames(2:end);
```

Estimate the anchor boxes using the `boxLabelDatastore` object.

```
numAnchors = 5;
anchorBoxes = estimateAnchorBoxes(blds,numAnchors);
```

Specify the image size.

```
inputImageSize = [128 228 3];
```

Use a pretrained ResNet-50 network as a base network for the YOLO v2 network.

```
baseNet = imagePretrainedNetwork("resnet50");
```

Specify the network layer to use for feature extraction. You can use the `analyzeNetwork` function to see all the layer names in a network.

```
featureLayer = "activation_49_relu";
```

Create the YOLO v2 object detection network.

```
detector = yolov2ObjectDetector(baseNet,classes,anchorBoxes, ...
    DetectionNetworkSource=featureLayer)
```

```
detector =
  yolov2ObjectDetector with properties:

                 Network: [1×1 dlnetwork]
               InputSize: [224 224 3]
       TrainingImageSize: [224 224]
             AnchorBoxes: [5×2 double]
              ClassNames: vehicle
    ReorganizeLayerSource: ''
              LossFactors: [5 1 1 1]
               ModelName: ''
```

Visualize the network using the network analyzer.

```
analyzeNetwork(detector.Network)
```

Combine Box Label Datastore and Image Label Datastore

Load a table of vehicle class training data that contains bounding boxes with labels.

```
data = load('vehicleTrainingData.mat');
trainingData = data.vehicleTrainingData;
```

Add the fullpath to the local vehicle data folder.

```
dataDir = fullfile(toolboxdir('vision'),'visiondata');
trainingData.imageFilename = fullfile(dataDir,trainingData.imageFilename);
```

Create an `imageDatastore` object using the file names in the table.

```
imds = imageDatastore(trainingData.imageFilename);
```

Create a `boxLabelDatastore` object using the table with label data.

```
blds = boxLabelDatastore(trainingData(:,2:end));
```

Combine the `imageDatastore` and `boxLabelDatastore` objects.

```
cds = combine(imds,blds);
```

Read the data for training. Use the `read` object function to return images, bounding boxes, and labels.

```
read(cds)
```

```
ans=1×3 cell array
    {128×228×3 uint8}    {[126 78 20 16]}    {[vehicle]}
```

Combine Multiple Class Ground Truth Data

Load a table of vehicle class training data that contains bounding boxes with labels.

```
load('vehicleTrainingData.mat');
```

Load a table of stop signs and cars class training data that contains bounding boxes with labels.

```
load('stopSignsAndCars.mat');
```

Create ground truth tables from the training data.

```
vehiclesTbl  = vehicleTrainingData(:,2:end);
stopSignsTbl = stopSignsAndCars(:,2:end);
```

Create a `boxLabelDatastore` object using two tables: one with vehicle label data and the other with the stop signs and cars label data.

```
blds = boxLabelDatastore(vehiclesTbl,stopSignsTbl);
```

Create an `imageDatastore` object using the file names in the training data tables.

```
dataDir = fullfile(toolboxdir('vision'),'visiondata');
vehicleFiles = fullfile(dataDir,vehicleTrainingData.imageFilename);
stopSignFiles = fullfile(dataDir,stopSignsAndCars.imageFilename);
imds = imageDatastore([vehicleFiles;stopSignFiles]);
```

Combine the `imageDatastore` and `boxLabelDatastore` objects.

```
cds = combine(imds,blds);
```

Read the data for training. Use the `read` object function to return images, bounding boxes, and labels.

```
read(cds)
```

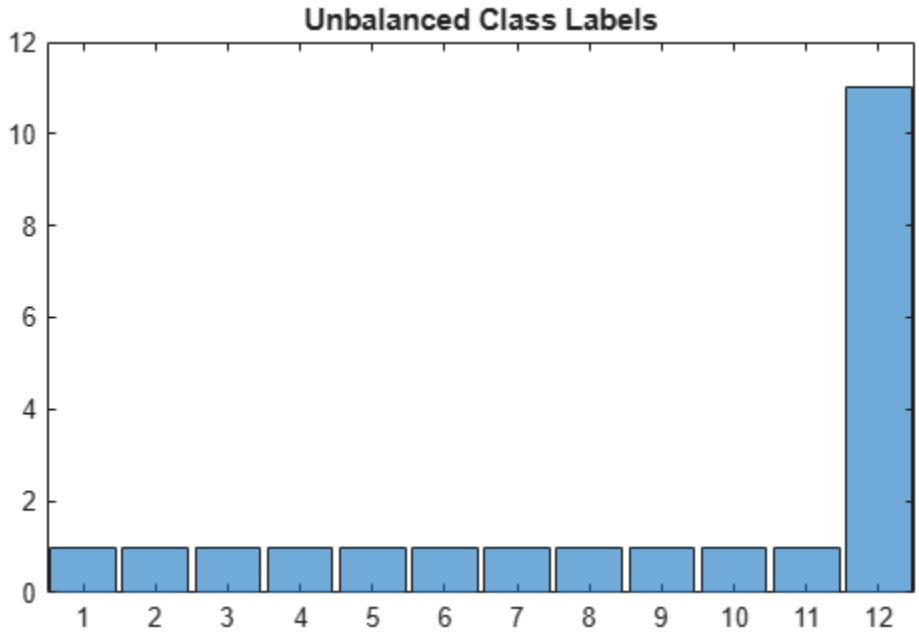
```
ans=1×3 cell array
    {128×228×3 uint8}    {[126 78 20 16]}    {[vehicle]}
```

Sample Block Sets to Use in Blocked Image Object Detection

Load box labels data that contains boxes and labels for one image. The height and width of each box is 20-by-20 pixels.

```
d = load("balanceBoxLabelsData.mat");
boxLabels = d.BoxLabels;
```

Create a blocked image of size 500-by-500 pixels.



```
blockedImages = blockedImage(zeros([500 500]));
```

Choose the images size of each observation.

```
blockSize = [50 50];
```

Visualize using a histogram to identify any class imbalance in the box labels.

```
blds = boxLabelDatastore(boxLabels);
datasetCount = countEachLabel(blds);
figure
unbalancedLabels = datasetCount.Label;
unbalancedCount  = datasetCount.Count;
h1 = histogram(Categories=unbalancedLabels,BinCounts=unbalancedCount);
title("Unbalanced Class Labels")
```

Measure the distribution of box labels. If the coefficient of variation is more than 1, then there is class imbalance.

```
cvBefore = std(datasetCount.Count)/mean(datasetCount.Count)
```

```
cvBefore =
1.5746
```

Choose a heuristic value for number of observations by finding the mean of the counts of each class, multiplied by the number of classes.

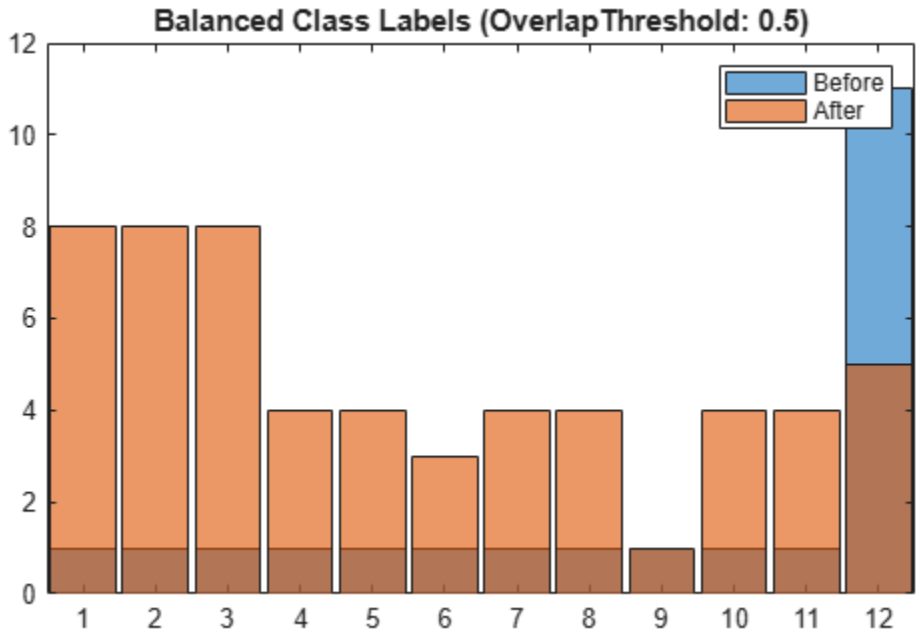
```
numClasses = height(datasetCount);
numObservations = mean(datasetCount.Count) * numClasses;
```

Control the amount a box can be cut using `OverlapThreshold`. Using a lower threshold value will cut objects more at the border of a block. Increase this value to reduce the amount an object can be clipped at the border, at the expense of a less balanced box labels.

```
ThresholdValue = 0.5;
```

Balance `boxLabels` using the `balanceBoxLabels` function.

```
locationSet = balanceBoxLabels(boxLabels,blockedImages,blockSize, ...
        numObservations,OverlapThreshold=ThresholdValue);
```



```
[==================================================] 100%
Elaps[==================================================] 100%
Elapsed time: 00:00:00
Estimated time remaining: 00:00:00
Balancing box labels complete.
```

Count the labels that are contained within the image blocks.

```
bldsBalanced = boxLabelDatastore(boxLabels,locationSet);
balancedDatasetCount = countEachLabel(bldsBalanced);
```

Overlay another histogram against the original label count to see if the box labels are balanced. If the labels appear to be not balanced by looking at the histograms, increase the value for `numObservations`.

```
hold on
balancedLabels = balancedDatasetCount.Label;
balancedCount  = balancedDatasetCount.Count;
h2 = histogram(Categories=balancedLabels,BinCounts=balancedCount);
title(h2.Parent,"Balanced Class Labels (OverlapThreshold: " + ThresholdValue + ")" )
legend(h2.Parent,["Before" "After"])
```

Measure the distribution of the new balanced box labels.

```
cvAfter = std(balancedCount)/mean(balancedCount)
```

```
cvAfter =
0.4588
```

Version History

Introduced in R2019b

R2022b: Project cuboids from 3-D world coordinates to 2-D image coordinates

Updated to support 3-D projected cuboid labels.

pixelLabelImageDatastore

(To be removed) Datastore for semantic segmentation networks

Note `pixelLabelImageDatastore` will be removed in a future release. Use the `imageDatastore` and `pixelLabelDatastore` objects and the `combine` function instead.

Description

Use `pixelLabelImageDatastore` to create a datastore for training a semantic segmentation network using deep learning.

Creation

Syntax

```
pximds = pixelLabelImageDatastore(gTruth)
pximds = pixelLabelImageDatastore(imds,pxds)
pximds = pixelLabelImageDatastore( ___ ,Name,Value)
```

Description

`pximds = pixelLabelImageDatastore(gTruth)` returns a datastore for training a semantic segmentation network based on the input `groundTruth` object or array of `groundTruth` objects. Use the output `pixelLabelImageDatastore` object with the `trainnet` function to train convolutional neural networks for semantic segmentation.

`pximds = pixelLabelImageDatastore(imds,pxds)` returns a datastore based on the input image datastore and the pixel label datastore objects. `imds` is an `ImageDatastore` object that represents the training input to the network. `pxds` is a `PixelLabelDatastore` object that represents the required network output.

`pximds = pixelLabelImageDatastore( ___ ,Name,Value)` additionally uses name-value arguments to set the `DispatchInBackground` and `OutputSizeMode` properties. For 2-D data, you can also use name-value pairs to specify the `ColorPreprocessing`, `DataAugmentation`, and `OutputSize` augmentation properties. You can specify multiple name-value arguments.

For example, `pixelLabelImageDatastore(gTruth,'PatchesPerImage',40)` creates a pixel label image datastore that randomly generates 40 patches from each ground truth object in `gTruth`.

Input Arguments

gTruth — Ground truth data

`groundTruth` object | array of `groundTruth` objects

Ground truth data, specified as a `groundTruth` object or as an array of `groundTruth` objects. Each `groundTruth` object contains information about the data source, the list of label definitions, and all marked labels for a set of ground truth labels.

`imds` — Collection of images
`ImageDatastore` object

Collection of images, specified as an `ImageDatastore` object.

`pxds` — Collection of pixel labeled images
`PixelLabelDatastore` object

Collection of pixel labeled images, specified as a `PixelLabelDatastore` object. The object contains the pixel labeled images for each image contained in the `imds` input object.

Properties

`Images` — Image file names
character vector | cell array of character vectors

This property is read-only.

Image file names used as the source for ground truth images, specified as a character vector or a cell array of character vectors.

`PixelLabelData` — Pixel label file names
character | cell array of characters

This property is read-only.

Pixel label data file names used as the source for ground truth label images, specified as a character or a cell array of characters.

`ClassNames` — Class names
cell array of character vectors

This property is read-only.

Class names, specified as a cell array of character vectors.

`ColorPreprocessing` — Color channel preprocessing
`'none'` (default) | `'gray2rgb'` | `'rgb2gray'`

Color channel preprocessing for 2-D data, specified as `'none'`, `'gray2rgb'`, or `'rgb2gray'`. Use this property when you need the image data created by the data source must be only color or grayscale, but the training set includes both. Suppose you need to train a network that expects color images but some of your training images are grayscale. Set `ColorPreprocessing` to `'gray2rgb'` to replicate the color channels of the grayscale images in the input image set. Using the `'gray2rgb'` option creates *M*-by-*N*-by-3 output images.

The `ColorPreprocessing` property is not supported for 3-D data. To perform color channel preprocessing of 3-D data, use the `transform` function.

`DataAugmentation` — Preprocessing applied to input images
`'none'` (default) | `imageDataAugmenter` object

Preprocessing applied to input images, specified as an `imageDataAugmenter` object or `'none'`. When `DataAugmentation` is `'none'`, no preprocessing is applied to input images. Training data can be augmented in real-time during training.

The `DataAugmentation` property is not supported for 3-D data. To preprocess 3-D data, use the `transform` function.

`DispatchInBackground` — Dispatch observations in background
`false` (default) | `true`

Dispatch observations in the background during training, prediction, and classification, specified as `false` or `true`. To use background dispatching, you must have Parallel Computing Toolbox. If `DispatchInBackground` is `true` and you have Parallel Computing Toolbox, then `pixelLabelImageDatastore` asynchronously reads patches, adds noise, and queues patch pairs.

`MiniBatchSize` — Number of observations in each batch
positive integer

Number of observations that are returned in each batch. The default value is equal to the `ReadSize` of image datastore `imds`. You can change the value of `MiniBatchSize` only after you create the datastore. For training, prediction, or classification, the `MiniBatchSize` property is set to the mini-batch size defined in `trainingOptions`.

`NumObservations` — Total number of observations in the datastore
positive integer

This property is read-only.

Total number of observations in the denoising image datastore. The number of observations is the length of one training epoch.

`OutputSize` — Size of output images
`[]` (default) | vector of two positive integers

This property is read-only.

Size of output images, specified as a vector of two positive integers. The first element specifies the number of rows in the output images, and the second element specifies the number of columns. When you specify `OutputSize`, image sizes are adjusted as necessary. By default, this property is empty, which means that the images are not adjusted.

The `OutputSize` property is not supported for 3-D data. To set the output size of 3-D data, use the `transform` function.

`OutputSizeMode` — Method used to resize output images
`'resize'` (default) | `'centercrop'` | `'randcrop'`

Method used to resize output images, specified as one of the following. This property applies only when you set `OutputSize` to a value other than `[]`.

- `'resize'` — Scale the image to fit the output size. For more information, see `imresize`.
- `'centercrop'` — Take a crop from the center of the training image. The crop has the same size as the output size.
- `'randcrop'` — Take a random crop from the training image. The random crop has the same size as the output size.

Data Types: `char` | `string`

Object Functions

combine	Combine data from multiple datastores
countEachLabel	Count occurrence of pixel or box labels
hasdata	Determine if data is available to read
partitionByIndex	(To be removed) Partition pixelLabelImageDatastore according to indices
preview	Preview subset of data in datastore
read	Read data from label datastore
readall	Read all data in datastore
readByIndex	(To be removed) Read data specified by index from pixelLabelImageDatastore
reset	Reset datastore to initial state
shuffle	Return shuffled version of label datastore
transform	Transform datastore

Examples

Create Datastore for Training Semantic Segmentation Network

Load the training data.

```
dataSetDir = fullfile(toolboxdir("vision"),"visiondata","triangleImages");
imageDir = fullfile(dataSetDir,"trainingImages");
labelDir = fullfile(dataSetDir,"trainingLabels");
```

Create an image datastore for the images.

```
imds = imageDatastore(imageDir);
```

Create a `pixelLabelDatastore` for the ground truth pixel labels.

```
classNames = ["triangle" "background"];
labelIDs   = [255 0];
pxds = pixelLabelDatastore(labelDir,classNames,labelIDs);
```

Combine the image and pixel label datastore for training.

```
trainingData = pixelLabelImageDatastore(imds,pxds);
```

Tips

- The `pixelLabelDatastore` `pxds` and the `imageDatastore` `imds` store files that are located in a folder in lexicographical order. For example, if you have twelve files named `'file1.jpg'`, `'file2.jpg'`, ... , `'file11.jpg'`, and `'file12.jpg'`, then the files are stored in this order:

  ```
  'file1.jpg'
  'file10.jpg'
  'file11.jpg'
  'file12.jpg'
  'file2.jpg'
  'file3.jpg'
  ...
  'file9.jpg'
  ```

  Files that are stored in a cell array are read in the same order as they are stored.

If the order of files in `pxds` and `imds` are not the same, then you may encounter a mismatch when you read a ground truth image and corresponding label data using a `pixelLabelImageDatastore`. If this occurs, then rename the pixel label files so that they have the correct order. For example, rename `'file1.jpg'`, ... , `'file9.jpg'` to `'file01.jpg'`, ..., `'file09.jpg'`.

- To extract semantic segmentation data from a `groundTruth` object generated by the Video Labeler, use the `pixelLabelTrainingData` function.

Version History

Introduced in R2018a

R2025a: Warns
Warns starting in R2025a

The `pixelLabelImageDatastore` issues a warning that it will be removed in a future release. Use the `imageDatastore` and `pixelLabelDatastore` objects and the `combine` function instead.

R2022b: To be removed
Not recommended starting in R2022b

The `pixelLabelImageDatastore` will be removed in a future release.

partitionByIndex

(To be removed) Partition `pixelLabelImageDatastore` according to indices

Note `pixelLabelImageDatastore` object and the `partitionByIndex` function will be removed in a future release. For more information, see “Version History”.

Syntax

```
pximds2 = partitionByIndex(pximds,ind)
```

Description

`pximds2 = partitionByIndex(pximds,ind)` partitions a subset of observations in a pixel label image datastore, `pximds`, into a new datastore, `pximds2`. The desired observations are specified by indices, `ind`.

Input Arguments

`pximds` — Pixel label image datastore

`pixelLabelImageDatastore`

Pixel label image datastore, specified as a `pixelLabelImageDatastore` object.

`ind` — Indices

vector of positive integers

Indices of observations, specified as a vector of positive integers.

Output Arguments

`pximds2` — Output datastore

`pixelLabelImageDatastore` object

Output datastore, returned as a `pixelLabelImageDatastore` object containing a subset of files from `pximds`.

Version History

Introduced in R2018a

R2025a: Warns

Warns starting in R2025a

The `pixelLabelImageDatastore` object and the `partitionByIndex` function issue a warning that it will be removed in a future release. Use the `imageDatastore` and `pixelLabelDatastore` objects and the `combine` function instead of the `pixelLabelImageDatastore` object. There is no replacement for the `partitionByIndex` function.

R2022b: To be removed
Not recommended starting in R2022b

The `pixelLabelImageDatastore` object and the `partitionByIndex` function will be removed in a future release.

`readall` | `read`

readByIndex

(To be removed) Read data specified by index from `pixelLabelImageDatastore`

Note `pixelLabelImageDatastore` object and the `readByIndex` function will be removed in a future release. For more information, see “Version History”.

Syntax

```
data = readByIndex(pximds,ind)
[data,info] = readByIndex(pximds,ind)
```

Description

`data = readByIndex(pximds,ind)` returns a subset of observations from a pixel label image datastore, `pximds`. The desired observations are specified by indices, `ind`.

`[data,info] = readByIndex(pximds,ind)` also returns information about the observations, including metadata, in `info`.

Input Arguments

`pximds` — Pixel label image datastore

`pixelLabelImageDatastore`

Pixel label image datastore, specified as a `pixelLabelImageDatastore` object.

`ind` — Indices

vector of positive integers

Indices of observations, specified as a vector of positive integers.

Output Arguments

`data` — Observations from datastore

table

Observations from the datastore, returned as a table with `length(ind)` number of rows.

`info` — Information about read data

structure array

Information about read data, returned as a structure array. The structure array can contain the following fields.

Field Name	Description
`Filename`	`Filename` is a fully resolved path containing the path string, name of the file, and file extension.

Field Name	Description
`FileSize`	Total file size, in bytes. For MAT-files, `FileSize` is the total number of key-value pairs in the file.

dicePixelClassificationLayer

(To be removed) Create pixel classification layer using generalized Dice loss for semantic segmentation

Note The `DicePixelClassificationLayer` object will be removed in a future release. Use the `trainnet` function and specify the loss using the `generalizedDice` function. For more information, see “Version History”.

Description

A Dice pixel classification layer provides a categorical label for each image pixel or voxel using generalized Dice loss.

The layer uses generalized Dice loss to alleviate the problem of class imbalance in semantic segmentation problems. Generalized Dice loss controls the contribution that each class makes to the loss by weighting classes by the inverse size of the expected region.

Creation

Syntax

```
layer = dicePixelClassificationLayer
layer = dicePixelClassificationLayer(Name,Value)
```

Description

`layer = dicePixelClassificationLayer` creates a Dice pixel classification output layer for semantic image segmentation networks. The layer outputs the categorical label for each image pixel or voxel processed by a CNN. The layer automatically ignores undefined pixel labels during training.

`layer = dicePixelClassificationLayer(Name,Value)` returns a Dice pixel classification output layer using name-value arguments to set the optional `Classes` and `Name` properties. You can specify multiple name-value arguments.

For example, `dicePixelClassificationLayer("Name","pixclass")` creates a Dice pixel classification layer with the name `"pixclass"`.

Properties

`Classes` — Classes of the output layer

`"auto"` (default) | categorical vector | string array | cell array of character vectors

Classes of the output layer, specified as a categorical vector, string array, cell array of character vectors, or `"auto"`. If `Classes` is `"auto"`, then the software automatically sets the classes at training time. If you specify the string array or cell array of character vectors `str`, then the software sets the classes of the output layer to `categorical(str,str)`.

Data Types: `char` | `categorical` | `string` | `cell`

`OutputSize` — Output size
`'auto'` (default)

This property is read-only.

The output size of the layer. The value is `'auto'` prior to training, and is specified as a numeric value at training time.

`LossFunction` — Loss function
`'generalizedDiceLoss'` (default)

This property is read-only.

Loss function used for training, specified as `'generalizedDiceLoss'`.

`Name` — Layer name
`''` (default) | character vector

Layer name, specified as a character vector. For `Layer` array input, the `trainnet` and `dlnetwork` functions automatically assign names to unnamed layers.

Data Types: `char`

`NumInputs` — Number of inputs
1 (default)

This property is read-only.

Number of inputs to the layer, stored as `1`. This layer accepts a single input only.

Data Types: `double`

`InputNames` — Input names
`{'in'}` (default)

This property is read-only.

Input names, stored as `{'in'}`. This layer accepts a single input only.

Data Types: `cell`

Examples

Create 2-D Semantic Segmentation Network with Dice Pixel Classification Layer

Predict the categorical label of every pixel in an input image using a generalized Dice loss function.

```
layers = [
      imageInputLayer([480 640 3])
      convolution2dLayer(3,16,'Stride',2,'Padding',1)
      reluLayer
      transposedConv2dLayer(2,4,'Stride',2)
      softmaxLayer
```

```
      dicePixelClassificationLayer
      ]

layers =
  6×1 Layer array with layers:

     1   ''   Image Input                     480×640×3 images with 'zerocenter' normalization
     2   ''   2-D Convolution                16 3×3 convolutions with stride [2  2] and paddi
     3   ''   ReLU                           ReLU
     4   ''   2-D Transposed Convolution     4 2×2 transposed convolutions with stride [2  2]
     5   ''   Softmax                        Softmax
     6   ''   Dice Pixel Classification Layer   Generalized Dice loss
```

More About

Dice Loss

The Dice loss function is based on the Sørensen-Dice similarity coefficient for measuring overlap between two segmented images.

The generalized Dice loss function L used by `dicePixelClassificationLayer` for the loss between one image Y and the corresponding ground truth T is given by:

$$L = 1 - \frac{2\sum_{k=1}^{K} w_k \sum_{m=1}^{M} Y_{km} T_{km}}{\sum_{k=1}^{K} w_k \sum_{m=1}^{M} Y_{km}^2 + T_{km}^2}$$

K is the number of classes, M is the number of elements along the first two dimensions of Y, and w_k is a class specific weighting factor that controls the contribution each class makes to the loss. This weighting helps counter the influence of larger regions on the Dice score, making it easier for the network to learn how to segment smaller regions. w_k is typically the inverse area of the expected region:

$$w_k = \frac{1}{\left(\sum_{m=1}^{M} T_{km}\right)^2}$$

There are several variations of generalized Dice Loss functions [1], [2]. The function used in `dicePixelClassificationLayer` has squared terms to ensure that the derivative is 0 when the prediction matches the ground truth [3].

Version History

Introduced in R2019b

R2024a: `dicePixelClassificationLayer` will be removed

Not recommended starting in R2024a

The `dicePixelClassificationLayer` object will be removed in a future release. Follow these steps to update your code:

- Define your network as a `dlnetwork` object. You can use functions such as `addLayers` and `connectLayers` to build the network. Do not include output layers in the network.

- Define a custom loss function that uses the `generalizedDice` function. Here is a sample loss function appropriate for Dice pixel classification:

```
function loss = modelLoss(Y,T)
  z = generalizedDice(Y,T);
  loss = 1 - mean(z,"all");
end
```

- Train the network using the `trainnet` function with the custom loss function. For example, this code trains a `dlnetwork` network called `net` using the training data `images` and the custom loss function `modelLoss`.

```
netTrained = trainnet(images,net,@modelLoss,options);
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The code generator represents characters in an 8-bit ASCII codeset that the locale setting determines. Therefore, the use of non-ASCII characters in class names, layer names, layer description, or network names might result in errors. For more information, see “Encoding of Characters in Code Generation” (MATLAB Coder).

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- To generate CUDA or C++ code by using GPU Coder, you must first construct and train a deep neural network. Once the network is trained and evaluated, you can configure the code generator to generate code and deploy the convolutional neural network on platforms that use NVIDIA or ARM® GPU processors. For more information, see “Deep Learning with GPU Coder” (GPU Coder).
- For this layer, you can generate code that takes advantage of the NVIDIA CUDA deep neural network library (cuDNN), NVIDIA TensorRT high performance inference library, or the ARM `Compute Library` for Mali GPU.
- The code generator represents characters in an 8-bit ASCII codeset that the locale setting determines. Therefore, the use of non-ASCII characters in class names, layer names, layer

description, or network names might result in errors. For more information, see “Encoding of Characters in Code Generation” (MATLAB Coder).

focalLossLayer

(To be removed) Create focal loss layer using focal loss function

Note The `FocalLossLayer` object will be removed in a future release. Use the `trainnet` function and specify the loss as the `focalCrossEntropy` function. For more information, see "Version History".

Description

A focal loss layer predicts object classes using focal loss. Add the focal loss layer to train an object detection, semantic segmentation, or a classification network when imbalance exists between foreground and background classes. To compensate for class imbalance, the focal loss function multiplies the cross entropy function with a modulating factor that increases the sensitivity of the network to misclassified observations.

Creation

Syntax

```
layer = focalLossLayer
layer = focalLossLayer(Name,Value)
```

Description

`layer = focalLossLayer` creates a focal loss layer for deep learning networks.

`layer = focalLossLayer(Name,Value)` sets properties of the focal loss layer by using one or more name-value pair arguments. Enclose each property name in quotes.

For example, `focalLossLayer('Name','focalloss')` creates a focal loss layer with the name `'focalloss'` and the specified balancing and focusing parameters.

Properties

`Alpha` — Balancing parameter
0.25 (default) | positive real number

Balancing parameter of the focal loss function, specified as a positive real number. The `Alpha` value scales the loss function linearly and is typically set to `0.25`. If you decrease `Alpha`, increase `Gamma`.

`Gamma` — Focusing parameter
2.0 (default) | positive real number

Focusing parameter of the focal loss function, specified as a positive real number. Increasing the value of `Gamma` increases the sensitivity of the network to misclassified observations.

`Classes` — Object classes to detect

`'auto'` (default) | string vector | categorical vector | cell array of character vectors

Object classes that the network is trained to detect, specified as a string vector, categorical vector, cell array of character vectors, or `'auto'`. When you set `Classes` to `'auto'`, the classes are automatically set at training time. When you specify a string vector or cell array of character vectors, then the elements of `Classes` are sorted according to the output of the `categories` function.

Data Types: `string` | `categorical` | `cell` | `char`

`Name` — Layer name

`''` (default) | character vector

Layer name, specified as a character vector. For `Layer` array input, the `trainnet` and `dlnetwork` functions automatically assign names to unnamed layers.

Data Types: `char`

Examples

Create Focal Loss Layer

Specify class names.

```
classes = ["Vehicle","Background"];
```

Specify the balancing parameter and focusing parameter of the focal loss function. Create a focal loss layer named `"focallosslayer"` for the two classes, displaying results.

```
layer = focalLossLayer(Classes=classes,Name="focallosslayer")
```

```
layer =
  FocalLossLayer with properties:

           Name: 'focallosslayer'

   Hyperparameters
          Gamma: 2
          Alpha: 0.2500
        Classes: [2x1 categorical]
    LossFunction: 'focalLoss'
```

Create 2-D Semantic Segmentation Network with Focal Loss Layer

Create a DeepLab v3+ network based on ResNet-18.

```
imageSize = [480 640 3];
numClasses = 5;
network = "resnet18";
lgraph = deeplabv3plusLayers(imageSize,numClasses,network,DownsamplingFactor=16)
```

```
lgraph =
  LayerGraph with properties:

     InputNames: {'data'}
```

```
    OutputNames: {'classification'}
         Layers: [100x1 nnet.cnn.layer.Layer]
    Connections: [113x2 table]
```

Display the output layer of the network. The output layer of the DeepLab v3+ network is a `PixelClassificationLayer` that uses cross-entropy loss to predict the categorical label for every pixel in an input 2-D image.

```
lgraph.Layers(end)
```

```
ans =
  PixelClassificationLayer with properties:

            Name: 'classification'
         Classes: 'auto'
    ClassWeights: 'none'
      OutputSize: 'auto'

   Hyperparameters
    LossFunction: 'crossentropyex'
```

Replace the output `PixelClassificationLayer` with the `FocalLossLayer` to handle imbalanced classes in data.

```
layer = focalLossLayer("Name","focalloss");
lgraph = replaceLayer(lgraph,"classification",layer);
```

Display the network.

```
analyzeNetwork(lgraph);
```

Create 3-D Semantic Segmentation Network with Focal Loss Layer

Create a 3-D U-Net network for semantic segmentation by using the `unet3dLayers` function. Set the encoder-decoder depth to 2 and specify the number of output channels for the first convolution layer as 16.

```
imageSize = [128 128 128 3];
numClasses = 5;
lgraph = unet3dLayers(imageSize,numClasses, ...
    EncoderDepth=2,NumFirstEncoderFilters=16);
figure
plot(lgraph)
```

Create a focal loss layer and replace the `Segmentation-Layer` in the network with the focal loss layer. The layer predicts the categorical label for every voxel in an input 3-D volume.

```
layer = focalLossLayer(Name="focalloss");
lgraph = replaceLayer(lgraph,"Segmentation-Layer",layer)
```

```
lgraph =
  LayerGraph with properties:

     InputNames: {'ImageInputLayer'}
```

```
    OutputNames: {'focalloss'}
         Layers: [40x1 nnet.cnn.layer.Layer]
    Connections: [41x2 table]
```

Display the network.

```
analyzeNetwork(lgraph);
```

More About

Focal Loss

The focal loss function is based on cross-entropy loss. Focal loss compensates for class imbalance by using a modulating factor that emphasizes hard negatives during training.

The focal loss function, L, used by the `focalLossLayer` object for the loss between one image Y and the corresponding ground truth T is given by:

$$L = -\frac{1}{M}\sum_{m=1}^{M}\sum_{k=1}^{K} T_{mk}\alpha(1-Y_{mk})^{\gamma}\ln(Y_{mk})$$

K is the number of classes. M is the number of observations, which is typically the number of elements along the first two dimensions of Y multiplied by the number of anchor boxes. The function used by the `focalLossLayer` object ensures that the input to the natural logarithm is greater than 0.

Version History

Introduced in R2020a

R2024a: `focalLossLayer` will be removed

Not recommended starting in R2024a

The `focalLossLayer` object will be removed in a future release. Follow these steps to update your code:

- Define your network as a `dlnetwork` object. You can use functions such as `addLayers` and `connectLayers` to build the network. Do not include output layers in the network.
- Train the network using the `trainnet` function and specify the loss using the `focalCrossEntropy` function. For example, this code trains a `dlnetwork` network called `net` using the training data `images`.

  ```
  netTrained = trainnet(images,net,@focalCrossEntropy,options);
  ```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The code generator represents characters in an 8-bit ASCII codeset that the locale setting determines. Therefore, the use of non-ASCII characters in class names, layer names, layer description, or network names might result in errors. For more information, see “Encoding of Characters in Code Generation” (MATLAB Coder).

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- To generate CUDA or C++ code by using GPU Coder, you must first construct and train a deep neural network. Once the network is trained and evaluated, you can configure the code generator to generate code and deploy the convolutional neural network on platforms that use NVIDIA or ARM GPU processors. For more information, see “Deep Learning with GPU Coder” (GPU Coder).
- For this layer, you can generate code that takes advantage of the NVIDIA CUDA deep neural network library (cuDNN), NVIDIA TensorRT high performance inference library, or the ARM `Compute Library` for Mali GPU.
- The code generator represents characters in an 8-bit ASCII codeset that the locale setting determines. Therefore, the use of non-ASCII characters in class names, layer names, layer description, or network names might result in errors. For more information, see “Encoding of Characters in Code Generation” (MATLAB Coder).

patchEmbeddingLayer

Patch embedding layer

Description

A patch embedding layer maps patches of pixels to vectors. Use this layer in vision transformer neural networks to encode information about patches in images.

Creation

Syntax

```
layer = patchEmbeddingLayer(patchSize,outputSize)
layer = patchEmbeddingLayer(patchSize,outputSize,Name=Value)
```

Description

`layer = patchEmbeddingLayer(patchSize,outputSize)` creates a patch embedding layer and sets the `PatchSize` and `OutputSize` properties.

This feature requires a Deep Learning Toolbox license.

`layer = patchEmbeddingLayer(patchSize,outputSize,Name=Value)` sets additional properties using one or more name-value arguments.

Properties

Patch Embedding

`PatchSize` — Size of patches to split input images into
positive integer | row vector of positive integers

This property is read-only.

Size of patches to split input images into, specified as a positive integer or row vector of positive integers.

If `PatchSize` is a vector, then each element of `PatchSize` is the size of the patch in the corresponding spatial dimension of the input. If `PatchSize` is a scalar, then the layer uses the same value for all spatial dimensions of the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`SpatialFlattenMode` — Mode for flattening output of convolution operation
`"column-major"` (default) | `"row-major"`

Mode for flattening the output of the convolution operation, specified as `"column-major"` or `"row-major"`.

If `SpatialFlattenMode` is `"column-major"`, then the flatten operation outputs the data in its column-major representation. For example, consider the input:

```
A = [
   1 2 3
   4 5 6
   7 8 9];
```

The output in column-major representation is:

```
AFlat = [1 4 7 2 5 8 3 6 9];
```

If `SpatialFlattenMode` is `"row-major"`, then the flatten operation outputs the data in its row-major representation. For example, consider the input:

```
A = [
   1 2 3
   4 5 6
   7 8 9];
```

The output in row-major representation is:

```
AFlat = [1 2 3 4 5 6 7 8 9];
```

Set this option when creating or importing models that require this representation.

`OutputSize` — Size of output vectors
positive integer

This property is read-only.

Size of output vectors, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InputSize` — Number of input channels
`"auto"` (default) | positive integer

This property is read-only.

Number of input channels, specified as one of these values:

- `"auto"` — Automatically determine the number of input channels at training time.
- Positive integer — Configure the layer for the specified number of input channels. `InputSize` and the number of channels in the layer input data must match. For example, if the input is an RGB image, then `InputSize` must be 3.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

Parameters and Initialization

`WeightsInitializer` — Function to initialize weights
`"glorot"` (default) | `"he"` | `"narrow-normal"` | `"zeros"` | `"ones"` | function handle

Function to initialize the weights, specified as one of these values:

- `"glorot"` — Initialize the weights with the Glorot initializer “[1] [2]” on page 2-623 (also known as Xavier initializer). The Glorot initializer independently samples from a normal distribution with zero mean and a variance of `2/(numIn + numOut)`, where `numIn` and `numOut` are the values of the `InputSize` and `OutputSize` properties, respectively.
- `"he"` – Initialize the weights with the He initializer [3]. The He initializer samples from a normal distribution with zero mean and a variance of `2/numIn`, where `numIn` is the value of the `InputSize` property.
- `"narrow-normal"` — Initialize the weights by independently sampling from a normal distribution with zero mean and a standard deviation of 0.01.
- `"zeros"` — Initialize the weights with zeros.
- `"ones"` — Initialize the weights with ones.
- Function handle — Initialize the weights with a custom function. If you specify a function handle, then the function must have the form `weights = func(sz)`, where `sz` is the size of the weights.

The layer initializes the weights only when the `Weights` property is empty.

Data Types: `char` | `string` | `function_handle`

`BiasInitializer` — Function to initialize biases
`"zeros"` (default) | `"narrow-normal"` | `"ones"` | function handle

Function to initialize the biases, specified as one of these values:

- `"zeros"` — Initialize the biases with zeros.
- `"ones"` — Initialize the biases with ones.
- `"narrow-normal"` — Initialize the biases by independently sampling from a normal distribution with a mean of zero and a standard deviation of 0.01.
- Function handle — Initialize the biases with a custom function. If you specify a function handle, then the function must have the form `bias = func(sz)`, where `sz` is the size of the biases.

The layer initializes the biases only when the `Bias` property is empty.

The `PatchEmbeddingLayer` object stores this property as a character vector or a function handle.

Data Types: `char` | `string` | `function_handle`

`Weights` — Learnable weights
`[]` (default) | numeric array

Learnable weights.

If `PatchSize` is a positive integer, then `Weights` is an `PatchSize`-by-...-by-`PatchSize`-by-`InputSize`-by-`OutputSize` numeric array or `[]`, where the number of dimensions of size `PatchSize` is the number of spatial dimensions of the input.

If `PatchSize` is a vector, then `Weights` is an `PatchSize(1)`-by-...-by-`PatchSize(K)`-by-`InputSize`-by-`OutputSize` numeric array or `[]`, where `K` is the number of spatial dimensions of the input.

The layer weights are learnable parameters. You can specify the initial value of the weights directly using the `Weights` property of the layer. When you train a network, if the `Weights` property of the layer is nonempty, then the `trainnet` function uses the `Weights` property as the initial value. If the

`Weights` property is empty, then the software uses the initializer specified by the `WeightsInitializer` property of the layer.

Data Types: `single` | `double`

`Bias` — Layer biases
`[]` (default) | column vector

Layer biases, specified as a numeric column vector of length `OutputSize` or `[]`.

The layer biases are learnable parameters. When you train a neural network, if `Bias` is nonempty, then the `trainnet` function uses the `Bias` property as the initial value. If `Bias` is empty, then software uses the initializer specified by the `BiasInitializer` property.

Data Types: `single` | `double`

Learning Rate and Regularization

`WeightLearnRateFactor` — Learning rate factor for weights
`1` (default) | nonnegative scalar

Learning rate factor for the weights, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the weights in this layer. For example, if `WeightLearnRateFactor` is `2`, then the learning rate for the weights in this layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

Data Types: `double`

`BiasLearnRateFactor` — Learning rate factor for biases
`1` (default) | nonnegative scalar

Learning rate factor for the biases, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the biases in this layer. For example, if `BiasLearnRateFactor` is `2`, then the learning rate for the biases in the layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

The `PatchEmbeddingLayer` object stores this property as `double` type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`WeightL2Factor` — L_2 regularization factor for weights
`1` (default) | nonnegative scalar

L_2 regularization factor for the weights, specified as a nonnegative scalar.

The software multiplies this factor by the global L_2 regularization factor to determine the L_2 regularization for the weights in this layer. For example, if `WeightL2Factor` is `2`, then the L_2 regularization for the weights in this layer is twice the global L_2 regularization factor. You can specify the global L_2 regularization factor using the `trainingOptions` function.

Data Types: `double`

`BiasL2Factor` — L_2 regularization factor for biases
`0` (default) | nonnegative scalar

L_2 regularization factor for the biases, specified as a nonnegative scalar.

The software multiplies this factor by the global L_2 regularization factor to determine the L_2 regularization for the biases in this layer. For example, if `BiasL2Factor` is `2`, then the L_2 regularization for the biases in this layer is twice the global L_2 regularization factor. The software determines the global L_2 regularization factor based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Layer

`Name` — Layer name
`''` (default) | character vector

Layer name, specified as a character vector. For `Layer` array input, the `trainnet` and `dlnetwork` functions automatically assign names to unnamed layers.

Data Types: `char`

`NumInputs` — Number of inputs
`1` (default)

This property is read-only.

Number of inputs to the layer, stored as `1`. This layer accepts a single input only.

Data Types: `double`

`InputNames` — Input names
`{'in'}` (default)

This property is read-only.

Input names, stored as `{'in'}`. This layer accepts a single input only.

Data Types: `cell`

`NumOutputs` — Number of outputs
`1` (default)

This property is read-only.

Number of outputs from the layer, stored as `1`. This layer has a single output only.

Data Types: `double`

`OutputNames` — Output names
`{'out'}` (default)

This property is read-only.

Output names, stored as `{'out'}`. This layer has a single output only.

Data Types: `cell`

Examples

Create Patch Embedding Layer

Create a patch embedding layer that embeds patches of size 16 with an output size of 768.

```
patchSize = 16;
embeddingOutputSize = 768;
layer = patchEmbeddingLayer(patchSize,embeddingOutputSize)
```

```
layer =
  PatchEmbeddingLayer with properties:

                     Name: ''
                PatchSize: 16
                InputSize: 'auto'
               OutputSize: 768
        SpatialFlattenMode: 'column-major'
        WeightsInitializer: 'glorot'
           BiasInitializer: 'zeros'
    WeightLearnRateFactor: 1
      BiasLearnRateFactor: 1
           WeightL2Factor: 1
             BiasL2Factor: 1

   Learnable Parameters
                  Weights: []
                     Bias: []

   State Parameters
    No properties.

  Show all properties
```

Create a `dlnetwork` object.

```
net = dlnetwork;
```

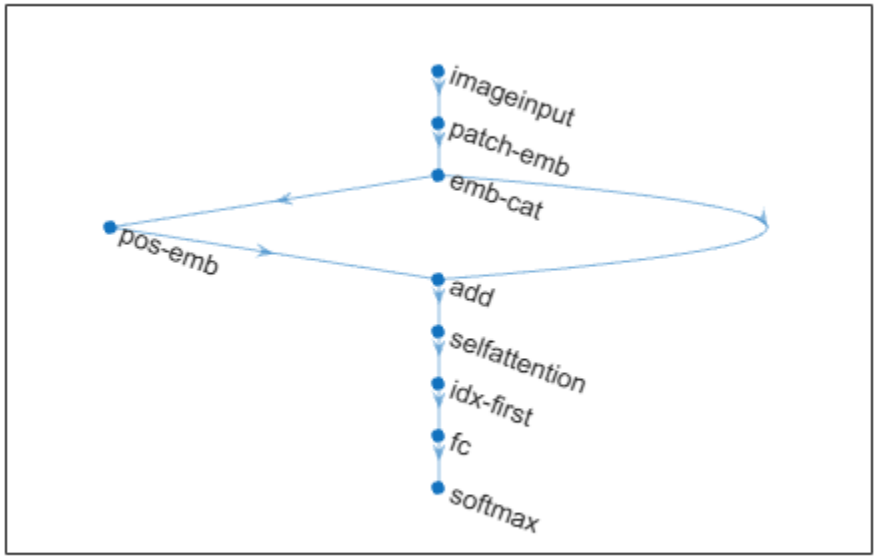
Specify layers of the network, including a patch embedding layer.

```
inputSize = [384 384 3];

maxPosition = (inputSize(1)/patchSize)^2 + 1;

numHeads = 4;
numKeyChannels = 4*embeddingOutputSize;

numClasses = 1000;



layers = [
    imageInputLayer(inputSize)
    patchEmbeddingLayer(patchSize,embeddingOutputSize,Name="patch-emb")
    embeddingConcatenationLayer(Name="emb-cat")
    positionEmbeddingLayer(embeddingOutputSize,maxPosition,Name="pos-emb");
    additionLayer(2,Name="add")
    selfAttentionLayer(numHeads,numKeyChannels,AttentionMask="causal")
    indexing1dLayer(Name="idx-first")
    fullyConnectedLayer(numClasses)
    softmaxLayer];
net = addLayers(net,layers);
```

Connect the embedding concatenation layer with the "in2" input of the addition layer.

```
net = connectLayers(net,"emb-cat","add/in2");
```

View the neural network architecture.

```
plot(net)
```

Algorithms

Patch Embedding Layer

A patch embedding layer maps patches of pixels to vectors. You can use this layer in vision transformer neural networks to encode information about patches in images.

The layer uses a convolution operation with the layer weights and biases to extract and project patches from the input. In particular, the layer:

1. Splits the input into non-overlapping patches.
2. Flattens the patches.
3. Projects the flattened patches to the output size.
4. Flattens the spatial dimensions of the projected output.

Layer Input and Output Formats

Most layers in a layer array or layer graph pass data to subsequent layers as formatted `dlarray` objects. The format of a `dlarray` object is a string of characters in which each character describes the corresponding dimension of the data. The format consists of one or more of these characters:

- `"S"` — Spatial
- `"C"` — Channel
- `"B"` — Batch
- `"T"` — Time
- `"U"` — Unspecified

For example, you can describe 2-D image data that is represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, as having the format `"SSCB"` (spatial, spatial, channel, batch).

You can interact with these `dlarray` objects in automatic differentiation workflows, such as those for:

- developing a custom layer
- using a `functionLayer` object
- using the `forward` and `predict` functions with `dlnetwork` objects

This table shows the supported input formats of `PatchEmbeddingLayer` objects and the corresponding output format. If the software passes the output of the layer to a custom layer that does not inherit from the `nnet.layer.Formattable` class, or to a `FunctionLayer` object with the `Formattable` property set to `0` (`false`), then the layer receives an unformatted `dlarray` object with dimensions ordered according to the formats in this table. The formats listed here are only a subset of the formats that the layer supports. The layer might support additional formats, such as formats with additional `"S"` (spatial) or `"U"` (unspecified) dimensions.

Input Format	Output Format
`"SCB"` (spatial, channel, batch)	`"SCB"` (spatial, channel, batch)
`"SSCB"` (spatial, spatial, channel, batch)	`"SCB"` (spatial, channel, batch)
`"SSSCB"` (spatial, spatial, spatial, channel, batch)	`"SCB"` (spatial, channel, batch)
`"SCBT"` (spatial, channel, batch, time)	`"SCBT"` (spatial, channel, batch, time)
`"SSCBT"` (spatial, spatial, channel, batch, time)	`"SCBT"` (spatial, channel, batch, time)
`"SSSCBT"` (spatial, spatial, spatial, channel, batch, time)	`"SCBT"` (spatial, channel, batch, time)
`"SC"` (spatial, channel)	`"SC"` (spatial, channel)
`"SSC"` (spatial, spatial, channel)	`"SC"` (spatial, channel)
`"SSSC"` (spatial, spatial, spatial, channel)	`"SC"` (spatial, channel)

In `dlnetwork` objects, `PatchEmbeddingLayer` objects also support these input and output format combinations.

Input Format	Output Format
`"SCT"` (spatial, channel, time)	`"SCT"` (spatial, channel, time)
`"SSCT"` (spatial, spatial, channel, time)	`"SCT"` (spatial, channel, time)
`"SSSCT"` (spatial, spatial, spatial, channel, time)	`"SCT"` (spatial, channel, time)

Version History

Introduced in R2023b

R2024a: Specify spatial flattening mode of patch embedding layers

Specify the mode for flattening output of the convolution operation using the `SpatialFlattenMode` option. Set this option when creating or importing models that require this representation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Code generation supports only 1-D and 2-D spatial data. 3-D spatial or more than 3-D spatial data format such as "SSS" or "SSSS" is not supported.
- You can generate generic C/C++ code that does not depend on third-party libraries and deploy the generated code to hardware platforms.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- Code generation supports only 1-D and 2-D spatial data. 3-D spatial or more than 3-D spatial data format such as "SSS" or "SSSS" is not supported.
- You can generate CUDA code that is independent of deep learning libraries and deploy the generated code to platforms that use NVIDIA GPU processors.

pixelClassificationLayer

(To be removed) Create pixel classification layer for semantic segmentation

Note The `pixelClassificationLayer` object will be removed in a future release. Use the `trainnet` function and specify the loss using the `crossentropy` function. For more information, see "Version History".

Description

A pixel classification layer provides a categorical label for each image pixel or voxel.

Creation

Syntax

```
layer = pixelClassificationLayer
layer = pixelClassificationLayer(Name=Value)
```

Description

`layer = pixelClassificationLayer` creates a pixel classification output layer for semantic image segmentation networks. The layer outputs the categorical label for each image pixel or voxel processed by a CNN. The layer automatically ignores undefined pixel labels during training.

`layer = pixelClassificationLayer(Name=Value)` returns a pixel classification output layer using one or more name-value arguments to set the optional `Classes`, `ClassWeights`, and `Name`. For example, `pixelClassificationLayer(Name="pixclass")` creates a pixel classification layer with the name `pixclass`.

Properties

`Classes` — Classes of the output layer

`"auto"` (default) | categorical vector | string array | cell array of character vectors

Classes of the output layer, specified as a categorical vector, string array, cell array of character vectors, or `"auto"`. If `Classes` is `"auto"`, then the software automatically sets the classes at training time. If you specify the string array or cell array of character vectors `str`, then the software sets the classes of the output layer to `categorical(str,str)`.

Data Types: `char` | `categorical` | `string` | `cell`

`ClassWeights` — Class weights

`"none"` (default) | vector of real scalar

Class weights, specified as `"none"` or as a vector of real scalar. The elements of the vector correspond to the classes in `Classes`. If you specify `ClassWeights`, then you must specify `Classes`.

Use class weighting to balance classes when there are underrepresented classes in the training data.

`OutputSize` — Output size
`"auto"` (default)

This property is read-only.

The output size of the layer. The value is `"auto"` prior to training, and is specified as a numeric value at training time.

`LossFunction` — Loss function
`"crossentropyex"` (default)

This property is read-only.

Loss function used for training, specified as `"crossentropyex"`.

`Name` — Layer name
`''` (default) | character vector

Layer name, specified as a character vector. For `Layer` array input, the `trainnet` and `dlnetwork` functions automatically assign names to unnamed layers.

Data Types: `char`

`NumInputs` — Number of inputs
`1` (default)

This property is read-only.

Number of inputs to the layer, stored as `1`. This layer accepts a single input only.

Data Types: `double`

`InputNames` — Input names
`{'in'}` (default)

This property is read-only.

Input names, stored as `{'in'}`. This layer accepts a single input only.

Data Types: `cell`

Examples

Use Pixel Classification Layer to Create Semantic Segmentation Network

Predict the categorical label of every pixel in an input image.

```
layers = [
         imageInputLayer([32 32 3])
         convolution2dLayer(3,16,Stride=2,Padding=1)
         reluLayer
         transposedConv2dLayer(3,1,Stride=2,Cropping=1)
         softmaxLayer
```

```
        pixelClassificationLayer
      ]

layers =
  6×1 Layer array with layers:

     1   ''   Image Input                 32×32×3 images with 'zerocenter' normalization
     2   ''   2-D Convolution             16 3×3 convolutions with stride [2  2] and padding [1
     3   ''   ReLU                        ReLU
     4   ''   2-D Transposed Convolution  1 3×3 transposed convolutions with stride [2  2] and
     5   ''   Softmax                     Softmax
     6   ''   Pixel Classification Layer  Cross-entropy loss
```

Use Weighting to Balance Classes in Training Data

Balance classes using inverse class frequency weighting when some classes are underrepresented in the training data. First, count class frequencies over the training data using pixelLabelDatastore. Then, set the 'ClassWeights' in pixelClassificationLayer to the computed inverse class frequencies.

Set the location of image and pixel label data.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata");
imDir = fullfile(dataDir,"building");
pxDir = fullfile(dataDir,"buildingPixelLabels");
```

Create a pixel label image datastore using the ground truth images in `imds` and the pixel labeled images in `pxds`.

```
imds = imageDatastore(imDir);
classNames = ["sky" "grass" "building" "sidewalk"];
pixelLabelID = [1 2 3 4];
pxds = pixelLabelDatastore(pxDir,classNames,pixelLabelID);
```

Tabulate class distribution in dataset.

```
tbl = countEachLabel(pxds)
```

```
tbl=4×3 table
        Name        PixelCount    ImagePixelCount
    ____________    __________    _______________

    {'sky'     }    3.1485e+05       1.536e+06
    {'grass'   }    1.5979e+05       1.536e+06
    {'building'}    1.0312e+06       1.536e+06
    {'sidewalk'}         25313       9.216e+05
```

Calculate inverse frequency class weights.

```
totalNumberOfPixels = sum(tbl.PixelCount);
frequency = tbl.PixelCount / totalNumberOfPixels;
inverseFrequency = 1./frequency
```

```
inverseFrequency = 4×1

    4.8632
```

```
    9.5827
    1.4848
   60.4900
```

Set 'ClassWeights' to the inverse class frequencies.

```
  layer = pixelClassificationLayer(...
      Classes=tbl.Name,ClassWeights=inverseFrequency)
```

```
layer =
  PixelClassificationLayer with properties:

           Name: ''
        Classes: [sky    grass    building    sidewalk]
   ClassWeights: [4×1 double]
     OutputSize: 'auto'

   Hyperparameters
    LossFunction: 'crossentropyex'
```

Version History

Introduced in R2017b

R2024a: `pixelClassificationLayer` will be removed

Not recommended starting in R2024a

The `pixelClassificationLayer` object will be removed in a future release. Follow these steps to update your code:

- Define your network as a `dlnetwork` object. You can use functions such as `addLayers` and `connectLayers` to build the network. Do not include output layers in the network.
- Define a custom loss function that uses the `crossentropy` function. Here is a sample loss function appropriate for pixel classification:

  ```
  function loss = modelLoss(Y,T)
    mask = ~isnan(T);
    targets(isnan(T)) = 0;
    loss = crossentropy(Y,T,Mask=mask,NormalizationFactor="mask-included");
  end
  ```

- Train the network using the `trainnet` function with the custom loss function. For example, this code trains a `dlnetwork` network called `net` using the training data `images` and the custom loss function `modelLoss`.

  ```
  netTrained = trainnet(images,net,@modelLoss,options);
  ```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The code generator represents characters in an 8-bit ASCII codeset that the locale setting determines. Therefore, the use of non-ASCII characters in class names, layer names, layer

description, or network names might result in errors. For more information, see “Encoding of Characters in Code Generation” (MATLAB Coder).

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- To generate CUDA or C++ code by using GPU Coder, you must first construct and train a deep neural network. Once the network is trained and evaluated, you can configure the code generator to generate code and deploy the convolutional neural network on platforms that use NVIDIA or ARM GPU processors. For more information, see “Deep Learning with GPU Coder” (GPU Coder).
- For this layer, you can generate code that takes advantage of the NVIDIA CUDA deep neural network library (cuDNN), NVIDIA TensorRT high performance inference library, or the ARM `Compute Library` for Mali GPU.
- The code generator represents characters in an 8-bit ASCII codeset that the locale setting determines. Therefore, the use of non-ASCII characters in class names, layer names, layer description, or network names might result in errors. rcnnBoxRegressionLayer

(Not recommended) Box regression layer for Fast and Faster R-CNN

Note `RCNNBoxRegressionLayer` is not recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` detector. For more information, see “Version History”.

Description

A box regression layer refines bounding box locations by using a smooth L1 loss function. Use this layer to create a Fast or Faster R-CNN object detection network.

Creation

Syntax

```
layer = rcnnBoxRegressionLayer
layer = rcnnBoxRegressionLayer('Name',Name)
```

Description

`layer = rcnnBoxRegressionLayer` creates a box regression layer for a Fast or Faster R-CNN object detection network.

`layer = rcnnBoxRegressionLayer('Name',Name)` creates a box regression layer and sets the optional `Name` property.

Properties

`Name` — Layer name
`''` (default) | character vector

Layer name, specified as a character vector. For `Layer` array input, the `trainnet` and `dlnetwork` functions automatically assign names to unnamed layers.

Data Types: `char`

`NumInputs` — Number of inputs
`1` (default)

This property is read-only.

Number of inputs to the layer, stored as `1`. This layer accepts a single input only.

Data Types: `double`

`InputNames` — Input names
`{'in'}` (default)

This property is read-only.

Input names, stored as `{'in'}`. This layer accepts a single input only.

Data Types: `cell`

Examples

Create R-CNN Box Regression Layer

Create an R-CNN box regression layer with the name `'rcnn_box_reg'`.

```
rcnnBoxRegression = rcnnBoxRegressionLayer('Name','rcnn_box_reg');
```

Version History

Introduced in R2018b

R2024b: Not Recommended

Not recommended starting in R2024b

Starting in R2024b, R-CNN object detectors are no longer recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` object. These object detectors are faster than R-CNN object detectors. For more information, see “Choose an Object Detector”.

Extended Capabilities

regionProposalLayer

(Not recommended) Region proposal layer for Faster R-CNN

Note `RegionProposalLayer` is not recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` detector. For more information, see "Version History".

Description

A region proposal layer outputs bounding boxes around potential objects in an image as part of the region proposal network (RPN) within Faster R-CNN. These outputs are further refined by additional layers within Faster R-CNN to produce the final object detection results.

There are two inputs to this layer:

- `'scores'` — The classification scores produced by the RPN classification branch
- `'boxDeltas'` — The bounding box deltas produced by the RPN regression branch

Use the input names when connecting or disconnecting the region proposal layer to other layers using `connectLayers` or `disconnectLayers` (requires Deep Learning Toolbox).

Creation

Syntax

```
layer = regionProposalLayer(anchorBoxes)
layer = regionProposalLayer(anchorBoxes,'Name',Name)
```

Description

`layer = regionProposalLayer(anchorBoxes)` creates a region proposal layer for building Faster R-CNN object detection networks, and sets the `AnchorBoxes` property.

`layer = regionProposalLayer(anchorBoxes,'Name',Name)` creates a region proposal layer and sets the optional `Name` property.

Properties

`AnchorBoxes` — Anchor boxes
M-by-2 matrix

Anchor boxes, specified as an *M*-by-2 matrix defining the [*height width*] of *M* anchor boxes.

Anchor boxes are predefined bounding box templates of fixed size. The size of each anchor box is typically determined based on a priori knowledge of the scale and aspect ratio of objects in the training dataset. An RPN network is trained to predict the translation and rescaling needed to align the anchor boxes with the ground truth bounding boxes. [1]

`Name` — Layer name
`''` (default) | character vector

Layer name, specified as a character vector. For `Layer` array input, the `trainnet` and `dlnetwork` functions automatically assign names to unnamed layers.

Data Types: `char`

`NumInputs` — Number of inputs
2 (default)

Number of inputs of the layer. This layer has two inputs.

Data Types: `double`

`InputNames` — Input names
`{'scores' 'boxDeltas'}` (default)

Input names of the layer. This layer has two inputs, named `'scores'` and `'boxDeltas'`.

Data Types: `cell`

`NumOutputs` — Number of outputs
1 (default)

This property is read-only.

Number of outputs from the layer, stored as `1`. This layer has a single output only.

Data Types: `double`

`OutputNames` — Output names
`{'out'}` (default)

This property is read-only.

Output names, stored as `{'out'}`. This layer has a single output only.

Data Types: `cell`

Examples

Create Region Proposal Layer

Define three square anchor boxes for the region proposal layer.

```
anchorBoxes = [
    16 16
    64 64
    128 128
    ];
```

Create a region proposal layer with the name `'region_proposal'`.

```
regionProposal = regionProposalLayer(anchorBoxes,'Name','region_proposal');
```

roiAlignLayer

Non-quantized ROI pooling layer for Mask-CNN

Description

An ROI align layer outputs fixed size feature maps for every rectangular ROI within an input feature map. Use this layer to create a Mask R-CNN network.

Given an input feature map of size [*H W C N*], where *C* is the number of channels and *N* is the number of observations, the output feature map size is [*h w C* `sum`(*M*)], where *h* and *w* are the specified output size. *M* is a vector of length *N* and *M*(*i*) is the number of ROIs associated with the *i*-th input feature map.

There are two inputs to this layer:

- `'in'` — The input feature map
- `'roi'` — A list of ROIs to pool

Use the input names when connecting or disconnecting the ROI align layer to other layers using `connectLayers` or `disconnectLayers` (requires Deep Learning Toolbox).

Creation

Syntax

```
layer = roiAlignLayer(outputSize)
layer = roiAlignLayer(outputSize,Name,Value)
```

Description

`layer = roiAlignLayer(outputSize)` creates an ROI align layer with pooled output size `outputSize`. The `outputSize` input sets the OutputSize property.

`layer = roiAlignLayer(outputSize,Name,Value)` set properties of the ROI align layer by using one or more name-value pair arguments. Enclose each property name in quotes.

For example, `roiAlignLayer([7 7],'Name','roialignlayer')` creates an ROI align layer with a pooled output size of 7-by-7 pixels and name `'roialignlayer'`.

Properties

`OutputSize` — Pooled output size
vector of two positive integers

Pooled output size, specified as a vector of two positive integers `[h w]`, where `h` is the height and `w` is the width.

Data Types: `double`

`ROIScale` — Scale of input feature map to input image
1 (default) | positive number

Scale of the input feature map to the input image, specified as a positive number.

Data Types: `double`

`SamplingRatio` — Number of samples in each pooled bin
`'auto'` (default) | row vector of two positive integers

Number of samples in each pooled bin, specified as `'auto'` or a row vector of two positive integers. The two elements are the number of vertical and horizontal samples, respectively.

If you do not specify the sampling ratio, then the number of vertical samples has the default value `ceil(`*`roiHeight/outputHeight`*`)`. Likewise, the number of horizontal samples has the default value `ceil(`*`roiWidth/outputWidth`*`)`.

Data Types: `double` | `char`

`Name` — Layer name
`''` (default) | character vector

Layer name, specified as a character vector. For `Layer` array input, the `trainnet` and `dlnetwork` functions automatically assign names to unnamed layers.

Data Types: `char`

`NumInputs` — Number of inputs
2 (default)

Number of inputs of the layer. This layer accepts two inputs.

Data Types: `double`

`InputNames` — Input names
`{'in' 'roi'}` (default)

Input names of the layer.

Data Types: `cell`

`NumOutputs` — Number of outputs
1 (default)

This property is read-only.

Number of outputs from the layer, stored as `1`. This layer has a single output only.

Data Types: `double`

`OutputNames` — Output names
`{'out'}` (default)

This property is read-only.

Output names, stored as `{'out'}`. This layer has a single output only.

Data Types: `cell`

Examples

Create ROI Align Layer

Specify the pooled output size.

```
outputSize = [7 7];
```

Create an ROI align layer named 'roialign'.

```
layer = roiAlignLayer(outputSize,'Name','roialign')
```

```
layer =
  ROIAlignLayer with properties:

            Name: 'roialign'
       NumInputs: 2
      InputNames: {'in'  'roi'}
      OutputSize: [7 7]

   Hyperparameters
         ROIScale: 1
    SamplingRatio: 'auto'
```

More About

ROI Align Layer

An ROI align layer outputs fixed size feature maps for every rectangular ROI within an input feature map. The layer first partitions an ROI into fixed sized bins of size `OutputSize` without quantizing the grid points. Each bin is further sampled at `SamplingRatio` locations. The value at each sampled point is inferred using bilinear interpolation. The average of the sampled values is returned as the output value of each pooled bin.

roiInputLayer

(Not recommended) ROI input layer for Fast R-CNN

Note `ROIInputLayer` is not recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` detector. For more information, see "Version History".

Description

An ROI input layer inputs images to a Fast R-CNN object detection network.

Creation

Syntax

```
layer = roiInputLayer
layer = roiInputLayer('Name',Name)
```

Description

`layer = roiInputLayer` creates an ROI input layer.

`layer = roiInputLayer('Name',Name)` creates an ROI input layer and sets the optional `Name` property.

Properties

`Name` — Layer name
`''` (default) | character vector

Layer name, specified as a character vector. For `Layer` array input, the `trainnet` and `dlnetwork` functions automatically assign names to unnamed layers.

Data Types: `char`

`NumOutputs` — Number of outputs
`1` (default)

This property is read-only.

Number of outputs from the layer, stored as `1`. This layer has a single output only.

Data Types: `double`

`OutputNames` — Output names
`{'out'}` (default)

This property is read-only.

Output names, stored as `{'out'}`. This layer has a single output only.

Data Types: `cell`

Examples

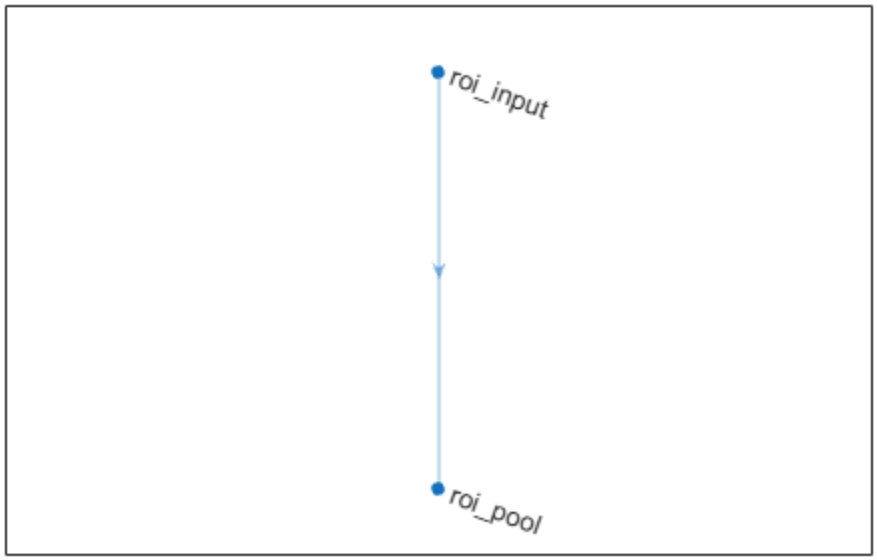
Connect ROI Input Layer to ROI Max Pooling Layer

Create a `dlnetwork` object.

```
net = dlnetwork;
```

Create an array of layers that includes an ROI input layer and an ROI max pooling layer with output size [4 4]. Add the layers to the network.

```
outputSize = [4 4];
layers = [
    roiInputLayer(Name="roi_input")
    roiMaxPooling2dLayer(outputSize,Name="roi_pool")]
```



```
layers =
  2×1 Layer array with layers:

     1   'roi_input'   ROI Input         M-by-4 rectangular ROIs
     2   'roi_pool'    ROI Max Pooling   ROI Max Pooling with pooled output size [4 4]
```

```
net = addLayers(net,layers);
```

Connect the output of the ROI input layer with the `"roi"` input of the ROI max pooling layer. Remove the connection between the ROI input layer and the `"in"` input of the ROI max pooling layer.

```
net = connectLayers(net,"roi_input","roi_pool/roi");
net = disconnectLayers(net,"roi_input","roi_pool/in");
plot(net)
```

roiMaxPooling2dLayer

Neural network layer used to output fixed-size feature maps for rectangular ROIs

Description

An ROI max pooling layer outputs fixed size feature maps for every rectangular ROI within the input feature map. Use this layer to create a Fast or Faster R-CNN object detection network.

Given an input feature map of size [*H W C N*], where *C* is the number of channels and *N* is the number of observations, the output feature map size is [*height width C* `sum`(*M*)], where *height* and *width* are the output size. *M* is a vector of length *N* and *M*(*i*) is the number of ROIs associated with the *i*-th input feature map.

There are two inputs to this layer:

- `'in'` — The input feature map that will be cropped
- `'roi'` — A list of ROIs to pool

Use the input names when connecting or disconnecting the ROI max pooling layer to other layers using `connectLayers` or `disconnectLayers` (requires Deep Learning Toolbox).

Creation

Syntax

```
layer = roiMaxPooling2dLayer(outputSize)
layer = roiMaxPooling2dLayer(outputSize,'Name',Name)
```

Description

`layer = roiMaxPooling2dLayer(outputSize)` creates a max pooling layer for ROIs and sets the `OutputSize` property.

`layer = roiMaxPooling2dLayer(outputSize,'Name',Name)` creates a max pooling layer for ROIs and sets the optional `Name` property. To create a network containing an ROI max pooling layer, you must specify a layer name.

Properties

`OutputSize` — Pooled output size
two-element vector of positive integers

Pooled output size, specified as a two-element vector of positive integers of the form `[`*`height width`*`]`.

`Name` — Layer name
`''` (default) | character vector

Layer name, specified as a character vector. For `Layer` array input, the `trainnet` and `dlnetwork` functions automatically assign names to unnamed layers.

Data Types: `char`

`NumInputs` — Number of inputs
2 (default)

Number of inputs of the layer. This layer has two inputs.

Data Types: `double`

`InputNames` — Input names
`{'in' 'roi'}` (default)

Input names of the layer. This layer has two inputs, named `'in'` and `'roi'`.

Data Types: `cell`

`NumOutputs` — Number of outputs
1 (default)

This property is read-only.

Number of outputs from the layer, stored as `1`. This layer has a single output only.

Data Types: `double`

`OutputNames` — Output names
`{'out'}` (default)

This property is read-only.

Output names, stored as `{'out'}`. This layer has a single output only.

Data Types: `cell`

Examples

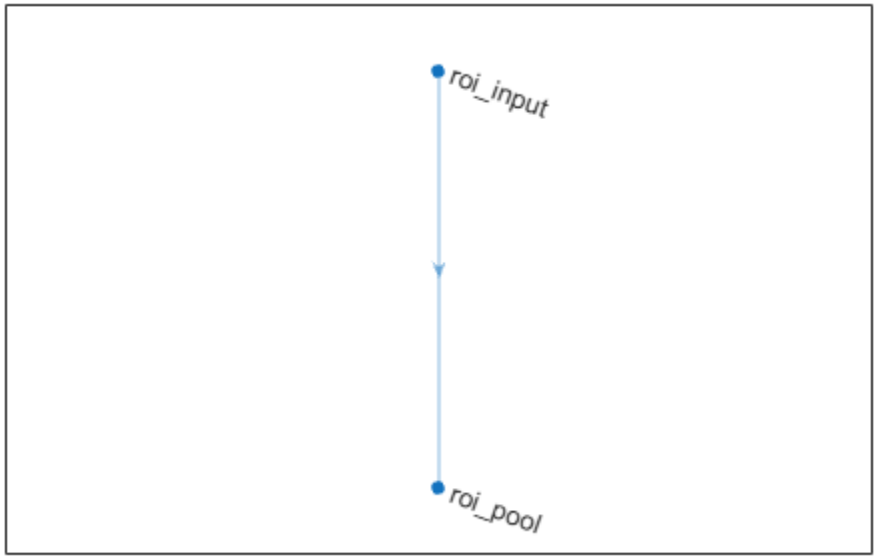
Connect ROI Input Layer to ROI Max Pooling Layer

Create a `dlnetwork` object.

```
net = dlnetwork;
```

Create an array of layers that includes an ROI input layer and an ROI max pooling layer with output size [4 4]. Add the layers to the network.

```
outputSize = [4 4];
layers = [
    roiInputLayer(Name="roi_input")
    roiMaxPooling2dLayer(outputSize,Name="roi_pool")]
```



```
layers =
  2×1 Layer array with layers:
```

```
     1   'roi_input'   ROI Input         M-by-4 rectangular ROIs
     2   'roi_pool'    ROI Max Pooling   ROI Max Pooling with pooled output size [4 4]
```

```
net = addLayers(net,layers);
```

Connect the output of the ROI input layer with the `"roi"` input of the ROI max pooling layer. Remove the connection between the ROI input layer and the `"in"` input of the ROI max pooling layer.

```
net = connectLayers(net,"roi_input","roi_pool/roi");
net = disconnectLayers(net,"roi_input","roi_pool/in");
plot(net)
```

rpnClassificationLayer

(Not recommended) Classification layer for region proposal networks (RPNs)

Note `RPNClassificationLayer` is not recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` detector. For more information, see “Version History”.

Description

A region proposal network (RPN) classification layer classifies image regions as either *object* or *background* by using a cross entropy loss function. Use this layer to create a Faster R-CNN object detection network.

Creation

Syntax

```
layer = rpnClassificationLayer
layer = rpnClassificationLayer('Name',Name)
```

Description

`layer = rpnClassificationLayer` creates a two-class classification layer for a Faster R-CNN object detection network.

`layer = rpnClassificationLayer('Name',Name)` creates a two-class classification layer and sets the optional `Name` property.

Properties

`Name` — Layer name
`''` (default) | character vector

Layer name, specified as a character vector. For `Layer` array input, the `trainnet` and `dlnetwork` functions automatically assign names to unnamed layers.

Data Types: `char`

`NumInputs` — Number of inputs
`1` (default)

This property is read-only.

Number of inputs to the layer, stored as `1`. This layer accepts a single input only.

Data Types: `double`

`InputNames` — Input names
`{'in'}` (default)

This property is read-only.

Input names, stored as `{'in'}`. This layer accepts a single input only.

Data Types: `cell`

Examples

Create Classification Branch of RPN

Create an RPN softmax layer with the name `'rpn_softmax'`.

```
rpnSoftmax = rpnSoftmaxLayer('Name','rpn_softmax')
```

```
rpnSoftmax =
  RPNSoftmaxLayer with properties:

    Name: 'rpn_softmax'
```

Create an RPN classification layer with the name `'rpn_cls'`.

```
rpnClassification = rpnClassificationLayer('Name','rpn_cls')
```

```
rpnClassification =
  RPNClassificationLayer with properties:

    Name: 'rpn_cls'
```

Add the RPN softmax and RPN classification layers to a `Layer` array, to form the classification branch of an RPN.

```
numAnchors = 3;
rpnClassLayers = [
    convolution2dLayer(1,numAnchors*2,'Name','conv1x1_box_cls')
    rpnSoftmax
    rpnClassification
    ]
```

```
rpnClassLayers =
  3×1 Layer array with layers:

rpnSoftmaxLayer

(Not recommended) Softmax layer for region proposal network (RPN)

Note `RPNSoftmaxLayer` is not recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` detector. For more information, see "Version History".

Description

A region proposal network (RPN) softmax layer applies a softmax activation function to the input. Use this layer to create a Faster R-CNN object detection network.

Creation

Syntax

```
layer = rpnSoftmaxLayer
layer = rpnSoftmaxLayer('Name',Name)
```

Description

`layer = rpnSoftmaxLayer` creates a softmax layer for a Faster R-CNN object detection network.

`layer = rpnSoftmaxLayer('Name',Name)` creates a softmax layer and sets the optional `Name` property.

Properties

`Name` — Layer name
`''` (default) | character vector

Layer name, specified as a character vector. For `Layer` array input, the `trainnet` and `dlnetwork` functions automatically assign names to unnamed layers.

Data Types: `char`

`NumInputs` — Number of inputs
`1` (default)

This property is read-only.

Number of inputs to the layer, stored as `1`. This layer accepts a single input only.

Data Types: `double`

`InputNames` — Input names
`{'in'}` (default)

This property is read-only.

Input names, stored as `{'in'}`. This layer accepts a single input only.

Data Types: `cell`

`NumOutputs` — Number of outputs
`1` (default)

This property is read-only.

Number of outputs from the layer, stored as `1`. This layer has a single output only.

Data Types: `double`

`OutputNames` — Output names
`{'out'}` (default)

This property is read-only.

Output names, stored as `{'out'}`. This layer has a single output only.

Data Types: `cell`

Examples

Create Classification Branch of RPN

Create an RPN softmax layer with the name `'rpn_softmax'`.

```
rpnSoftmax = rpnSoftmaxLayer('Name','rpn_softmax')
```

```
rpnSoftmax =
  RPNSoftmaxLayer with properties:

    Name: 'rpn_softmax'
```

Create an RPN classification layer with the name `'rpn_cls'`.

```
rpnClassification = rpnClassificationLayer('Name','rpn_cls')
```

```
rpnClassification =
  RPNClassificationLayer with properties:

    Name: 'rpn_cls'
```

Add the RPN softmax and RPN classification layers to a `Layer` array, to form the classification branch of an RPN.

```
numAnchors = 3;
rpnClassLayers = [
    convolution2dLayer(1,numAnchors*2,'Name','conv1x1_box_cls')
    rpnSoftmax
    rpnClassification
    ]
```

```
rpnClassLayers =
  3×1 Layer array with layers:

     1   'conv1x1_box_cls'   2-D Convolution             6 1×1 convolutions with stride [1  1] ar
     2   'rpn_softmax'       RPN Softmax                 rpn softmax
     3   'rpn_cls'           RPN Classification Output   cross-entropy loss with 'object' and 'ba
```

ssdMergeLayer

Create SSD merge layer for object detection

Description

An SSD merge layer merges the outputs of feature maps for subsequent regression and classification loss computation. Use the merged feature maps to compute focal loss for classification and smooth L1 loss for regression.

Creation

Syntax

```
layer = ssdMergeLayer(NumChannels,NumInputs)
layer = ssdMergeLayer(NumChannels,NumInputs,'Name',Name)
```

Description

`layer = ssdMergeLayer(NumChannels,NumInputs)` creates an SSD merge layer, specifying the `NumChannels` and `NumInputs` properties as the number of feature map channels and number of inputs to merge, respectively.

`layer = ssdMergeLayer(NumChannels,NumInputs,'Name',Name)` creates an SSD merge layer and sets the optional `Name` property using a name-value pair. Enclose the property name in single quotes.

For example, `ssdMergeLayer(4,6,'Name','sm1')` creates an SSD merge layer with the name `'sm1'` that merges four dimensions and six feature maps.

Properties

`NumChannels` — Number of feature map channels
positive integer

Number of feature map channels per anchor box, specified as a positive integer. For regression problems, `NumChannels` is 4 (for x, y, w, and h). For classification problems, `NumChannels` equals the number of classes that are being detected plus one for the background class.

`NumInputs` — Number of inputs to merge
positive integer

Number of inputs to merge, specified as a positive integer.

`Name` — Layer name
`''` (default) | character vector

Layer name, specified as a character vector. For `Layer` array input, the `trainnet` and `dlnetwork` functions automatically assign names to unnamed layers.

Data Types: `char`

Examples

Create SSD Merge Layer for Regression

Specify the number of feature map channels per anchor box. Regression merges four channels.

```
numChannels = 4;
```

Specify the number of inputs to merge.

```
numInputs = 6;
```

Create an SSD merge layer named `regressionMergeLayer`.

```
layer = ssdMergeLayer(numChannels,numInputs,'Name','regressionMergeLayer')
```

```
layer =
  SSDMergeLayer with properties:

           Name: 'regressionMergeLayer'
    NumChannels: 4
      NumInputs: 6
```

Setup SSD Merge Layer For Classification

Specify the number of classes, e.g. person and vehicle.

```
numClasses = 2
```

```
numClasses =
2
```

Specify the number of inputs.

```
numInputs = 6
```

```
numInputs =
6
```

Create an SSD merge layer for classification. The number of channels equals the number of classes + 1 for the background class.

```
numChannels = numClasses + 1;
clsMergeLayer = ssdMergeLayer(numChannels, numInputs,'Name','clsMergeLayer')
```

```
clsMergeLayer =
  SSDMergeLayer with properties:

           Name: 'clsMergeLayer'
    NumChannels: 3
      NumInputs: 6
```

Version History

Introduced in R2020a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

To generate CUDA or C++ code by using GPU Coder, you must first construct and train a deep neural network. Once the network is trained and evaluated, you can configure the code generator to generate code and deploy the convolutional neural network on platforms that use NVIDIA or ARM GPU processors. For more information, see “Deep Learning with GPU Coder” (GPU Coder).

For this layer, you can generate code that takes advantage of the NVIDIA CUDA deep neural network library (cuDNN), or the NVIDIA TensorRT high performance inference library.

yolov2OutputLayer

(To be removed) Create output layer for YOLO v2 object detection network

Note `yolov2OutputLayer` will be removed in a future release. Create a YOLO v2 object detection network using the `yolov2ObjectDetector` object instead. For more information, see "Version History".

Description

The `yolov2OutputLayer` function creates a `YOLOv2OutputLayer` object, which represents the output layer for you only look once version 2 (YOLO v2) object detection network. The output layer provides the refined bounding box locations of the target objects.

Creation

Syntax

```
layer = yolov2OutputLayer(anchorBoxes)
layer = yolov2OutputLayer(anchorBoxes,Name,Value)
```

Description

`layer = yolov2OutputLayer(anchorBoxes)` creates a `YOLOv2OutputLayer` object, `layer`, which represents the output layer for YOLO v2 object detection network. The layer outputs the refined bounding box locations that are predicted using a predefined set of anchor boxes specified at the input.

`layer = yolov2OutputLayer(anchorBoxes,Name,Value)` sets the additional properties using name-value pairs and the input from the preceding syntax. Enclose each property name in single quotes. For example, `yolov2OutputLayer('Name','yolo_Out')` creates an output layer with the name 'yolo_Out'.

Input Arguments

`anchorBoxes` — Set of anchor boxes
M-by-2 matrix

Set of anchor boxes, specified as an *M*-by-2 matrix, where each row is of the form [*height width*]. The matrix defines the height and the width of *M* number of anchor boxes. This input sets the `AnchorBoxes` property of the output layer. You can use the clustering approach for estimating anchor boxes from the training data. For more information, see "Estimate Anchor Boxes from Training Data".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Properties

`Name` — Layer name
`''` (default) | character vector

Layer name, specified as a character vector. For `Layer` array input, the `trainnet` and `dlnetwork` functions automatically assign names to unnamed layers.

Data Types: `char`

`LossFunction` — Loss function
`'mean-squared-error'` (default)

This property is read-only.

Loss function, set as `'mean-squared-error'`. For more information about the loss function, see “Loss Function for Bounding Box Refinement” on page 2-657.

`AnchorBoxes` — Set of anchor boxes
M-by-2 matrix

This property is read-only.

Set of anchor boxes used for training, specified as a *M*-by-2 matrix defining the width and the height of *M* number of anchor boxes. This property is set by the input `anchorBoxes`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`LossFactors` — Weights in the loss function
`[5 1 1 1]` (default) | 1-by-4 vector

This property is read-only.

Weights in the loss function, specified as a 1-by-4 vector of form [K_1 K_2 K_3 K_4]. Weights increase the stability of the network model by penalizing incorrect bounding box predictions and false classifications. For more information about the weights in loss the function, see “Loss Function for Bounding Box Refinement” on page 2-657.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Classes` — Classes of the output layer
'auto' (default) | categorical vector | string array | cell array of character vectors

Classes of the output layer, specified as a categorical vector, string array, cell array of character vectors, or `'auto'`. Use this name-value pair to specify the names of the object classes in the input training data.

If the value is set to `'auto'`, then the software automatically sets the classes at training time. If you specify the string array or cell array of character vectors `str`, then the software sets the classes of the output layer to `categorical(str)`. The default value is `'auto'`.

Data Types: `char` | `string` | `cell` | `categorical`

`NumInputs` — Number of inputs
`1` (default)

This property is read-only.

Number of inputs to the layer, stored as `1`. This layer accepts a single input only.

Data Types: `double`

`InputNames` — Input names
`{'in'}` (default)

This property is read-only.

Input names, stored as `{'in'}`. This layer accepts a single input only.

Data Types: `cell`

Examples

Create YOLO v2 Output Layer

Create a YOLO v2 output layer with two anchor boxes.

Define the height and the width of the anchor boxes.

```
anchorBoxes = [16 16;32 32];
```

Specify the names of the object classes in the training data.

```
classNames = {'Vehicle','Person'};
```

Generate a YOLO v2 output layer with the name `"yolo_Out"`.

```
layer = yolov2OutputLayer(anchorBoxes,'Name','yolo_Out','Classes',classNames);
```

Inspect the properties of the YOLO v2 output layer.

```
layer
```

```
layer =
  YOLOv2OutputLayer with properties:

            Name: 'yolo_Out'

   Hyperparameters
         Classes: [2x1 categorical]
    LossFunction: 'mean-squared-error'
     AnchorBoxes: [2x2 double]
     LossFactors: [5 1 1 1]
```

You can read the values for `Classes` property by using dot notation `layer.Classes`. The function stores the class names as a categorical array.

```
layer.Classes
```

```
ans = 2x1 categorical
     Vehicle
```

```
Person
```

More About

Loss Function for Bounding Box Refinement

During training, the output layer of YOLO v2 network predicts refined bounding box locations by optimizing the mean squared error loss between predicted bounding boxes and the ground truth. The loss function is defined as

$$
\begin{aligned}
&K_1 \sum_{i=0}^{S^2} \sum_{j=0}^{B} 1_{ij}^{obj} \left[(x_i - \hat{x}_i)^2 + (y_i - \hat{y}_i)^2 \right] \\
&+ K_1 \sum_{i=0}^{S^2} \sum_{j=0}^{B} 1_{ij}^{obj} \left[\left(\sqrt{w_i} - \sqrt{\hat{w}_i}\right)^2 + \left(\sqrt{h_i} - \sqrt{\hat{h}_i}\right)^2 \right] \\
&+ K_2 \sum_{i=0}^{S^2} \sum_{j=0}^{B} 1_{ij}^{obj} \left(C_i - \hat{C}_i\right)^2 \\
&+ K_3 \sum_{i=0}^{S^2} \sum_{j=0}^{B} 1_{ij}^{noobj} \left(C_i - \hat{C}_i\right)^2 \\
&+ K_4 \sum_{i=0}^{S^2} 1_{i}^{obj} \sum_{c \in classes} \left(p_i(c) - \hat{p}_i(c)\right)^2
\end{aligned}
$$

where:

- S is the number of grid cells
- B is the number of bounding boxes in each grid cell.
- 1_{ij}^{obj} is 1 if the *jth* bounding box in grid cell i is responsible for detecting the object. Otherwise it is set to 0. A grid cell i is responsible for detecting the object, if the overlap between the ground truth and a bounding box in that grid cell is greater than or equal to 0.6.
- 1_{ij}^{noobj} is 1 if the *jth* bounding box in grid cell i does not contain any object. Otherwise it is set to 0.
- 1_{i}^{obj} is 1 if an object is detected in grid cell i. Otherwise it is set to 0.
- K_1, K_2, K_3, and K_4 are the weights. To adjust the weights, modify the `LossFactors` property.

The loss function can be split into three parts:

- Localization loss

  The first and second terms in the loss function comprise the localization loss. It measures error between the predicted bounding box and the ground truth. The parameters for computing the localization loss include the position, size of the predicted bounding box, and the ground truth. The parameters are defined as follows.

  - (x_i, y_i), is the center of the *jth* bounding box relative to grid cell i.
  - $(\hat{x}_i, \hat{y}_i)$, is the center of the ground truth relative to grid cell i.

- w_i and h_i is the width and the height of the *jth* bounding box in grid cell i, respectively. The size of the predicted bounding box is specified relative to the input image size.
- $\widehat{w}_i$ and $\widehat{h}_i$ is the width and the height of the ground truth in grid cell i, respectively.
- K_1 is the weight for localization loss. Increase this value to increase the weightage for bounding box prediction errors.

- Confidence loss

  The third and fourth terms in the loss function comprise the confidence loss. The third term measures the objectness (confidence score) error when an object is detected in the *jth* bounding box of grid cell i. The fourth term measures the objectness error when no object is detected in the *jth* bounding box of grid cell i. The parameters for computing the confidence loss are defined as follows.

  - C_i is the confidence score of the *jth* bounding box in grid cell i.
  - $\hat{C}_i$ is the confidence score of the ground truth in grid cell i.
  - K_2 is the weight for objectness error, when an object is detected in the predicted bounding box. You can adjust the value of K_2 to weigh confidence scores from grid cells that contain objects.
  - K_3 is the weight for objectness error, when an object is not detected in the predicted bounding box. You can adjust the value of K_3 to weigh confidence scores from grid cells that do not contain objects.

  The confidence loss can cause the training to diverge when the number of grid cells that do not contain objects is more than the number of grid cells that contain objects. To remedy this, increase the value for K_2 and decrease the value for K_3.

- Classification loss

  The fifth term in the loss function comprises the classification loss. For example, suppose that an object is detected in the predicted bounding box contained in grid cell i. Then, the classification loss measures the squared error between the class conditional probabilities for each class in grid cell i. The parameters for computing the classification loss are defined as follows.

  - $p_i(c)$ is the estimated conditional class probability for object class c in grid cell i.
  - $\widehat{p}_i(c)$ is the actual conditional class probability for object class c in grid cell i.
  - K_4 is the weight for classification error when an object is detected in the grid cell. Increase this value to increase the weightage for classification loss.

Tips

To improve prediction accuracy, you can:

- Train the network with more number of images. You can expand the training dataset through data augmentation. For information on how to apply data augmentation for training dataset, see “Preprocess Images for Deep Learning” (Deep Learning Toolbox).
- Perform multiscale training by using the `trainYOLOv2ObjectDetector` function. To do so, specify the `TrainingImageSize` argument of `trainYOLOv2ObjectDetector` function for training the network.
- Choose anchor boxes appropriate to the dataset for training the network. You can use the `estimateAnchorBoxes` function to compute anchor boxes directly from the training data.

Version History

Introduced in R2019a

R2025a: To be removed

Warns starting in R2025a

The `yolov2OutputLayer` object will be removed in a future release. When you call the `yolov2OutputLayer` object, it issues a warning that it will be removed. Create a YOLO v2 object detection network by using the `yolov2ObjectDetector` object instead, using these steps:

- Define your network as a `dlnetwork` object. You can load a pretrained feature extraction network by using the `imagePretrainedNetwork` function. Alternatively, you can use functions such as `addLayers` and `connectLayers` to build the network. Do not include output layers in the network.
- Create a `yolov2ObjectDetector` object using the `dlnetwork` as the custom network. You can specify the anchor boxes, class names, and loss factors using the `AnchorBoxes`, `ClassNames`, and `LossFactors` name-value arguments, respectively.

R2024b: To be removed

Not recommended starting in R2024b

The `yolov2OutputLayer` object will be removed in a future release. Create a YOLO v2 object detection network using the `yolov2ObjectDetector` object instead, using these steps:

- Define your network as a `dlnetwork` object. You can use functions such as `addLayers` and `connectLayers` to build the network. Do not include output layers in the network.
- Create a `yolov2ObjectDetector` using the `dlnetwork` as the custom network. You can specify the anchor boxes, class names, and loss factors using the `AnchorBoxes`, `ClassNames`, and `LossFactors` name-value arguments, respectively.

yolov2TransformLayer

Create transform layer for YOLO v2 object detection network

Description

The `yolov2TransformLayer` function creates a `YOLOv2TransformLayer` object, which represents the transform layer for you only look once version 2 (YOLO v2) object detection network. The transform layer in YOLO v2 object detection network improves the stability of the network by constraining the location predictions. The transform layer extracts activations of the last convolutional layer and transforms the bounding box predictions to fall within the bounds of the ground truth.

Creation

Syntax

```
layer = yolov2TransformLayer(numAnchorBoxes)
layer = yolov2TransformLayer(numAnchorBoxes,Name,Value)
```

Description

`layer = yolov2TransformLayer(numAnchorBoxes)` creates the transform layer for YOLO v2 object detection network.

`layer = yolov2TransformLayer(numAnchorBoxes,Name,Value)` sets the `Name` property using a name-value pair. Enclose the property name in single quotes. For example, `yolov2TransformLayer('Name','yolo_Transform')` creates a transform layer with the name 'yolo_Transform'.

Input Arguments

`numAnchorBoxes` — Number of anchor boxes
positive integer

Number of anchor boxes used for training, specified as a positive integer. This input sets the `NumAnchorBoxes` property of the transform layer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Properties

`Name` — Layer name
`''` (default) | character vector

Layer name, specified as a character vector. For `Layer` array input, the `trainnet` and `dlnetwork` functions automatically assign names to unnamed layers.

Data Types: `char`

`NumAnchorBoxes` — Number of anchor boxes
positive integer

This property is read-only.

Number of anchor boxes used for training, specified as a positive integer. This property is set by the input `numAnchorBoxes`.

`NumInputs` — Number of inputs
`1` (default)

This property is read-only.

Number of inputs to the layer, stored as `1`. This layer accepts a single input only.

Data Types: `double`

`InputNames` — Input names
`{'in'}` (default)

This property is read-only.

Input names, stored as `{'in'}`. This layer accepts a single input only.

Data Types: `cell`

`NumOutputs` — Number of outputs
`1` (default)

This property is read-only.

Number of outputs from the layer, stored as `1`. This layer has a single output only.

Data Types: `double`

`OutputNames` — Output names
`{'out'}` (default)

This property is read-only.

Output names, stored as `{'out'}`. This layer has a single output only.

Data Types: `cell`

Examples

Create YOLO v2 Transform Layer

Specify the number of anchor boxes.

```
numAnchorBoxes = 5;
```

Create a YOLO v2 transform layer with the name "yolo_Transform".

```
layer = yolov2TransformLayer(numAnchorBoxes,'Name','yolo_Transform');
```

Inspect the properties of the YOLO v2 transform layer.

```
layer
```

```
layer =
  YOLOv2TransformLayer with properties:

             Name: 'yolo_Transform'
    NumAnchorBoxes: 5

   Learnable Parameters
    No properties.

   State Parameters
    No properties.

  Show all properties
```

Algorithms

Layer Input and Output Formats

Most layers in a layer array or layer graph pass data to subsequent layers as formatted `dlarray` objects. The format of a `dlarray` object is a string of characters in which each character describes the corresponding dimension of the data. The format consists of one or more of these characters:

- `"S"` — Spatial
- `"C"` — Channel
- `"B"` — Batch
- `"T"` — Time
- `"U"` — Unspecified

For example, you can describe 2-D image data that is represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, as having the format `"SSCB"` (spatial, spatial, channel, batch).

You can interact with these `dlarray` objects in automatic differentiation workflows, such as those for:

- developing a custom layer
- using a `functionLayer` object
- using the `forward` and `predict` functions with `dlnetwork` objects

This table shows the supported input formats of `yolov2TransformLayer` objects and the corresponding output format. If the software passes the output of the layer to a custom layer that does not inherit from the `nnet.layer.Formattable` class, or to a `FunctionLayer` object with the `Formattable` property set to `0` (`false`), then the layer receives an unformatted `dlarray` object with dimensions ordered according to the formats in this table. The formats listed here are only a subset of the formats that the layer supports. The layer might support additional formats, such as formats with additional `"S"` (spatial) or `"U"` (unspecified) dimensions.

Input Format	Output Format
`"SSCB"` (spatial, spatial, channel, batch)	`"SSCB"` (spatial, spatial, channel, batch)

Version History

Introduced in R2019a

R2024b: Support for formatted `dlarray` data

`yolov2TransformLayer` can accept formatted `dlarray` data with the format `"SSCB"` (spatial, spatial, channel, batch). When you pass formatted `dlarray` data to the layer, the layer returns data of the same format. For more information, see “Layer Input and Output Formats” on page 2-663.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

To generate CUDA or C++ code by using GPU Coder, you must first construct and train a deep neural network. Once the network is trained and evaluated, you can configure the code generator to generate code and deploy the convolutional neural network on platforms that use NVIDIA or ARM GPU processors. For more information, see “Deep Learning with GPU Coder” (GPU Coder).

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

pixelLabelDatastore

Datastore for pixel label data

Description

You can use a `PixelLabelDatastore` object to read pixel label data for semantic segmentation.

To read pixel label data from a `PixelLabelDatastore`, use the `read` function. This function returns a categorical array that contains a categorical label assigned to every (*i*,*j*) pixel location or (*i*,*j*,*k*) voxel location.

Creation

Create a `PixelLabelDatastore` object using the `pixelLabelDatastore` function described here. Once the object is created, you can use functions that access and manage the data. You can use dot notation to modify the `ReadSize` and `ReadFcn` properties.

Syntax

```
pxds = pixelLabelDatastore(gTruth)
pxds = pixelLabelDatastore(location,classNames,pixelLabelIDs)
pxds = pixelLabelDatastore( ___ ,Name=Value)
```

Description

`pxds = pixelLabelDatastore(gTruth)` creates a `PixelLabelDatastore` object from a `groundTruth` object or an array of `groundTruth` objects.

`pxds = pixelLabelDatastore(location,classNames,pixelLabelIDs)` creates a `PixelLabelDatastore` object from image files that store pixel label data, in the folder or files specified by `location`. The function creates the object using pixel IDs that map image pixel label values to class names.

`pxds = pixelLabelDatastore( ___ ,Name=Value)` creates a `PixelLabelDatastore` object using name-value arguments to set one or both of the `ReadSize` or `AlternateFileSystemRoots` properties. For image file input, you can also use name-value pair arguments to set the `ReadFcn` property or to specify options on page 2-668 about files to include in the datastore. You can specify multiple name-value pairs. Enclose each property name in quotes.

For example, `pixelLabelDatastore(loc,names,ids,ReadSize=8,FileExtensions="png")` creates a pixel label datastore that includes only PNG images and that reads eight images during each call to the `read` function.

Input Arguments

`gTruth` — Ground truth data
`groundTruth` object | array of `groundTruth` objects

Ground truth data, specified as a `groundTruth` object or as an array of `groundTruth` objects. Each `groundTruth` object contains information about the data source, the list of label definitions, and all marked labels for a set of ground truth labels.

`location` — Folder or image file names

character vector | cell array of character vectors | string array

Folder or image file names, specified as a character vector, string array, or cell array of character vectors. Images must contain `uint8` data.

`location`	Description
character vector, string scalar	Name of a folder. Files within subfolders of the specified folder are not automatically included in the datastore. The datastore includes only images with supported file formats and ignores any other format. See a list of supported file formats by using the `imformats` function.
cell array of character vectors, array of strings	File names of multiple images.

`pixelLabelDatastore` expands the file names and stores the full file paths in the `Files` property.

You can use the wildcard character (*) when specifying `location`. This character indicates that all matching files or all files in the matching folders are included in the datastore.

If the files are not in the current folder, then you must include the full or relative path.

If the files are not available locally, then the full path of the files or folders must be an internationalized resource identifier (IRI), such as `hdfs://`*`hostname`*`:`*`portnumber`*`/`*`path_to_file`*. For information on using a `datastore` with Amazon S3™ and HDFS™, see “Work with Remote Data”.

Example: `"file1.jpg"`

Example: `"../dir/data/file1.png"`

Example: `["C:\dir\data\file1.tif","C:\dir\data\file2.tif"]`

Example: `'C:\dir\data\*.jpg'`

Data Types: `char` | `string`

`classNames` — Class names

cell array of character vectors | cell array of strings

Class names, specified as a cell array of strings or character vectors. `pixelLabelDatastore` converts the names to a cell array and stores the names in the `ClassNames` property.

Example: `["sky" "grass" "building" "sidewalk"]`

`pixelLabelIDs` — IDs to relate pixel labels to class names

vector | *m*-by-3 matrix | cell array of column vectors | cell array of *m*-by-3 matrices

IDs to map pixel labels to `ClassNames`, specified as a vector, an *m*-by-3 matrix, a cell array of column vectors, or a cell array of *m*-by-3 matrices. Values must be integers in the range [0, 255]. *m*-by-3 matrices are only supported for RGB images.

Format	Description
vector	The length of the vector must equal the number of class names. Values must be unique.
m-by-3 matrix	*m* corresponds to the number of class names. Each row contains a 3-element vector representing the RGB pixel value to associate with each class name. Vectors must be unique. Use this format for pixel label data stored as RGB images.
cell array of column vectors cell array of *m*-by-3 matrices	Use a cell array to map multiple pixel label IDs to one class name.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `pixelLabelDatastore(IncludeSubfolders=true)` specifies to include all files and subfolders within each folder.

`IncludeSubfolders` — Include subfolders

`false` (default) | `true`

Include subfolders, specified as `false` (`0`), or `true` (`1`). Specify `true` to include all files and subfolders within each folder or `false` to include only the files within each folder.

The `IncludeSubfolders` argument is not supported when you specify ground truth data `gTruth`.

`FileExtensions` — File extensions

character vector | cell array of character vectors | string scalar | string array

File extensions of files to include in the datastore, specified as a character vector, cell array of character vectors, string scalar, or string array. By default, the datastore includes files with all extensions supported by the `imformats` function.

The `FileExtensions` argument is not supported when you specify ground truth data `gTruth`.

Example: `["png" "gif" "bmp"]`

Properties

`Files` — Files included in datastore

character vector | cell array of character vectors

This property is read-only.

Files included in the datastore, specified as a character vector or cell array of character vectors. Each character vector is a full path to a file. When you create a `PixelLabelDatastore` object, use the `location` argument to set this property.

`ClassNames` — Class names

cell array of character vectors

This property is read-only.

Class names, specified as a cell array of character vectors.

`ReadSize` — Maximum number of image files

1 (default) | positive integer

Maximum number of image files to read in each call to the `read` function, specified as a positive integer.

`AlternateFileSystemRoots` — Alternate file system root paths

string vector | cell array

Alternate file system root paths, specified as the name-value argument consisting of `"AlternateFileSystemRoots"` and a string vector or a cell array. Use `"AlternateFileSystemRoots"` when you create a datastore on a local machine, but need to access and process the data on another machine (possibly of a different operating system). Also, when processing data using the Parallel Computing Toolbox and the MATLAB Parallel Server™, and the data is stored on your local machines with a copy of the data available on different platform cloud or cluster machines, you must use `"AlternateFileSystemRoots"` to associate the root paths.

- To associate a set of root paths that are equivalent to one another, specify `"AlternateFileSystemRoots"` as a string vector. For example,

  ```
  ["Z:\datasets","/mynetwork/datasets"]
  ```

- To associate multiple sets of root paths that are equivalent for the datastore, specify `"AlternateFileSystemRoots"` as a cell array containing multiple rows where each row represents a set of equivalent root paths. Specify each row in the cell array as either a string vector or a cell array of character vectors. For example:

  - Specify `"AlternateFileSystemRoots"` as a cell array of string vectors.

    ```
    {["Z:\datasets", "/mynetwork/datasets"];...
     ["Y:\datasets", "/mynetwork2/datasets","S:\datasets"]}
    ```

  - Alternatively, specify `"AlternateFileSystemRoots"` as a cell array of cell array of character vectors.

    ```
    {{'Z:\datasets','/mynetwork/datasets'};...
     {'Y:\datasets', '/mynetwork2/datasets','S:\datasets'}}
    ```

The value of `"AlternateFileSystemRoots"` must satisfy these conditions:

- Contains one or more rows, where each row specifies a set of equivalent root paths.
- Each row specifies multiple root paths and each root path must contain at least two characters.
- Root paths are unique and are not subfolders of one another.
- Contains at least one root path entry that points to the location of the files.

For more information, see “Set Up Datastore for Processing on Different Machines or Clusters”.

Example: `["Z:\datasets","/mynetwork/datasets"]`

Data Types: `string` | `cell`

ReadFcn — Function that reads pixel labeled image data

`@readDatastoreImage` (default) | function handle

Function that reads pixel labeled image data, specified as a function handle. The custom read function must take an image file name as input, and then output the corresponding pixel labeled data as a categorical array. For example, if `customreader` is the specified function to read the image data, then it must have a signature similar to the following:

```
function C = customreader(filename)
...
end
```

If the read function has more than one output argument, then only the first one is used. The rest are ignored.

The `ReadFcn` property is not supported when you specify ground truth data `gTruth`.

Example: `@customreader`

Object Functions

combine	Combine data from multiple datastores
countEachLabel	Count occurrence of pixel or box labels
hasdata	Determine if data is available to read from label datastore
numpartitions	Number of partitions for label datastore
partition	Partition label datastore
preview	Read first row of data in datastore
read	Read data from label datastore
readall	Read all data in label datastore
readimage	Read specified pixel label data file
reset	Reset label datastore to initial state
shuffle	Return shuffled version of label datastore
transform	Transform datastore
subset	Create subset of datastore or FileSet
isPartitionable	Determine whether datastore is partitionable
isShuffleable	Determine whether datastore is shuffleable

Examples

Read and Display Pixel Label Data

Overlay pixel label data on an image.

Set the location of the image and pixel label data.

```
dataDir = fullfile(toolboxdir('vision'),'visiondata');
imDir = fullfile(dataDir,'building');
pxDir = fullfile(dataDir,'buildingPixelLabels');
```

Create an image datastore.

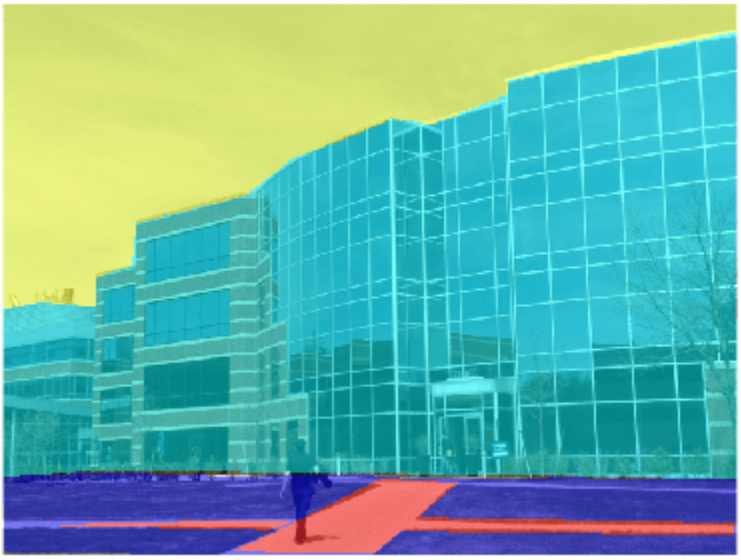
```
imds = imageDatastore(imDir);
```

Create a pixel label datastore.

```
classNames = ["sky" "grass" "building" "sidewalk"];
pixelLabelID = [1 2 3 4];
pxds = pixelLabelDatastore(pxDir,classNames,pixelLabelID);
```

Read the image and pixel label data. `read(pxds)` returns a categorical matrix, `C`. The element C(i,j) in the matrix is the categorical label assigned to the pixel at the location I(i,j).

```
I = read(imds);
C = read(pxds);
```



Display the label categories in `C`.

```
categories(C{1})
```

```
ans = 4×1 cell
    {'sky'     }
    {'grass'   }
    {'building'}
    {'sidewalk'}
```

Overlay and display the pixel label data onto the image.

```
B = labeloverlay(I,C{1});
figure
imshow(B)
```

Read and Display 3-D Pixel Label Data

Specify the location of 3-D volume and pixel label data. This data is a labeled 3-D MRI scan of a brain.

```
dataDir = fullfile(toolboxdir("images"),"imdata");
imDir = fullfile(dataDir,"BrainMRILabeled","images");
pxDir = fullfile(dataDir,"BrainMRILabeled","labels");
```

Specify a custom read function. This example specifies a function called `samplePXDSMatReader` (defined at the end of the example) that read 3-D image data from MAT image files.

```
matReader = @samplePXDSMatReader;
```

Create an image datastore.

```
imds = imageDatastore(imDir,"FileExtensions",".mat","ReadFcn",matReader);
```

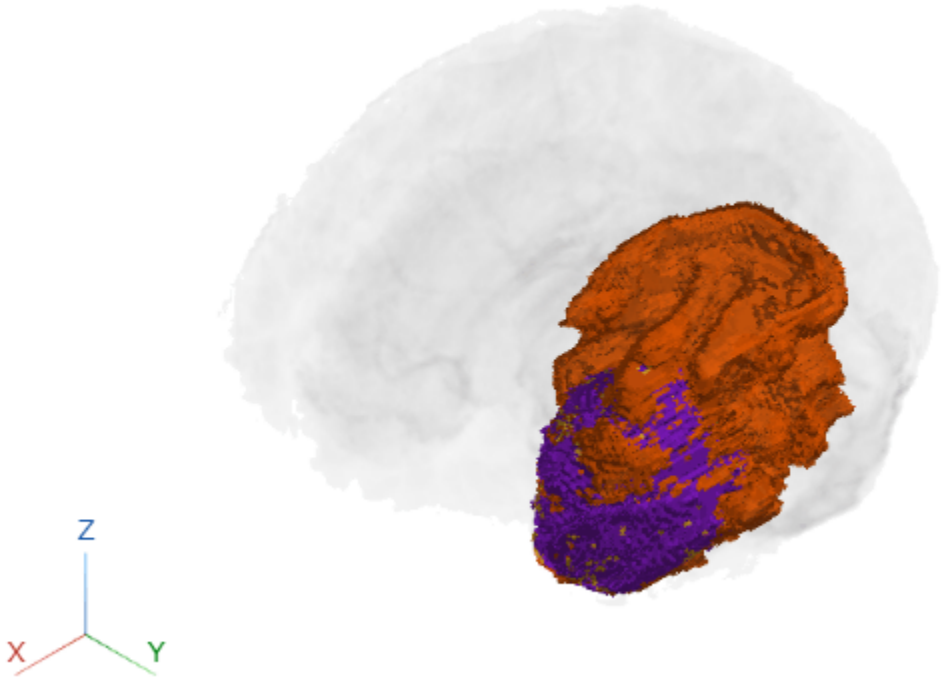
Create a pixel label datastore.

```
classNames = ["edema","nonEnhancingTumor","enhancingTumour"];
pixelLabelID = [1 2 3];
pxds = pixelLabelDatastore(pxDir,classNames,pixelLabelID,"FileExtensions",".mat","ReadFcn",matRea
```

Read volume and pixel label data. `L` is a categorical matrix, where `L(i,j,k)` is the categorical label assigned to `V(i,j,k)`.

```
V = read(imds);
L = read(pxds);
```

Display the label categories.



```
C = categories(L{1})
```

```
C = 3×1 cell array
    "'edema'"
    "'nonEnhancingTumor'"
    "'enhancingTumour'"
```

Visualize the result using the `viewer3d` and `volshow` functions. Display the labels by specifying the `OverlayData` and `OverlayAlpha` name-value arguments.

```
viewer = viewer3d(BackgroundColor="white",BackgroundGradient="off",CameraZoom=2);

h = volshow(V,Parent=viewer, ...
    RenderingStyle="GradientOpacity", ...
    GradientOpacityValue=0.8, ...
    Alphamap=linspace(0,0.2,256), ...
    OverlayData=L{1}, ...
    OverlayAlpha=0.8);
```

This example defines a helper function, `samplePXDSMatReader`, to read the 3-D image data from the image files. This function loads a MAT file and returns the first variable saved in that file.

```
function data = samplePXDSMatReader(filename)
    inp = load(filename);
    f = fields(inp);
    data = inp.(f{1});
end
```

Tips

- A `pixelLabelDatastore` stores files in lexicographical order. For example, if you have twelve files named `"file1.jpg"`, `"file2.jpg"`, ... , `"file11.jpg"`, and `"file12.jpg"`, then the files are stored in this order:

  ```
  "file1.jpg"
  "file10.jpg"
  "file11.jpg"
  "file12.jpg"
  "file2.jpg"
  "file3.jpg"
  ...
  "file9.jpg"
  ```

  In contrast, an `imageDatastore` stores files in the order they are added to the datastore. If you simultaneously read a ground truth image and pixel label data, then you may encounter a

mismatch between the images and the labels. If this occurs, then rename the pixel label files so that they have the correct order. For example, rename `"file1.jpg"`, ... , `"file9.jpg"` to `"file01.jpg"`, ..., `"file09.jpg"`.

- To extract semantic segmentation data from a `groundTruth` object generated by the Video Labeler app, use the `pixelLabelTrainingData` function.

KAZEPoints

Object for storing KAZE interest points

Description

This object provides the ability to pass data between the `detectKAZEFeatures` and `extractFeatures` functions. You can also use this object to manipulate and plot the data returned by these functions. Use the object to fill points interactively, where you might want to mix a non-KAZE interest point detector with a KAZE descriptor.

Creation

Syntax

```
points = KAZEPoints(location)
points = KAZEPoints(location,Name=Value)
```

Description

`points = KAZEPoints(location)` constructs a `KAZEPoints` object from an *M*-by-2 array [*x y*] of location coordinates.

The scalar KAZEPoints object contains many points. Therefore `numel(KAZEPoints)` always returns `1`. This value can be different than the result of `length(KAZEPoints)`, which returns the true number of points contained in the object.

`points = KAZEPoints(location,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `points = KAZEPoints(Metric=10)` sets the strength of detected KAZE features to `10`.

Input Arguments

`location` — Location coordinates

M-by-2 array

Location of points, specified as an *M*-by-2 array of [*x y*] coordinates.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `points = KAZEPoints(Metric=10)` sets the strength of detected KAZE features to `10`.

`Scale` — Scale

`1.6` (default) | scalar | *M*-element vector

Scale, specified as a scalar or an or *M*-element vector. The scale sets the size at which the interest points are detected and must be a value greater than or equal to `1.6`.

`Metric` — Strength of detected feature
0.0 (default) | numeric scalar | vector

Strength of detected features, specified as a numeric scalar. The KAZE algorithm uses a determinant of an approximated Hessian.

`Orientation` — Orientation
0.0 (default) | radians | scalar | *M*-element vector

Orientation of the detected feature, specified as an angle in radians. The angle is measured from the *x*-axis with the origin set by the `location` input. `Orientation` property can be useful for visualizations. The `extractFeatures` function sets this property. Do not set it manually.

Properties

`Location` — Location of points
`[]` (default) | *M*-by-2 matrix

This property is read-only.

Location of points, specified as an *M*-by-2 matrix. Each row is of the form [*x* *y*] and represents the location of a point. *M* is the number of points. You cannot set this property, use the `location` input argument instead.

`Count` — Number of points
`0` (default) | nonnegative integer

This property is read-only.

Number of points held by the object, specified as a nonnegative integer.

Object Functions

isempty	Determine if points object is empty
length	Number of stored points
plot	Plot detected feature points
selectStrongest	Select points with strongest metrics
size	Return size of points object
selectUniform	Select uniformly distributed subset of point features
select	Select point or region features during code generation

Examples

Detect KAZE Features

Detect KAZE features and display 10 strongest points.

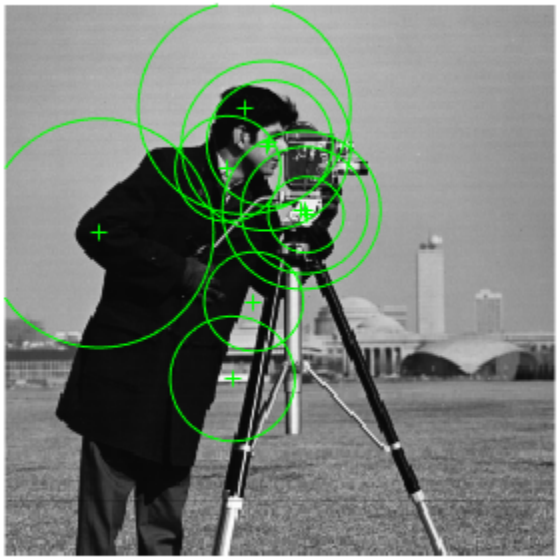
Read an image.

```
I = imread('cameraman.tif');
```

Detect KAZE features in the image.

```
points = detectKAZEFeatures(I);
```

Select the 10 strongest points.



```
strongest = selectStrongest(points,10);
```

Display the selected points.

```
imshow(I);
hold on;
```

Display the location and scale. The size of the circles displayed relate to the scale.

```
plot(strongest);
hold on;
```

Display the [x y] coordinates for the strongest points in the MATLAB Command Window.

```
strongest.Location
```

```
ans = 10×2 single matrix

  138.5041   95.8063
  139.9253   95.8802
  111.8975   48.2950
  106.4036  174.1800
   44.3964  106.4899
  122.0368   65.9064
  116.2702  138.2877
  123.6542   64.7193
  104.2719   76.5821
  140.6228   97.9271
```

Detect KAZE Features and Display Specific Points

Read an image into the workspace.

```
I = imread("cameraman.tif");
```

Detect KAZE features in the image.

```
points = detectKAZEFeatures(I);
```

Select and display the last 5 points detected.

```
imshow(I);
hold on;
plot(points(end-4:end));
hold off;
```

Tips

- Although `KAZEPoints` may hold many points, it is a scalar object. Therefore, `numel(points)` always returns `1`. This value may differ from the resulting value of `length(points)`, which returns the true number of points held by the object.

Version History

Introduced in R2017b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- To index locations with this object, use the syntax: `points.Location(idx,:)`, for `points` object. See visionRecovertformCodeGeneration_kernel.m, which is used in the “Introduction to Code Generation with Feature Matching and Registration” example.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

binaryFeatures

Object for storing binary feature vectors

Description

This object provides the ability to pass data between the `extractFeatures` and `matchFeatures` functions. It can also be used to manipulate and plot the data returned by `extractFeatures`.

Creation

Syntax

```
features = binaryFeatures(featureVectors)
```

Description

`features = binaryFeatures(featureVectors)` constructs a `binaryFeatures` object from the *M*-by-*N* input matrix, `featureVectors`. This matrix contains *M* feature vectors stored in *N* uint8 containers.

Input Arguments

`featureVectors` — Input feature vectors
M-by-*N* matrix

Input feature vectors, specified as an *M*-by-*N* input matrix. This matrix contains *M* binary feature vectors stored in *N* uint8 containers.

Read-only Properties

`Features` — Feature vectors
M-by-*N* matrix

Feature vectors, saved as an *M*-by-*N* input matrix. This matrix contains *M* binary feature vectors stored in *N* uint8 containers.

`NumBits` — Number of bits per feature vector
integer

Number of bits per feature vector, saved as an integer. `NumBits` equals the number of uint8 feature vector containers times 8.

`NumFeatures` — Number of feature vectors
integer

Number of feature vectors contained in the `binaryFeatures` object, saved as a positive integer.

Examples

Match Two Sets of Binary Feature Vectors

Input feature vectors.

```
features1 = binaryFeatures(uint8([1 8 7 2; 8 1 7 2]));
features2 = binaryFeatures(uint8([8 1 7 2; 1 8 7 2]));
```

Match the vectors using the Hamming distance.

```
[indexPairs matchMetric] = matchFeatures(features1, features2)
```

```
indexPairs = 2×2 uint32 matrix

   1   2
   2   1

matchMetric = 2×1 single column vector

     0
     0
```

`extractFeatures` | `extractHOGFeatures` | `matchFeatures`

cameraIntrinsics

Object for storing intrinsic camera parameters

Description

Store information about a camera’s intrinsic calibration parameters, including lens distortion.

Creation

Syntax

```
intrinsics = cameraIntrinsics(focalLength,principalPoint,imageSize)
intrinsics = cameraIntrinsics(focalLength,principalPoint,imageSize,
PropertyName=Value)
```

Description

`intrinsics = cameraIntrinsics(focalLength,principalPoint,imageSize)` returns a camera intrinsics object that contains the focal length and the camera's principal point. The three input arguments set the FocalLength, PrincipalPoint, and ImageSize properties, respectively.

`intrinsics = cameraIntrinsics(focalLength,principalPoint,imageSize, PropertyName=Value)` specifies options using one or more properties on page 2-682 in addition to the previous syntax. For example, `RadialDistortion=[0 10]` sets the radial lens distortion property, to the vector `[0 10]`.

Properties

`FocalLength` — Focal length

2-element vector

Focal length in x and y, stored as a 2-element vector $[f_x\ f_y]$ in pixels.

$f_x = F * s_x$
$f_y = F * s_y$

F is the focal length in world units, typically in millimeters. s_x and s_y are the number of pixels per world unit in the x and y direction respectively. Thus, f_x and f_y are in pixels.

The focal length F influences the angle of view and thus affects the area of the scene that appears focused in an image. For a fixed subject distance:

- A short focal length offers a wide angle of view allowing to capture large area of the scene under focus. It emphasizes both the subject and the scene background.
- A long focal length offers a narrow angle of view, thus reducing the area of the scene under focus. It emphasizes more on the subject and restricts the amount of background from being captured.

You cannot set the value of `FocalLength` after you create the `cameraIntrinsics` object.

`PrincipalPoint` — Optical center of camera

two-element vector

Optical center of camera, stored as a two-element vector [*cx cy*] in pixels. The vector contains the coordinates of the optical center of the camera.

You cannot set the value of `PrincipalPoint` after you create the `cameraIntrinsics` object.

`ImageSize` — Image size produced by the camera

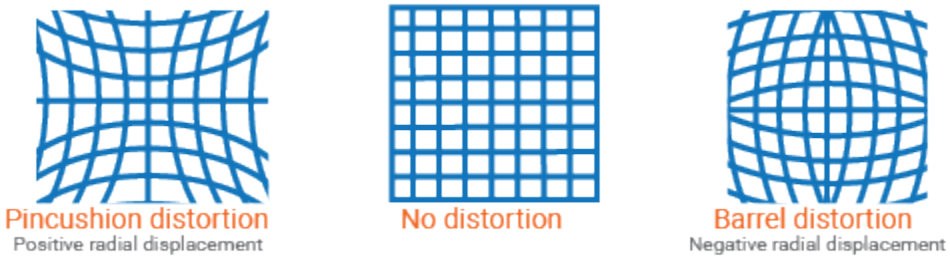
two-element vector

Image size produced by the camera, stored as a two-element vector, [*mrows ncols*].

You cannot set the value of `ImageSize` after you create the `cameraIntrinsics` object.

`RadialDistortion` — Radial lens distortion coefficients

`[0 0]` (default) | 2-element vector | 3-element vector | 6-element vector



Radial lens distortion coefficients, specified as a 2-, 3-, or 6-element vector.

- 2-element vector — [*k1 k2*].
- 3-element vector — [*k1 k2 k3*].
- 6-element vector — [*k1 k2 k3 k4 k5 k6*].

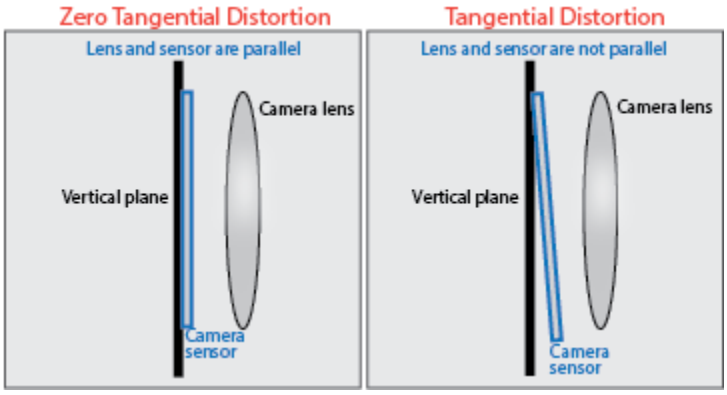
In the Robot Operating System (ROS), the 3-element vector is referred to as the plumb_bob model, while the 6-element vector is known as the rational_polynomial model.

Radial distortion is the displacement of image points along radial lines extending from the principal point.

- As image points move away from the principal point (positive radial displacement), image magnification decreases and a pincushion-shaped distortion occurs on the image.
- As image points move toward the principal point (negative radial displacement), image magnification increases and a barrel-shaped distortion occurs on the image.

The camera parameters object calculates the radial-distorted location of a point, denoted as ($x_{\text{distorted}}$, $y_{\text{distorted}}$):

$$x_{distorted} = x\left(\frac{1 + k_1 * r^2 + k_2 * r^4 + k_3 * r^6}{1 + k_4 * r^2 + k_5 * r^4 + k_6 * r^6}\right)$$



$$y_{distorted} = y\left(\frac{1 + k_1 * r^2 + k_2 * r^4 + k_3 * r^6}{1 + k_4 * r^2 + k_5 * r^4 + k_6 * r^6}\right)$$

x, y is a undistorted image point in normalized image coordinates in world units, with the origin at the optical center.
$r^2 = x^2 + y^2$
k_1, k_2, ..., k_6 are radial distortion coefficients of the lens. Typically, two coefficients are sufficient and k_3, ..., k_6 are only needed for wide-angle lenses.

`TangentialDistortion` — Tangential distortion coefficients

`[0 0]` (default) | two-element vector

Tangential distortion coefficients, specified as a 2-element vector, $[p_1\ p_2]$. Tangential distortion occurs when the lens and the image plane are not parallel.

The camera parameters object calculates the tangential distorted location of a point. You can denote the distorted points as $(x_{distorted}, y_{distorted})$, as follows:

$$x_{distorted} = x + [2 * p_1 * x * y + p_2 * (r^2 + 2 * x^2)]$$
$$y_{distorted} = y + [p_1 * (r^2 + 2*y^2) + 2 * p_2 * x * y]$$

x, y are undistorted pixel locations
p_1 and p_2 are tangential distortion coefficients of the lens
$r^2 = x^2 + y^2$
The undistorted pixel locations appear in normalized image coordinates, with the origin at the optical center. The coordinates are expressed in world units.

`Skew` — Camera axes skew

`0` (default) | numeric scalar

Camera axes skew, specified as a numeric scalar. If the x and the y axes are exactly perpendicular, then the skew must be `0`.

`K` — Camera intrinsic matrix

3-by-3 identity matrix (default) | 3-by-3 matrix

This property is read-only.

Camera intrinsic matrix, specified as a 3-by-3 matrix. The matrix has the format

$$\begin{bmatrix} f_x & s & c_x \\ 0 & f_y & c_y \\ 0 & 0 & 1 \end{bmatrix}$$

The coordinates $[c_x\ c_y]$ represent the optical center (the principal point), in pixels. When the x and y axis are exactly perpendicular, the skew parameter, s, equals `0`.

$f_x = F*s_x$
$f_y = F*s_y$

F is the focal length in world units, typically expressed in millimeters.
s_x and s_y are the number of pixels per world unit in the x and y direction respectively.
f_x and f_y are expressed in pixels.

Examples

Create an Object Containing Fundamental Camera Parameters

Define camera parameters without lens distortion or skew.

Specify the focal length and principal point in pixels.

```
focalLength    = [800 800];
principalPoint = [320 240];
imageSize      = [480 640];
```

Create a camera intrinsics object.

```
intrinsics = cameraIntrinsics(focalLength,principalPoint,imageSize)
```

```
intrinsics =
  cameraIntrinsics with properties:

             FocalLength: [800 800]
          PrincipalPoint: [320 240]
               ImageSize: [480 640]
        RadialDistortion: [0 0]
    TangentialDistortion: [0 0]
                    Skew: 0
                       K: [3×3 double]
```

Version History

Introduced in R2017a

R2022b: Supports premultiply matrix convention
Behavior changed in R2022b

Starting in R2022b, many Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, a property of the `cameraIntrinsics` object has changed to support the premultiply convention.

- The new `K` property replaces the old `IntrinsicMatrix` property. The value of `K` is the transpose of `IntrinsicMatrix`.

For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

R2024b: Import OpenCV pinhole camera model with six radial distortion coefficients

The `cameraIntrinsics` has been updated to support OpenCV pinhole camera model with 6 radial distortion coefficients.

cameraIntrinsicsKB

Intrinsic camera parameters based on Kannala-Brandt model

Description

The `cameraIntrinsicsKB` object stores information about the intrinsic calibration parameters about the intrinsic calibration parameters, using the Kannala-Brandt [1] model, for a fisheye lens.

Creation

Create a `cameraIntrinsicsKB` object by using the `cameraIntrinsicsFromOpenCV` function.

Properties

`FocalLength` — Focal length
two-element vector

This property is read-only.

Focal length, stored as a two-element vector of the form [f_x f_y], with values in pixels.
$f_x = F \cdot s_x$
$f_y = F \cdot s_y$

F is the focal length in world units, typically millimeters. s_x and s_y are the number of pixels per world unit in the x- and y-directions, respectively.

The focal length F influences the angle of view, and thus affects the area of the scene that appears focused in an image. For a fixed subject distance:

- A short focal length offers a wide angle of view enabling the camera to capture a large area of the scene under focus. It emphasizes both the subject and the scene background.
- A long focal length offers a narrow angle of view, thus reducing the area of the scene under focus. It emphasizes the subject more, and restricts the amount of background from captured by the camera.

For more information on how to set this property at object creation, see the `intrinsicMatrix` argument of the `cameraIntrinsicsFromOpenCV` function.

`PrincipalPoint` — Optical center of camera
two-element vector

This property is read-only.

Optical center of the camera, stored as a two-element vector of the form [cx cy], with values in pixels. The vector contains the coordinates of the optical center of the camera.

For more information on how to set this property at object creation, see the `intrinsicMatrix` argument of the `cameraIntrinsicsFromOpenCV` function.

`ImageSize` — Image size produced by camera

two-element vector

This property is read-only.

Image size produced by the camera, stored as a two-element vector of the form [*mrows ncols*]. Specify this value at object creation by using the `imageSize` argument of the `cameraIntrinsicsFromOpenCV` function.

`DistortionCoefficients` — Polynomial coefficients

four-element vector

This property is read-only.

Polynomial coefficients, stored as a four-element vector of the form [*k1 k2 k3 k4*]. These values specify the polynomial coefficients for the fisheye distortion function:

$$\theta_d = \theta(1 + k_1\theta^2 + k_2\theta^4 + k_3\theta^6 + k_4\theta^8)$$

$$\theta = \text{atan}(\gamma)$$

$$k_1, k_2, k_3, k_4$$

where *k1*, *k2*, *k3*, and *k4* are the distortion coefficients of the lens.

For more information on how to set this property at object creation, see the `distortionCoefficients` argument of the `cameraIntrinsicsFromOpenCV` function.

K — Camera intrinsic matrix

3-by-3 identity matrix (default) | 3-by-3 matrix

This property is read-only.

Camera intrinsic matrix, stored as a 3-by-3 matrix. The matrix has this format:

$$\begin{bmatrix} fx & 0 & cx \\ 0 & fy & cy \\ 0 & 0 & 1 \end{bmatrix}$$

where *cx* and *cy* are the corresponding values of the `PrincipalPoint`, and *fx* and *fy* are the corresponding values of `FocalLength`.

For more information on how to set this property at object creation, see the `intrinsicMatrix` argument of the `cameraIntrinsicsFromOpenCV` function.

Examples

Undistort Image Using Fisheye Camera Parameters from OpenCV

Define OpenCV fisheye parameters in the workspace.

```
intrinsicMatrix = [875.88  0.00   1005.62; ...
                   0.00    874.76 741.52; ...
```

```
                    0.00,   0.00,  1.00];
distortionCoeffs = [0.08, -0.16, 0.35, -0.26];
```

Define the image size returned by the camera.

```
imageSize =[1500 2000];
```

Import the intrinsic camera parameters for a fisheye lens from OpenCV.

```
intrinsicsKB = cameraIntrinsicsFromOpenCV(intrinsicMatrix,distortionCoeffs,imageSize)
```

```
intrinsicsKB =
  cameraIntrinsicsKB with properties:

              FocalLength: [875.8800 874.7600]
            PrincipalPoint: [1.0066e+03 742.5200]
                 ImageSize: [1500 2000]
    DistortionCoefficients: [0.0800 -0.1600 0.3500 -0.2600]
                         K: [3×3 double]
```

Load an image to undistort.

```
filename = fullfile(toolboxdir("vision"),"visiondata", ...
    "calibration","gopro","gopro01.jpg");
I = imread(filename);
```

Undistort the image and display the results.

```
J = undistortImage(I,intrinsicsKB);
imshowpair(I,J,"montage");
title("Original Image (left) vs. Corrected Image (right)");
```

Algorithms

The Kannale-Brandt model extends the ideal pinhole model by accounting for lens distortion to represent a real camera.

The distorted points are ($x_{\text{distorted}}$, $y_{\text{distorted}}$), where:

$$x_{distorted} = \frac{\theta_d}{\gamma} \times x$$

$$y_{distorted} = \frac{\theta_d}{\gamma} \times y$$

The undistorted pixel locations in normalized image coordinates are (x,y), where:

$$\gamma^2 = x^2 + y^2$$

$$\theta_d = \theta(1 + k_1\theta^2 + k_2\theta^4 + k_3\theta^6 + k_4\theta^8)$$

$$\theta = \text{atan}(\gamma)$$

$$k_1, k_2, k_3, k_4$$

where *k1*, *k2*, *k3*, and *k4* are the distortion coefficients of the lens.

Version History

Introduced in R2024a

R2025a: Generate C/C++ code using MATLAB Coder

The `cameraIntrinsicsKB` function now supports the generation of C/C++ code (requires MATLAB Coder).

pcplayer

Visualize streaming 3-D point cloud data

Description

Visualize 3-D point cloud data streams from devices such as Microsoft Kinect®.

To improve performance, `pcplayer` automatically downsamples the rendered point cloud during interaction with the figure. The downsampling occurs only for rendering the point cloud and does not affect the saved points.

You can set the default center of rotation for the point cloud viewer to rotate around the axes center or around a point. Set the default behavior from the “Computer Vision Toolbox Preferences”.

Creation

Syntax

```
player = pcplayer(xlimits,ylimits,zlimits)
player = pcplayer(xlimits,ylimits,zlimits,Name=Value)
```

Description

`player = pcplayer(xlimits,ylimits,zlimits)` returns a player with `xlimits`,`ylimits`, and `zlimits` set for the axes limits.

`player = pcplayer(xlimits,ylimits,zlimits,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `ViewPlane="XY"` sets the plane to the x-y axes from which to visualize the point cloud.

Input Arguments

`xlimits` — Range of *x*-axis coordinates
1-by-2 vector

Range of *x*-axis coordinates, specified as a 1-by-2 vector in the format [*min max*]. `pcplayer` does not display data outside these limits.

`ylimits` — Range of *y*-axis coordinates
1-by-2 vector

Range of *y*-axis coordinates, specified as a 1-by-2 vector in the format [*min max*]. `pcplayer` does not display data outside these limits.

`zlimits` — Range of *z*-axis coordinates
1-by-2 vector

Range of *z*-axis coordinates, specified as a 1-by-2 vector in the format [*min max*].`pcplayer` does not display data outside these limits.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `ViewPlane="XY"` sets the plane to the x-y axes from which to visualize the point cloud.

`MarkerSize` — Diameter of marker

`6` (default) | positive scalar

Diameter of marker, specified as a positive scalar. The value specifies the approximate diameter of the point marker. MATLAB graphics defines the unit as points. A marker size larger than six can reduce the rendering performance.

`BackgroundColor` — Background color

`[0 0 0]` (black) (default) | RGB triplet | hexadecimal color code | character vector

Background color, specified as an RGB triplet, hexadecimal color code, or a character vector that specifies a long or short color name.

`VerticalAxis` — Vertical axis

`"Z"` (default) | `"X"` | `"Y"`

Vertical axis, specified as `"X"`, `"Y"`, or `"Z"`. When you reload a saved figure, any action on the figure resets the vertical axis to the *z*-axis.

`VerticalAxisDir` — Vertical axis direction

`"Up"` (default) | `"Down"`

Vertical axis direction, specified as `"Up"` or `"Down"`. When you reload a saved figure, any action on the figure resets the direction to the up direction.

`Projection` — Camera projection for 3-D views

`"perspective"` (default) | `"orthographic"`

Camera projection for 3-D views, specified as one of these values:

- `"perspective"` — Projects the viewing volume as the frustum of a pyramid (a pyramid whose apex has been cut off parallel to the base). Objects further from the camera appear smaller. Distance causes foreshortening, which enables you to perceive the depth of 3-D objects. This projection type is useful when you want to display realistic views of real objects. Perspective projection does not preserve the relative dimensions of objects. Instead, it displays a distant line segment smaller than a nearer line segment of the same length. Lines that are parallel in the data might not appear parallel in the scene.
- `"orthographic"` — This projection type maintains the correct relative dimensions of graphics objects regarding the distance of a given point from the viewer. Relative distance from the camera does not affect the size of objects. Lines that are parallel in the data parallel appear parallel on the screen. This projection type is useful when it is important to maintain the actual size of objects and the angles between objects.

`ViewPlane` — Plane to visualize point cloud

`"XY"` (default) | `"YX"` | `"XZ"` | `"ZX"` | `"YZ"` | `"ZY"`

Plane to visualize point cloud, specified as `"XY"`, `"YX"`, `"XZ"`, `"ZX"`, `"YZ"`, `"ZY"`. The `ViewPlane` sets the line of sight from the camera, centered in the selected plane, to the center of the plot.

`ColorSource` — Point cloud property for color map
`"auto"` (default) | `"X"` | `"Y"` | `"Z"` | `"Intensity"` | `"Color"` | `"Row"` | `"Column"`

Point cloud property for color map, specified as `"auto"`,`"X"`, `"Y"`, `"Z"`, `"Intensity"`, `"Color"`, `"Row"`, `"Column"`. The `pcshow` function uses the value of `ColorSource` to assign a color map for rendering the point cloud. The values use these properties:

- `"X"` — *x* coordinates in the `Location` property of the input point cloud.
- `"Y"` — *y* coordinates in the `Location` property of the input point cloud.
- `"Z"` — *z* coordinates in the `Location` property of the input point cloud.
- `"Intensity"` — `Intensity` property of the input point cloud.
- `"Color"` — `Color` property of the input point cloud.
- `"Row"` — Using the row values of an organized point cloud.
- `"Column"` — Using the column values of an organized point cloud.

When you set `ColorSource` to `"auto"`, the function sets the color map depending on which property values are available in the input point cloud object:

Available Point Cloud Property	Color Source
`Location` only	Maps the Z-value to a color value in the current color map.
`Location` and `Intensity`	Maps the z-value to a color value in the current color map.
`Location` and `Color`	Maps the color values to the current color map.
`Location`, `Intensity`, and `Color`	Maps the color values to the current color map.

`AxesVisibility` — State of axes visibility
`"off"` or logical `0` (`false`) (default) | `"on"` or logical `1` (`true`)

State of axes visibility, specified as `"off"` or `"on"`, or as numeric or logical `0` (`false`) or `1` (`true`). A value of `"off"` is equivalent to `false`, and `"on"` is equivalent to `true`. Thus, you can use the value of this property as a logical value. The value is stored as an on/off logical value of type `matlab.lang.OnOffSwitchState`.

- `"off"` — Hide the axes without deleting it. You still can access the properties of an invisible axes object. (Child objects such as lines remain visible.)
- `"on"` — Display the axes and its children.

`Parent` — Axes on which to display the visualization
`axes` graphics object

Axes on which to display the visualization, specified as an `Axes` object. To create an `Axes` object, use the `axes` function. To display the visualization in a new figure, leave `"Parent"` unspecified.

Properties

Axes — Player axes handle

`axes` graphics object

Player axes handle, specified as an `axes` graphics object.

Object Functions

hide	Hide player figure
isOpen	Visible or hidden status for player
show	Show player
view	Display point cloud

Examples

Terminate a Point Cloud Processing Loop

Create the player and add data.

```
player = pcplayer([0 1],[0 1],[0 1]);
```

Display continuous player figure. Use the `isOpen` function to check if player figure window is open.

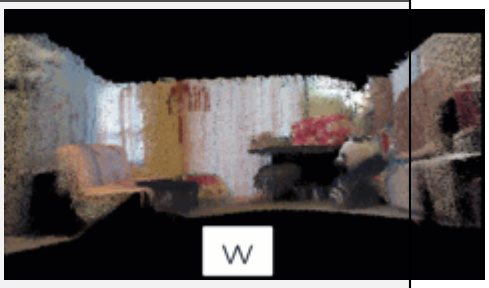
```
while isOpen(player)
     ptCloud = pointCloud(rand(1000,3,"single"));
     view(player,ptCloud);
end
```

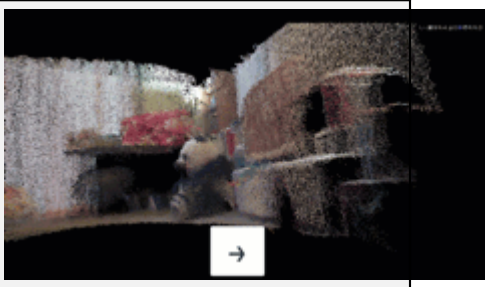
Terminate while-loop by closing pcplayer figure window.

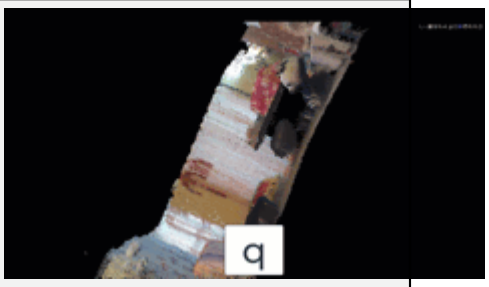
More About

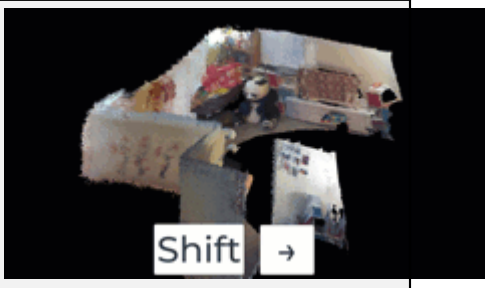
Axes Toolbar Operations

Keyboard shortcuts are enabled only for the rotate (default) mode. To view the axes toolbar operations, point to the figure and select one of these options. Click the Restore View icon to reset the display.

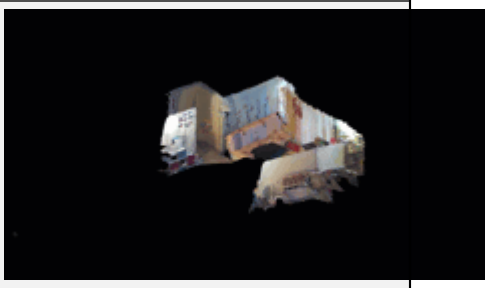


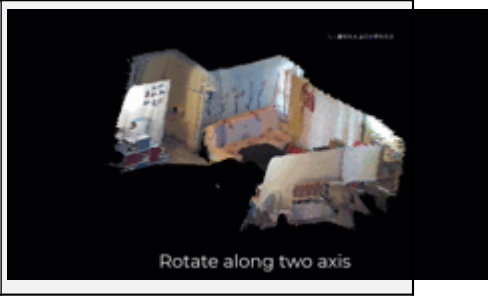






Feature	Description
Vertical Axis	Select an *X*-, *Y*-, or *Z*-direction to set the direction of that axis of the point cloud as the positive vertical direction. Use the keyboard arrow keys to move the point cloud with respect to the direction selected.
View Plane	Select the viewing angle of the point cloud figure as the *XY*, *YX*, *XZ*, *ZX*, *YZ*, or *ZY* plane.
Background Color	Display a color chart from which you can select a background color.
Axes On/Off	Turn the display axes on or off.





<table>
<tr><th>Feature</th><th>Description</th></tr>
<tr><td>Projection</td><td>Select perspective or orthogonal view.</td></tr>
<tr><td>Export</td><td>•  — Save the content as a tightly cropped image or PDF.
•  — Copy the content as an image.
•  — Copy the content as a vector graphic.</td></tr>
<tr><td>Brush</td><td>Enable data brushing mode.</td></tr>
<tr><td>Data Tips</td><td>View the point data values of a point by selecting it in the point cloud figure. The Data Tips display shows the x, y, and z values of the points. Point clouds for depth images and lidar contain these additional data properties:<table><tr><th>Point Cloud Data Source</th><th>Data Value Properties</th></tr><tr><td>Depth image (RGB-D sensor)</td><td>Color, Row, and Column</td></tr><tr><td>Lidar</td><td>Intensity, Range, Azimuth angle, Elevation angle, Row, and Column</td></tr></table></td></tr>
<tr><td>Rotate 3D</td><td>Drag to rotate the point cloud figure. You can also right-click any point on the point cloud figure and select Rotate Around a Point to specify that point as the center of rotation for the figure. To return to axes rotation, right-click again and select Rotate Around Axes Center.

While in Rotate 3D mode, you can also select the color source for the point cloud by right-clicking anywhere in the point cloud figure and selecting Color Source, and then selecting an option from the list. The figure applies the active colormap to the point cloud based on the values in the selected source. For a point cloud of only position data, the Color Source options are X, Y, Z, and User Specified. Point clouds for depth image and lidar data include these additional color source options:<table><tr><th>Point Cloud Data Source</th><th>Color Source Options</th></tr><tr><td>Depth image (RGB-D sensor)</td><td>Color, Row, and Column</td></tr><tr><td>Lidar</td><td>Intensity, Range, Azimuth angle, Elevation angle, Row, and Column</td></tr></table></td></tr>
<tr><td>Pan, Zoom in, and Zoom out</td><td>Maneuver the point cloud in the figure, or zoom the point cloud figure in or out.</td></tr>
<tr><td>Restore View</td><td>Restore the original view of the axes.</td></tr>

Move Camera Through a Scene

To navigate into a point cloud and observe the scene, use these keyboard shortcuts:

Action	Keyboard Shortcut	Example
Move forward or backward through the scene. The camera and the target can move.	**w** — Forward **s** — Backward	
Move left or right through the scene. The camera and the target can move.	**a** — Left **d** — Right	
Look around the scene (pitch/yaw rotation of the camera). Camera position is fixed, target moves.	**Up arrow** — Camera pitches up **Down arrow** — Camera pitches down **Left arrow** — Camera turns left in yaw **Right arrow** — Camera turns right in yaw	
Roll the scene (roll rotation of the camera).	**q** — Camera moves clockwise. (Scene appears to move counterclockwise.) **e** — Camera moves counterclockwise. (Scene appears to move clockwise.)	
Rotate the scene (rotate the camera around the point cloud). Camera position changes, target is fixed.	**Shift** + **Left** or **Right** — Camera orbits horizontally around the point cloud. (Scene appears to stand still as camera moves externally around it horizontally.) **Shift** + **Up** or **Down** — Camera orbits vertically around the point cloud. (Scene appears to stand still as camera moves externally around it vertically.)	
Zoom in or out.	**z** — Zoom in **x** — Zoom out	

Action	Keyboard Shortcut	Example
Look at a view plane.	1 — **XY** 2 — **YX** 3 — **XZ** 4 — **ZX** 5 — **YZ** 6 — **ZY** Camera positioned in the selected plane with a line of sight to the center of the plot.	
Switch between rotate and pan.	**Space bar** — Press and hold the space bar to switch the interaction to pan. Release the space bar to switch back to rotate.	
Rotate in X-, Y-, and Z-dimensions.	**T** — Adds rotate interaction in the third dimension.	

Color Formats

Color Name	Short Name	RGB Triplet	Appearance
`"red"`	`"r"`	`[1 0 0]`	
`"green"`	`"g"`	`[0 1 0]`	
`"blue"`	`"b"`	`[0 0 1]`	
`"cyan"`	`"c"`	`[0 1 1]`	
`"magenta"`	`"m"`	`[1 0 1]`	
`"yellow"`	`"y"`	`[1 1 0]`	
`"black"`	`"k"`	`[0 0 0]`	

Color Name	Short Name	RGB Triplet	Appearance
"white"	"w"	[1 1 1]	

Performance and Tips

- To improve performance, the function automatically downsamples the rendered point cloud when you rotate, pan, or zoom in or out by clicking the mouse. Downsampling is not applied for zoom in or out by using the mouse scroll mechanism. When using data tips, the figure does not apply downsampling. The downsampling occurs only for rendering the point cloud and does not affect the saved points.
- The keyboard shortcuts described in “Move Camera Through Scene” on page 3-1210 are not supported when loading a saved figure or for popped-out windows using Live Editor.
- When you reload a saved figure, any action on the figure resets the vertical axis to the *z*-axis and in the up direction.
- To visualize a large point cloud (greater than one million points), use the `pcviewer` object.

Version History

Introduced in R2015b

R2022b: Projection display default behavior changed to perspective

The default projection for the camera 3-D view display is changed from orthographic to perspective. You can use the new `Projection` name-value argument to specify the projection as `"perspective"` or `"orthographic"`. Prior to R2022b, the display rendered the point cloud in an orthographic view only.

view

Display point cloud

Syntax

```
view(player,ptCloud)
view(player,xyzPoints)
view(player,xyzPoints,color)
view(player,xyzPoints,colorMap)
```

Description

`view(player,ptCloud)` displays a point cloud in the `pcplayer` figure window, `player`. The points, locations, and colors are stored in the `ptCloud` object.

`view(player,xyzPoints)` displays the points of a point cloud at the locations specified by the `xyzPoints` matrix. The color of each point is determined by the *z* value.

`view(player,xyzPoints,color)` displays a point cloud with colors specified by `color`.

`view(player,xyzPoints,colorMap)` displays a point cloud with colors specified by `colorMap`.

Examples

View Rotating 3-D Point Cloud

Load point cloud.

```
ptCloud = pcread("teapot.ply");
```

Define a rotation matrix and 3-D transform.

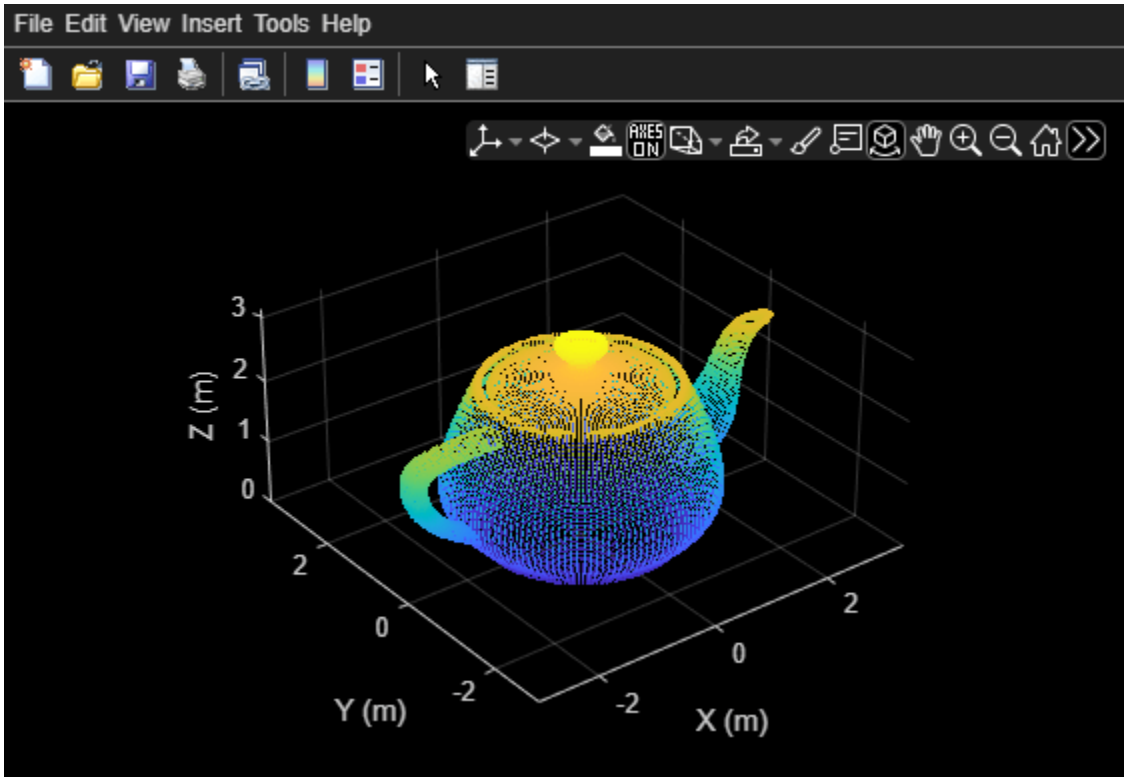
```
x = pi/180;
R = [ cos(x) sin(x) 0 0
     -sin(x) cos(x) 0 0
      0         0   1 0
      0         0   0 1];

tform = affine3d(R);
```

Compute *x*, *y*, and *z* limits that ensure that the rotated teapot is not clipped.

```
lower = min([ptCloud.XLimits ptCloud.YLimits]);
upper = max([ptCloud.XLimits ptCloud.YLimits]);

xlimits = [lower upper];
ylimits = [lower upper];
zlimits = ptCloud.ZLimits;
```



Create the player and customize player axis labels.

```
player = pcplayer(xlimits,ylimits,zlimits);

xlabel(player.Axes,"X (m)");
ylabel(player.Axes,"Y (m)");
zlabel(player.Axes,"Z (m)");
```

Rotate the teapot around the *z*-axis.

```
for i = 1:360
    ptCloud = pctransform(ptCloud,tform);
    view(player,ptCloud);
end
```

Input Arguments

`ptCloud` — Point cloud

`pointCloud` object

Point cloud, specified as a `pointCloud` object. The object contains the locations, intensities, and RGB colors to render the point cloud.

Point Cloud Property	Color Rendering Result
`Location` only	Maps the z-value to a color value in the current color map.
`Location` and `Intensity`	Maps the intensity to a color value in the current color map.

Point Cloud Property	Color Rendering Result
`Location` and `Color`	Use provided color.
`Location`, `Intensity`, and `Color`	Use provided color.

`player` — Player

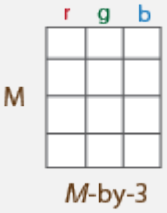
`pcplayer` object

Player for visualizing 3-D point cloud data streams, specified as a `pcplayer` object.

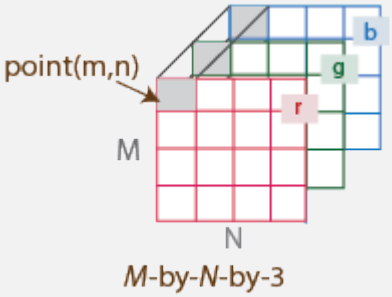
`xyzPoints` — Point cloud *x*, *y*, and *z* locations

M-by-3 numeric matrix | *M*-by-*N*-by-3 numeric matrix

Point cloud *x*, *y*, and *z* locations, specified as either an *M*-by-3 or an *M*-by-*N*-by-3 numeric matrix. The *M*-by-*N*-by-3 numeric matrix is commonly referred to as an organized point cloud. The `xyzPoints` numeric matrix contains *M* or *M*-by-*N* [*x*,*y*,*z*] points. The *z* values in the numeric matrix, which generally correspond to depth or elevation, determine the color of each point.



`color` — Color for points in the point cloud



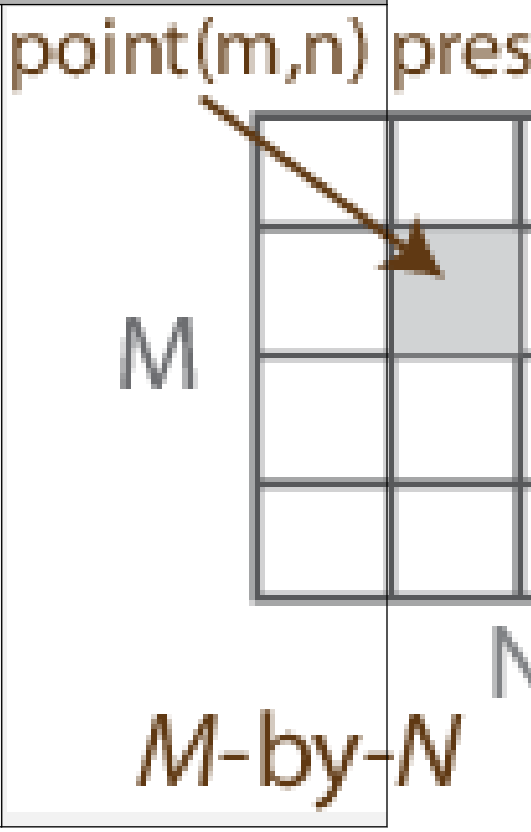
1-by-3 RGB vector | short name of color | long name of color | *M*-by-3 matrix | *M*-by-*N*-by-3 matrix

Color for points in the point cloud, specified as a 1-by-3-RGB vector, an *M*-by-3 matrix, an *M*-by-*N*-by-3 matrix, a short color name, or a long color name. For details on color values, see the Color Value on page 3-1212 table.

- For `single` or `double` datatype, the `Color` RGB value must be specified in the range [0, 1].
- For `uint8` datatype, the `Color` RGB value must be specified in the range [0, 255].
- The function stores the `Color` value as either an *M*-by-3 or *M*-by-*N*-by-3. If you specify the color as a string or a 1-by-3 vector, the function converts it to one of these dimensions.

Color	Format	Example
Specify one color for all points	short or long color name	`"r"` `"red"`
	1-by-3 vector (RGB triplet)	 `[255 0 0]`
Specify a color for each point	cell array of character vectors	`["red","yellow","blue"]`

	M-by-3 matrix, as a list of RGB values	`255 0 0`
		`255 0 0`
		`0 255 255`
		



Color	Format	Example
	M-by-*N*-by-3 matrix for an organized point cloud containing RGB values for each point, where *M*-by-*N* is the dimension of the point cloud.	

`colorMap` — Point cloud color map for points
M-by-1 vector | *M*-by-*N* matrix

Point cloud color map for points, specified as one of:

- *M*-by-1 vector
- *M*-by-*N* matrix

Points Input	Color Selection	Valid Values of `C`	
`xyzPoints`	Different color for each point	Vector or *M*-by-*N* matrix. The matrix must contain values that are linearly mapped to a color listed in the current `colormap`.	

Points Input	Color Selection	Valid Values of C	
			

More About

Color Value

Color Name	Short Name	RGB Triplet	Appearance
"red"	"r"	[1 0 0]

pointTrack

Object for storing matching points from multiple views

Description

Use this object to store 2-D points in an image that match across multiple views of the same image.

Creation

```
track = pointTrack(viewIDs,points)
```

Description

`track = pointTrack(viewIDs,points)` returns an object that stores matching 2-D points from multiple views. You can also create this point track object using the `findTracks` object function of the `imageviewset` object.

Input Arguments

`viewIDs` — View IDs of image poses

M-element vector

View IDs of image poses, specified as an *M*-element vector of scalar integers.

`points` — 2-D points that match across multiple image views

M-by-2 matrix

2-D points that match across multiple image views, specified as an *M*-by-2 matrix of (*x*,*y*) point coordinates. You can use the `matchFeatures` function to find these points, and then save them using this object.

Output Arguments

`track` — Point track object

`pointTrack` object

Point track object, returned as a `pointTrack` object. You can use this object to store matching 2-D points from multiple views. You can also create this point track object using the `findTracks` object function of the `imageviewset` object.

Examples

Create a Point Track Object

Save (*x* , *y*) points and view IDs.

```
points = [10,20;11,21;12,22];
viewIDs = [1 2 3];
```

Create a `pointTrack` object to save points and IDs. The matched 2-D image points correspond to the same 3-D world point. Separate `pointTrack` objects are needed to track different 3-D world points across views.

```
track = pointTrack(viewIDs,points);
```

vision.PointTracker

Namespace: `vision`

Track points in video using Kanade-Lucas-Tomasi (KLT) algorithm

Description

The point tracker object tracks a set of points using the Kanade-Lucas-Tomasi (KLT), feature-tracking algorithm. You can use the point tracker for video stabilization, camera motion estimation, and object tracking. It works particularly well for tracking objects that do not change shape and for those that exhibit visual texture. The point tracker is often used for short-term tracking as part of a larger tracking framework.

As the point tracker algorithm progresses over time, points can be lost due to lighting variation, out of plane rotation, or articulated motion. To track an object over a long period of time, you may need to reacquire points periodically.

To track a set of points:

1. Create the `vision.PointTracker` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
pointTracker = vision.PointTracker
pointTracker = vision.PointTracker(Name,Value)
```

Description

`pointTracker = vision.PointTracker` returns a point tracker object that tracks a set of points in a video.

`pointTracker = vision.PointTracker(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `pointTracker = vision.PointTracker('NumPyramidLevels',3)`

Initialize Tracking Process:

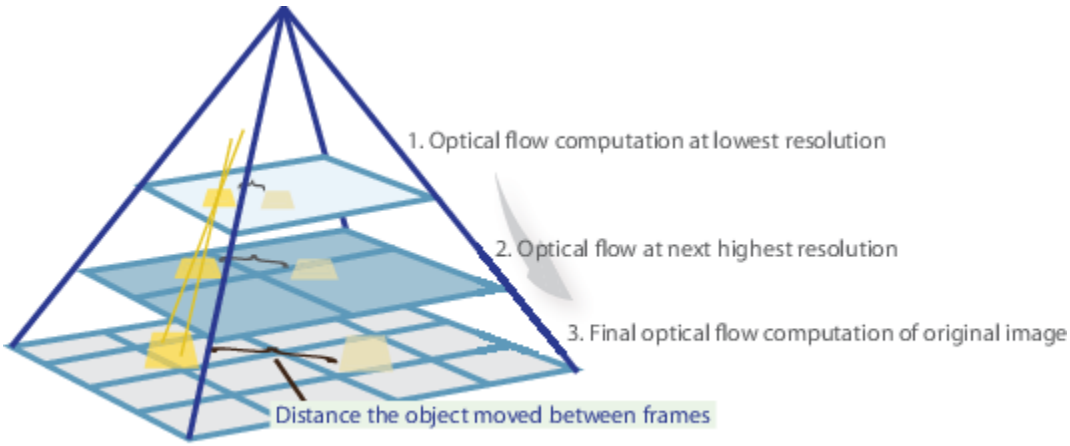
To initialize the tracking process, you must use `initialize` to specify the initial locations of the points and the initial video frame.

`initialize(pointTracker,points,I)` initializes points to track and sets the initial video frame. The initial locations `points`, must be an *M*-by-2 array of [x y] coordinates. The initial video frame, `I`, must be a 2-D grayscale or RGB image and must be the same size and data type as the video frames passed to the object.

The `detectFASTFeatures`, `detectSURFFeatures`, `detectHarrisFeatures`, and `detectMinEigenFeatures` functions are few of the many ways to obtain the initial points for tracking.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.



If a property is *tunable*, you can change its value at any time.

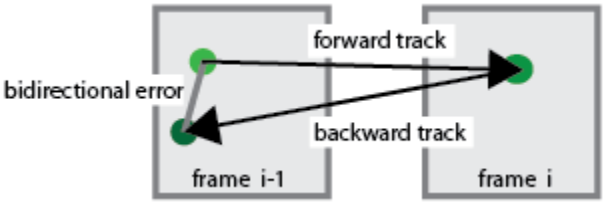
For more information on changing property values, see System Design in MATLAB Using System Objects.

`NumPyramidLevels` — Number of pyramid levels

integer (default) | 3

Number of pyramid levels, specified as integer. The point tracker implementation of the KLT algorithm uses image pyramids. The tracker generates an image pyramid, where each level is reduced in resolution by a factor of two compared to the previous level. Selecting a pyramid level greater than 1, enables the algorithm to track the points at multiple levels of resolution, starting at the lowest level. Increasing the number of pyramid levels allows the algorithm to handle larger displacements of points between frames. However, computation cost also increases. Recommended values are between 1 and 4.

Each pyramid level is formed by down-sampling the previous level by a factor of two in width and height. The point tracker begins tracking each point in the lowest resolution level, and continues tracking until convergence. The object propagates the result of that level to the next level as the initial guess of the point locations. In this way, the tracking is refined with each level, up to the original image. Using the pyramid levels allows the point tracker to handle large pixel motions, which can comprise distances greater than the neighborhood size.



`MaxBidirectionalError` — Forward-backward error threshold

`inf` (default) | scalar

Forward-backward error threshold, specified as a scalar. If you set the value to less than `inf`, the tracker tracks each point from the previous to the current frame. It then tracks the same points back

to the previous frame. The object calculates the bidirectional error. This value is the distance in pixels from the original location of the points to the final location after the backward tracking. The corresponding points are considered invalid when the error is greater than the value set for this property. Recommended values are between `0` and `3` pixels.

Using the bidirectional error is an effective way to eliminate points that could not be reliably tracked. However, the bidirectional error requires additional computation. When you set the `MaxBidirectionalError` property to `inf`, the object does not compute the bidirectional error.

`BlockSize` — Size of neighborhood
`[31 31]` (default) | two-element vector

Size of neighborhood around each point being tracked, specified as a two-element vector, [*height*, *width*]. The *height* and *width* must be odd integers. This neighborhood defines the area for the spatial gradient matrix computation. The minimum value for `BlockSize` is `[5 5]`. Increasing the size of the neighborhood, increases the computation time.

`MaxIterations` — Maximum number of search iterations
`30` (default) | integer

Maximum number of search iterations for each point, specified as an integer. The KLT algorithm performs an iterative search for the new location of each point until convergence. Typically, the algorithm converges within 10 iterations. This property sets the limit on the number of search iterations. Recommended values are between `10` and `50`.

Usage

Syntax

```
[points,point_validity] = pointTracker(I)
[points,point_validity,scores] = pointTracker(I)
setPoints(pointTracker,points)
setPoints(pointTracker,points,point_validity)
```

Description

`[points,point_validity] = pointTracker(I)` tracks the points in the input frame, `I`.

`[points,point_validity,scores] = pointTracker(I)` additionally returns the confidence score for each point.

`setPoints(pointTracker,points)` sets the points for tracking. The function sets the *M*-by-2 `points` array of [*x* *y*] coordinates with the points to track. You can use this function if the points need to be redetected because too many of them have been lost during tracking.

`setPoints(pointTracker,points,point_validity)` additionally lets you mark points as either valid or invalid. The input logical vector `point_validity` of length *M*, contains the true or false value corresponding to the validity of the point to be tracked. The length *M* corresponds to the number of points. A false value indicates an invalid point that should not be tracked. For example, you can use this function with the `estgeotform2d` function to determine the transformation between the point locations in the previous and current frames. You can mark the outliers as invalid.

Input Arguments

`I` — Video frame
grayscale | truecolor (RGB)

Video frame, specified as grayscale or truecolor (RGB).

Output Arguments

`points` — Tracked points
M-by-2 array

Tracked points, returned as an *M*-by-2 array of [*x*, *y*] coordinates that correspond to the new locations of the points in the input frame, `I`.

`point_validity` — Reliability of track
M-by-1 logical array

Reliability of track for each point, returned as an *M*-by-1 logical array. A point can be invalid for several reasons. The point can become invalid if it falls outside of the image. Also, it can become invalid if the spatial gradient matrix computed in its neighborhood is singular. If the bidirectional error is greater than the `MaxBidirectionalError` threshold, this condition can also make the point invalid.

`scores` — Confidence score
M-by-1 array

Confidence score between `0` and `1`, returned as an *M*-by-1 array. The values correspond to the degree of similarity between the neighborhood around the previous location and new location of each point. These values are computed as a function of the sum of squared differences between the previous and new neighborhoods. The greatest tracking confidence corresponds to a perfect match score of `1`.

Object Functions

To use an object function, specify the System object™ as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to vision.PointTracker

initialize Initialize video frame and points to track

Common to All System Objects

step Run System object algorithm

release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Track a Face in Scene

Create System objects for reading and displaying video and for drawing a bounding box of the object.

```
videoReader = VideoReader('visionface.avi');
videoPlayer = vision.VideoPlayer('Position',[100,100,680,520]);
```

Read the first video frame, which contains the object, define the region.

```
objectFrame = readFrame(videoReader);
objectRegion = [264,122,93,93];
```

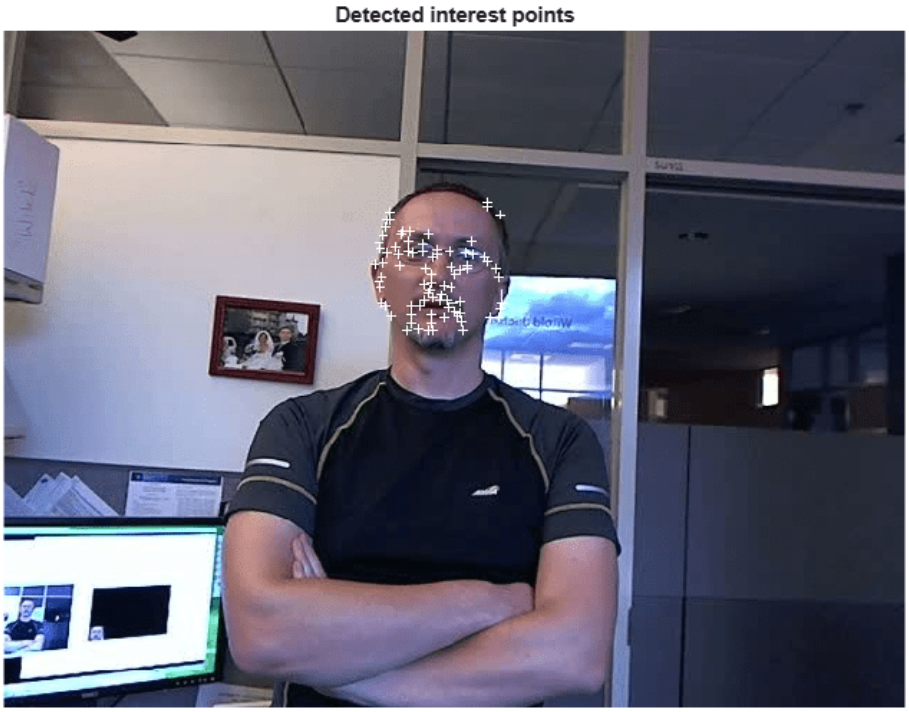
As an alternative, you can use the following commands to select the object region using a mouse. The object must occupy the majority of the region:

figure; imshow(objectFrame);

objectRegion=round(getPosition(imrect))

Show initial frame with a red bounding box.

```
objectImage = insertShape(objectFrame,'rectangle',objectRegion,'ShapeColor','red');
figure;
imshow(objectImage);
title('Red box shows object region');
```



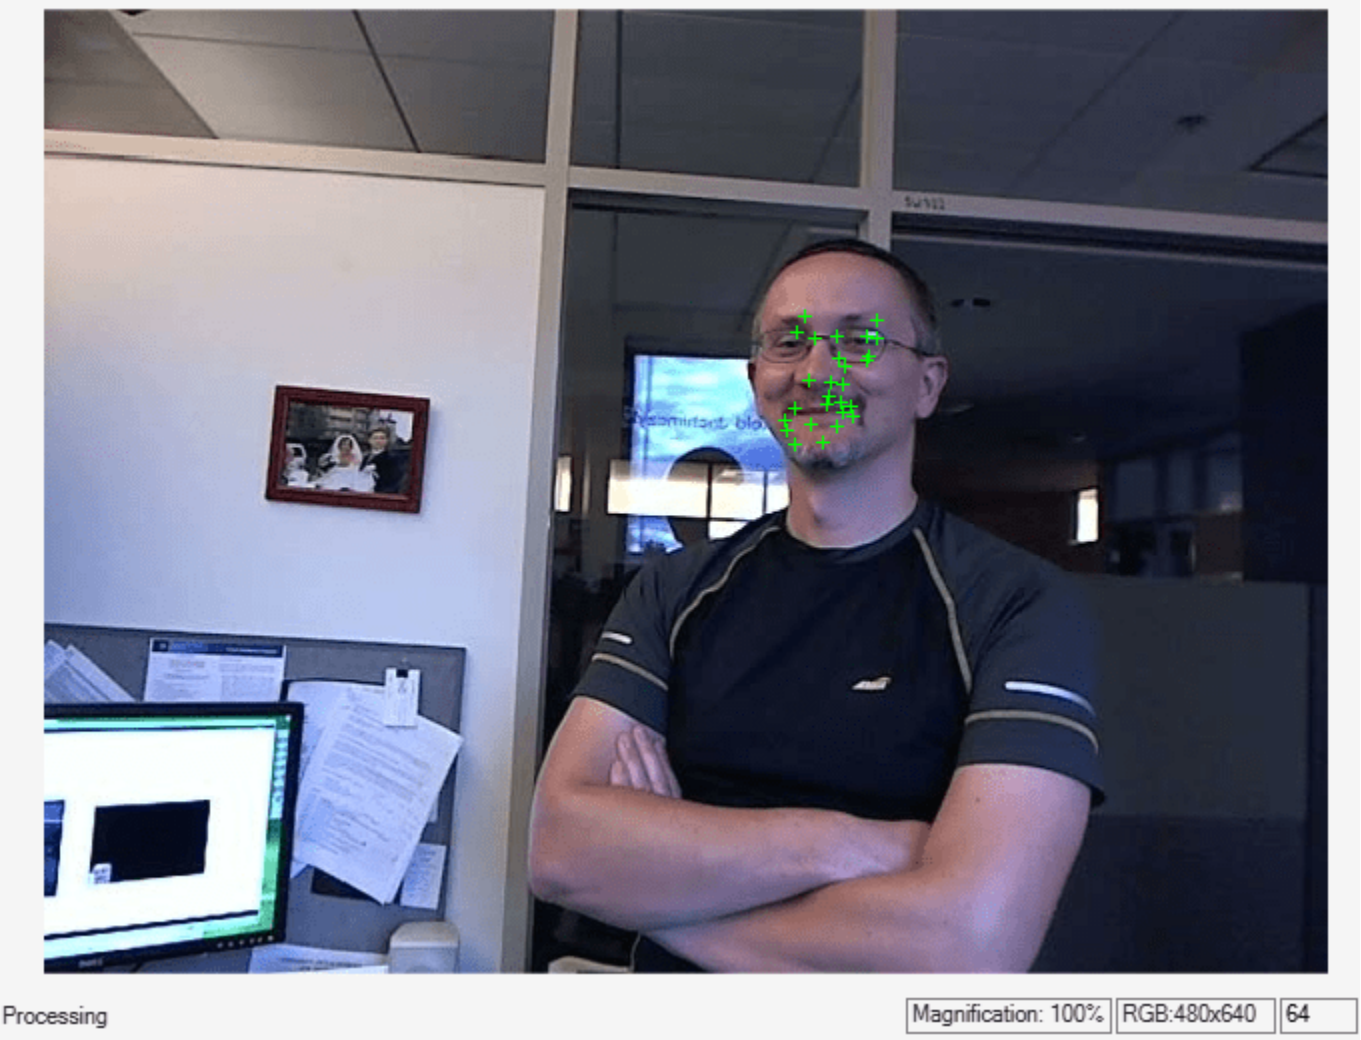
Detect interest points in the object region.

```
points = detectMinEigenFeatures(im2gray(objectFrame),'ROI',objectRegion);
```

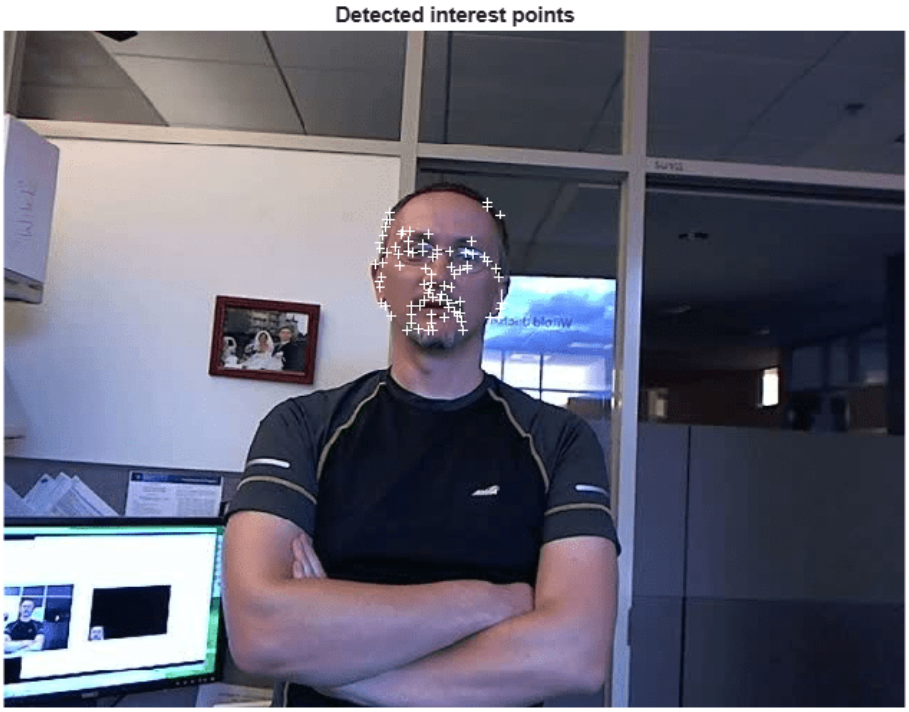
Display the detected points.

```
pointImage = insertMarker(objectFrame,points.Location,'+','MarkerColor','white');
figure;
imshow(pointImage);
title('Detected interest points');
```

Create a tracker object.



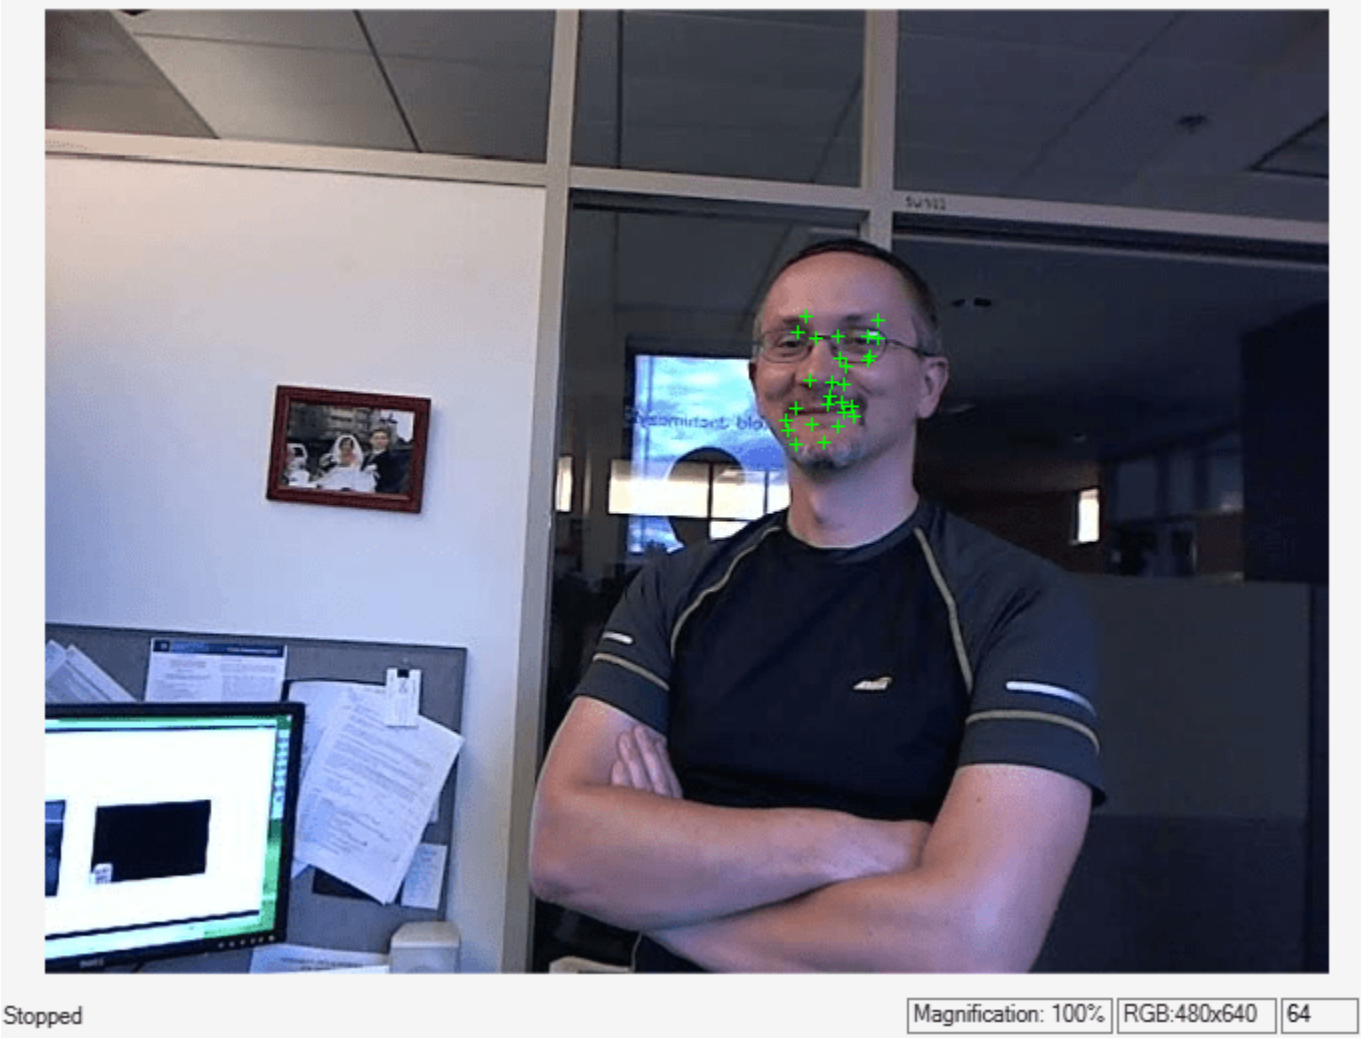
```
tracker = vision.PointTracker('MaxBidirectionalError',1);
```



Initialize the tracker.

```
initialize(tracker,points.Location,objectFrame);
```

Read, track, display points, and results in each video frame.



```
while hasFrame(videoReader)
      frame = readFrame(videoReader);
      [points,validity] = tracker(frame);
      out = insertMarker(frame,points(validity, :),'+');
      videoPlayer(out);
end
```

Processing
Magnification: 100%
RGB:480x640
64

Release the video player.

```
release(videoPlayer);
```

viewSet

(To be removed) Object for managing data for structure-from-motion and visual odometry

Note The `viewSet` object will be removed in a future release. Use the `imageviewset` object instead. For more information, see “Version History”.

Description

A `viewSet` object stores views and connections between views. A view includes feature points and an absolute camera pose. A connection between two views includes point correspondences and the relative camera pose between them. Once you populate a `viewSet` object, you can use it to find point tracks across multiple views and retrieve the camera poses to be used by the `triangulateMultiview` and `bundleAdjustment` functions.

Creation

Syntax

```
vSet = viewSet
```

Description

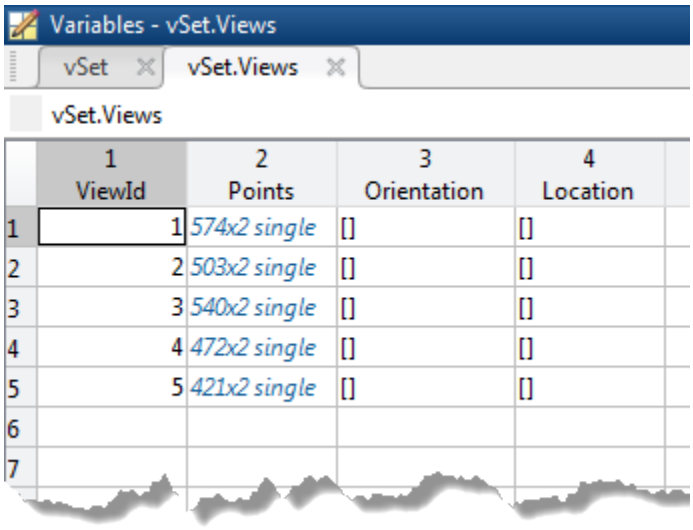
`vSet = viewSet` creates an empty `viewSet` object. You can add views and connections using the `addView` and `addConnection` object functions.

Properties

`NumViews` — Number of views

integer

This property is read-only.

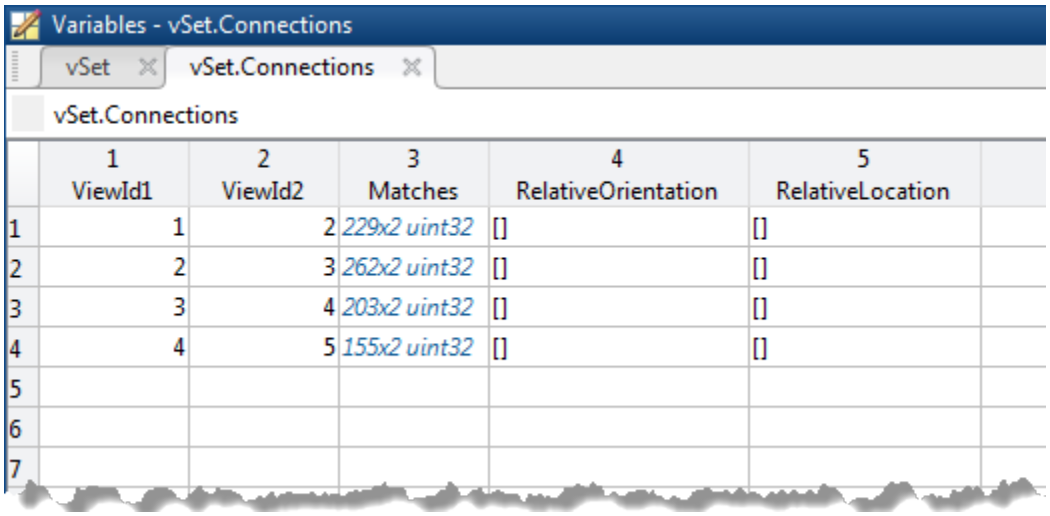


Number of views, stored as an integer.

`Views` — View attributes

four-column table

This property is read-only.



View attributes, stored as a four-column table. The table contains columns for `ViewID`, `Points`, `Orientation`, and `Location`. Use the `poses` method to obtain the IDs, orientation, and location for the points.

`Connections` — Pairwise connections between views
five-column table

This property is read-only.

Pairwise connections between views, stored as a five-column table. The columns are `ViewID1`, `ViewID2`, `Matches`, `RelativeOrientation`, and `RelativeLocation`. The number of entries in the table represent the number of connections. Each index in the `Matches` column represents a connection between the two views indicated by the view IDs.

Object Functions

addConnection	(To be removed) Add connection between two views
addView	(To be removed) Add new view to view set object
deleteConnection	(To be removed) Delete connection between two views from view set object
deleteView	(To be removed) Delete existing view from view set object
findTracks	(To be removed) Find matched points across multiple views
hasConnection	(To be removed) Check if connection exists between two views

hasView	(To be removed) Check if view exists
poses	(To be removed) Returns camera poses associated to views
updateConnection	(To be removed) Modify connection between two views in view set object
updateView	(To be removed) Modify existing view in view set object

Examples

Find Point Tracks Across Sequence of Images

Load images.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata','structureFromMotion');
imds = imageDatastore(imageDir);
```

Compute features for the first image.

```
I = rgb2gray(read(imds));
pointsPrev = detectSURFFeatures(I);
[featuresPrev,pointsPrev] = extractFeatures(I,pointsPrev);
```

Create a `viewSet` object.

```
vSet = viewSet;
vSet = addView(vSet,1,'Points',pointsPrev);
```

Compute features and matches for the rest of the images.

```
for i = 2:length(imds.Files)
 I = rgb2gray(read(imds));
 points = detectSURFFeatures(I);
 [features, points] = extractFeatures(I,points);
 vSet = addView(vSet,i,'Points',points);
 pairsIdx = matchFeatures(featuresPrev,features);
 vSet = addConnection(vSet,i-1,i,'Matches',pairsIdx);
 featuresPrev = features;
end
```

Find point tracks.

```
tracks = findTracks(vSet);
```

Version History

Introduced in R2016a

R2020a: `viewSet` object will be removed

Not recommended starting in R2020a

The `viewSet` object will be removed in a future release. Manage views and pairwise connections between views of data using the `imageviewset` object instead. The `imageviewset` object adds additional support for simultaneous localization and mapping (SLAM) data,

data used in structure-from-motion, visual odometry, and simultaneous localization and mapping (SLAM) data. View attributes can be feature descriptors, feature points, or absolute camera poses.

Pairwise connections between views can be point matches, relative camera poses, or an information matrix.

addView

(To be removed) Add new view to view set object

Note The `viewSet` object and its `addView` function will be removed in a future release. Use the `imageviewset` object and its `addView` function instead. For more information, see "Version History".

Syntax

```
vSet = addView(vSet,viewId)
vSet = addView(vSet,viewId,Name,Value)
```

Description

`vSet = addView(vSet,viewId)` adds the view specified by `viewID` to the specified `viewSet` object.

`vSet = addView(vSet,viewId,Name,Value)` specifies additional options using one or more name-value pair arguments.

Examples

Add View to View Set Object

Create an empty viewSet object.

```
vSet = viewSet;
```

Detect interest points in the image.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata','structureFromMotion');
I = imread(fullfile(imageDir,'image1.jpg'));
points = detectSURFFeatures(im2gray(I));
```

Add the points to the object.

```
vSet = addView(vSet,1,'Points',points,'Orientation',eye(3),'Location',[0,0,0]);
```

Input Arguments

vSet — View set object
`viewSet` object

`viewSet` object.

viewId — Camera pose view ID
integer

Camera pose view ID in the `viewSet` object, specified as an integer.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'Location','[0,0,0]'`

`Points` — Image points
M-by-2 matrix | points object

Image points, specified as the comma-separated pair consisting of '`Points`' and an *M*-by-2 matrix of [*x*,*y*] coordinates or any points object.

`Orientation` — Absolute orientation of the camera
3-by-3 matrix

Absolute orientation of the camera, specified as the comma-separated pair consisting of '`Orientation`' and a 3-by-3 matrix.

`Location` — Absolute location of the camera
three-element vector

Absolute location of the camera, specified as the comma-separated pair consisting of '`Location`' and a three-element vector.

Output Arguments

`vSet` — View set object
`viewSet` object

`viewSet` object containing the added view specified by `viewId`.

Version History

Introduced in R2016a

R2020a: `addView` function of `viewSet` object will be removed
Not recommended starting in R2020a

The `viewSet` object and its `addView` function will be removed in a future release. Instead, manage views and pairwise connections between views of data using use the `imageviewset` object. Add views to the `imageviewset` object using its `addView` function.

See Also

`addView` | `imageviewset`

updateView

(To be removed) Modify existing view in view set object

Note The `viewSet` object and its `updateView` function will be removed in a future release. Use the `imageviewset` object and its `updateView` function instead. For more information, see "Version History".

Syntax

```
vSet = updateView(vSet,viewId)
vSet = updateView(vSet,viewId,Name,Value)
vSet = updateView(vSet,views)
```

Description

`vSet = updateView(vSet,viewId)` modifies the view specified by `viewId` in the specified `viewSet` object, `vSet`.

`vSet = updateView(vSet,viewId,Name,Value)` specifies additional options using one or more name-value pair arguments.

`vSet = updateView(vSet,views)` modifies a view or a set of views specified by the `view` table.

Examples

Update View in View Set Object

Create an empty `viewSet` object.

```
vSet = viewSet;
```

Detect interest points in the image.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata','structureFromMotion');
I = imread(fullfile(imageDir,'image1.jpg'));
points = detectSURFFeatures(rgb2gray(I));
```

Add the points to the object.

```
vSet = addView(vSet,1,'Points',points);
```

Update the view to specify the camera pose.

```
vSet = updateView(vSet, 1,'Orientation',eye(3),'Location',[0,0,0]);
```

Input Arguments

`vSet` — View set object

`viewSet` object

`viewSet` object.

`viewId` — Camera pose view ID

integer

Camera pose view ID in the `viewSet` object, specified as an integer.

`views` — Camera views

table

Camera views, specified as a table. The table must contain a column named `ViewID`, and one or more columns named `Points`, `Orientation`, or `Location`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Location`, `'[0,0,0]'`

`Points` — Image points

M-by-2 matrix | points object

Image points, specified as the comma-separated pair consisting of '`Points`' and an *M*-by-2 matrix of [*x*,*y*] coordinates or any points object.

`Orientation` — Orientation of the second camera relative to the first camera

3-by-3 matrix

Orientation of the second camera relative to the first camera, specified as the comma-separated pair consisting of '`Orientation`' and a 3-by-3 matrix that represents the [*x*,*y*,*z*] orientation of the second camera.

`Location` — Location of the second camera relative to the first camera

three-element vector

Location of the second camera relative to the first camera, specified as the comma-separated pair consisting of '`Location`' and a three-element vector that represents the [*x*,*y*,*z*] location of the second camera in the first camera’s coordinate system.

Output Arguments

`vSet` — View set object

`viewSet` object

`viewSet` object containing the modified view specified by `viewId`.

Version History

Introduced in R2016a

R2020a: `updateView` function of `viewSet` object will be removed
Not recommended starting in R2020a

The `viewSet` object and its `updateView` function will be removed in a future release. Instead, manage views and pairwise connections between views of data using use the `imageviewset` object. Update connections between views of the `imageviewset` object using its `updateView` function.

See Also

`imageviewset` | `updateView`

deleteView

(To be removed) Delete existing view from view set object

Note The `viewSet` object and its `deleteView` function will be removed in a future release. Use the `imageviewset` object and its `deleteView` function instead. For more information, see "Version History".

Syntax

```
vSet = deleteView(vSet,viewId)
```

Description

`vSet = deleteView(vSet,viewId)` deletes an existing view or a set of views from the specified `viewSet` object,`vSet`.

Examples

Delete a View from View Set Object

Create an empty viewSet object.

```
vSet = viewSet;
```

Detect interest points in the image.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata','structureFromMotion');
I = imread(fullfile(imageDir,'image1.jpg'));
points = detectSURFFeatures(im2gray(I));
```

Add a view.

```
vSet = addView(vSet,1,'Points',points);
```

Delete the view.

```
vSet = deleteView(vSet,1);
```

Input Arguments

vSet — View set object
`viewSet` object

A `viewSet` object.

viewId — View IDs
integer scalar | vector

View IDs, specified as an integer scalar for a single view, or as a vector of integers for a set of views.

Output Arguments

vSet — View set object
`viewSet` object

`viewSet` object.

Version History

Introduced in R2016a

R2020a: `deleteView` function of `viewSet` object will be removed
Not recommended starting in R2020a

The `viewSet` object and its `deleteView` function will be removed in a future release. Instead, manage views and pairwise connections between views of data using use the `imageviewset` object. Delete views from the `imageviewset` object using its `deleteView` function.

See Also

`imageviewset` | `deleteView`

hasView

(To be removed) Check if view exists

Note The `viewSet` object and its `hasView` function will be removed in a future release. Use the `imageviewset` object and its `hasView` function instead. For more information, see "Version History".

Syntax

```
tf = hasView(vSet,viewId)
```

Description

`tf = hasView(vSet,viewId)` returns `1` if the view specified by `viewID` exists and `0` if it does not exist.

Examples

Check If View Exists

Create an empty viewSet object.

```
vSet = viewSet;
```

Detect interest points in the image.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata','structureFromMotion');
I = imread(fullfile(imageDir,'image1.jpg'));
points = detectSURFFeatures(im2gray(I));
```

Add a new view.

```
vSet = addView(vSet, 1,'Points',points);
```

Confirm that the view with ID 1 exists.

```
tf = hasView(vSet,1);
```

Input Arguments

vSet — View set object
`viewSet` object

`viewSet` object.

viewId — View ID
integer

View ID in the `viewSet` object, specified as an integer.

Output Arguments

`tf` — Validity of view connection

logical

Validity of view connection, returned as a logical `1` or `0`.

Version History

Introduced in R2016a

R2020a: `hasView` function of `viewSet` object will be removed

Not recommended starting in R2020a

The `viewSet` object and its `hasView` function will be removed in a future release. Instead, manage views and pairwise connections between views of data using use the `imageviewset` object. Check if a view exists in the `imageviewset` object using its `hasView` function.

See Also

`imageviewset` | `hasView`

addConnection

(To be removed) Add connection between two views

Note The `viewSet` object and its `addConnection` function will be removed in a future release. Use the `imageviewset` object and its `addConnection` function instead. For more information, see "Version History".

Syntax

```
vSet = addConnection(vSet,viewId1,viewId2)
vSet = addConnection(vSet,viewId1,viewId2,Name,Value)
```

Description

`vSet = addConnection(vSet,viewId1,viewId2)` adds a connection between two views in the specified `viewSet` object, `vSet`.

`vSet = addConnection(vSet,viewId1,viewId2,Name,Value)` specifies additional options using one or more name-value pair arguments.

Examples

Add Connection Between Two Views

Create an empty `viewSet` object.

```
vSet = viewSet;
```

Read a pair of images.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata','structureFromMotion');
I1 = im2gray(imread(fullfile(imageDir,'image1.jpg')));
I2 = im2gray(imread(fullfile(imageDir,'image2.jpg')));
```

Detect interest points in the two images.

```
points1 = detectSURFFeatures(I1);
points2 = detectSURFFeatures(I2);
```

Add the points to the `viewSet` object.

```
vSet = addView(vSet,1,'Points',points1);
vSet = addView(vSet,2,'Points',points2);
```

Extract feature descriptors from both images.

```
features1 = extractFeatures(I1,points1);
features2 = extractFeatures(I2,points2);
```

Match features and store the matches.

```
indexPairs = matchFeatures(features1,features2);
```

Add the connection between the two views.

```
vSet = addConnection(vSet,1,2,'Matches',indexPairs);
```

Input Arguments

`vSet` — View set object

`viewSet` object

`viewSet` object.

`viewId1` — View ID 1

integer

View ID 1 in the `viewSet` object, specified as an integer.

`viewId2` — View ID 2

integer

View ID 2 in the `viewSet` object, specified as an integer.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'Location','[0,0,0]'`

`Matches` — Indices of matched points between two views

M-by-2 matrix

Indices of matched points between two views, specified as the comma-separated pair consisting of '`Matches`' and an *M*-by-2 matrix.

`Orientation` — Orientation of the second camera relative to the first camera

3-by-3 matrix

Orientation of the second camera relative to the first camera, specified as the comma-separated pair consisting of '`Orientation`' and a 3-by-3 matrix that represents the [*x*,*y*,*z*] orientation of the second camera.

`Location` — Location of the second camera relative to the first camera

three-element vector

Location of the second camera relative to the first camera, specified as the comma-separated pair consisting of '`Location`' and a three-element vector that represents the [*x*,*y*,*z*] location of the second camera in the first camera's coordinate system.

Output Arguments

vSet — View set object
`viewSet` object

`viewSet` object.

Version History

Introduced in R2016a

R2020a: `addConnection` function of `viewSet` object will be removed
Not recommended starting in R2020a

The `viewSet` object and its `addConnection` function will be removed in a future release. Instead, manage views and pairwise connections between views of data using use the `imageviewset` object. Add connections to the `imageviewset` object using its `addConnection` function.

See Also

`addConnection` | `imageviewset`

updateConnection

(To be removed) Modify connection between two views in view set object

Note The `viewSet` object and its `updateConnection` function will be removed in a future release. Use the `imageviewset` object and its `updateConnection` function instead. For more information, see “Version History”.

Syntax

```
vSet = updateConnection(vSet,viewId1,viewId2)
vSet = updateConnection(vSet,viewId1,viewId2,Name,Value)
```

Description

`vSet = updateConnection(vSet,viewId1,viewId2)` modifies a connection between two views in the specified view set object, `vSet`.

`vSet = updateConnection(vSet,viewId1,viewId2,Name,Value)` specifies additional options using one or more name-value pair arguments. Unspecified arguments have default values.

Examples

Update Connection Between Two Views in View Set Object

Create an empty `viewSet` object.

```
vSet = viewSet;
```

Read a pair of images.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata','structureFromMotion');
I1 = rgb2gray(imread(fullfile(imageDir,'image1.jpg')));
I2 = rgb2gray(imread(fullfile(imageDir,'image2.jpg')));
```

Detect interest points in the two images.

```
points1 = detectSURFFeatures(I1);
points2 = detectSURFFeatures(I2);
```

Add the points to the `viewSet` object.

```
vSet = addView(vSet, 1,'Points',points1);
vSet = addView(vSet, 2,'Points',points2);
```

Extract feature descriptors.

```
features1 = extractFeatures(I1,points1);
features2 = extractFeatures(I2,points2);
```

Match features and store the matches.

```
indexPairs = matchFeatures(features1, features2);
vSet = addConnection(vSet,1,2,'Matches',indexPairs);
```

Update the connection to store a relative pose between the views.

```
vSet = updateConnection(vSet,1,2,'Orientation', eye(3),'Location',[1 0 0]);
```

Input Arguments

`vSet` — View set object

`viewSet` object

`viewSet` object.

`viewId1` — View ID 1

integer

View ID 1 in the `viewSet` object, specified as an integer.

`viewId2` — View ID 2

integer

View ID 2 in the `viewSet` object, specified as an integer.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'Location', '[0,0,0]'`

`Matches` — Indices of matched points between two views

M-by-2 matrix

Indices of matched points between two views, specified as the comma-separated pair consisting of '`Matches`' and an *M*-by-2 matrix.

`Orientation` — Orientation of the second camera relative to the first camera

3-by-3 matrix

Orientation of the second camera relative to the first camera, specified as the comma-separated pair consisting of '`Orientation`' and a 3-by-3 matrix that represents the [*x*,*y*,*z*] orientation of the second camera.

`Location` — Location of the second camera relative to the first camera

three-element vector

Location of the second camera relative to the first camera, specified as the comma-separated pair consisting of '`Location`' and a three-element vector that represents the [*x*,*y*,*z*] location of the second camera in the first camera's coordinate system.

Output Arguments

vSet — View set object
`viewSet` object

`viewSet` object containing the modified connection.

Version History

Introduced in R2016a

R2020a: `updateConnection` function of `viewSet` object will be removed
Not recommended starting in R2020a

The `viewSet` object and its `updateConnection` function will be removed in a future release. Instead, manage views and pairwise connections between views of data using use the `imageviewset` object. Update connections between views of the `imageviewset` object using its `updateConnection` function.

See Also

`imageviewset` | `updateConnection`

deleteConnection

(To be removed) Delete connection between two views from view set object

Note The `viewSet` object and its `deleteConnection` function will be removed in a future release. Use the `imageviewset` object and its `deleteConnection` function instead. For more information, see “Version History”.

Syntax

```
vSet = deleteConnection(vSet,viewId1,viewId2)
```

Description

`vSet = deleteConnection(vSet,viewId1,viewId2)` deletes a connection between two views in the specified `viewSet` object, `vSet`.

Examples

Delete a Connection Between Two Views in View Set Object

Create an empty viewSet object.

```
vSet = viewSet;
```

Read a pair of images.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata','structureFromMotion');
I1 = im2gray(imread(fullfile(imageDir,'image1.jpg')));
I2 = im2gray(imread(fullfile(imageDir,'image2.jpg')));
```

Detect interest points in the two images.

```
points1 = detectSURFFeatures(I1);
points2 = detectSURFFeatures(I2);
```

Add the points to the `viewSet` object.

```
vSet = addView(vSet,1,'Points',points1);
vSet = addView(vSet,2,'Points',points2);
```

Extract feature descriptors.

```
features1 = extractFeatures(I1,points1);
features2 = extractFeatures(I2,points2);
```

Match features and store the matches.

```
indexPairs = matchFeatures(features1, features2);
vSet = addConnection(vSet,1,2,'Matches',indexPairs);
```

Delete the connection between the views.

```
vSet = deleteConnection(vSet,1,2);
```

Input Arguments

`vSet` — View set object
`viewSet` object

`viewSet` object.

`viewId1` — View ID 1
integer

View ID 1 in the `viewSet` object, specified as an integer.

`viewId2` — View ID 2
integer

View ID 2 in the `viewSet` object, specified as an integer.

Output Arguments

`vSet` — View set object
`viewSet` object

`viewSet` object.

Version History

Introduced in R2016a

R2020a: `deleteConnection` function of `viewSet` object will be removed
Not recommended starting in R2020a

The `viewSet` object and its `deleteConnection` function will be removed in a future release. Instead, manage views and pairwise connections between views of data using use the `imageviewset` object. Delete connections from the `imageviewset` object using its `deleteConnection` function.

See Also

`imageviewset` | `deleteConnection`

hasConnection

(To be removed) Check if connection exists between two views

Note The `viewSet` object and its `hasConnection` function will be removed in a future release. Use the `imageviewset` object and its `hasConnection` function instead. For more information, see "Version History".

Syntax

```
tf = hasConnection(vSet,viewId1,viewId2)
```

Description

`tf = hasConnection(vSet,viewId1,viewId2)` returns true if both views exist and have a connection.

Examples

Check Whether a Connection Exists Between Two Views

Create an empty `viewSet` object.

```
vSet = viewSet;
```

Add a pair of views.

```
vSet = addView(vSet,1);
vSet = addView(vSet,2);
```

Add a connection.

```
vSet = addConnection(vSet,1,2);
```

Confirm that the connection exists.

```
tf = hasConnection(vSet,1,2);
```

Input Arguments

vSet — View set object

`viewSet` object

`viewSet` object.

viewId1 — View ID 1

integer

View ID 1 in the `viewSet` object, specified as an integer.

`viewId2` — View ID 2
integer

View ID 2 in the `viewSet` object, specified as an integer.

Output Arguments

`tf` — Validity of view connection
logical

Validity of view connection, returned as a logical `1` or `0`.

Version History

Introduced in R2016a

R2020a: `hasConnection` function of `viewSet` object will be removed
Not recommended starting in R2020a

The `viewSet` object and its `hasConnection` function will be removed in a future release. Instead, manage views and pairwise connections between views of data using use the `imageviewset` object. Check if a connection between views exists in the `imageviewset` object using its `hasConnection` function.

findTracks

(To be removed) Find matched points across multiple views

Note The `viewSet` object and its `findTracks` function will be removed in a future release. Use the `imageviewset` object and its `findTracks` function instead. For more information, see "Version History".

Syntax

```
tracks = findTracks(vSet)
tracks = findTracks(vSet,viewIds)
```

Description

`tracks = findTracks(vSet)` finds point tracks across multiple views.

`tracks = findTracks(vSet,viewIds)` finds point tracks across a subset of views.

Examples

Find Point Tracks Across Sequence of Images

Load images.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata','structureFromMotion');
imds = imageDatastore(imageDir);
```

Compute features for the first image.

```
I = rgb2gray(read(imds));
pointsPrev = detectSURFFeatures(I);
[featuresPrev,pointsPrev] = extractFeatures(I,pointsPrev);
```

Create a `viewSet` object.

```
vSet = viewSet;
vSet = addView(vSet,1,'Points',pointsPrev);
```

Compute features and matches for the rest of the images.

```
for i = 2:length(imds.Files)
 I = rgb2gray(read(imds));
 points = detectSURFFeatures(I);
 [features, points] = extractFeatures(I,points);
 vSet = addView(vSet,i,'Points',points);
 pairsIdx = matchFeatures(featuresPrev,features);
 vSet = addConnection(vSet,i-1,i,'Matches',pairsIdx);
 featuresPrev = features;
end
```

Find point tracks.

```
tracks = findTracks(vSet);
```

Input Arguments

`vSet` — View set object
`viewSet` object

`viewSet` object.

`viewIds` — Subset of views
vector of integers

Subset of views in the `viewSet` object, specified as a vector of integers.

Output Arguments

`tracks` — Point track objects
array of `pointTrack` objects

Point track objects, returned as an array of `pointTrack` objects. Each track contains 2-D projections of the same 3-D world point.

Version History

Introduced in R2016a

R2020a: `findTracks` function of `viewSet` object will be removed
Not recommended starting in R2020a

The `viewSet` object and its `findTracks` function will be removed in a future release. Instead, manage views and pairwise connections between views of data using use the `imageviewset` object. Finds point track across views of the `imageviewset` object using its `findTracks` function.

See Also

`imageviewset` | `findTracks`

poses

(To be removed) Returns camera poses associated to views

Note The `viewSet` object and its `poses` function will be removed in a future release. Use the `imageviewset` object and its `poses` function instead. For more information, see “Version History”.

Syntax

```
cameraPoses = poses(vSet)
cameraPoses = poses(vSet,viewIds)
```

Description

`cameraPoses = poses(vSet)` returns the camera poses that correspond to the views contained in the input `viewSet` object, `vSet`.

`cameraPoses = poses(vSet,viewIds)` returns the camera poses that correspond to a subset of views specified by the vector `viewIds`.

Examples

Retrieve Camera Poses from View Set Object

Create an empty `viewSet` object.

```
vSet = viewSet;
```

Add views to the object.

```
vSet = addView(vSet,1,'Orientation',eye(3),'Location',[0,0,0]);
vSet = addView(vSet,2,'Orientation',eye(3),'Location',[1,0,0]);
```

Retrieve the absolute camera poses.

```
camPoses = poses(vSet);
```

Input Arguments

`vSet` — View set object
`viewSet` object

`viewSet` object.

`viewIds` — View IDs
integer scalar | vector

View IDs, specified as an integer scalar for a single view, or as a vector of integers for a set of views.

Output Arguments

`cameraPoses` — Camera pose information
three-column table

Camera pose information, returned as a three-column table. The table contains columns for `ViewId`, `Orientation`, and `Location`. The view IDs correspond to the IDs in the `viewSet` object. The orientations are specified as 3-by-3 rotation matrices and locations are specified as three-element vectors. You can pass the `cameraPoses` table to the `triangulateMultiview` and the `bundleAdjustment` functions.

Version History

Introduced in R2016a

R2020a: `poses` function of `viewSet` object will be removed
Not recommended starting in R2020a

The `viewSet` object and its `poses` function will be removed in a future release. Instead, manage views and pairwise connections between views of data using use the `imageviewset` object. Return camera poses associated with views of the `imageviewset` object using its `poses` function.

See Also

`triangulateMultiview` | `bundleAdjustment` | `imageviewset` | `poses`

acfObjectDetector

Detect objects using aggregate channel features

Description

The `acfObjectDetector` object detects objects from an image using the aggregate channel features (ACF) object detector. To use the ACF detector on an image, pass the trained detector to the `detect` function.

The ACF object detector recognizes specific objects in images, based on the training images and the object ground truth locations used with the `trainACFObjectDetector` function.

Creation

Create an `acfObjectDetector` object by calling the `trainACFObjectDetector` function with training data.

```
detector = trainACFObjectDetector(trainingData,...)
```

Syntax

```
detector = acfObjectDetector(classifier,trainingOptions)
```

Description

`detector = acfObjectDetector(classifier,trainingOptions)` creates an ACF object detector based on the specified pretrained `classifier` and `trainingOptions`. You can use this syntax to recreate an ACF object detector for code generation.

Input Arguments

`classifier` — Pretrained `acfObjectDetector` object classifier
structure field

Pretrained `acfObjectDetector` object classifier, specified as a structure of an Adaboost classifier. You can obtain the classifier structure field by converting a pretrained ACF classifier object to a structure by using the `toStruct` function.

`trainingOptions` — Pretrained `acfObjectDetector` object training options
structure field

Pretrained `acfObjectDetector` object training options, specified as a structure of feature pyramid parameters. You can obtain the training option structure field by converting a pretrained ACF classifier object to a structure by using the `toStruct` function.

Properties

`ModelName` — Name of classification model

character vector | string scalar

Name of the classification model, specified as a character vector or string scalar. By default, the name is set to the heading of the second column of the `trainingData` table specified in the `trainACFObjectDetector` function. You can modify this name after creating your `acfObjectDetector` object.

Example: `'stopSign'`

`ObjectTrainingSize` — Size of training images

[*height width*] vector

This property is read-only.

Size of training images, specified as a [*height width*] vector.

Example: `[100 100]`

`NumWeakLearners` — Number of weak learners

integer

This property is read-only.

Number of weak learners used in the detector, specified as an integer. `NumWeakLearners` is less than or equal to the maximum number of weak learners for the last training stage. To restrict this maximum, you can use the `'MaxWeakLearners'` name-value pair in the `trainACFObjectDetector` function.

Object Functions

detect	Detect objects using ACF object detector
toStruct	Convert a trained aggregate channel features (ACF) object detector into structure

Examples

Train Stop Sign Detector Using ACF Object Detector

Use the `trainACFObjectDetector` with training images to create an ACF object detector that can detect stop signs. Test the detector with a separate image.

Load the training data.

```
load('stopSignsAndCars.mat')
```

Prefix the full path to the stop sign images.

```
stopSigns = fullfile(toolboxdir('vision'),'visiondata',stopSignsAndCars{:,1});
```

Create datastores to load the ground truth data for stop signs.

```
imds = imageDatastore(stopSigns);
blds = boxLabelDatastore(stopSignsAndCars(:,2));
```

Combine the image and box label datastores.

```
ds = combine(imds,blds);
```

Train the ACF detector. Set the number of negative samples to use at each stage to 2. You can turn off the training progress output by specifying `Verbose=false`, as a `Name-Value` argument.

```
acfDetector = trainACFObjectDetector(ds,NegativeSamplesFactor=2);
```

```
ACF Object Detector Training
The training will take 4 stages. The model size is 34x31.
Sample positive examples(~100% Completed)

Stage 4:
Sample negative examples(~100% Completed)
Found 84 new negative examples for training.
Compute aggregated channel features...Completed.
Train classifier with 42 positive examples and 84 negative examples...Completed.
The trained classifier has 61 weak learners.
--------------------------------------------
ACF object detector training is completed. Elapsed time is 17.9982 seconds.
```

Test the ACF detector on a test image.

```
img = imread('stopSignTest.jpg');
[bboxes,scores] = detect(acfDetector,img);
```

Display the detection results and insert the bounding boxes for objects into the image.

```
for i = 1:length(scores)
   annotation = sprintf('Confidence = %.1f',scores(i));
   img = insertObjectAnnotation(img,'rectangle',bboxes(i,:),annotation);
end

figure
imshow(img)
```

Recreate ACF Object Detector for Code Generation

Load the ACF stop sign detector from the `stopSignDetector.mat` file, which is present in the current working folder as a supporting file.

```
stopSignDetector = load('stopSignDetectorACF.mat');
detector = stopSignDetector.detector
```

```
detector =

  acfObjectDetector with properties:

            ModelName: 'stopSign'
    ObjectTrainingSize: [34 31]
       NumWeakLearners: 61
```

Convert the detector into a structure by using the `toStruct` function.

```
detectorStruct = toStruct(detector);
```

To generate code, pass the structure to a MATLAB® function. Then inside the MATLAB function, create an identical ACF stop sign detector using the existing detector properties.

```
detector1 = acfObjectDetector(detectorStruct.Classifier,detectorStruct.TrainingOptions)
```

```
detector1 =

  acfObjectDetector with properties:

            ModelName: 'stopSign'
    ObjectTrainingSize: [34 31]
       NumWeakLearners: 61
```

You can pass `detector1` to the `detect` function as an input to detect stop signs from images.

Version History

Introduced in R2017a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use the `toStruct` function to pass the `acfObjectDetector` object into generated code. For more information, see “Generate Code for Detecting Objects in Images by Using ACF Object Detector”.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

Functions

`trainACFObjectDetector` | `detectPeopleACF` | `trainCascadeObjectDetector` | `groundTruth`

rcnnObjectDetector

(Not recommended) Detect objects using R-CNN deep learning detector

Note `rcnnObjectDetector` is not recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` detector. For more information, see "Version History".

Description

The `rcnnObjectDetector` object detects objects from an image, using a R-CNN (region-based convolutional neural networks) object detector. To detect objects in an image, pass the trained detector to the `detect` function. To classify image regions, pass the detector to the `classifyRegions` function.

Use of the `rcnnObjectDetector` requires Statistics and Machine Learning Toolbox™ and Deep Learning Toolbox.

When using the `detect` or `classifyRegions` functions with `rcnnObjectDetector`, use of a CUDA enabled NVIDIA GPU is highly recommended. The GPU reduces computation time significantly. Usage of the GPU requires Parallel Computing Toolbox. For information about the supported compute capabilities, see "GPU Computing Requirements" (Parallel Computing Toolbox).

Creation

Create a `rcnnObjectDetector` object by calling the `trainRCNNObjectDetector` function with training data (requires Deep Learning Toolbox).

```
detector = trainRCNNObjectDetector(trainingData,...)
```

Properties

`Network` — Convolutional neural network
`SeriesNetwork` | `DAGNetwork`

Convolutional neural network (CNN) used within the R-CNN detector, specified as a `SeriesNetwork` or `DAGNetwork` object.

`RegionProposalFcn` — Custom region proposal method
function handle

Custom region proposal method, specified as a function name. A custom function `proposalFcn` must have the following functional form:

```
[bboxes,scores] = proposalFcn(I)
```

The input argument `I` is an image. The function must return rectangular bounding boxes in an *M*-by-4 array. Each row of `bboxes` contains a four-element vector, [*x*,*y*,*width*,*height*], that specifies the

upper–left corner and size of a bounding box in pixels. The function must also return a score for each bounding box in an *M*-by-1 vector. Higher scores indicate that the bounding box is more likely to contain an object.

`ClassNames` — Object class names
cell array

Object class names, specified as a cell array. The array contains the names of the object classes the R-CNN detector was trained to find.

`BoxRegressionLayer` — Bounding box regression layer
character vector

This property is read-only.

Bounding box regression layer name, specified as a character vector. This property is set during training using the `BoxRegressionLayer` argument of `trainRCNNObjectDetector`.

Object Functions

detect	(Not recommended) Detect objects using R-CNN deep learning detector
classifyRegions	(Not recommended) Classify objects in image regions using R-CNN object detector

Examples

Train R-CNN Stop Sign Detector

Load training data and network layers.

```
load('rcnnStopSigns.mat', 'stopSigns', 'layers')
```

Add the image directory to the MATLAB path.

```
imDir = fullfile(matlabroot, 'toolbox', 'vision', 'visiondata',...
  'stopSignImages');
addpath(imDir);
```

Set network training options to use mini-batch size of 32 to reduce GPU memory usage. Lower the InitialLearnRate to reduce the rate at which network parameters are changed. This is beneficial when fine-tuning a pre-trained network and prevents the network from changing too rapidly.

```
options = trainingOptions('sgdm', ...
  'MiniBatchSize', 32, ...
  'InitialLearnRate', 1e-6, ...
  'MaxEpochs', 10);
```

Train the R-CNN detector. Training can take a few minutes to complete.

```
rcnn = trainRCNNObjectDetector(stopSigns, layers, options, 'NegativeOverlapRange', [0 0.3]);
```

```
*********************************************************************
Training an R-CNN Object Detector for the following object classes:

* stopSign
```

```
--> Extracting region proposals from 27 training images...done.

--> Training a neural network to classify objects in training data...

Training on single CPU.
Initializing input data normalization.

|========================================================================================|
Training finished: Max epochs completed.

Network training complete.

--> Training bounding box regression models for each object class...100.00%...done.

Detector training complete.
*********************************************************************
```

Test the R-CNN detector on a test image.

```
img = imread('stopSignTest.jpg');

[bbox, score, label] = detect(rcnn, img, MiniBatchSize=32);
```

Display strongest detection result.

```
[score, idx] = max(score);

bbox = bbox(idx, :);
annotation = sprintf('%s: (Confidence = %f)', label(idx), score);

detectedImg = insertObjectAnnotation(img, 'rectangle', bbox, annotation);

figure
imshow(detectedImg)
```

Remove the image directory from the path.

```
rmpath(imDir);
```

Resume Training an R-CNN Object Detector

Resume training an R-CNN object detector using additional data. To illustrate this procedure, half the ground truth data will be used to initially train the detector. Then, training is resumed using all the data.

Load training data and initialize training options.

```
load('rcnnStopSigns.mat', 'stopSigns', 'layers')

stopSigns.imageFilename = fullfile(toolboxdir('vision'),'visiondata', ...
    stopSigns.imageFilename);

options = trainingOptions('sgdm', ...
    'MiniBatchSize', 32, ...
    'InitialLearnRate', 1e-6, ...
    'MaxEpochs', 10, ...
    'Verbose', false);
```

Train the R-CNN detector with a portion of the ground truth.

```
rcnn = trainRCNNObjectDetector(stopSigns(1:10,:), layers, options, 'NegativeOverlapRange', [0 0.
```

Get the trained network layers from the detector. When you pass in an array of network layers to `trainRCNNObjectDetector`, they are used as-is to continue training.

```
network = rcnn.Network;
layers = network.Layers;
```

Resume training using all the training data.

```
rcnnFinal = trainRCNNObjectDetector(stopSigns, layers, options);
```

Create a Network for Multiclass R-CNN Object Detection

Create an R-CNN object detector for two object classes: dogs and cats.

```
objectClasses = {'dogs','cats'};
```

The network must be able to classify both dogs, cats, and a "background" class in order to be trained using `trainRCNNObjectDetector`. In this example, a one is added to include the background.

```
numClassesPlusBackground = numel(objectClasses) + 1;
```

The final fully connected layer of a network defines the number of classes that the network can classify. Set the final fully connected layer to have an output size equal to the number of classes plus a background class.

```
layers = [ ...
    imageInputLayer([28 28 1])
    convolution2dLayer(5,20)
    fullyConnectedLayer(numClassesPlusBackground);
    softmaxLayer()
    classificationLayer()];
```

These network layers can now be used to train an R-CNN two-class object detector.

Use A Saved Network In R-CNN Object Detector

Create an R-CNN object detector and set it up to use a saved network checkpoint. A network checkpoint is saved every epoch during network training when the `trainingOptions` 'CheckpointPath' parameter is set. Network checkpoints are useful in case your training session terminates unexpectedly.

Load the stop sign training data.

```
load('rcnnStopSigns.mat','stopSigns','layers')
```

Add full path to image files.

```
stopSigns.imageFilename = fullfile(toolboxdir('vision'),'visiondata', ...
      stopSigns.imageFilename);
```

Set the 'CheckpointPath' using the `trainingOptions` function.

```
checkpointLocation = tempdir;
options = trainingOptions('sgdm','Verbose',false, ...
    'CheckpointPath',checkpointLocation);
```

Train the R-CNN object detector with a few images.

```
rcnn = trainRCNNObjectDetector(stopSigns(1:3,:),layers,options);
```

Load a saved network checkpoint.

```
wildcardFilePath = fullfile(checkpointLocation,'convnet_checkpoint__*.mat');
contents = dir(wildcardFilePath);
```

Load one of the checkpoint networks.

```
filepath = fullfile(contents(1).folder,contents(1).name);
checkpoint = load(filepath);

checkpoint.net
```

```
ans =

  SeriesNetwork with properties:

    Layers: [15×1 nnet.cnn.layer.Layer]
```

Create a new R-CNN object detector and set it up to use the saved network.

```
rcnnCheckPoint = rcnnObjectDetector();
rcnnCheckPoint.RegionProposalFcn = @rcnnObjectDetector.proposeRegions;
```

Set the Network to the saved network checkpoint.

```
rcnnCheckPoint.Network = checkpoint.net
```

```
rcnnCheckPoint =

  rcnnObjectDetector with properties:

            Network: [1×1 SeriesNetwork]
         ClassNames: {'stopSign'  'Background'}
    RegionProposalFcn: @rcnnObjectDetector.proposeRegions
```

Version History

Introduced in R2016b

R2024b: Not Recommended

Not recommended starting in R2024b

Starting in R2024b, R-CNN object detectors are no longer recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` object. These object detectors are faster than R-CNN object detectors. For more information, see “Choose an Object Detector”.

bagOfFeatures

Bag of visual words object

Description

You can construct a bag of visual words for use in image category classification, and image retrieval.

Creation

Syntax

```
bag = bagOfFeatures(imds)
bag = bagOfFeatures(imds,'CustomExtractor',extractorFcn)
bag = bagOfFeatures(imds,Name=Value)
```

Description

`bag = bagOfFeatures(imds)` returns a bag of features object. The `bag` output object is generated using samples from the `imds` input. By default, the visual vocabulary is created from SURF features extracted from images in `imds`.

`bag = bagOfFeatures(imds,'CustomExtractor',extractorFcn)` returns a bag of features that uses a custom feature extractor function to extract features from images in `imds`. `extractorFcn` is a function handle to a custom feature extraction function.

`bag = bagOfFeatures(imds,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `bag = bagOfFeatures(imds,Verbose=true)` additionally sets `Verbose` to `true`.

This object supports parallel computing using multiple MATLAB workers. Enable parallel computing from the “Computer Vision Toolbox Preferences” dialog box. To open Computer Vision Toolbox preferences, on the **Home** tab, in the **Environment** section, click **Preferences**. Then select Computer Vision Toolbox.

Input Arguments

`imds` — Images
`ImageDatastore` object

Images, specified as an `ImageDatastore` object. The `bagOfFeatures` extracts an equal number of strongest features from the images contained in the `imds` object. The number of strongest features is defined as:

number of strongest features = `min`(*number of features found in each set*) x `StrongestFraction`

The object obtains the `StrongestFraction` value from the `StrongestFeatures` property.

`extractorFcn` — Custom feature extractor function
function handle

Custom feature extractor function, specified as a function handle. This custom function extracts features to learn the visual vocabulary of the object.

The function, `extractorFcn`, must be specified as a function handle for a file:

```
extractorFcn = @exampleBagOfFeaturesExtractor;
bag = bagOfFeatures(imds,CustomExtractor=extractorFcn)
```

where `exampleBagOfFeaturesExtractor` is a MATLAB function. For example:

```
function [features,featureMetrics,location] = exampleBagOfFeaturesExtractor(img)
...
```

The function must be on the path or in the current working directory. The arguments are defined as:

Argument	Input/Output	Description
`img`	Input	• Binary, grayscale, or truecolor image. • The input image is from the image set that was originally passed into `bagOfFeatures`.
`features`	Output	• A `binaryFeatures` object. • An *M*-by-*N* numeric matrix of image features, where *M* is the number of features and *N* is the length of each feature vector. • The feature length, *N*, must be greater than zero and be the same for all images processed during the `bagOfFeatures` creation process. • If you cannot extract features from an image, supply an empty feature matrix and an empty feature metrics vector. Use the empty matrix and vector if, for example, you did not find any keypoints for feature extraction. • Numeric, real, and nonsparse.
`featureMetrics`	Output	• An *M*-by-1 vector of feature metrics indicating the strength of each feature vector. • Used to apply the `'SelectStrongest'` criteria in `bagOfFeatures` framework. • Numeric, real, and nonsparse.
`location`	Output	• An *M*-by-2 matrix of 1-based [*x* *y*] values. • The [*x* *y*] values can be fractional. • Numeric, real, and nonsparse.

For more details on the custom extractor function and its input and output requirements, see “Create a Custom Feature Extractor”.

You can open an example function file, and use it as a template by typing the following command at the MATLAB command-line:

```
edit('exampleBagOfFeaturesExtractor.m')
```

Properties

`CustomExtractor` — Custom extraction function

function handle

Custom feature extractor function, specified as a handle to a function. The custom feature extractor function extracts features used to learn the visual vocabulary for `bagOfFeatures`. You must specify '`CustomExtractor`' and the function handle, `extractorFcn`, to a custom feature extraction function.

The function, `extractorFcn`, must be specified as a function handle for a file:

```
extractorFcn = @exampleBagOfFeaturesExtractor;
bag = bagOfFeatures(imds,CustomExtractor=extractorFcn)
```

where `exampleBagOfFeaturesExtractor` is a MATLAB function such as:

```
function [features,featureMetrics] = exampleBagOfFeaturesExtractor(img)
...
```

The function must be on the path or in the current working directory.

For more details on the custom extractor function and its input and output requirements, see “Create a Custom Feature Extractor”. You can open an example function file, and use it as a template by typing the following command at the MATLAB command-line:

```
edit('exampleBagOfFeaturesExtractor.m')
```

`TreeProperties` — Vocabulary tree properties

`[1 500]` (default) | two-element vector

Vocabulary tree properties, specified as a two-element vector in the form [*numLevels branchingFactor*]. *numLevels* is an integer that specifies the number of levels in the vocabulary tree. *branchingFactor* is an integer that specifies a factor to control the amount the vocabulary can grow at successive levels in the tree. The maximum number of visual words represented by the vocabulary tree is *branchingFactor*^*numLevels*. Typical values for *numLevels* is between `1` and `6`. Typical values for *branchingFactor* is between `10` and `500`. Use an empirical analysis to select optimal values.

Increase the branching factor to generate a larger vocabulary. Increasing the vocabulary improves classification and image retrieval accuracy, but will also increase the time to encode images. You can use a vocabulary tree with multiple levels to create vocabularies on the order of 10,000 visual words or more. A multilevel tree reduces the time required to encode images with large vocabularies, but will take longer to create. You can use a tree with one level for vocabularies that contain only 100 - 1000 visual words.

`StrongestFeatures` — Fraction of strongest features

`0.8` (default) | `[0,1]`

Fraction of strongest features, specified as the comma-separated pair consisting of '`StrongestFeatures`' and a value in the range [0,1]. The value represents the fraction of strongest features to use from each label in the `imds` input.

`Verbose` — Enable progress display to screen

`true` (default) | false

Enable progress display to screen, specified as the comma-separated pair consisting of 'Verbose' and the logical `true` or `false`.

`PointSelection` — Selection method for picking point locations
`"Grid"` (default) | `"Detector"`

Selection method for picking point locations for SURF feature extraction, specified as the comma-separated pair consisting of 'PointSelection' and either `"Grid"` or `"Detector"`. There are two stages for feature extraction. First, you select a method for picking the point locations, (SURF `"Detector"` or `"Grid"`), with the `PointSelection` property. The second stage extracts the features. The feature extraction uses a SURF extractor for both point selection methods.

When you set `PointSelection` to `"Detector"`, the feature points are selected using a speeded up robust feature (SURF) detector. Otherwise, the points are picked on a predefined grid with spacing defined by 'GridStep'. This property applies only when you are not specifying a custom extractor with the `CustomExtractor` property.

`GridStep` — Grid step size
`[8 8]` (default) | 1-by-2 [*x y*] vector

Grid step size in pixels, specified as the comma-separated pair consisting of `"Grid"` and an 1-by-2 [*x y*] vector. This property applies only when you set `PointSelection` to `"Grid"` and you are not specifying a custom extractor with the `CustomExtractor` property. The steps in the *x* and *y* directions define the spacing of a uniform grid. Intersections of the grid lines define locations for feature extraction.

`BlockWidth` — Patch size to extract upright SURF descriptor
`[32 64 96 128]` (default) | 1-by-*N* vector

Patch size to extract upright SURF descriptor, specified as the comma-separated pair consisting of 'BlockWidth' and a 1-by-*N* vector of *N* block widths. This property applies only when you are not specifying a custom extractor with the `CustomExtractor` property. Each element of the vector corresponds to the size of a square block from which the function extracts upright SURF descriptors. Use multiple square sizes to extract multiscale features. All the square specified are used for each extraction points on the grid. This property only applies when you set `PointSelection` to `"Grid"`. The block width corresponds to the scale of the feature. The minimum `BlockWidth` is 32 pixels.

`Upright` — Orientation of SURF feature vector
`true` (default) | `false`

Orientation of SURF feature vector, specified as a logical scalar. This property applies only when you are not specifying a custom extractor with the `CustomExtractor` property. Set this property to `true`

when you do not need to estimate the orientation of the SURF feature vectors. Set it to `false` when you need the image descriptors to capture rotation information.

Object Functions

encode Create histogram of visual word occurrences

Examples

Create a Bag of Visual Words

Create an image datastore.

```
setDir  = fullfile(toolboxdir('vision'),'visiondata','imageSets');
imds = imageDatastore(setDir,'IncludeSubfolders',true,'LabelSource',...
    'foldernames');
```

Create the bag of features. This process can take a few minutes.

```
bag = bagOfFeatures(imds);
```

```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

For code generation, the `bagOfFeatures` function does not support the `ImageDatastore` object as input. Instead, specify the input as a structure with fields `Images` and `Labels`. The `Images` field must contain a cell array of grayscale or RGB color images. The `Labels` field must contain image labels stored as categorical arrays.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set `'UseParallel'` to `true` or enable this by default using the Computer Vision Toolbox preferences.

For more information, see “Parallel Computing Toolbox Support”.

encode

Create histogram of visual word occurrences

Syntax

```
featureVector = encode(bag,I)
[featureVector,words] = encode(bag,I)

featureVector= encode(bag,imds)
[featureVector,words] = encode(bag,imds)

[___] = encode(___,Name,Value)
```

Description

`featureVector = encode(bag,I)` returns a feature vector that represents a histogram of visual word occurrences contained in the input image, `I`. The input bag contains the `bagOfFeatures` object.

`[featureVector,words] = encode(bag,I)` optionally returns the visual words as a `visualWords` object. The `visualWords` object stores the visual words that occur in `I` and stores the locations of those words.

`featureVector= encode(bag,imds)` returns a feature vector that represents a histogram of visual word occurrences contained in `imds`. The input `bag` contains the `bagOfFeatures` object.

`[featureVector,words] = encode(bag,imds)` optionally returns an array of `visualWords` occurrences in `imds`. The `visualWords` object stores the visual words that occur in `I` and stores the locations of those words.

`[___] = encode(___,Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `encode('SparseOutput',false)`

This method supports parallel computing using multiple MATLAB workers. Enable parallel computing from the “Computer Vision Toolbox Preferences” dialog box. To open Computer Vision Toolbox preferences, on the **Home** tab, in the **Environment** section, click **Preferences**. Then select **Computer Vision Toolbox**.

Examples

Encode an Image into a Feature Vector

Load a set of image.

```
setDir  = fullfile(toolboxdir('vision'),'visiondata','imageSets');
imds = imageDatastore(setDir,'IncludeSubfolders',true,'LabelSource',...
    'foldernames');
```

Pick the first two images from each label.

```
trainingSet = splitEachLabel(imds,2);
```

Create bag of features.

```
bag = bagOfFeatures(trainingSet);
```

```

* Finished creating Bag-Of-Features
```

Encode one of the images into a feature vector.

```
img = readimage(trainingSet,1);
featureVector = encode(bag,img);
```

```
Encoding images using Bag-Of-Features.
--------------------------------------
* Encoding an image...done.
```

Input Arguments

bag — Bag of features

`bagOfFeatures` object

Bag of features, specified as a `bagOfFeatures` object.

I — Input image

grayscale image | truecolor image

Input image, `I`, specified as a grayscale or a truecolor image.

imds — Images

`ImageDatastore` object

Images, specified as an `ImageDatastore` object.

Name-Value Pair Arguments

Example: 'SparseOutput',`false`

`Normalization` — Type of normalization
`'L2'` (default) | `'none'`

Type of normalization applied to the feature vector, specified as the comma-separated pair consisting of '`Normalization`' and either `'L2'` or `'none'`.

`SparseOutput` — Output sparsity
`false` (default) | `true`

Output sparsity, specified as the comma-separated pair consisting of '`SparseOutput`' and as `true` or `false`. Set this property to `true` to return the visual word histograms in a sparse matrix. Setting this property to `true` reduces memory consumption for large visual vocabularies where the visual word histograms contain many zero elements.

`Verbose` — Enable progress display to screen
`true` (default) | false

Enable progress display to screen, specified as the comma-separated pair consisting of '`Verbose`' and the logical `true` or `false`.

Output Arguments

`featureVector` — Histogram of visual word occurrences
1-by-`bag.VocabularySize` | *M*-by-`bag.VocabularySize`

Histogram of visual word occurrences, specified as *M*-by-`bag.VocabularySize` vector, where *M* is the total number of images in `imds`, `numel(imds.Files)`.

`words` — Visual words object
`visualWords` object

Visual words object, returned as a visual words object or an array of visual words objects. The `visualWords` object stores the visual words that occur in the images and stores the locations of those words.

Version History

Introduced in R2014b

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- For code generation, the function does not support the `ImageDatastore` object as input.
- To input more than one image, specify them as a cell array.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set `'UseParallel'` to `true` or enable this by default using the Computer Vision Toolbox preferences.

For more information, see “Parallel Computing Toolbox Support”.

See Also

`bagOfFeatures`

imageCategoryClassifier

Predict image category

Description

The `imageCategoryClassifier` object contains a linear support vector machine (SVM) classifier trained to recognize an image category.

You must have a Statistics and Machine Learning Toolbox license to use this classifier. This classifier supports parallel computing using multiple MATLAB workers. Enable parallel computing using the "Computer Vision Toolbox Preferences" dialog. To open the Computer Vision Toolbox preferences, on the **Home** tab, in the **Environment** section, click **Preferences**. Select **Computer Vision System Toolbox**.

Creation

Use the `trainImageCategoryClassifier` function to create the `imageCategoryClassifier` object.

```
bag = bagOfFeatures(trainingSet);
categoryClassifier = trainImageCategoryClassifier(trainingSet,bag);
```

Properties

`Labels` — Category labels
cell array

Category labels, specified as a cell array.

`NumCategories` — Number of trained categories
integer

Number of trained categories, stored as an integer value.

Object Functions

evaluate	Evaluate image classifier on collection of image sets
predict	Predict image category

Examples

Train, Evaluate, and Apply Image Category Classifier

Load two image categories.

```
setDir  = fullfile(toolboxdir('vision'),'visiondata','imageSets');
imds = imageDatastore(setDir,'IncludeSubfolders',true,'LabelSource',...
    'foldernames');
```

Split the data set into a training and test data. Pick 30% of images from each set for the training data and the remainder 70% for the test data.

```
[trainingSet,testSet] = splitEachLabel(imds,0.3,'randomize');
```

Create bag of visual words.

```
bag = bagOfFeatures(trainingSet);
```

```

predict

Predict image category

Syntax

```
[labelIdx,score] = predict(categoryClassifier,I)
[labelIdx,score] = predict(categoryClassifier,imds)
[labelIdx,score] = predict( ___ ,'Verbose',true)
```

Description

`[labelIdx,score] = predict(categoryClassifier,I)` returns the predicted label index and score for the input image.

`predict` supports parallel computing using multiple MATLAB workers. Enable parallel computing using the “Computer Vision Toolbox Preferences” dialog. To open Computer Vision Toolbox preferences, on the **Home** tab, in the **Environment** section, click **Preferences**. Select Computer Vision Toolbox.

`[labelIdx,score] = predict(categoryClassifier,imds)` returns the predicted label index and score for the images specified in `imds`.

`[labelIdx,score] = predict( ___ ,'Verbose',true)` also enables progress display to the screen. Set to `false` to turn it off.

Examples

Predict Category for Image

Load two image category sets.

```
setDir  = fullfile(toolboxdir('vision'),'visiondata','imageSets');
imds = imageDatastore(setDir,'IncludeSubfolders',true,'LabelSource',...
    'foldernames');
```

Separate the two sets into training and test data. Pick 30% of images from each set for the training data and the remainder 70% for the test data.

```
[trainingSet,testSet] = splitEachLabel(imds,0.3,'randomize');
```

Create a bag of visual words.

```
bag = bagOfFeatures(trainingSet);
```

```
Creating Bag-Of-Features.
-------------------------
* Image category 1: books
* Image category 2: cups
* Selecting feature point locations using the Grid method.
* Extracting SURF features from the selected feature point locations.
```

```
** The GridStep is [8 8] and the BlockWidth is [32 64 96 128].

* Extracting features from 4 images...done. Extracted 76800 features.

* Keeping 80 percent of the strongest features from each category.

* Creating a 500 word visual vocabulary.
* Number of levels: 1
* Branching factor: 500
* Number of clustering steps: 1

* [Step 1/1] Clustering vocabulary level 1.

* Encoding an image...done.

categoryClassifier.Labels(labelIdx)

ans = 1×1 cell array
    {'books'}
```

Input Arguments

`I` — Input image

M-by-*N*-by-3 truecolor image | *M*-by-*N* 2-D grayscale image

Input image, specified as either an *M*-by-*N*-by-3 truecolor image or an *M*-by-*N* 2-D grayscale image.

`categoryClassifier` — Image category classifier

`imageCategoryClassifier` object

Image category classifier, specified as an `imageCategoryClassifier` object.

`imds` — Images
`ImageDatastore` object

Images, specified as an `ImageDatastore` object.

Output Arguments

`labelIdx` — Predicted label index
M-by-1 vector | scalar

Predicted label index, returned as either an *M*-by-1 vector for *M* images or a scalar value for a single image. The `labelIdx` output value corresponds to the index of an image set used to train the bag of features. The prediction index corresponds to the class with the lowest average binary loss of the ECOC SVM classifier.

`score` — Prediction score
1-by-*N* vector | *M*-by-*N* matrix

Prediction score, specified as a 1-by-*N* vector or an *M*-by-*N* matrix. *N* represents the number of classes. *M* represents the number of images in the `imageSet` input object, `imgSet`. The score provides a negated average binary loss per class. Each class is a support vector machine (SVM) multiclass classifier that uses the error-correcting output codes (ECOC) approach.

Version History

Introduced in R2014b

Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set `'UseParallel'` to `true` or enable this by default using the Computer Vision Toolbox preferences.

`imageCategoryClassifier` | `evaluate`

evaluate

Evaluate image classifier on collection of image sets

Syntax

```
confMat = evaluate(categoryClassifier,imds)
[confMat,knownLabelIdx,predictedLabelIdx,score] = evaluate(
categoryClassifier,imds)
```

Description

`confMat = evaluate(categoryClassifier,imds)` returns a normalized confusion matrix, `confMat`.

`[confMat,knownLabelIdx,predictedLabelIdx,score] = evaluate(categoryClassifier,imds)` additionally returns the corresponding label indexes and score.

Examples

Train, Evaluate, and Apply Image Category Classifier

Load two image categories.

```
setDir  = fullfile(toolboxdir('vision'),'visiondata','imageSets');
imds = imageDatastore(setDir,'IncludeSubfolders',true,'LabelSource',...
    'foldernames');
```

Split the data set into a training and test data. Pick 30% of images from each set for the training data and the remainder 70% for the test data.

```
[trainingSet,testSet] = splitEachLabel(imds,0.3,'randomize');
```

Create bag of visual words.

```
bag = bagOfFeatures(trainingSet);
```

```

```

Display the classification label.

```
categoryClassifier.Labels(labelIdx)
```

```
ans = 1×1 cell array
    {'cups'}
```

Input Arguments

`imds` — Data store object of images

`ImageDatastore` object

Images, specified in an `ImageDatastore` object.

`categoryClassifier` — Image category classifier

`imageCategoryClassifier` object

Image category classifier, specified as an `imageCategoryClassifier` object.

Output Arguments

`confMat` — Confusion matrix

matrix

Confusion matrix, returned as a matrix. The row indices correspond to known labels and the columns correspond to the predicted labels.

`knownLabelIdx` — Label index for image set

M-by-1 vector | scalar

Label index for image set, returned as an *M*-by-1 vector for *M* images. The `knownLabelIdx` output value corresponds to the index of an image set used to train the bag of features.

`predictedLabelIdx` — Predicted label index

M-by-1 vector

Predicted label index, returned as an *M*-by-1 vector for *M* images. The `predictedLabelIdx` output value corresponds to the index of an image set used to train the bag of features. The predicted index corresponds to the class with the largest value in the `score` output.

`score` — Prediction score

M-by-*N* matrix

Prediction score, specified as an *M*-by-*N* matrix. *N* represents the number of classes. *M* represents the number of images in the `imageSet` input object, `imgSet`. The score provides a negated average

binary loss per class. Each class is a support vector machine (SVM) multiclass classifier that uses the error-correcting output codes (ECOC) approach.

intrinsicsEstimationErrors

Object for storing standard errors of estimated camera intrinsics and distortion coefficients

Description

The `intrinsicsEstimationErrors` object contains the standard errors of estimated camera intrinsics and distortion coefficients. You can access the intrinsics and distortion standard errors using the object properties. You can display the standard errors using the `displayErrors` object function.

Creation

Syntax

```
[params,imgsUsed,Errors] = estimateCameraParameters(imagePoints,worldPoints)
```

Description

`[params,imgsUsed,Errors] = estimateCameraParameters(imagePoints,worldPoints)` creates an `intrinsicsEstimationErrors` object by calling the `estimateCameraParameters` function with image points and world points. The function returns a `stereoCalibrationErrors` or `cameraCalibrationErrors` object as the third output argument, which contains the `intrinsicsEstimationErrors` as a read-only property.

Properties

`SkewError` — Standard error of camera axes skew estimate
scalar

This property is read-only.

Standard error of the camera axes skew estimate, specified as a scalar.

`FocalLengthError` — Standard error of focal length estimate
scalar

Standard error of the focal length estimate, specified as a scalar.

`PrincipalPointError` — Standard error of principal point estimate
scalar

This property is read-only.

Standard error of the principal point estimate, specified as a scalar.

`RadialDistortionError` — Standard error of radial distortion estimate
scalar

This property is read-only.

Standard error of the radial distortion estimate, specified as a scalar.

`TangentialDistortionError` — Standard error of tangential distortion estimate
scalar

This property is read-only.

Standard error of the tangential distortion estimate, specified as a scalar.

Examples

Display Intrinsics Errors

Create a set of calibration images.

```
images = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
 "calibration","mono"));
```

Detect the calibration pattern.

```
[imagePoints,patternDims] = detectCheckerboardPoints(images.Files);
```

Generate the world coordinates of the corners of the squares. Square size of the checkerboard is 29 millimeters.

```
squareSize = 29; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Calibrate the camera.

```
I = readimage(images,1);
imageSize = [size(I,1) size(I,2)];
[params,~,errors] = estimateCameraParameters(imagePoints,worldPoints, ...
                                    ImageSize=imageSize);
```

Display the standard intrinsics errors.

```
displayErrors(errors.IntrinsicsErrors,params);
```

```
Focal length (pixels):   [  714.1884 +/- 3.3219      710.3783 +/- 4.0579  ]
Principal point (pixels):[  563.6478 +/- 5.3967      355.7255 +/- 3.3036  ]
Radial distortion:       [   -0.3536 +/- 0.0091        0.1730 +/- 0.0488  ]
```

extrinsicsEstimationErrors

Object for storing standard errors of estimated camera extrinsics and distortion coefficients

Description

The `extrinsicsEstimationErrors` object contains the standard errors of estimated camera extrinsics. You can access the extrinsics standard errors using the object properties. You can display the standard errors using the `displayErrors` object function.

Creation

Syntax

```
[params,imgsUsed,Errors] = estimateCameraParameters(imagePoints,worldPoints)
```

Description

`[params,imgsUsed,Errors] = estimateCameraParameters(imagePoints,worldPoints)` creates an `extrinsicsEstimationErrors` object by calling the `estimateCameraParameters` function with image points and world points. The function returns a `stereoCalibrationErrors` or `cameraCalibrationErrors` object as the third argument, which contains the `extrinsicsEstimationErrors` as a read-only property.

Properties

`RotationVectorsError` — Standard error of the camera rotations estimate
scalar

This property is read-only.

Standard error of the camera rotations estimate, specified as a scalar.

`TranslationVectorsError` — Standard error of the camera translations estimate
scalar

Standard error of the camera translations estimate, specified as a scalar.

Examples

Display Extrinsics Errors

Create a set of calibration images.

```
images = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
 "calibration","mono"));
```

Detect the calibration pattern.

```
[imagePoints,patternDims] = detectCheckerboardPoints(images.Files);
```

Generate the world coordinates of the corners of the squares. Square size of the checkerboard is 29 millimeters.

```
squareSize = 29; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Calibrate the camera.

```
I = readimage(images,1);
imageSize = [size(I,1),size(I,2)];
[params,~,errors] = estimateCameraParameters(imagePoints,worldPoints, ...
                                    ImageSize=imageSize);
```

Display the standard extrinsics errors.

```
displayErrors(errors.ExtrinsicsErrors,params);
```

```

BRISKPoints

Object for storing BRISK interest points

Description

This object provides the ability to pass data between the `detectBRISKFeatures` and `extractFeatures` functions. You can also use it to manipulate and plot the data returned by these functions. You can use the object to fill the points interactively in situations where you might want to mix a non-BRISK interest point detector with a BRISK descriptor.

Creation

Syntax

```
points = BRISKPoints(location)
points = BRISKPoints(location,Name=Value)
```

Description

`points = BRISKPoints(location)` constructs a `BRISKPoints` object from `location`, an *M*-by-2 array of [x y] point coordinates.

`points = BRISKPoints(location,Name=Value)` sets properties using one or more name-value arguments, in addition to all input arguments from the previous syntax.

Input Arguments

`location` — Point locations

M-by-2 array

Point locations, specified as an *M*-by-2 array of [*x* *y*] point coordinates.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `points = BRISKPoints(location,Metric=12.0)` specifies a radius of `12.0` (in pixels) of the BRISK sampling pattern used during feature extraction.

`Scale` — Scale

`12.0` (default) | scalar

Scale at which the interest points are detected, specified by the radius (in pixels) of the BRISK sampling pattern used during feature extraction.

`Metric` — Strength of detected feature

`0.0` (default) | numeric scalar

Strength of detected feature, specified as a numeric value. The BRISK algorithm uses the FAST corner score as a metric.

`Orientation` — Orientation of detected feature

`0.0` (default) | angle in radians

Orientation of the detected feature, specified as an angle, in radians. The angle is measured counterclockwise from the *x*-axis with the origin specified by the `Location` property. Do not set this property manually. Use the call to `extractFeatures` to fill in this value. The `extractFeatures` function modifies the default value of `0.0`. Using BRISK interest points to extract a non-BRISK descriptor (e.g. SURF, FREAK, MSER, etc.) can alter `Orientation` values. The `Orientation` is mainly useful for visualization purposes.

Properties

`Count` — Number of points

`0` (default) | integer

This property is read-only.

Number of points held by the BRISK object, specified as a numeric value.

`Location` — Point locations

M-by-2 array

Point locations, specified as an *M*-by-2 array of [x y] point coordinates.

Object Functions

plot	Plot detected feature points
isempty	Determine if points object is empty
length	Number of stored points
selectStrongest	Select points with strongest metrics
size	Return size of points object
selectUniform	Select uniformly distributed subset of point features
select	Select point or region features during code generation

Examples

Detect BRISK Features in an Image

Read an image and detect the BRISK interest points.

```
I = imread('cameraman.tif');
points = detectBRISKFeatures(I);
```

Select and plot the 10 strongest interest points.

```
  strongest = selectStrongest(points, 10);
  imshow(I); hold on;
  plot(strongest);
```

Display the [x y] coordinates.

```
strongest.Location
```

```
ans = 10×2 single matrix

  136.8434  114.7649
  143.7372  126.8453
  135.2803  123.5254
  134.8544  125.0714
  114.8065   47.3621
  105.1597  162.2291
  129.8372  108.4799
  114.6876  131.6573
  135.2267  127.3643
   92.4255   63.2960
```

Tips

Although `BRISKPoints` can hold many points, it is a scalar object. Therefore, `numel(BRISKPoints)` always returns `1`. This value can differ from `length(BRISKPoints)`, which returns the true number of points held by the object.

Version History

Introduced in R2014a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- To index locations with this object, use the syntax: `points.Location(idx,:)`, for `points` object. See visionRecovertformCodeGeneration_kernel.m, which is used in the “Introduction to Code Generation with Feature Matching and Registration” example.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

imageSet

(Removed) Define collection of images

Note The `imageSet` object has been removed. To manage collections of image data use an `imageDatastore` object instead. For more information, see “Version History”.

Description

An `imageSet` object stores information about an image data set or a collection of image data sets. You can use this object to manage your image data. The object contains image descriptions, locations of images, and the number of images in your collection.

Creation

Syntax

```
imgSet = imageSet(imageLocation)
imgSetVector = imageSet(imgFolder,'recursive')
```

Description

`imgSet = imageSet(imageLocation)` creates an `imageSet` object.

`imgSetVector = imageSet(imgFolder,'recursive')` returns a vector of image sets found through a recursive search starting from `imgFolder`. The `imgSetVector` output is a 1-by-*NumFolders* vector of `imageSet` objects, where *NumFolders* is the number of folders that contain at least one image.

Input Arguments

`imageLocation` — Image file location

character vector | cell array

Image file location, specified as a character vector or a cell array. The vector must specify the folder name that contains the images. The image files name extensions must be supported by `imread`. The cell array must contain image locations.

Example: {'*imagePath1*','*imagePath2*', ..., '*imagePathX*'}, where each *imagePath* represents the path to an image.

`imgFolder` — Start recursive image search folder

character vector

Start recursive image search folder, specified as a character vector. The function searches the folder structure recursively, starting from `imgFolder`.

Properties

`Description` — Information about image set
character vector

Information about the image set, specified as a character vector. When you create an image set by recursively searching folders or by specifying a single folder location, the `Description` property is set to the folder name. When you specify individual image files, the `Description` property is not set. You can set the property manually.

Data Types: `char`

`Count` — Number of images in image set
positive integer

Number of images in the image set, specified as a positive integer.

Data Types: `double` | `single`

`ImageLocation` — Image locations
cell array of character vectors

Image locations, specified as a cell array of character vectors.

Data Types: `cell`

Object Functions

partition	(Removed) Divide image set into subsets
read	(Removed) Read image at specified index
select	(Removed) Select subset of images from image set

Version History

Introduced in R2014b

R2024b: Removed
Errors starting in R2024b

`imageSet` has been removed.

R2023b: `imageSet` will be removed in a future release
Not recommended starting in R2023b

`imageSet` will be removed in a future release. Use `imageDatastore` instead, which offers more functionality.

R2016b: `imageSet` is not recommended
Not recommended starting in R2016b

`imageSet` is not recommended. Use `imageDatastore` instead, which offers more functionality.

partition

(Removed) Divide image set into subsets

Note The `partition` function of the `imageSet` object is not recommended. Instead, use the `imageDatastore` object and its `partition` function. For more information, see "Version History".

Syntax

```
[set1,set2,...,setN] = partition(imgSet,groupSizes)
[set1,set2,...,setN] = partition(imgSet,groupPercentages)
[set1,set2,...,setN] = partition( ___ ,method)
```

Description

`[set1,set2,...,setN] = partition(imgSet,groupSizes)` partitions the input image set, `imgSet`, into subsets of size `groupSizes`.

`[set1,set2,...,setN] = partition(imgSet,groupPercentages)` partitions the input image set, `imgSet`, in terms of percentages.

`[set1,set2,...,setN] = partition( ___ ,method)` additionally specifies a method, `'sequential'` or `'randomized'`.

Input Arguments

`imgSet` — Image set

scalar `imageSet` object | array of `imageSet` objects

Image set, specified as a scalar `imageSet` object or an array of `imageSet` objects.

`groupSizes` — Group size

positive integer | vector of positive integers

Group size of images, specified as a positive integer or vector of positive integers. The number of output arguments must be between 1 and `length(groupSizes) + 1`.

Example: `[20 60]` returns 20 images in `set1`, 60 images in `set2`, and any remaining images in `set3`.

`groupPercentages` — Group size percentage

scalar

Group size of images by percentage.

Example: `[0.1 0.5]` returns 10% of images in `set1`, 50% in `set2`, and the remainder in `set3`.

`method` — Image selection method

`'sequential'` (default) | `'randomized'`

Image selection method, specified as either `method` or `'randomized'`. When you set `method` to `'randomized'` the images are randomly selected to form the new sets. When you set `method` to `'sequential'` the images are selected sequentially.

Output Arguments

`set1,set2,...,setN` — Partitioned image sets
array of `imageSet` objects

Partitioned image sets, returned as an array of `imageSet` objects.

Version History

Introduced in R2014b

R2024b: Removed
Errors starting in R2024b

`partition` has been removed.

R2016b: `partition` is not recommended
Not recommended starting in R2016b

The `imageSet` object and its `partition` function are not recommended. Instead, manage collections of image data using an `imageDatastore` object, and partition data in the image datastore using the `partition` function. There are no plans to remove the `partition` function of the `imageSet` object.

See Also

`imageDatastore` | `partition`

read

(Removed) Read image at specified index

Note The `read` function of the `imageSet` object is not recommended. Instead, use an `imageDatastore` object and its `read` and `readimage` functions. For more information, see "Version History".

Syntax

```
im = read(imgSet,idx)
```

Description

`im = read(imgSet,idx)` returns an image from the image set, `imgSet`, located at the index `idx`.

Input Arguments

`imgSet` — Image set
`imageSet` object

Image set, specified as an `imageSet` object.

`idx` — Image location index
positive integer

Image location index, specified as a positive integer.

Output Arguments

`im` — Image
numeric array

Image, returned as a numeric array.

Version History

Introduced in R2014b

R2024b: Removed
Errors starting in R2024b

`partition` has been removed.

R2016b: `read` is not recommended
Not recommended starting in R2016b

The `imageSet` object and its `read` function are not recommended. Instead, manage collections of image data using an `imageDatastore` object, and read images from the image datastore using the

`read` and `readimage` functions. There are no plans to remove the `read` function of the `imageSet` object.

See Also

`imageDatastore` | `read` | `readimage`

select

(Removed) Select subset of images from image set

Note The `select` function of the `imageSet` object is not recommended. Instead, use an `imageDatastore` object and its `subset` function. For more information, see "Version History".

Syntax

```
imgSetOut = select(imgSet,idx)
```

Description

`imgSetOut = select(imgSet,idx)` returns a subset of image set, `imgSet`, using the selection of images specified by the index `idx`.

Input Arguments

`imgSet` — Image set

`imageSet` object

Image set, specified as an `imageSet` object.

`idx` — Image location index

scalar | vector of linear indices | vector of logical indices

Image location index, specified as a scalar, vector of linear indices, or a vector of logical indices. The function uses the `idx` index to select the subset of images.

Output Arguments

`imgSetOut` — Subset of input image set

`imageSet` object

Subset of the input image set, returned as an `imageSet` object.

Version History

Introduced in R2014b

R2024b: Removed

Errors starting in R2024b

`partition` has been removed.

R2016b: `select` is not recommended

Not recommended starting in R2016b

The `imageSet` object and its `select` function are not recommended. Instead, manage collections of image data using an `imageDatastore` object, and select subsets of images from the image datastore

using the `subset` function. There are no plans to remove the `select` function of the `imageSet` object.

See Also

`imageDatastore` | `subset`

invertedImageIndex

Search index that maps visual words to images

Description

An `invertedImageIndex` object is a search index that stores a visual word-to-image mapping. You can use this object with the `retrieveImages` function to search for an image.

Creation

Syntax

```
imageIndex = invertedImageIndex(bag)
imageIndex = invertedImageIndex(bag,'SaveFeatureLocations',tf)
```

Description

`imageIndex = invertedImageIndex(bag)` returns a search index object that stores the visual word-to-image mapping based on the input bag of visual words, `bag`. The `bag` argument sets the bagOfFeatures property.

`imageIndex = invertedImageIndex(bag,'SaveFeatureLocations',tf)` specifies whether or not to save the feature location data in `imageIndex`. To save image feature locations in the `imageIndex` object, specify the logical value `tf` as `true`. You can use location data to verify the spatial or geometric image search results. If you do not require feature locations, you can reduce memory consumption by specifying `tf` as `false`.

Properties

`ImageLocation` — Indexed image locations
cell array

Indexed image locations, specified as a cell array that contains the path and folder locations of images.

`ImageWords` — Visual words
M-element vector of `visualWords` objects

Visual words, specified as a *M*-element vector of `visualWords` objects. *M* is the number of indexed images in the `invertedImageIndex` object. Each `visualWords` object contains the `WordIndex`, `Location`, `VocabularySize`, and `Count` properties for the corresponding indexed image.

`WordFrequency` — Word occurrence
N-element column

Word occurrence, specified as an *N*-element column. The column contains the percentage of images in which each visual word occurs. These percentages are analogous to document frequency in text retrieval applications.

To reduce the search set, when looking for the most relevant images, you can suppress the most common words. You can also suppress rare words that you suspect come from outliers in the image set.

You can control how much the top and bottom end of the visual word distribution affects the search results by tuning the `WordFrequencyRange` property.

`BagOfFeatures` — Bag of visual words
`bagOfFeatures` object

Bag of visual words, specified as the `bagOfFeatures` object used to create the index.

`MatchThreshold` — Required similarity percentage for potential image match
`0.01` (default) | numeric value in range [0,1]

Required similarity percentage for potential image match, specified as a numeric value in the range [0,1]. To obtain more search results, lower this threshold.

`WordFrequencyRange` — Word frequency range
`[0.01 0.9]` (default) | two-element vector

Word frequency range, specified as a two-element vector of a lower and an upper percentage, [*lower upper*]. Percentages must be in the range [0, 1], and the value of *lower* must be less than the value of *upper*. Use the word frequency range to ignore common words (the upper percentage range) or rare words (the lower percentage range) within the image index. These words often occur as repeated patterns or outliers, respectively, and can reduce search accuracy. To find potential values for this property, before you set this value, plot the sorted `WordFrequency` values.

`ImageID` — Indexed image identifiers
vector of integers

Indexed image identifiers, specified as a vector of integers that uniquely identify indexed images. Using the same identifier for `invertedImageIndex` and `imageviewset` eliminates the need to index the same image differently in each object.

Object Functions

addImages	Add new images to image index
removeImages	Remove images from image index
addImageFeatures	Add features of image to image index

Examples

Search ROI for Object

Define a set of images to search.

```
imageFiles = ...
  {'elephant.jpg', 'cameraman.tif', ...
   'peppers.png',  'saturn.png', ...
   'pears.png',    'stapleRemover.jpg', ...
   'football.jpg', 'mandi.tif', ...
   'kids.tif',     'liftingbody.png', ...
   'office_5.jpg', 'gantrycrane.png', ...
```

```
    'moon.tif',     'circuit.tif', ...
    'tape.png',     'coins.png'};

imds = imageDatastore(imageFiles);
```

Learn the visual vocabulary of the image view set.

```
numLevels = 1;
branchingFactor = 1000;
bag = bagOfFeatures(imds,'PointSelection','Detector', ...
  'TreeProperties',[numLevels,branchingFactor]);

Creating Bag-Of-Features.
-------------------------

* Selecting feature point locations using the Detector method.
* Extracting SURF features from the selected feature point locations.
** detectSURFFeatures is used to detect key points for feature extraction.

* Extracting features from 16 images...done. Extracted 3680 features.

* Keeping 80 percent of the strongest features from each category.

* Balancing the number of features across all image categories to improve clustering.
** Image category 1 has the least number of strongest features: 2944.
** Using the strongest 2944 features from each of the other image categories.

* Creating a 1000 word visual vocabulary.
* Number of levels: 1
* Branching factor: 1000
* Number of clustering steps: 1

* [Step 1/1] Clustering vocabulary level 1.
* Number of features          : 2944
* Number of clusters          : 1000
* Initializing cluster centers...100.00%.
* Clustering...completed 6/100 iterations (~0.11 seconds/iteration)...converged in 6 iterations.

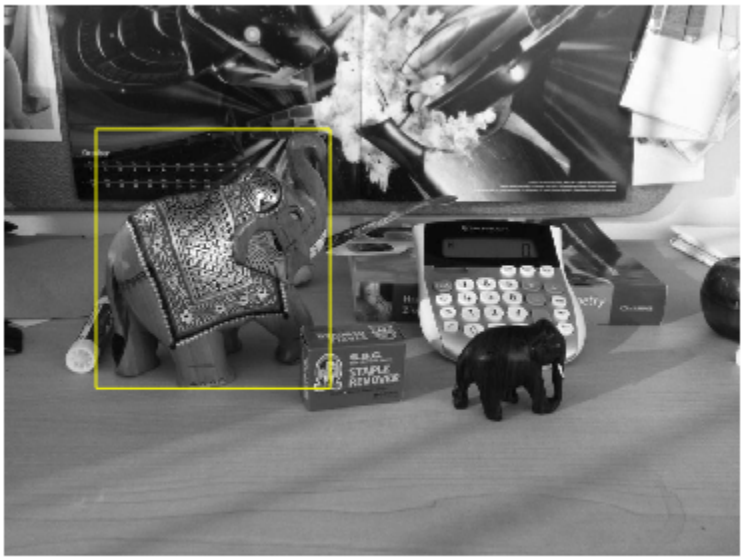
* Finished creating Bag-Of-Features
```

Create an image search index and add the image view set images.

```
imageIndex = invertedImageIndex(bag);

addImages(imageIndex,imds);

Encoding images using Bag-Of-Features.
--------------------------------------



* Encoding 16 images...done.
```

Specify a query image and an ROI in which to search for the target object, an elephant. You can also use the `imrect` function to select an ROI interactively. For example, `queryROI = getPosition(imrect)`.

```
queryImage = imread('clutteredDesk.jpg');
queryROI = [130 175 330 365];

figure
```

```
imshow(queryImage)
rectangle('Position',queryROI,'EdgeColor','yellow')
```

Find images that contain the object.

```
imageIDs = retrieveImages(queryImage,imageIndex,'ROI',queryROI)
```

```
imageIDs = 15×1 uint32 column vector

addImages

Add new images to image index

Syntax

```
addImages(imageIndex,imds)
addImages(imageIndex,I,imageId)
addImages( ___ ,Verbose=tf)
```

Description

`addImages(imageIndex,imds)` adds the images in `imds` to `imageIndex`.

`addImages(imageIndex,I,imageId)` adds an image, `I`, to `imageIndex`, specified by the image identifier `imageId`.

`addImages( ___ ,Verbose=tf)` specifies whether or not to display progress information, in addition to any combination of input arguments from previous syntaxes. By default, the `addImages` function displays progress information. To hide the display, specify `tf` as `false`.

Examples

Add Image to Image Index

Define a set of images to search

```
imageFiles = ...
  {'elephant.jpg', 'cameraman.tif', ...
   'peppers.png',  'saturn.png',...
   'pears.png',    'stapleRemover.jpg', ...
   'football.jpg', 'mandi.tif', ...
   'kids.tif',     'liftingbody.png', ...
   'office_5.jpg', 'gantrycrane.png', ...
   'moon.tif',     'circuit.tif', ...
   'tape.png',     'coins.png'};

imds = imageDatastore(imageFiles);
```

Learn the visual vocabulary of the image view set.

```
numlevels = 1;
branchingFactor = 1000;
bag = bagOfFeatures(imds,'PointSelection','Detector', ...
        'TreeProperties',[numlevels,branchingFactor],'Verbose',false);
```

Create an image search index.

```
imageIndex = invertedImageIndex(bag);
```

Add to the image view set images to the image search index.

```
addImages(imageIndex,imds);

Encoding images using Bag-Of-Features.
--------------------------------------

* Encoding 16 images...done.
```

Input Arguments

`imageIndex` — Image search index

`invertedImageIndex` object

Image search index, specified as an `invertedImageIndex` object.

`imds` — Images

`ImageDatastore` object

Images, specified as an `ImageDatastore` object. `imds` contains new images to add to an existing index. The function does not ignore duplicate images.

`I` — Input image

M-by-*N*-by-3 array | *M*-by-*N* 2-D matrix

Input image, specified as either an *M*-by-*N*-by-3 array, representing a truecolor image, or an *M*-by-*N* array, representing a 2-D grayscale image.

`imageId` — Indexed image identifier

positive integer

Indexed image identifier, specified as an positive integer.

Tips

- The `addImages` function supports parallel computing using multiple MATLAB workers. Enable parallel computing from the “Computer Vision Toolbox Preferences” dialog box. To open Computer Vision Toolbox preferences, on the **Home** tab, in the **Environment** section, select **Preferences**. Then select **Computer Vision Toolbox**.

Version History

Introduced in R2015a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

For code generation, the `addImages` object does not support the `ImageDatastore` object as input. Instead, specify the input as a structure with fields `Images` and `Locations`. The `Images` field must contain a cell array of grayscale or RGB color images. The `Locations` field must contain a cell array of the file paths to the locations of input images.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

removeImages

Remove images from image index

Syntax

```
removeImages(imageIndex,imageIds)
```

Description

`removeImages(imageIndex,imageIds)` removes the images from the `imageIndex` object that correspond to the `imageIds` input.

Examples

Remove Indexed Image

Create image set.

```
dataDir  = fullfile(toolboxdir('vision'),'visiondata','imageSets','cups');
imds = imageDatastore(dataDir);
```

Index the image set.

```
imageIndex = indexImages(imds)
```

* Finished creating Bag-Of-Features
```

Create an image search index.

```
imageIndex = invertedImageIndex(bag,'SaveFeatureLocations',false);
```

Load an image and extract features from it.

```
I = imread('coins.png');
```

Detect SURF points from the image.

```
points = detectSURFFeatures(I);
```

Extract image features from the SURF points.

```
features = extractFeatures(I,points);
```

Add the image features into the image index.

```
imageId = 1;
addImageFeatures(imageIndex,features,imageId)
```

Input Arguments

`imageIndex` — Image search index

`invertedImageIndex` object

Image search index, specified as an `invertedImageIndex` object.

`features` — Feature descriptors

M-by-*N* matrix | `binaryFeatures` object

Feature descriptors, specified as an *M*-by-*N* matrix or a `binaryFeatures` object. Each descriptor is of length *N*. To add image features to the image index using `addImageFeatures`, you must set the `SaveFeatureLocations` property of the `invertedImageIndex` object to `false`.

`imageId` — Indexed image identifier

positive integer

Indexed image identifier, specified as a positive integer.

Version History

cameraCalibrationErrors

Object for storing standard errors of estimated camera parameters

Description

`cameraCalibrationErrors` contains the standard errors of estimated camera parameters. You can access the intrinsics and extrinsics standard errors using the object properties. You can display the standard errors using the object's `displayErrors` object function.

Creation

Create a `cameraCalibrationErrors` object by calling the `estimateCameraParameters` function.

Properties

`IntrinsicsErrors` — Standard intrinsics error
`intrinsicsEstimationErrors` object

Standard error of the estimated intrinsics for a camera, specified as a `intrinsicsEstimationErrors` object.

`ExtrinsicsErrors` — Standard extrinsics error
`extrinsicsEstimationErrors` object

Standard error of the estimate rotations and translations for a camera relative to the calibration pattern, specified as a `extrinsicsEstimationErrors` object.

Object Functions

displayErrors Display standard errors of camera parameter estimates

Examples

Estimate and Display Camera Calibration Standard Errors

Create a set of calibration images.

```
images = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
 "calibration","mono"));
```

Detect the calibration pattern.

```
[imagePoints,patternDims] = detectCheckerboardPoints(images.Files);
```

Generate the world coordinates of the corners of the squares. The units of the square size are in millimeters.

```
squareSize = 29; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Calibrate the camera.

```
I = readimage(images,1);

stereoCalibrationErrors

Object for storing standard errors of estimated stereo parameters

Description

The `stereoCalibrationErrors` object contains the standard errors of the estimated calibration parameters of a pair of stereo cameras. The object stores the estimated intrinsic parameters for camera one and camera two, the extrinsic parameters for camera one, and the rotation and translation of camera two relative to camera one. You can access the standard error values by using the object properties. To display the standard errors, use the `displayErrors` object function.

Creation

Create a stereo camera calibration errors object by using the `estimateCameraParameters` function to calibrate a pair of stereo cameras. The `stereoCalibrationErrors` object is the third output argument of the `estimateCameraParameters` function. For example:

```
[params,imgsUsed,Errors] = estimateCameraParameters(imagePoints,worldPoints)
```

Properties

`Camera1IntrinsicsErrors` — Standard errors of estimated intrinsic parameters and distortion coefficients for camera one
`intrinsicsEstimationErrors` object

Standard errors of estimated intrinsic parameters and distortion coefficients for camera one, specified as an `intrinsicsEstimationErrors` object.

`Camera1ExtrinsicsErrors` — Standard errors of estimated extrinsic parameters and distortion coefficients for camera one
`extrinsicsEstimationErrors` object

Standard errors of estimated extrinsic parameters and distortion coefficients for camera one, specified as an `extrinsicsEstimationErrors` object.

`Camera2IntrinsicsErrors` — Standard errors of estimated intrinsic parameters and distortion coefficients for camera two
`intrinsicsEstimationErrors` object

Standard errors of estimated intrinsic parameters and distortion coefficients for camera two, specified as an `intrinsicsEstimationErrors` object.

`RotationOfCamera2Error` — Standard errors of rotated vector of camera two relative to camera one
three-element vector

Standard errors of the rotated vector of camera two relative to camera one, specified as a three-element vector.

`TranslationOfCamera2Error` — Standard errors of translation of camera two relative to camera one
three-element vector

Standard errors of the translation of camera two relative to camera one, specified as a three-element vector.

Object Functions

displayErrors Display standard errors of stereo camera parameter estimation

Examples

Estimate and Display Stereo Calibration Standard Errors

Specify two sets of calibration images.

```
imageDir = fullfile(toolboxdir("vision"),"visiondata", ...
  "calibration","stereo");
leftImages = imageDatastore(fullfile(imageDir,"left"));
rightImages = imageDatastore(fullfile(imageDir,"right"));
```

Detect the checkerboards.

```
[imagePoints,patternDims] = detectCheckerboardPoints( ...
  leftImages.Files,rightImages.Files);
```

Generate the world coordinates of the corners of the squares. Square size is in millimeters.

```
squareSize = 108; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Calibrate the stereo camera system. Here, both cameras have the same resolution.

```
I = readimage(leftImages,1);
imageSize = size(I,1:2);
[params, ~, errors] = estimateCameraParameters(imagePoints,worldPoints, ...
                                  ImageSize=imageSize);
```

Display standard stereo calibration errors.

```
displayErrors(errors,params);
```

```

displayErrors

Display standard errors of stereo camera parameter estimation

Syntax

```
displayErrors(estimationErrors,stereoParams)
```

Description

`displayErrors(estimationErrors,stereoParams)` displays the standard errors of stereo camera parameter estimation, as well as the estimated parameters, from the calibration of a pair of stereo cameras.

Examples

Estimate and Display Stereo Calibration Standard Errors

Specify two sets of calibration images.

```
imageDir = fullfile(toolboxdir("vision"),"visiondata", ...
  "calibration","stereo");
leftImages = imageDatastore(fullfile(imageDir,"left"));
rightImages = imageDatastore(fullfile(imageDir,"right"));
```

Detect the checkerboards.

```
[imagePoints,patternDims] = detectCheckerboardPoints( ...
  leftImages.Files,rightImages.Files);
```

Generate the world coordinates of the corners of the squares. Square size is in millimeters.

```
squareSize = 108; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Calibrate the stereo camera system. Here, both cameras have the same resolution.

```
I = readimage(leftImages,1);
imageSize = size(I,1:2);
[params, ~, errors] = estimateCameraParameters(imagePoints,worldPoints, ...
                                    ImageSize=imageSize);
```

Display standard stereo calibration errors.

```
displayErrors(errors,params);
```

```

Input Arguments

`estimationErrors` — Estimation errors
`stereoCalibrationErrors` object

Estimation errors, specified as a `stereoCalibrationErrors` object.

`stereoParams` — Stereo parameters
`stereoParameters` object

Stereo parameters, specified as a `stereoParameters` object.

Object for storing MSER regions

Description

This object describes MSER regions and corresponding ellipses that have the same second moments as the regions. It passes data between the `detectMSERFeatures` and `extractFeatures` functions. The object can also be used to manipulate and plot the data returned by these functions.

Creation

Syntax

```
regions = MSERRegions(pixellist)
```

Description

`regions = MSERRegions(pixellist)` constructs an MSER regions object, `regions` regions from the pixel list,`pixellist`.

Input Arguments

`pixellist` — Point coordinates for detected MSER regions

M-by-1 cell array

Point coordinates for detected MSER regions, specified as a *M*-by-1 cell array. Each cell contains a *P*-by-2 array of [x y] coordinates for the detected MSER regions, where *P* varies based on the number of pixels in a region.

Properties

`Location` — Locations of ellipses

M-by-2 array (default)

This property is read-only.

Locations of ellipses, stored as an *M*-by-2 array of [*x y*] coordinates. The ellipses that have the same second moments as the MSER regions.

`Axes` — Major and minor axis

two-element vector (default)

This property is read-only.

Major and minor axis, stored as a two-element vector, [majorAxis minorAxis]. This vector specifies the major and minor axis of the ellipse that have the same second moments as the MSER regions.

`Orientation` — Ellipse orientation

scalar in the range -pi/2 to +pi/2

This property is read-only.

Ellipse orientation, stored as a value in the range from -pi/2 to +pi/2 radians. This value represents the orientation of the ellipse as measured from the *X*-axis to the major axis of the ellipse. You can use this property for visualization purposes.

`Count` — Number of stored regions

`0` (default) | integer

Number of stored regions, specified as an integer.

Object Functions

isempty	Determine if points object is empty
length	Number of stored points
size	Return size of points object
plot	Plot MSER regions
select	Select point or region features during code generation

Examples

Detect MSER Features in an Image

Load an image.

```
I = imread('cameraman.tif');
```

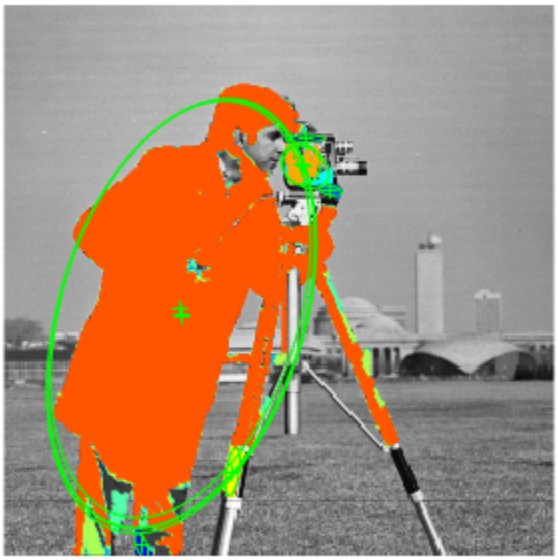
Detect and store regions.

```
regions = detectMSERFeatures(I);
```

Display the centroids and axes of detected regions.

```
imshow(I); hold on;
plot(regions);
```

Display MSER Feature Regions from the MSERRegions Object



Detect and display the first 10 regions contained in the MSERRegions object.

Detect MSER features.

```
I = imread('cameraman.tif');
regions = detectMSERFeatures(I);
```

Display the first 10 regions in the MSERRegions object.

```
imshow(I); hold on;
plot(regions(1:10),'showPixelList', true);
```

Combine MSER Region Detector with SURF Descriptors

Extract and display SURF descriptors at locations identified by MSER detector.

Read image.

```
I = imread('cameraman.tif');
```

Detect MSER features.

```
regionsObj = detectMSERFeatures(I);
```

Extract and display SURF descriptors.

```
[features, validPtsObj] = extractFeatures(I, regionsObj);
imshow(I); hold on;
plot(validPtsObj,'showOrientation',true);
```

Tips

Although `MSERRegions` may hold many regions, it is a scalar object. Therefore, `numel(MSERRegions)` always returns `1`. This value may differ from `length(MSERRegions)`, which returns the true number of regions held by the object.

Version History

Introduced in R2012a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- For code generation, you must specify both the `pixellist` cell array and the `length` of each array, as the second input. The object outputs, `regions.PixelList` as an array. The region sizes are defined in `regions.Lengths`.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

cornerPoints

Object for storing corner points

Description

This object stores information about point features detected from a 2-D grayscale image.

Creation

Syntax

```
points = cornerPoints(location)
points = cornerPoints(location,Name,Value)
```

Description

`points = cornerPoints(location)` constructs a `cornerPoints` object from an *M*-by-2 array [*x y*] of location coordinates.

`points = cornerPoints(location,Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `points = cornerPoints('Metric',0.0)`

Input Arguments

`location` — Location coordinates

M-by-2 array

Location of points, specified as an *M*-by-2 array of [*x y*] coordinates.

Properties

`Location` — Location of keypoints

`[]` (default) | *M*-by-2 matrix

This property is read-only.

Location of keypoints, specified as an *M*-by-2 matrix. Each row is of the form [*x y*] and represents the location of a keypoint. *M* is the number of keypoints. You cannot set this property, use the `location` input argument instead.

`Count` — Number of points

`0` (default) | integer

Number of points held by the corner points object, specified as a numeric value.

`Metric` — Strength of detected feature

`0.0` (default) | numeric scalar

Strength of detected feature, specified as a numeric value. The algorithm uses a determinant of an approximated Hessian.

Object Functions

plot	Plot detected feature points
isempty	Determine if points object is empty
length	Number of stored points
selectStrongest	Select points with strongest metrics
size	Return size of points object
selectUniform	Select uniformly distributed subset of point features
select	Select point or region features during code generation
gather	Retrieve cornerPoints from the GPU

Examples

Plot Strongest Features from Detected Point Features

Read an image.

```
I = imread('cameraman.tif');
```

Detect point features.

```
points = detectHarrisFeatures(I);
```

Display the ten strongest points.

```
strongest = selectStrongest(points,10);
imshow(I)
hold on
plot(strongest)
```

Display the (x,y) coordinates of the strongest points.

```
strongest.Location
```

```
ans = 10×2 single matrix

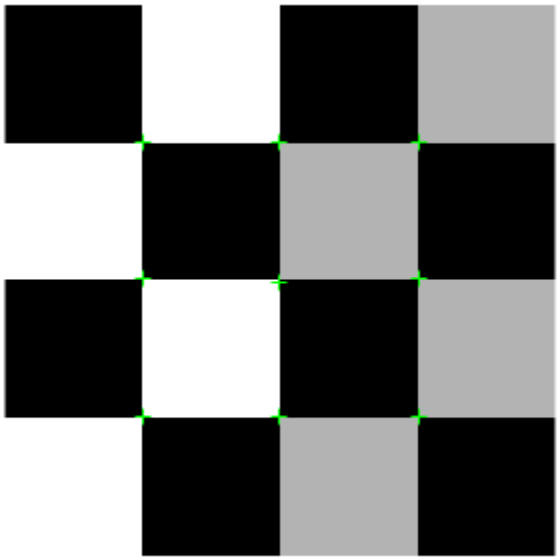
  112.4516  208.4412
  108.6510  228.1681
  136.6969  114.7962
  181.4160  205.9876
  135.5823  123.4529
  100.4951  174.3253
  146.7581   94.7393
  135.2899   92.6485
  129.8439  110.0350
  130.5716   91.0424
```

Create Corner Points Object and Display Points

Create a checkerboard image.

```
I = checkerboard(50,2,2);
```

Load the locations of corner points.



```
location = [51    51    51   100   100   100   151   151   151; ...
            50   100   150    50   101   150    50   100   150]';
```

Save the points in a `cornerPoints` object.

```
points = cornerPoints(location);
```

Display the points on the checkerboard.

```
imshow(I)
hold on
plot(points)
```

Tips

Although `cornerPoints` may hold many points, it is a scalar object. Therefore, `numel(cornerPoints)` always returns `1`. This value may differ from `length(cornerPoints)`, which returns the true number of points held by the object.

Version History

Introduced in R2012a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- To index locations with this object, use the syntax: `points.Location(idx,:)`, for `points` object. See visionRecovertformCodeGeneration_kernel.m, which is used in the “Introduction to Code Generation with Feature Matching and Registration” example.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

SURFPoints

Object for storing SURF interest points

Description

This object provides the ability to pass data between the `detectSURFFeatures` and `extractFeatures` functions. It can also be used to manipulate and plot the data returned by these functions. You can use the object to fill the points interactively. You can use this approach in situations where you might want to mix a non-SURF interest point detector with a SURF descriptor.

Creation

Syntax

```
points = SURFPoints(location)
```

Description

`points = SURFPoints(location)` constructs a `SURFPoints` object from an *M*-by-2 array of [*x y*] point coordinates.

Input Arguments

`location` — Point coordinates

M-by-2 array of [*x y*] point coordinates.

Point coordinates, specified as an *M*-by-2 array of form [*x y*] coordinates. *M* denotes the number of points.

Properties

`Count` — Number of points

`0` (default) | integer

Number of points held by the object, specified as a numeric value.

`Location` — Point locations

M-by-2 array

Point locations, specified as an *M*-by-2 array of [*x y*] point coordinates.

`Scale` — Scale

`1.6` (default) | numeric scalar | *M*-element vector

Scale at which the feature was detected, specified as a numeric scalar or as an *M*-element vector. Values must be greater than or equal to `1.6`.

`Metric` — Strength of detected feature

`0.0` (default) | numeric scalar | *M*-element vector

Strength of detected feature, specified as a numeric value or as an *M*-element vector. The SURF algorithm uses a determinant of approximated Hessian as the metric.

`Orientation` — Orientation

`0.0` (default) | angle in radians | numeric scalar | *M*-element vector

Orientation of the detected feature, specified as a numeric scalar or an *M*-element vector. Values must be an angle, in radians. The angle is measured counter-clockwise from the X-axis with the origin specified by the `Location` property. Do not set this property manually. Rely instead, on the call to `extractFeatures` to fill in this value. The `extractFeatures` function modifies the default value of `0.0`.The `Orientation` is mainly useful for visualization purposes.

`SignOfLaplacian` — Sign of Laplacian

`0` (default) | `-1` | `1`

Sign of the Laplacian determined during the detection process, specified as `-1`, `0`, or `1`. You can use this parameter to accelerate the feature matching process.

Blobs with identical metric values but different signs of Laplacian can differ by their intensity values. For example, a white blob on a background versus a black blob on a white background. You can use this parameter to quickly eliminate blobs that do not match.

For non-SURF detectors, this property is not relevant. For example, for corner features, you can simply use the default value of `0`.

Object Functions

plot	Plot detected feature points
isempty	Determine if points object is empty
length	Number of stored points
selectStrongest	Select points with strongest metrics
size	Return size of points object
selectUniform	Select uniformly distributed subset of point features
select	Select point or region features during code generation

Examples

Detect SURF Features

Read in image.

```
I = imread('cameraman.tif');
```

Detect SURF features.

```
points = detectSURFFeatures(I);
```

Display location and scale for the 10 strongest points.

```
strongest = points.selectStrongest(10);
imshow(I); hold on;
plot(strongest);
```

Display [x y] coordinates for the 10 strongest points on command line.

```
strongest.Location
```

```
ans = 10×2 single matrix

  139.7482   95.9542
  107.4502  232.0347
  116.6112  138.2446
  105.5152  172.1816
  113.6975   48.7220
  104.4210   75.7348
  111.3914  154.4597
  106.2879  175.2709
  131.1298   98.3900
  124.2933   64.4942
```

Detect SURF Features and Display the Last 5 Points

Read in image.

```
I = imread('cameraman.tif');
```

Detect SURF feature.

```
points = detectSURFFeatures(I);
```

Display the last 5 points.

```
imshow(I); hold on;
plot(points(end-4:end));
```

Tips

Although `SURFPoints` may hold many points, it is a scalar object. Therefore, `numel(points)` always returns `1`. This value may differ from `length(points)`, which returns the true number of points held by the object.

ORBPoints

Object for storing ORB keypoints

Description

An `ORBPoints` object stores the Oriented FAST and rotated BRIEF (ORB) keypoints in an image. You can specify the keypoints and store them as an `ORBPoints` object. You can also use the `detectORBFeatures` function to detect the ORB keypoints in an image. The `detectORBFeatures` function stores the detected ORB keypoints as an `ORBPoints` object. Use “Object Functions” on page 2-842 to plot, select, and manipulate the detected ORB keypoints.

Creation

Syntax

```
points = ORBPoints
points = ORBPoints(location)
points = ORBPoints(location,Name,Value)
```

Description

`points = ORBPoints` creates an `ORBPoints` object with default property values.

`points = ORBPoints(location)` creates an `ORBPoints` object from a set of location coordinates specified by `location`. The location input sets the `Location` property.

`points = ORBPoints(location,Name,Value)` sets properties of the object using one or more name-value pair arguments. Enclose each property name in quotes. For example, `ORBPoints(location,'Count',15)` creates an `ORBPoints` object with `Count` property set to 15.

Properties

`Location` — Location of keypoints

[ ] (default) | *M*-by-2 matrix

This property is read-only.

Location of keypoints, specified as an *M*-by-2 matrix. Each row is of the form [*x* *y*] and represents the location of a keypoint. *M* is the number of keypoints. You cannot set this property as a name-value pair. Use the `location` input argument.

`Metric` — Strength of keypoints

[ ] (default) | scalar | *M*-element vector.

This property is read-only.

Strength of keypoints, specified as one of these values:

- A scalar — Detected keypoints have the same strength. In this case, the object assigns the same `Metric` value to all keypoints.
- An *M*-element vector — Detected keypoints have different strength values. In this case, the object assigns different `Metric` value to each keypoint. *M* is the number of keypoints.

Example: `ORBPoints(location,'Metric',0.5)`

Data Types: `single`

`Count` — Number of keypoints
`0` (default) | nonnegative integer

This property is read-only.

Number of keypoints held by the object, specified as a nonnegative integer.

`Scale` — Scale factor
`[]` (default) | scalar | *M*-element vector

This property is read-only.

Scale factor, specified as one of these values:

- A scalar — All keypoints are detected at the same level of decomposition. In this case, the object assigns the same `Scale` value to all keypoints.
- An *M*-element vector — The keypoints are detected at different levels of decomposition. In this case, the object assigns different `Scale` value to each keypoint. *M* is the number of keypoints.

The scale factor specifies the level of decomposition at which a keypoint is detected.

Example: `ORBPoints(location,'Scale',1.2)`

Data Types: `single`

`Orientation` — Angle of keypoints in radians
`[]` (default) | scalar | *M*-element vector

This property is read-only.

Angle of keypoints in radians, specified as one of these values:

- A scalar — Detected keypoints are of the same orientation. In this case, the object assigns the same `Orientation` value to all keypoints.
- An *M*-element vector — Detected keypoints are of different orientation. In this case, the object assigns different `Orientation` value to each keypoint. *M* is the number of keypoints.

The angle made by a keypoint is defined with reference to the horizontal axis of the image. The coordinate of the keypoint is set as the origin of the axis.

Example: `ORBPoints(location,'Orientation',0.7854)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Object Functions

isempty	Determine if points object is empty

length	Number of stored points
plot	Plot detected feature points
selectStrongest	Select points with strongest metrics
size	Return size of points object
selectUniform	Select uniformly distributed subset of point features
select	Select point or region features during code generation

Examples

Create and Modify Properties of ORBPoints

Read an image into the workspace.

```
I = imread('licensePlates.jpg');
```

Convert the image into a grayscale image.

```
I = im2gray(I);
```

Specify the location of keypoints in the image.

```
location = [400 398; ...
            485 343; ...
            274 323; ...
            274 367; ...
            241 313; ...
            302 213];
```

Create an `ORBPoints` object and display its properties.

```
points = ORBPoints(location)
```

```
points =
  6×1 ORBPoints array with properties:

       Location: [6×2 single]
         Metric: [6×1 single]
          Count: 6
          Scale: [6×1 single]
    Orientation: [6×1 single]
```

Inspect the `Scale` and `Orientation` properties of the `ORBPoints` object.

```
points.Scale
```

```
ans = 6×1 single column vector

     1
     1
     1
     1
     1
     1
```

```
points.Orientation
```

```
ans = 6×1 single column vector

     0
     0
     0
     0
     0
     0
```

Specify the scale value for each keypoint.

```
scale = [2.1 2.5 2.5 4 2.3 3.9];
```

Specify the angle values for the keypoints as 0.7854 radians.

```
angle = 0.7854;
```

Create an `ORBPoints` object with the keypoints and the updated scale and angle values. The output is an `ORBPoints` object containing keypoints with the modified `Scale` and `Orientation` properties.

```
points = ORBPoints(location,'Scale',scale,'Orientation',angle);
```

Inspect the updated `Scale` values.

```
points.Scale
```

```
ans = 6×1 single column vector

    2.1000
    2.5000
    2.5000
    4.0000
    2.3000
    3.9000
```

Inspect the updated `Orientation` values. Since the `Orientation` value is a scalar, the object assigns same value to all keypoints.

```
points.Orientation
```

```
ans = 6×1 single column vector

    0.7854
    0.7854
    0.7854
    0.7854
    0.7854
    0.7854
```

Display the image and plot the ORB keypoints on the image.

```
figure
imshow(I)
hold on
plot(points)
```

Detect and Store ORB Keypoints

Read an image into the workspace.

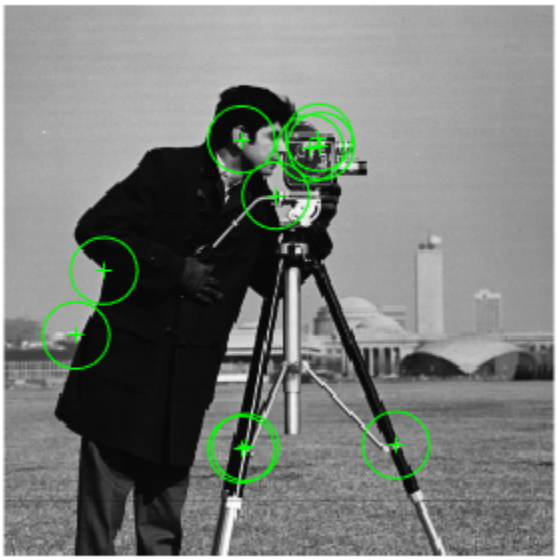
```
I = imread('cameraman.tif');
```

Use the `detectORBFeatures` function to detect ORB keypoints in the image. The function returns the detected ORB keypoints as an `ORBPoints` object.

```
points = detectORBFeatures(I);
```

Use the `selectUniform` object function to select 10 ORB keypoints. The output of the `selectUniform` object function is an `ORBPoints` object.

```
newPoints = selectUniform(points,10,size(I))
```



```
newPoints =
  10×1 ORBPoints array with properties:

       Location: [10×2 single]
         Metric: [10×1 single]
          Count: 10
          Scale: [10×1 single]
    Orientation: [10×1 single]
```

Display the location and scale of the selected keypoints on the image.

```
figure
imshow(I)
```

```
hold on
plot(newPoints)
```

Display the (*x*, *y*) coordinates of the selected keypoints.

```
x = newPoints.Location(:,1);
y = newPoints.Location(:,2);
[x y]
```

```
ans = 10×2 single matrix

   147    62
   111    63
   143    67
   127    89
    47   124
    34   154
   183   205
   113   206
   111   207
   148    66
```

Display the orientation of the selected keypoints.

```
newPoints.Orientation
```

```
ans = 10×1 single column vector

    5.4682
    0.7888
    5.3084
    6.2443
    2.8221
```

```
    3.8440
    6.1212
    6.0344
    4.8840
    5.5535
```

Tips

Although `ORBPoints` can hold many points, it is a scalar object. Therefore, `numel(ORBPoints)` always returns 1. This value can differ from `length(ORBPoints)`, which returns the true number of points held by the object.

Version History

Introduced in R2019a

vision.AlphaBlender

Namespace: `vision`

(Not recommended) Combine images, overlay images, or highlight selected pixels

Note The `vision.AlphaBlender` System object™ is not recommended. Use the `imblend` function to blend two images, instead.

Description

The `AlphaBlender` System object combines two images, overlays one image over another, or highlights selected pixels.

To combine two images, overlay one image over another, or highlight selected pixels:

1. Create the `vision.AlphaBlender` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
alphablend = vision.AlphaBlender
alphablend = vision.AlphaBlender(Name,Value)
```

Description

`alphablend = vision.AlphaBlender` creates an alpha blender System object, `alphablend`, which combines two images, overlays one image over another, or highlights selected pixels.

`alphablend = vision.AlphaBlender(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `alphablend = vision.AlphaBlender('Operation','Blend')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Operation` — Operation

`'Blend'` | `'Binary mask'` | `'Highlight selected pixels'`

Operation, specified as `'Blend'`, `'Binary mask'`, or `'Highlight selected pixels'`.

Operation	Description
`'Blend'`	Linearly combine the pixels of one image with the another image.
`'Binary mask'`	Overwrite the pixel values of one image with the pixel values of another image.
`'Highlight selected pixels'`	Uses the `mask` binary image input to determine which pixels are set to the maximum value supported by their data type.

`OpacitySource` — Source of opacity factor
`Property` (default) | `'Input port'`

Source of opacity factor, specified as `'Property'` or `'Input port'`. This property applies when you set the `Operation` property to `Blend`.

`Opacity` — Pixel scale value
`0.75` (default) | scalar | matrix

Pixel scale value, specified as a scalar or matrix. The object scales each pixel before combining the images. This property applies when you set the `OpacitySource` property to `Property`.

Tunable: Yes

`MaskSource` — Binary mask source
`'Property'` (default) | `'Input port'`

Binary mask source, specified as `'Property'` or `'Input port'`. This property applies when you set the `Operation` property to `Binary mask`

`Mask` — Overwrite scalar
`1` (default) | `0` | `binary scalar` | matrix of binary scalars

Overwrite scalar, specified as `0` or `1` for every pixel, or a matrix of `0`s and `1`s. This property applies when you set the `MaskSource` property to `Property`.

Tunable: Yes

`LocationSource` — Source for upper-left location
`'Property'` (default) | `'Input port'`

Source of location of the upper-left corner of second input image

Source for the upper-left corner location of the second input image, specified as `Property` or `Input port`.

`Location` — Location
`[1 1]` | two-element vector

Location of the upper-left corner of the second input image relative to the location of the first input image, specified as a two-element vector in the format [x y]. This property applies when you set the `LocationSource` property to `Property`.

See “Coordinate Systems” for a discussion on pixel coordinates and spatial coordinates, which are the two main coordinate systems used in the Computer Vision Toolbox.

Tunable: Yes

Fixed-Point Properties

`RoundingMethod` — Rounding method
`'Floor'` (default) | `'Convergent'` | `'Floor'` | ...

Rounding method, specified as `'Ceiling'`,`'Convergent'`, `'Floor'`, `'Nearest'`, `'Round'`, `'Simplest'`, or `'Zero'`.

`OverflowAction` — Overflow action
`'Wrap'` (default) | `'Saturate'`

Overflow action for fixed-point operations, specified as `'Wrap'` or `'Saturate'`.

`OpacityDataType` — Opacity word and fraction lengths
`'Same word length as input'` (default) | `'Custom'`

Opacity word and fraction lengths for fixed-point operations, specified as `'Same word length as input'` or `'Custom'`.

`CustomOpacityDataType` — Opacity word and fraction lengths
`numerictype([],16)` (default) | unscaled numerictype object

Opacity word and fraction lengths factor for fixed-point operations, specified as an unscaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OpacityDataType` property to `Custom`

`ProductDataType` — Product word and fraction lengths
`'Custom'` (default) | `'Same as first input'`

Product word and fraction lengths, specified as `'Custom'` or `'Same as first input'`.

`CustomProductDataType` — Product word and fraction lengths
`numerictype([],32,10)` (default) | scaled numerictype object

Product word and fraction lengths, specified as a scaled `numerictype` object with a `'Signedness'` of `'Auto'`. This property applies when you set the `'ProductDataType'` property to `'Custom'`

`AccumulatorDataType` — Accumulator word and fraction lengths
`'Same as product'` (default) | `'Custom'`

Accumulator word and fraction lengths, specified as `'Same as product'`, `'Same as first input'`, or `'Custom'`.

`CustomAccumulatorDataType` — Accumulator word and fraction lengths
`numerictype([],32,10)` (default) | scaled numerictype object

Accumulator word and fraction lengths, specified as a scaled `numerictype` object with a `'Signedness'` of `'Auto'`.

`OutputDataType` — Output word and fraction lengths
`'Same as product'` (default) | `'Custom'`

Output word and fraction lengths, specified as `'Same as first input'` or `'Custom'`.

`CustomOutputDataType` — Output word and fraction lengths
`numerictype([],32,10)` (default) | scaled numerictype object

Output word and fraction lengths, specified as a scaled `numerictype` object with a `'Signedness'` of `'Auto'`.

Usage

Syntax

```
ab = alphablend(I1,I2)
ab = alphablend(I1,I2,opacity)
ab = alphablend(I1,I2,mask)
ab = alphablend(I1,mask)
ab = alphablend(I1,I2,___,location)
```

Description

`ab = alphablend(I1,I2)` returns an alpha blender object that blends images `I1` and `I2`.

`ab = alphablend(I1,I2,opacity)` uses the `opacity` input to combine pixel values of `I1` and `I2`. To use the `opacity` input, you must set the `Operation` property to '`Blend`' and the `OpacitySource` property to '`Input port`'

`ab = alphablend(I1,I2,mask)` uses the `mask` input to overlay `I1` over `I2`. To use the `mask` input with an overlay, you must set the `Operation` property to `'Binary mask'` and the `MaskSource` property to `'Input port'`.

`ab = alphablend(I1,mask)` uses the `mask` input to determine which pixels in `I1` are set to the maximum value supported by their data type. To use the `mask` input with an overlay, you must set the `Operation` property to `'Highlight selected pixels'` and the `MaskSource` property to `'Input port'`.

`ab = alphablend(I1,I2,___,location)` additionally sets the upper-left corner `location` for `I2`. To use the `location` input, you must set the `LocationSource` property to `'Input port'`.

Input Arguments

`I1` — Input image
M-by-*N*-by-3 truecolor | *M*-by-*N* 2-D grayscale image

Input image, specified in truecolor or 2-D grayscale.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16`

`I2` — Input image
M-by-*N*-by-3 truecolor | *M*-by-*N* 2-D grayscale image

Input image, specified in truecolor or 2-D grayscale.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16`

`opacity` — Scale
scalar | matrix

Pixel scale value, specified as a scalar or matrix. The object scales each pixel before combining the images.

`mask` — Overwrite scalar
`binary scalar` | matrix of binary scalars

Overwrite scalar, specified as `0` or `1` for every pixel, or a matrix of `0`s and `1`s.

`location` — Location
two-element vector

Location of the upper-left corner of the second input image relative to the location of the first input image, specified as a two-element vector in the format [x y].

Tunable: Yes

Output Arguments

`alphablend` — Blended output image
M-by-*N*-by-3 truecolor | *M*-by-*N* 2-D grayscale image

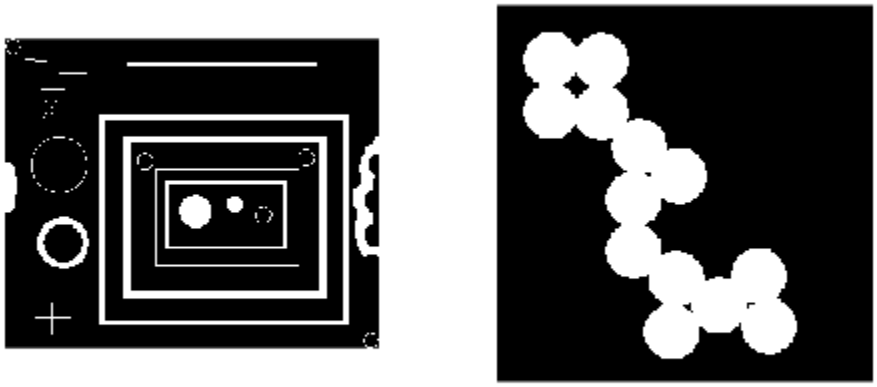
Output blended image, returned as a combined image, overlaid image, or an image with selected pixels highlighted.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

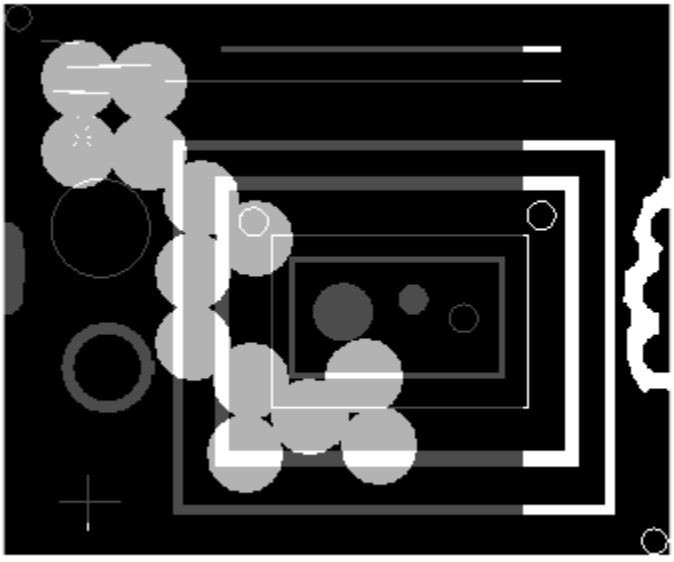
Common to All System Objects



step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Blend Two Images



Display the two images.

```
I1 = im2single(imread("blobs.png"));
I2 = im2single(imread("circles.png"));
subplot(1,2,1);
imshow(I1);
subplot(1,2,2);
imshow(I2);
```

Blend the two images and display the result.

```
J = imblend(I2,I1);
figure;
imshow(J);
```

Version History

Introduced in R2012a

R2026a: vision.AlphaBlender system object warns
Warns starting in R2026a

The `vision.AlphaBlender` system object issues a warning that it will be removed in a future release. Use the `imblend` function to blend two images, instead.

R2024b: vision.AlphaBlender system object is not recommended
Not recommended starting in R2024b

The `vision.AlphaBlender` system object is not recommended and will be removed in a future release. Use the `imblend` function to blend two images, instead.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

vision.BinaryFileReader

Namespace: `vision`

Read video data from binary files

Description

The `BinaryFileReader` object reads video data from binary files.

To read a binary file:

1. Create the `vision.BinaryFileReader` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
bFileReader = vision.BinaryFileReader
bFileReader = vision.BinaryFileReader(Name,Value)
bFileReader = vision.BinaryFileReader(file,Name,Value)
```

Description

`bFileReader = vision.BinaryFileReader` returns a binary file reader object, `bFileReader`, that reads binary video data from the specified file in `I420` Four Character Code (FOURCC) video format.

`bFileReader = vision.BinaryFileReader(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `bFileReader = vision.BinaryFileReader('Filename','vipmen.bin')`

`bFileReader = vision.BinaryFileReader(file,Name,Value)` returns a binary file reader System object, `bFileReader`, with the `Filename` property set to `file` and other specified properties set to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Filename` — File name
`vipmen.bin` (default) | character vector

File name, specified as a character vector. The full path for the file needs to be specified only if the file is not on the MATLAB path.

`VideoFormat` — Video file format
`'Four character codes'` (default) | `'Custom'`

Video file format, specified as `'Four character codes'` or `'Custom'`.

`FourCharacterCode` — Four Character Code video format
binary file format

Four Character Code video format, specified as one of the available video formats. For more information on four character codes, see https://en.wikipedia.org/wiki/FourCC. This property applies when you set the `VideoFormat` property to `'Four character codes'`.

`BitstreamFormat` — Format of data
`'Planar'` (default) | `'Packed'`

Format of data, specified as `'Planar'` or `'Packed'`.This property applies when you set the `VideoFormat` property to `Custom`.

`OutputSize` — Size of output
M-by-*N* matrix

Size of output, specified as an *M*-by-*N* matrix. This property applies when you set the `BitstreamFormat` property to `'Packed'`.

`VideoComponentCount` — Number of video components in video stream
3 (default) | 1 | 2 | 4

Number of video components in video stream, specified as 1, 2, 3 or 4. This number corresponds to the number of video component outputs. This property applies when you set the `VideoFormat` property to `'Custom'`.

`VideoComponentBits` — Bit size of video components
`[8 8 8]` (default) | vector

Bit size of video components, specified as an integer vector of length *N*, where *N* is the value of the `VideoComponentCount` property. This property applies when you set the `VideoFormat` property to `'Custom'`.

`VideoComponentSizes` — Size of video components
`[120 160; 60 80; 60 80]` (default) | *N*-by-2 array

Size of video components, specified as an *N*-by-2 array, where *N* is the value of the `VideoComponentCount` property. Each row of the matrix corresponds to the size of that video component, with the first element denoting the number of rows and the second element denoting the number of columns. This property applies when you set the `VideoFormat` property to `'Custom'` and the `BitstreamFormat` property to `'Planar'`.

`VideoComponentOrder` — Order of video components
`[1 2 3]` (default) | 1-by-*N* vector

Order of video components, specified as a 1-by-*N* vector. This property must be set to a vector of length *N*, where *N* is set according to how you set the `BitstreamFormat` property. When you set the `BitStreamFormat` property to `'Planar'`, you must set *N* equal to the value of the `VideoComponentCount` property. Otherwise, you can set *N* equal to or greater than the value of the `VideoComponentCount` property. This property applies when you set the `VideoFormat` property to `'Custom'`.

`InterlacedVideo` — Interlaced video status
`false` (default) | `true`

Interlaced video status, specified as `true` or `false`. Set this property to `true` if the video stream represents interlaced video data. This property applies when you set the `VideoFormat` property to `'Custom'`.

`LineOrder` — Fill binary file format
`'Top line first'` (default) | `'Bottom line first'`

Fill binary file format, specified as `'Top line first'`, or `'Bottom line first'`. If you set this property to `'Top line first'`, the first row of the video frame gets filled first. If you set this property to `'Bottom line first'`, the last row of the video frame gets filled first.

`SignedData` — Signed data
`false` (default) | `true`

Signed data, specified as `true` or `false`. Set this property to `true` for signed input data. This property applies when you set the `VideoFormat` property to `'Custom'`

`ByteOrder` — Byte order
`'Little endian'` (default) | `'Big endian'`

Byte order, specified as `'Little endian'` or `'Big endian'`. This property applies when you set the `VideoFormat` property to `'Custom'`.

`PlayCount` — Play count
1 (default) | positive integer

Play count for the number of times to play the file, specified as a positive integer.

Usage

Syntax

```
[Y,Cb,Cr] = bFileReader()
Y = bFileReader()
[Y,Cb,Cr,Alpha] = bFileReader()
[___,EOF] = bFileReader()
```

Description

`[Y,Cb,Cr] = bFileReader()` reads the luminance, `Y` and chrominance, `Cb` and `Cr` components of a video stream from the specified binary file when you set the `VideoFormat` property to `'Four character codes'`. Alternatively, it reads the values when you set the `VideoFormat` property to `'Custom'` and the `VideoComponentCount` property to 2.

`Y = bFileReader()` reads the video component `Y` from the binary file when you set the `VideoFormat` property to `'Custom'` and the `VideoComponentCount` property to `1`.

`[Y,Cb,Cr,Alpha] = bFileReader()` additionally reads the `Alpha` when you set the `VideoFormat` property to `'Custom'` and the `VideoComponentCount` property to `4`.

`[ ___ ,EOF] = bFileReader()` also returns the end-of-file indicator, `EOF`. `EOF` is set to `true` when the output contains the last video frame in the file.

Output Arguments

`Y` — Luminance value
M-by-*N* matrix

Luminance value, returned as an *M*-by-*N* matrix.

`Cb` — Chrominance value
M-by-*N* matrix

Chrominance value, returned as an *M*-by-*N* matrix.

`Cr` — Chrominance value
M-by-*N* matrix

Chrominance value, returned as an *M*-by-*N* matrix.

`Alpha` — Transparency
scalar

Transparency value, returned as a scalar in the range [0,1].

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to vision.BinaryFileReader

isDone	End-of-file status (logical)

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Read Binary Video File and Play Back on Screen

Create a binary file reader and video player object.

```
hbfr = vision.BinaryFileReader();
hvp = vision.VideoPlayer;
```

Use the while loop to play the default video.

```
while ~isDone(hbfr)
y = hbfr();
hvp(y);
end
```

Close the input file and the video display.

```
release(hbfr);
release(hvp);
```

`VideoReader` | `vision.BinaryFileWriter`

vision.BinaryFileWriter

Namespace: `vision`

Write binary video data to files

Description

The `BinaryFileWriter` object writes binary video data to files.

To write binary data to a file:

1. Create the `vision.BinaryFileWriter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
bFileWriter = vision.BinaryFileWriter
bFileWriter = vision.BinaryFileWriter(Name,Value)
```

Description

`bFileWriter = vision.BinaryFileWriter` returns a binary writer object that writes binary video data to an output file, `output.bin` in the `I420` Four Character Code format.

`bFileWriter = vision.BinaryFileWriter(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `bFileWriter = vision.BinaryFileWriter('Filename','output.bin')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Filename` — File name

`output.bin` (default) | character vector

File name, specified as a character vector.

`VideoFormat` — Video file format

`'Four character codes'` (default) | `'Custom'`

Video file format, specified as `'Four character codes'` or `'Custom'`.

`FourCharacterCode` — Four Character Code video format
binary file format

Four Character Code video format, specified as one of the available video formats. For more information on four character codes, see https://en.wikipedia.org/wiki/FourCC. This property applies when you set the `VideoFormat` property to `'Four character codes'`.

`BitstreamFormat` — Format of data
`'Planar'` (default) | `'Packed'`

Format of data, specified as `'Planar'` or `'Packed'`.This property applies when you set the `VideoFormat` property to `Custom`.

`VideoComponentCount` — Number of video components in video stream
3 (default) | 1 | 2 | 4

Number of video components in video stream, specified as 1, 2, 3 or 4. This number corresponds to the number of video component outputs. This property applies when you set the `VideoFormat` property to `'Custom'`.

`VideoComponentBitsSource` — Size of video components format
`'Auto'` (default) | `Property'`

Size of video components format, specified as `'Auto'` or `'Property'`. If this property is set to `'Auto'`, each component will have a `VideoComponentBits` property. This property applies when you set the `VideoFormat` property to `'Custom'`.

`VideoComponentBits` — Bit size of video components
`[8 8 8]` (default) | vector

Bit size of video components, specified as an integer vector of length *N*, where *N* is the value of the `VideoComponentCount` property. This property applies when you set the `VideoFormat` property to `'Custom'`.

`VideoComponentOrder` — Order of video components
`[1 2 3]` (default) | 1-by-*N* vector

Order of video components, specified as a 1-by-*N* vector. This property must be set to a vector of length *N*, where *N* is set according to how you set the `BitstreamFormat` property. When you set the `BitStreamFormat` property to `'Planar'`, you must set *N* equal to the value of the `VideoComponentCount` property. Otherwise, you can set *N* equal to or greater than the value of the `VideoComponentCount` property. This property applies when you set the `VideoFormat` property to `'Custom'`.

`InterlacedVideo` — Interlaced video status
`false` (default) | `true`

Interlaced video status, specified as `true` or `false`. Set this property to `true` if the video stream represents interlaced video data. This property applies when you set the `VideoFormat` property to `'Custom'`.

`LineOrder` — Fill binary file format
`'Top line first'` (default) | `'Bottom line first'`

Fill binary file format, specified as `'Top line first'`, or `'Bottom line first'`. If you set this property to `'Top line first'`, the first row of the video frame gets filled first. If you set this property to `'Bottom line first'`, the last row of the video frame gets filled first.

`SignedData` — Signed data
`false` (default) | `true`

Signed data, specified as `true` or `false`. Set this property to `true` for signed input data. This property applies when you set the `VideoFormat` property to `'Custom'`

`ByteOrder` — Byte order
`'Little endian'` (default) | `'Big endian'`

Byte order, specified as `'Little endian'` or `'Big endian'`. This property applies when you set the `VideoFormat` property to `'Custom'`.

Usage

Syntax

```
bFileWriter(Y,Cb,Cr)
bFileWriter(Y)
bFileWriter(Y,Cb)
bFileWriter(Y,Cb,Cr)
bFileWriter(Y,Cb,Cr,Alpha)
```

Description

`bFileWriter(Y,Cb,Cr)` writes one frame of video to the specified output file. `Y` , `Cb`, `Cr` represent the luma (Y) and chroma (Cb and Cr) components of a video stream. This option applies when you set the `VideoFormat` property to `'Four character codes'`.

`bFileWriter(Y)` writes video component `Y` to the output file when the `VideoFormat` property is set to `'Custom'` and the `VideoComponentCount` property is set to `1`.

`bFileWriter(Y,Cb)` writes video components `Y` and `Cb` to the output file when the `VideoFormat` property is `'Custom'` and the `VideoComponentCount` property is set to `2`.

`bFileWriter(Y,Cb,Cr)` writes video components `Y` , `Cb` and `Cr` to the output file when the `VideoFormat` property is set to `'Custom'` and the `VideoComponentCount` property is set to `3`.

`bFileWriter(Y,Cb,Cr,Alpha)` writes video components `Y` , `Cb`, `Cr` and `Alpha` to the output file when the `VideoFormat` property is set to `'Custom'`, and the `VideoComponentCount` property is set to `4`.

Input Arguments

`Y` — Luminance value
M-by-*N* matrix

Luminance value, returned as an *M*-by-*N* matrix.

`Cb` — Chrominance value
M-by-*N* matrix

Chrominance value, returned as an *M*-by-*N* matrix.

`Cr` — Chrominance value
M-by-*N* matrix

Chrominance value, returned as an *M*-by-*N* matrix.

`Alpha` — Transparency
scalar

Transparency value, returned as a scalar in the range [0,1].

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Write Video Data to a Binary File

Set the output file name and create binary file reader and writer objects.

```
filename = fullfile(tempdir,'output.bin');
bFileReader = vision.BinaryFileReader;
bFileWriter = vision.BinaryFileWriter(filename);
```

Write to the file.

```
while ~isDone(bFileReader)
    [y,cb,cr] = bFileReader();
    bFileWriter(y,cb,cr);
end
```

Close the files.

```
release(bFileReader);
release(bFileWriter);
```

`VideoReader` | `vision.BinaryFileReader`

vision.BlobAnalysis

Namespace: `vision`

Properties of connected regions

Description

To compute statistics for connected regions in a binary image

To track a set of points:

1. Create the `vision.BlobAnalysis` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
Hblob = vision.BlobAnalysis
Hblob = vision.BlobAnalysis(Name,Value)
```

Description

`Hblob = vision.BlobAnalysis` returns a blob analysis object, `H`, used to compute statistics for connected regions in a binary image.

`Hblob = vision.BlobAnalysis(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `Hblob = vision.BlobAnalysis('AreaOutputPort',true)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`AreaOutputPort` — Return blob area
`true` (default) | `false`

Return blob area, specified as `true` or `false`.

`CentroidOutputPort` — Return coordinates of blob centroids
`true` (default) | `false`

Return coordinates of blob centroids, specified as `true` or `false`.

`BoundingBoxOutputPort` — Return coordinates of bounding boxes
`true` (default) | `false`

Return coordinates of bounding boxes, specified as `true` or `false`.

`MajorAxisLengthOutputPort` — Return vector whose values represent lengths of ellipses' major axes
`false` (default) | `true`

Return vector whose values represent lengths of ellipses' major axes, specified as `true` or `false`. Set this property to `true` to output a vector whose values represent the lengths of the major axes of the ellipses that have the same normalized second central moments as the labeled regions. This property applies when you set the `OutputDataType` property to `double` or `single`.

`MinorAxisLengthOutputPort` — Return vector whose values represent lengths of ellipses' minor axes
`false` (default) | `true`

Return vector whose values represent lengths of ellipses' minor axes, specified as `true` or `false`. Set this property to `true` to output a vector whose values represent the lengths of the minor axes of the ellipses that have the same normalized second central moments as the labeled regions. This property is available when the `OutputDataType` property is `double` or `single`.

`OrientationOutputPort` — Return vector whose values represent angles between ellipses' major axes and x-axis
`false` (default) | `true`

Return vector whose values represent angles between ellipses' major axes and x-axis, specified as `true` or `false`. Set this property to true to output a vector whose values represent the angles between the major axes of the ellipses and the x-axis. This property applies when you set the `OutputDataType` property to `double` or `single`.

`EccentricityOutputPort` — Return vector whose values represent ellipses' eccentricities
`false` (default) | `true`

Return vector whose values represent ellipses' eccentricities, specified as `true` or `false`. Set this property to `true` to output a vector whose values represent the eccentricities of the ellipses that have the same second moments as the region. This property applies when you set the `OutputDataType` property to `double` or `single`.

`EquivalentDiameterSquaredOutputPort` — Return vector whose values represent equivalent diameters squared
`false` (default) | `true`

Return vector whose values represent equivalent diameters squared, specified as `true` or `false`. Set this property to `true` to output a vector whose values represent the equivalent diameters squared.

`ExtentOutputPort` — Return vector whose values represent results of dividing blob areas by bounding box areas
`false` (default) | `true`

Return vector whose values represent results of dividing blob areas by bounding box areas, specified as `true` or `false`.

`PerimeterOutputPort` — Return vector whose values represent estimates of blob perimeter lengths
`false` (default) | `true`

Return vector whose values represent estimates of blob perimeter lengths, specified as `true` or `false`.

`OutputDataType` — Output data type of statistics
`double` (default) | `single` | `Fixed point`

Output data type of statistics, specified as `double`,`single`, or `Fixed point`. Area and bounding box outputs are always an `int32` data type. `Major axis length`, `Minor axis length`, `Orientation` and `Eccentricity` do not apply when you set this property to `Fixed point`.

`Connectivity` — Connected pixels
`8` (default) | `4`

Connected pixels, specified as `4` or `8`.

`LabelMatrixOutputPort` — Maximum number of labeled regions in each input image
`50` (default) | positive scalar integer.

Maximum number of labeled regions in each input image, specified as a positive scalar integer. The maximum number of blobs the object outputs depends on both the value of this property, and on the size of the input image. The number of blobs the object outputs may be limited by the input image size.

`MinimumBlobArea` — Minimum blob area in pixels
`0` (default) | positive scalar integer.

Minimum blob area in pixels, specified as positive scalar integer.

Tunable: Yes

`MaximumBlobArea` — Maximum blob area in pixels
`intmax('uint32')` (default) | integer

Maximum blob area in pixels, specified as an integer.

Tunable: Yes

`ExcludeBorderBlobs` — Exclude blobs that contain at least one image border pixel
`false` (default) | `true`

Exclude blobs that contain at least one image border pixel, specified as `true` or `false`.

`MaximumCount` — Maximum number of labeled regions in each input image
`50` (default) | positive scalar integer

Maximum number of labeled regions in each input image, specified as a positive scalar integer. The maximum number of blobs the object outputs depends on both the value of this property, and on the size of the input image. The number of blobs the object outputs may be limited by the input image size

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest''Round'` | `'Simplest''Zero'`

Rounding method for fixed-point operations, specified as `'Floor'`, `'Ceiling'`, `'Convergent'`, `'Nearest'` , `'Round'` , `'Simplest'` , or `'Zero'`.

`OverflowAction` — Action to take when integer input is out-of-range
`'Wrap'` (default) | `'Saturate'`

Action to take when integer input is out-of-range, specified as `'Wrap'` or `'Saturate'`.

`ProductDataType` — Product data type
`'Same as input'` (default) | `'Custom'`

Product data type, specified as `'Same as input'` or `'Custom'`.

`CustomProductDataType` — Product word and fraction lengths
`numerictype(true,32,30)` (default) | scaled `numerictype` object

Product word and fraction lengths, specified as a scaled `numerictype` object. This property applies only when you set the `AccumulatorDataType` property to `'Custom'`.

`AccumulatorDataType` — Data type of accumulator
`'Same as product'` (default) | `'Same as input'` | `'Custom'`

Data type of accumulator, specified as `'Same as product'`, `'Same as input'`, or `'Custom'`.

`CustomAccumulatorDataType` — Accumulator word and fraction lengths
`numerictype(true,32,30)` (default) | scaled `numerictype` object

Accumulator word and fraction lengths, specified as a scaled `numerictype` object. This property applies only when you set the `AccumulatorDataType` property to `'Custom'`.

Usage

Syntax

```
[area,centroid,bbox] = Hblob(bw)
[___,majoraxis] = Hblob(bw)
[___,minoraxis] = Hblob(bw)
[bw___,orientation] = Hblob(bw)
[___,eccentricity] = Hblob(bw)
[___,EQDIASQ] = Hblob(bw)
[___,EXTENT] = Hblob(bw)
[___,perimeter] = Hblob(bw)
[___,label] = Hblob(bw)
```

Description

`[area,centroid,bbox] = Hblob(bw)` returns the area, centroid, and the bounding box of the blobs when the `AreaOutputPort`, `CentroidOutputPort` and `BoundingBoxOutputPort` properties are set to `true`. These are the only properties that are set to true by default. If you set any

additional properties to `true`, the corresponding outputs follow the `area`,`centroid`, and `bbox` outputs.

`[ ___ ,majoraxis] = Hblob(bw)` computes the major axis length `majoraxis` of the blobs found in input binary image `bw` when you set the `MajorAxisLengthOutputPort` property to `true`.

`[ ___ ,minoraxis] = Hblob(bw)` computes the minor axis length `minoraxis` of the blobs found in input binary image `BW` when you set the `MinorAxisLengthOutputPort` property to `true`.

`[bw ___ ,orientation] = Hblob(bw)` computes the `orientation` of the blobs found in input binary image `bw` when you set the `OrientationOutputPort` property to `true`.

`[ ___ ,eccentricity] = Hblob(bw)` computes the `eccentricity` of the blobs found in input binary image `bw` when you set the `EccentricityOutputPort` property to `true`.

`[ ___ ,EQDIASQ] = Hblob(bw)` computes the equivalent diameter squared `EQDIASQ` of the blobs found in input binary image `bw` when you set the `EquivalentDiameterSquaredOutputPort` property to `true`.

`[ ___ ,EXTENT] = Hblob(bw)` computes the `EXTENT` of the blobs found in input binary image `bw` when the `ExtentOutputPort` property is set to `true`.

`[ ___ ,perimeter] = Hblob(bw)` computes the `perimeter` of the blobs found in input binary image `bw` when you set the `PerimeterOutputPort` property to `true`.

`[ ___ ,label] = Hblob(bw)` returns a label matrix `label` of the blobs found in input binary image `bw` when you set the `LabelMatrixOutputPort` property to true.

Input Arguments

`bw` — Binary image
vector | matrix

Binary image, specified as a vector or matrix.

Output Arguments

`area` — Number of pixels in labeled regions
vector

Number of pixels in labeled regions, specified as a vector

`centroid` — Centroid coordinates
M-by-2 matrix.

Centroid coordinates, specified as an *M*-by-2 matrix. *M* is the number of blobs.

`bbox` — Bounding box coordinates
M-by-4 matrix

M-by-4 matrix in the format [*x y width height*], where M represents the number of blobs and [*x*,*y*] represents the upper-left corner of the bounding box.

`majoraxis` — Lengths of major axes of ellipses
vector

Lengths of major axes of ellipses, specified as a vector.

`minoraxis` — Lengths of minor axes of ellipses
vector

Lengths of minor axes of ellipses, specified as a vector.

`orientation` — Angles between the major axes of the ellipses and the x-axis
vector

Angles between the major axes of the ellipses and the x-axis, specified as a vector.

`eccentricity` — Eccentricities of the ellipses
vector

Eccentricities of the ellipses, specified as a vector

`EQDIASQ` — Equivalent diameter squared
vector

Equivalent diameter squared, specified as a vector.

`extent` — Ratio between area and bounding box
vector

Ratio between area and bounding box, specified as a vector. The vector contains the results of dividing the areas of the blobs by the area of their bounding boxes

`perimeter` — Estimate of the perimeter length
vector

Estimate of the perimeter length, specified as a vector. The vector contains an estimate of the perimeter length, in pixels, for each blob.

`label` — Label matrix
matrix

Label matrix, specified as a matrix.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Find Centroid of Blob

Create the blob analysis object.

```
hBlob = vision.BlobAnalysis('AreaOutputPort',false,'BoundingBoxOutputPort',false);
```

Create the blob.

```
img = logical([0 0 0 0 0 0; ...
         0 1 1 1 1 0; ...
         0 1 1 1 1 0; ...
         0 1 1 1 1 0; ...
         0 0 0 0 0 0]);
```

Find the coordinates for the centroid.

```
centroid = hBlob(img);
```

vision.BlockMatcher

Namespace: `vision`

Estimate motion between images or video frames

Description

To estimate motion between images or video frames.

1. Create the `vision.BlockMatcher` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
blkMatcher = vision.BlockMatcher
blkMatcher = vision.BlockMatcher(Name,Value)
```

Description

`blkMatcher = vision.BlockMatcher` returns an object, `blkMatcher`, that estimates motion between two images or two video frames. The object performs this estimation using a block matching method by moving a block of pixels over a search region.

`blkMatcher = vision.BlockMatcher(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `blkMatcher = vision.BlockMatcher('ReferenceFrameSource','Input port')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`ReferenceFrameSource` — Reference frame source
`'Property'` (default) | `'Input port'`

Reference frame source, specified as `'Input port'` or `'Property'`. When you set the `ReferenceFrameSource` property to `'Input port'`, a reference frame input must be specified to the `step` method of the block matcher object.

`ReferenceFrameDelay` — Number of frames between reference and current frames
`1` (default) | scalar integer

Number of frames between reference and current frames, specified as a scalar integer greater than or equal to zero. This property applies when you set the `ReferenceFrameSource` property to `'Property'`.

`SearchMethod` — Best match search method
`'Exhaustive'` (default) | `'Three-step'`

Best match search method, specified as `'Exhaustive'` or `'Three-step'`. Specify how to locate the block of pixels in frame k+1 that best matches the block of pixels in frame k. If you set this property to `'Exhaustive'`, the block matcher object selects the location of the block of pixels in frame k+1. The block matcher does so by moving the block over the search region one pixel at a time, which is computationally expensive.

If you set this property to `'Three-step'`, the block matcher object searches for the block of pixels in frame k+1 that best matches the block of pixels in frame k using a steadily decreasing step size. The object begins with a step size approximately equal to half the maximum search range. In each step, the object compares the central point of the search region to eight search points located on the boundaries of the region and moves the central point to the search point whose values is the closest to that of the central point. The object then reduces the step size by half, and begins the process again. This option is less computationally expensive, though sometimes it does not find the optimal solution.

`BlockSize` — Size of block in pixels
`[17 17]` (default) | two-element vector

Size of block, specified in pixels as a two-element vector.

`MaximumDisplacement` — Maximum displacement search
`[7 7]` (default) | two-element vector

Maximum displacement search, specified as a two-element vector. Specify the maximum number of pixels that any center pixel in a block of pixels can move, from image to image or from frame to frame. The block matcher object uses this property to determine the size of the search region.

`MatchCriteria` — Match criteria between blocks
`'Mean square error (MSE)'` (default) | `'Mean absolute difference (MAD')`

Match criteria between blocks, specified as `'Mean square error (MSE)'` or `'Mean absolute difference (MAD')`.

`OutputValue` — Motion output form
`'Magnitude-squared'` (default) | `'Horizontal and vertical components in complex form'`

Motion output form, specified as `'Magnitude-squared'` or `'Horizontal and vertical components in complex form'`.

`Overlap` — Input image subdivision overlap
`[0 0]` (default) | two-element vector

Input image subdivision overlap, specified in pixels as a two-element vector.

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest''Round'` | `'Simplest''Zero'`

Rounding method for fixed-point operations, specified as `'Floor'`, `'Ceiling'`, `'Convergent'`, `'Nearest'` , `'Round'` , `'Simplest'` , or `'Zero'`.

`OverflowAction` — Action to take when integer input is out-of-range
`'Wrap'` (default) | `'Saturate'`

Action to take when integer input is out-of-range, specified as `'Wrap'` or `'Saturate'`.

`ProductDataType` — Product data type
`'Same as input'` (default) | `'Custom'`

Product data type, specified as `'Same as input'` or `'Custom'`.

`CustomProductDataType` — Product word and fraction lengths
`numerictype(true,32,30)` (default) | scaled `numerictype` object

Product word and fraction lengths, specified as a scaled `numerictype` object. This property applies only when you set the `AccumulatorDataType` property to `'Custom'`.

`AccumulatorDataType` — Data type of accumulator
`'Same as product'` (default) | `'Same as input'` | `'Custom'`

Data type of accumulator, specified as `'Same as product'`, `'Same as input'`, or `'Custom'`.

`CustomAccumulatorDataType` — Accumulator word and fraction lengths
`numerictype(true,32,30)` (default) | scaled `numerictype` object

Accumulator word and fraction lengths, specified as a scaled `numerictype` object. This property applies only when you set the `AccumulatorDataType` property to `'Custom'`.

Usage

Syntax

```
V = blkMatcher(I)
C = blkMatcher(I)
Y = blkMatcher(I,iref)
```

Description

`V = blkMatcher(I)` computes the motion of input image `I` from one video frame to another, and returns `V` as a matrix of velocity magnitudes.

`C = blkMatcher(I)` computes the motion of input image `I` from one video frame to another, and returns `C` as a complex matrix of horizontal and vertical components, when you set the `OutputValue` property to `Horizontal and vertical components in complex form`.

`Y = blkMatcher(I,iref)` computes the motion between input image `I` and reference image `iref` when you set the `ReferenceFrameSource` property to `Input port`.

Input Arguments

`I` — Input data
scalar | vector | matrix

Input data, specified as a scalar, vector, or matrix of intensity values.

`iref` — Input reference data
scalar | vector | matrix

Input reference data, specified as a scalar, vector, or matrix of intensity values.

Output Arguments

`V` — Velocity magnitudes
matrix

Velocity magnitudes, returned as a matrix.

`C` — Horizontal and vertical components
matrix

Horizontal and vertical components, returned as a complex matrix.

`Y` — Motion between inputs
matrix

Motion between image and reference image, returned as a matrix.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Estimate Motion Using BlockMatcher

Read and convert an RGB image to grayscale.

```
img1 = im2double(im2gray(imread("onion.png")));
```

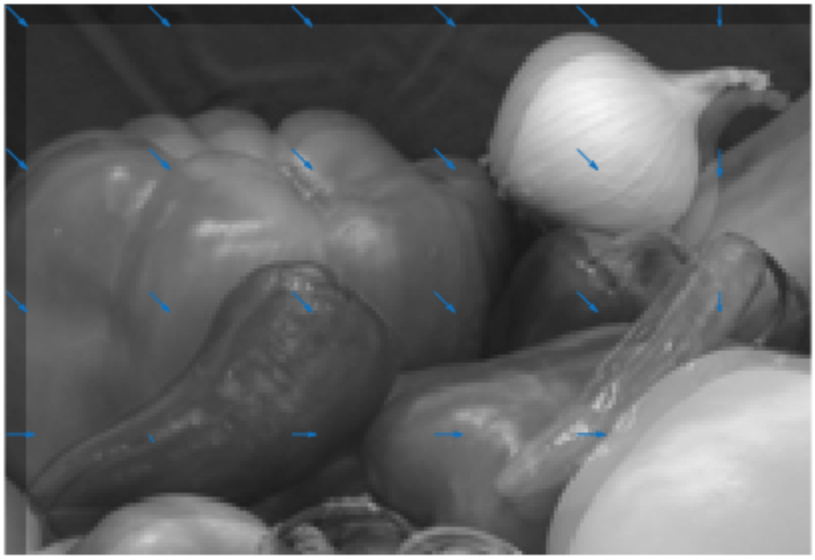
Create a block matcher and alpha blender object.

```
hbm = vision.BlockMatcher("ReferenceFrameSource",...
        "Input port","BlockSize",[35 35]);
hbm.OutputValue = "Horizontal and vertical components in complex form";
```

Offset the first image by [5 5] pixels to create a second image.

```
img2 = imtranslate(img1,[5,5]);
```

Compute motion for the two images.



```
motion = hbm(img1,img2);
```

Blend the two images.

```
img12 = imblend(img1,img2);
```

Use a quiver plot to show the direction of motion on the images.

```
[X,Y] = meshgrid(1:35:size(img1,2),1:35:size(img1,1));
imshow(img12)
hold on
quiver(X(:),Y(:),real(motion(:)),imag(motion(:)),0)
hold off
```

vision.CascadeObjectDetector

Namespace: `vision`

Detect objects using the Viola-Jones algorithm

Description

The cascade object detector uses the Viola-Jones algorithm to detect people's faces, noses, eyes, mouth, or upper body. You can also use the Image Labeler to train a custom classifier to use with this System object. For details on how the function works, see "Get Started with Cascade Object Detector".

To detect facial features or upper body in an image:

1. Create the `vision.CascadeObjectDetector` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
detector = vision.CascadeObjectDetector
detector = vision.CascadeObjectDetector(model)
detector = vision.CascadeObjectDetector(XMLFILE)
detector = vision.CascadeObjectDetector(Name,Value)
```

Description

`detector = vision.CascadeObjectDetector` creates a detector to detect objects using the Viola-Jones algorithm.

`detector = vision.CascadeObjectDetector(model)` creates a detector configured to detect objects defined by the input character vector, `model`.

`detector = vision.CascadeObjectDetector(XMLFILE)` creates a detector and configures it to use the custom classification model specified with the `XMLFILE` input.

`detector = vision.CascadeObjectDetector(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `detector = vision.CascadeObjectDetector('ClassificationModel','UpperBody')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`ClassificationModel` — Trained cascade classification model

`'FrontalFaceCART'` (default) | `character string`

Trained cascade classification model, specified as a character vector. The `ClassificationModel` property controls the type of object to detect. By default, the detector is configured to detect faces.

You can set this character vector to an XML file containing a custom classification model, or to one of the valid model character vectors listed below. You can train a custom classification model using the `trainCascadeObjectDetector` function. The function can train the model using Haar-like features, histograms of oriented gradients (HOG), or local binary patterns (LBP). For details on how to use the function, see “Get Started with Cascade Object Detector”.

Classification Model	Image Size Used to Train Model	Model Description
`'FrontalFaceCART'`(Default)	[20 20]	Detects faces that are upright and forward facing. This model is composed of weak classifiers, based on the classification and regression tree analysis (CART). These classifiers use Haar features to encode facial features. CART-based classifiers provide the ability to model higher-order dependencies between facial features. [1]
`'FrontalFaceLBP'`	[24 24]	Detects faces that are upright and forward facing. This model is composed of weak classifiers, based on a decision stump. These classifiers use local binary patterns (LBP) to encode facial features. LBP features can provide robustness against variation in illumination. [2]
`'UpperBody'`	[18 22]	Detects the upper-body region, which is defined as the head and shoulders area. This model uses Haar features to encode the details of the head and shoulder region. Because it uses more features around the head, this model is more robust against pose changes, e.g. head rotations/tilts. [3]
`'EyePairBig'` `'EyePairSmall'`	[11 45] [5 22]	Detects a pair of eyes. The `'EyePairSmall'` model is trained using a smaller image. This enables the model to detect smaller eyes than the `'EyePairBig'` model can detect.[4]
`'LeftEye'` `'RightEye'`	[12 18]	Detects the left and right eye separately. These models are composed of weak classifiers, based on a decision stump. These classifiers use Haar features to encode details.[4]
`'LeftEyeCART'` `'RightEyeCART'`	[20 20]	Detects the left and right eye separately. The weak classifiers that make up these models are CART-trees. Compared to decision stumps, CART-tree-based classifiers are better able to model higher-order dependencies. [5]

Classification Model	Image Size Used to Train Model	Model Description
`'ProfileFace'`	[20 20]	Detects upright face profiles. This model is composed of weak classifiers, based on a decision stump. These classifiers use Haar features to encode face details.
`'Mouth'`	[15 25]	Detects the mouth. This model is composed of weak classifiers, based on a decision stump, which use Haar features to encode mouth details.[4]
`'Nose'`	[15 18]	This model is composed of weak classifiers, based on a decision stump, which use Haar features to encode nose details.[4]

`MinSize` — Size of smallest detectable object

`[ ]` (default) | two-element vector

Size of smallest detectable object, specified as a two-element vector [*height width*]. Set this property in pixels for the minimum size region containing an object. The value must be greater than or equal to the image size used to train the model. Use this property to reduce computation time when you know the minimum object size prior to processing the image. When you do not specify a value for this property, the detector sets it to the size of the image used to train the classification model.

For details explaining the relationship between setting the size of the detectable object and the `ScaleFactor` property, see “Algorithms” on page 2-885 section.

Tunable: Yes

`MaxSize` — Size of largest detectable object

`[ ]` (default) | two-element vector

Size of largest detectable object, specified as a two-element vector [*height width*]. Specify the size in pixels of the largest object to detect. Use this property to reduce computation time when you know the maximum object size prior to processing the image. When you do not specify a value for this property, the detector sets it to `size(I)`.

For details explaining the relationship between setting the size of the detectable object and the `ScaleFactor` property, see the “Algorithms” on page 2-885 section.

`ScaleFactor` — Scaling for multiscale object detection

`1.1` (default) | scalar

Scaling for multiscale object detection, specified as a value greater than `1.0001`. The scale factor incrementally scales the detection resolution between `MinSize` and `MaxSize`. You can set the scale factor to an ideal value using:
`size(I)/(size(I)-0.5)`

The detector scales the search region at increments between `MinSize` and `MaxSize` using the following relationship:

search region = `round`((*Training Size*)*(`ScaleFactor`^{N}))

N is the current increment, an integer greater than zero, and *Training Size* is the image size used to train the classification model.

Tunable: Yes

`MergeThreshold` — Detection threshold
4 (default) | integer

Detection threshold, specified as an integer. The threshold defines the criteria needed to declare a final detection in an area where there are multiple detections around an object. Groups of colocated detections that meet the threshold are merged to produce one bounding box around the target object. Increasing this threshold may help suppress false detections by requiring that the target object be detected multiple times during the multiscale detection phase. When you set this property to `0`, all detections are returned without performing thresholding or merging operation. This property is tunable.

`UseROI` — Use region of interest
`false` (default) | `true`

Use region of interest, specified as `false` or `true`. Set this property to `true` to detect objects within a rectangular region of interest within the input image.

Usage

Syntax

```
bbox = detector(I)
bbox = detector(I,roi)
detectionResults = detector(ds)
```

Description

`bbox = detector(I)` returns an *M*-by-4 matrix, `bbox`, that defines *M* bounding boxes containing the detected objects. The detector performs multiscale object detection on the input image, `I`.

`bbox = detector(I,roi)` detects objects within the rectangular search region specified by `roi`. Set the `'UseROI'` property to `true` to use this syntax.`I` is a grayscale or truecolor (RGB) image.

`detectionResults = detector(ds)` detects objects within all the images returned by the `read` function of the input datastore.

Input Arguments

`I` — Input image
grayscale | truecolor (RGB)

Input image, specified as grayscale or truecolor (RGB).

`ds` — Datastore
`datastore` object

Datastore, specified as a `datastore` object containing a collection of images. Each image must be grayscale or RGB. The function processes only the first column of the datastore, which must contain images and must be cell arrays or tables with multiple columns. Therefore, datastore `read` function must return image data in the first column.

`model` — Classification model
`'FrontalFaceCART'` (default) | `character string`

Classification model, specified as a character vector. The `model` input describes the type of object to detect. There are several valid `model` character vectors, such as '`FrontalFaceCART`', '`UpperBody`', and '`ProfileFace`'. See the `ClassificationModel` property description for a full list of available models.

`XMLFILE` — Custom classification model
XML file

Custom classification model, specified as an XML file. The `XMLFILE` can be created using the `trainCascadeObjectDetector` function or OpenCV (Open Source Computer Vision) training functionality. You must specify a full or relative path to the `XMLFILE`, if it is not on the MATLAB path.

`roi` — Rectangular region of interest
four-element vector (default)

Rectangular region of interest within image `I`, specified as a four-element vector, [*x y width height*].

Output Arguments

`bbox` — Detections
M-by-4 matrix (default)

Detections, returned as an *M*-by-4 element matrix. Each row of the output matrix contains a four-element vector, [*x y width height*], that specifies in pixels, the upper-left corner and size of a bounding box.

`detectionResults` — Detection results
3-column table

Detection results, returned as a 3-column table with variable names, *Boxes*, *Scores*, and *Labels*. The *Boxes* column contains *M*-by-4 matrices, of *M* bounding boxes for the objects found in the image. Each row contains a bounding box as a 4-element vector in the format [*x*,*y*,*width*,*height*]. The format specifies the upper-left corner location and size in pixels of the bounding box in the corresponding image.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

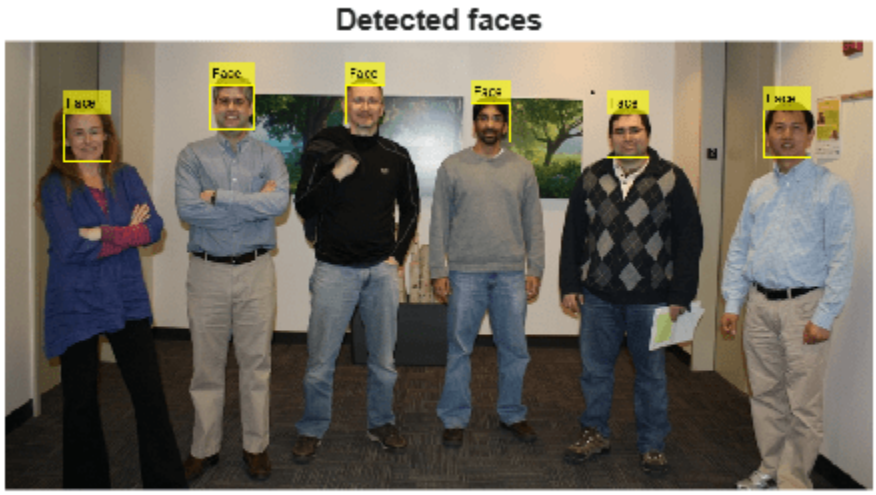
Examples

Detect Faces in an Image Using the Frontal Face Classification Model

Create a face detector object.

```
faceDetector = vision.CascadeObjectDetector;
```

Read the input image.



```
I = imread('visionteam.jpg');
```

Detect faces.

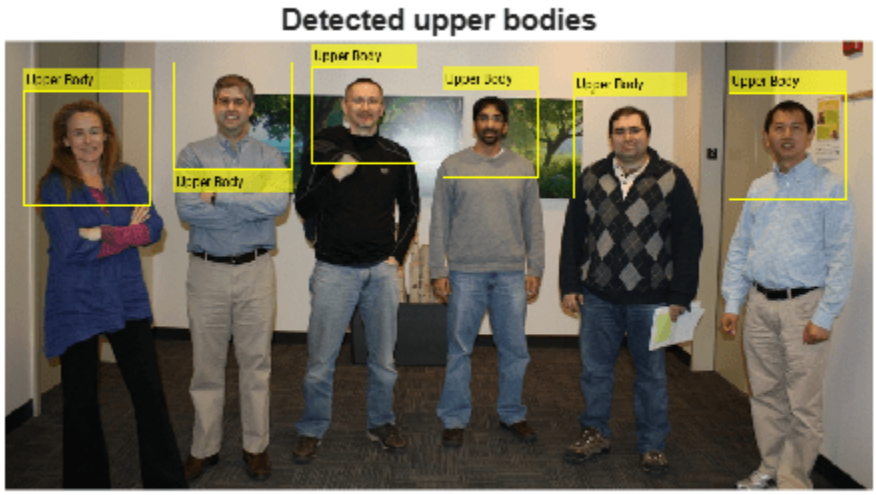
```
bboxes = faceDetector(I);
```

Annotate detected faces.

```
IFaces = insertObjectAnnotation(I,'rectangle',bboxes,'Face');
figure
imshow(IFaces)
title('Detected faces');
```

Detect Upper Body in Image Using Upper Body Classification Model

Create a body detector object and set properties.



```
bodyDetector = vision.CascadeObjectDetector('UpperBody');
bodyDetector.MinSize = [60 60];
bodyDetector.MergeThreshold = 10;
```

Read input image and detect upper body.

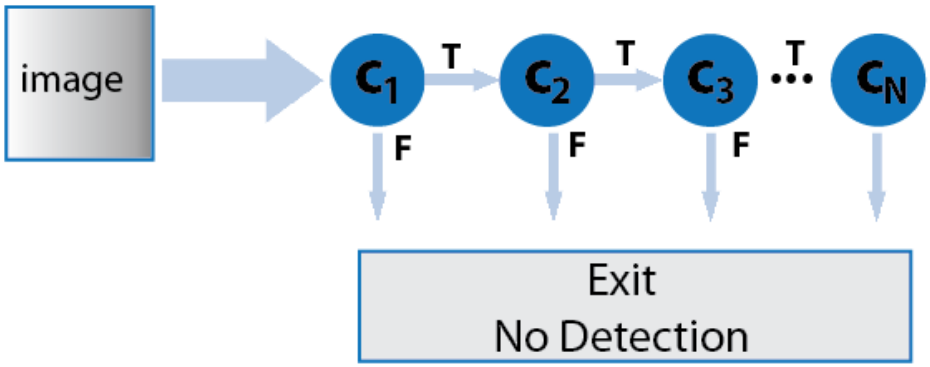
```
I2 = imread('visionteam.jpg');
bboxBody = bodyDetector(I2);
```

Annotate detected upper bodies.

```
IBody = insertObjectAnnotation(I2,'rectangle',bboxBody,'Upper Body');
figure
imshow(IBody)
title('Detected upper bodies');
```

Algorithms

Classification Model Training



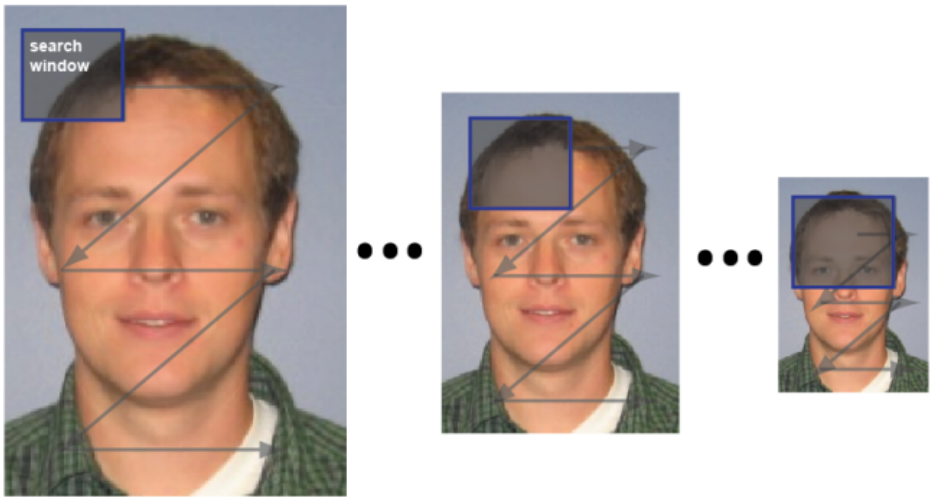
Each model is trained to detect a specific type of object. The classification models are trained by extracting features from a set of known images. These extracted features are then fed into a learning algorithm to train the classification model. Computer Vision Toolbox software uses the Viola-Jones cascade object detector. This detector uses HOG [7], LBP [8], and Haar-like [6] features and a cascade of classifiers trained using boosting.

The image size used to train the classifiers defines the smallest region containing the object. Training image sizes vary according to the application, type of target object, and available positive images. You must set the `MinSize` property to a value greater than or equal to the image size used to train the model.

Cascade of Classifiers

This object uses a cascade of classifiers to efficiently process image regions for the presence of a target object. Each stage in the cascade applies increasingly more complex binary classifiers, which allows the algorithm to rapidly reject regions that do not contain the target. If the desired object is not found at any stage in the cascade, the detector immediately rejects the region and processing is

terminated. By terminating, the object avoids invoking computation-intensive classifiers further down the cascade.



Multiscale Object Detection

The detector incrementally scales the input image to locate target objects. At each scale increment, a sliding window, whose size is the same as the training image size, scans the scaled image to locate objects. The `ScaleFactor` property determines the amount of scaling between successive increments.

The search region size is related to the `ScaleFactor` in the following way:

search region = `round`((*ObjectTrainingSize*)*(`ScaleFactor`^{N}))

N is the current increment, an integer greater than zero, and *ObjectTrainingSize* is the image size used to train the classification model.

The search window traverses the image for each scaled increment.

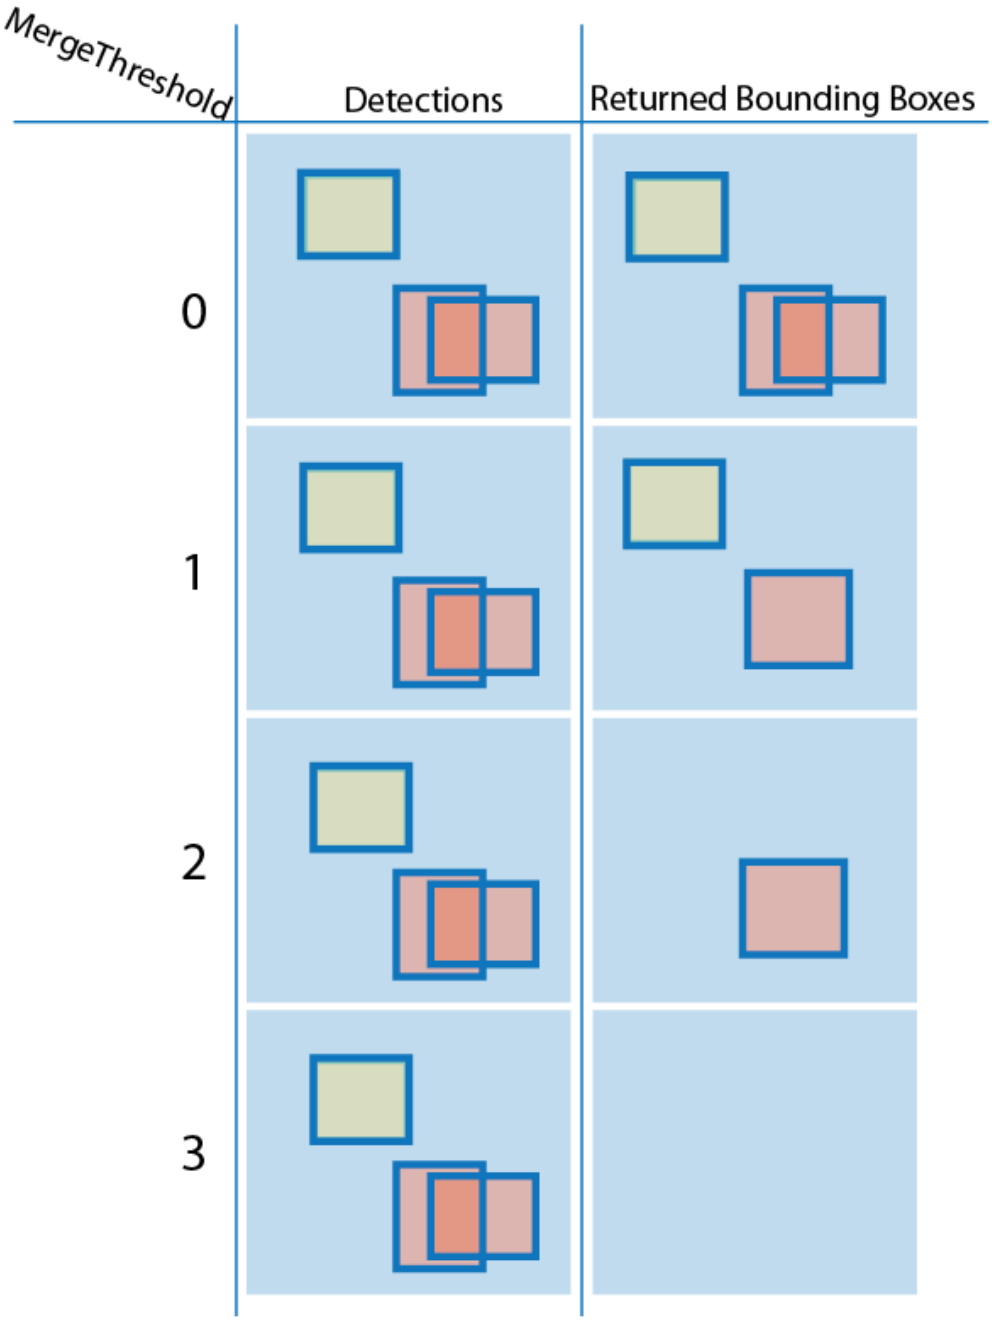
Relationship Between MinSize, MaxSize, and ScaleFactor

Understanding the relationship between the size of the object to detect and the scale factor will help you set the properties accordingly. The `MinSize` and `MaxSize` properties limit the size range of the

object to detect. Ideally, these properties are modified to reduce computation time when you know the approximate object size prior to processing the image. They are not designed to provide precise filtering of results, based on object size. The behavior of these properties is affected by the ScaleFactor. The scale factor determines the quantization of the search window sizes.

search region = `round`((*Training Size*)*(`ScaleFactor`^{N}))

The actual range of returned object sizes may not be exactly what you select for the `MinSize` and `MaxSize` properties. For example,
For a `ScaleFactor` value of `1.1` with a 24x24 training size, for `5` increments, the search region calculation would be:



```
>> search region = round(24*1.1.^(1:5))

>> 26 29 32 35 39
```

If you were to set `MaxSize` to `34`, due to the search region quantization, the actual maximum object size used by the algorithm would be `32`.

Merge Detection Threshold

For each increment in scale, the search window traverses over the image producing multiple detections around the target object. The multiple detections are merged into one bounding box per target object. You can use the `MergeThreshold` property to control the number of detections required before combining or rejecting the detections. The size of the final bounding box is an average of the sizes of the bounding boxes for the individual detections and lies between `MinSize` and `MaxSize`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Generates portable C code using a C++ compiler that links to OpenCV (Version 3.4.0) libraries. See “Portable C Code Generation for Functions That Use OpenCV Library”.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- `XMLFILE` must be a compile-time constant.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

vision.Deinterlacer

Namespace: `vision`

Remove motion artifacts by deinterlacing input video signal

Description

To remove motion artifacts by deinterlacing input video signal.

To track a set of points:

1. Create the `vision.Deinterlacer` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
Hdeinterlacer = vision.Deinterlacer
Hdeinterlacer = vision.Deinterlacer(Name,Value)
```

Description

`Hdeinterlacer = vision.Deinterlacer` returns a deinterlacing System object, `Hdeinterlacer`, that removes motion artifacts from images composed of weaved top and bottom fields of an interlaced signal.

`Hdeinterlacer = vision.Deinterlacer(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `varObj = vision.Deinterlacer('Method','Line repetition')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Method` — Method used to deinterlace input video

`'Line repetition'` (default) | `'Linear interpolation'` | `'Vertical temporal median filtering'`

Method used to deinterlace input video, specified as `'Line repetition'`, `'Linear interpolation'`, `'Vertical temporal median filtering'`.

`TransposedInput` — Indicate if input data is in row-major order
`false` (default) | `true`

Indicate if input data is in row-major order, specified as `true` or `false`. Set this property to `true` if the input buffer contains data elements from the first row first, then the second row second, and so on.

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest''Round'` | `'Simplest''Zero'`

Rounding method for fixed-point operations, specified as `'Floor'`, `'Ceiling'`, `'Convergent'`, `'Nearest'` , `'Round'` , `'Simplest'` , or `'Zero'`.

`OverflowAction` — Action to take when integer input is out-of-range
`'Wrap'` (default) | `'Saturate'`

Action to take when integer input is out-of-range, specified as `'Wrap'` or `'Saturate'`.

`ProductDataType` — Product data type
`'Same as input'` (default) | `'Custom'`

Product data type, specified as `'Same as input'` or `'Custom'`.

`CustomProductDataType` — Product word and fraction lengths
`numerictype(true,32,30)` (default) | scaled `numerictype` object

Product word and fraction lengths, specified as a scaled `numerictype` object. This property applies only when you set the `AccumulatorDataType` property to `'Custom'`.

`AccumulatorDataType` — Data type of accumulator
`'Same as product'` (default) | `'Same as input'` | `'Custom'`

Data type of accumulator, specified as `'Same as product'`, `'Same as input'`, or `'Custom'`.

`CustomAccumulatorDataType` — Accumulator word and fraction lengths
`numerictype(true,32,30)` (default) | scaled `numerictype` object

Accumulator word and fraction lengths, specified as a scaled `numerictype` object. This property applies only when you set the `AccumulatorDataType` property to `'Custom'`.

Usage

Syntax

```
value = Hdeinterlacer(input)
```

Description

`value = Hdeinterlacer(input)` deinterlaces the input according to the algorithm set in the Method property

Input Arguments

`input` — Input data
top and bottom fields of interlaced video

Input data, specified as a combination of top and bottom fields of interlaced video.

Output Arguments

`value` — Frames of deinterlaced video
top and bottom fields of interlaced video

Frames of deinterlaced video, returned as the same data type as the input

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

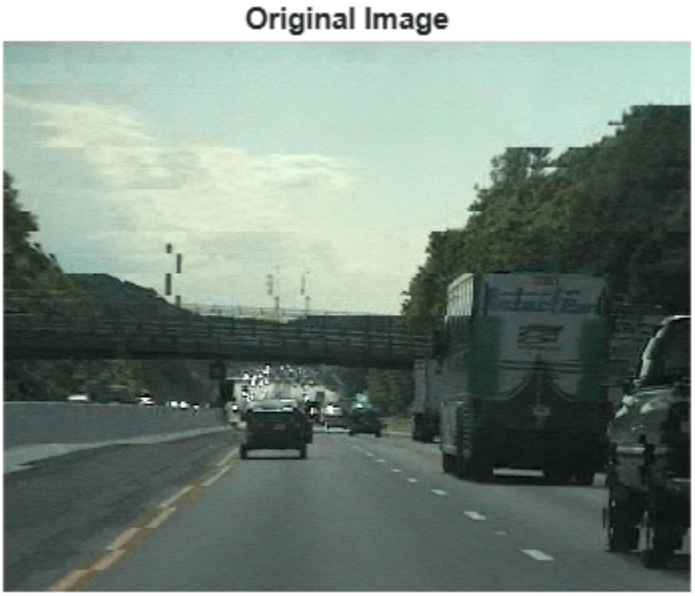
Examples

Remove Motion Artifacts from Image

Create a deinterlacer object.

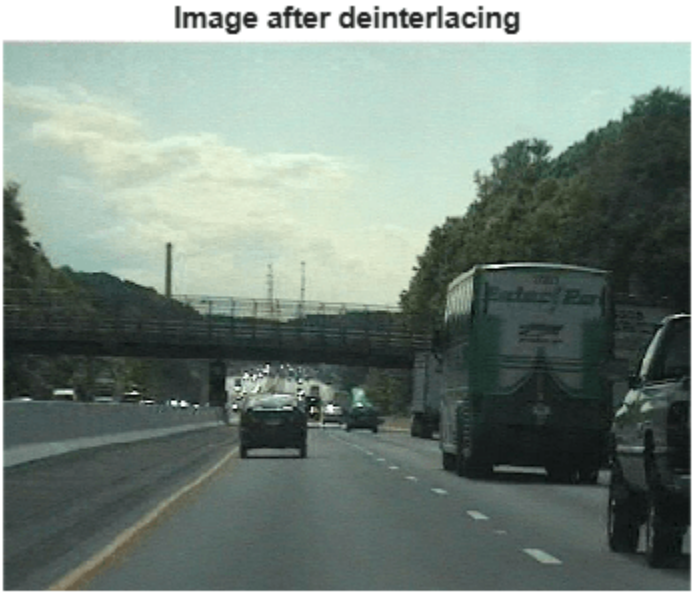
```
hdinterlacer = vision.Deinterlacer;
```

Read an image with motion artifacts.



```
I = imread('vipinterlace.png');
```

Apply the deinterlacer to the image.



```
clearimage = hdinterlacer(I);
```

Display the results.

```
imshow(I);
title('Original Image');
```

```
figure, imshow(clearimage);
title('Image after deinterlacing');
```

Deinterlacing

vision.ForegroundDetector

Namespace: `vision`

Foreground detection using Gaussian mixture models

Description

The `ForegroundDetector` compares a color or grayscale video frame to a background model to determine whether individual pixels are part of the background or the foreground. It then computes a foreground mask. By using background subtraction, you can detect foreground objects in an image taken from a stationary camera.

To detect foreground in an image :

1. Create the `vision.ForegroundDetector` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
detector = vision.ForegroundDetector
detector = vision.ForegroundDetector(Name,Value)
```

Description

`detector = vision.ForegroundDetector` computes and returns a foreground mask using the Gaussian mixture model (GMM).

`detector = vision.ForegroundDetector(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `detector = vision.ForegroundDetector('LearningRate',0.005)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`AdaptLearningRate` — Adapt learning rate
`'true'` (default) | `'false'`

Adapt learning rate, specified as `'true'` or `'false'`. This property enables the object to adapt the learning rate during the period specified by the `NumTrainingFrames` property. When you set this property to `true`, the object sets the `LearningRate` property to 1/(current frame number). When you set this property to `false`, the `LearningRate` property must be set at each time step.

`NumTrainingFrames` — Number of initial video frames for training background model
`150` (default) | integer

Number of initial video frames for training background model, specified as an integer. When you set the `AdaptLearningRate` to `false`, this property will not be available.

`LearningRate` — Learning rate for parameter updates
`0.005` (default) | numeric scalar

Learning rate for parameter updates, specified as a numeric scalar. Specify the learning rate to adapt model parameters. This property controls how quickly the model adapts to changing conditions. Set this property appropriately to ensure algorithm stability.

The learning rate specified by this property can only be implemented when you set the `AdaptLearningRate` to `true` and after the training period specified by `NumTrainingFrames` is over.

Tunable: Yes

`MinimumBackgroundRatio` — Threshold to determine background model
`0.7` (default) | numeric scalar

Threshold to determine background model, specified as a numeric scalar. Set this property to represent the minimum possibility for pixels to be considered background values. Multimodal backgrounds cannot be handled if this value is too small.

`NumGaussians` — Number of Gaussian modes in the mixture model
`5` (default) | positive integer

Number of Gaussian modes in the mixture model, specified as a positive integer. Typically, you would set this value to 3, 4 or 5. Set the value to 3 or greater to be able to model multiple background modes.

`InitialVariance` — Initial mixture model variance
`'Auto'` (default) | numeric scalar

Initial mixture model variance, specified as a numeric scalar or the `'Auto'` character vector.

Image Data Type	Initial Variance
`double/single`	(30/255)^2
`uint8`	30^2

This property applies to all color channels for color inputs.

Usage

Syntax

```
foregroundMask = detector(I)
foregroundMask = detector(I,learningRate)
```

Description

`foregroundMask = detector(I)` computes the foreground mask for input image `I`, and returns a logical mask. Values of `1` in the mask correspond to foreground pixels.

`foregroundMask = detector(I,learningRate)` computes the foreground mask using the `LearningRate`.

Input Arguments

`I` — Input image
grayscale | truecolor (RGB)

Input image, specified as grayscale or truecolor (RGB).

`learningRate` — Learning rate for parameter updates
`0.005` (default) | numeric scalar

Learning rate for parameter updates, specified as a numeric scalar. Specify the learning rate to adapt model parameters. This property controls how quickly the model adapts to changing conditions. Set this property appropriately to ensure algorithm stability.

The learning rate specified by this property can only be implemented when you set the `AdaptLearningRate` to `true` and after the training period specified by `NumTrainingFrames` is over.

Tunable: Yes

Output Arguments

`foregroundMask` — Foreground mask
binary mask

Foreground mask computed using a Gaussian mixture model, returned as a binary mask.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step Run System object algorithm

release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Detect Moving Cars In Video

Create a video source object to read file.

```
videoSource = VideoReader("viptraffic.avi");
```

Create a detector object and set the number of training frames to 5 (because it is a short video.) Set initial standard deviation.

```
detector = vision.ForegroundDetector(...
       NumTrainingFrames=5, ...
       InitialVariance=30*30);
```

Perform blob analysis.

```
blob = vision.BlobAnalysis(...
       CentroidOutputPort=false,...
       AreaOutputPort=false, ...
       BoundingBoxOutputPort=true, ...
       MinimumBlobAreaSource="Property",...
       MinimumBlobArea=250);
```

Play results. Draw bounding boxes around cars.

```
videoPlayer = vision.VideoPlayer();
while hasFrame(videoSource)
     frame  = readFrame(videoSource);
     fgMask = detector(frame);
     bbox   = blob(fgMask);
     out    = insertShape(frame,"rectangle",bbox,Color="green");
     videoPlayer(out);
     pause(0.1);
end
```

Release objects.

```
release(videoPlayer);
```

vision.GammaCorrector

Namespace: `vision`

(To be removed) Apply or remove gamma correction from images or video streams

Note `vision.GammaCorrector` function will be removed in a future release. Use the `imwarp` function to apply a linear geometric transformation to an image, instead.

Description

To apply gamma correction to input images or a video stream:

1. Create the `vision.GammaCorrector` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
gammaCorr = vision.GammaCorrector
gammaCorr = vision.GammaCorrector(Name,Value)
gammaCorr = vision.GammaCorrector(gamma,Name,Value)
```

Description

`gammaCorr = vision.GammaCorrector` returns a gamma corrector object, `gammaCorr`. You can use the gamma corrector to apply or remove gamma correction from images or video streams.

`gammaCorr = vision.GammaCorrector(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `gammaCorr = vision.GammaCorrector('Correction','Gamma')`

`gammaCorr = vision.GammaCorrector(gamma,Name,Value)` additionally sets the `Gamma` property.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Correction` — Specify gamma correction or linearization
`'Gamma'` (default) | `'De-gamma'`

Specify gamma correction or linearization, specified as `'Gamma'` or `'De-gamma'`.

`Gamma` — Gamma value of output or input
`2.2` (default) | numeric scalar

Gamma value of output or input, specified as numeric scalar greater than or equal to `1`. When you set the `Correction` property to `Gamma`, this property gives the desired gamma value of the output video stream. When you set the `Correction` property to `De-gamma`, this property indicates the gamma value of the input video stream.

`LinearSegment` — Enable gamma curve to have linear portion near origin
`true` (default) | `false`

Enable gamma curve to have linear portion near origin, specified as `true` or `false`.

`BreakPoint` — I-axis value of the end of gamma correction linear segment
`0.018` (default) | numeric scalar

I-axis value of the end of gamma correction linear segment, specified as a numeric scalar value in the range (0,1). This property applies when you set the `LinearSegment` property to `true`.

Usage

Syntax

```
y = gammaCorr(input)
```

Description

`y = gammaCorr(input)` applies or removes gamma correction from input `I`, and returns the gamma corrected or linearized output `y`.

Input Arguments

`input` — Input
M-by-*N* matrix of intensity values | *M*-by-*N*-*P* color video

Input, specified as an *M*-by-*N* matrix of intensity values or *M*-by-*N*-*P* color video, where *P* is the number of color planes.

Output Arguments

`y` — Corrected input
same as input (default)

Output, returned as an *M*-by-*N* matrix of intensity values or *M*-by-*N*-*P* color video, where *P* is the number of color planes.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Improve Image Contrast Using Gamma Correction

Create a gamma corrector object with the gamma property set to `2.0`.

```
hgamma = vision.GammaCorrector(2.0,'Correction','De-gamma');
```

Read an image.

```
img = imread('pears.png');
```

Apply gamma correction.

```
imgCor = hgamma(img);
```

Show the original and corrected images.

```
imshow(img); title('Original Image');
```

```
figure,
imshow(imgCor);
title('Enhanced Image after De-gamma Correction');
```

Version History

Introduced in R2012a

R2024a: `vision.GammaCorrector` function will be removed

Not recommended starting in R2024a

`vision.GammaCorrector` function will be removed in a future release. Use the `imwarp` function to apply a linear geometric transformation to an image, instead.

Extended Capabilities

`gamma` | `imwarp`

vision.HistogramBasedTracker

Namespace: `vision`

Histogram-based object tracking

Description

The histogram-based tracker incorporates the continuously adaptive mean shift (CAMShift) algorithm for object tracking. It uses the histogram of pixel values to identify the tracked object.

To track an object:

1. Create the `vision.HistogramBasedTracker` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
hbtracker = vision.HistogramBasedTracker
hbtracker = vision.HistogramBasedTracker(Name,Value)
```

Description

`hbtracker = vision.HistogramBasedTracker` returns a tracker that tracks an object by using the CAMShift algorithm. It uses the histogram of pixel values to identify the tracked object. To initialize the tracking process, you must use the `initializeObject` function to specify an exemplar image of the object.

`hbtracker = vision.HistogramBasedTracker(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `hbtracker = vision.HistogramBasedTracker('ObjectHistogram',[])`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`ObjectHistogram` — Normalized pixel value histogram
`[ ]` (default) | *N*-element vector.

Normalized pixel value histogram, specified as an *N*-element vector. This vector specifies the normalized histogram of the object's pixel values. Histogram values must be normalized to a value between `0` and `1`. You can use the `initializeObject` method to set the property.

Tunable: Yes

Usage

Syntax

```
bbox = hbtracker(I)
[bbox,orientation] = hbtracker(I)
[bbox,orientation,score] = hbtracker(I)
```

Description

`bbox = hbtracker(I)` returns a bounding box, of the tracked object. Before using the tracker, you must identify the object to track, and set the initial search window. Use the `initializeObject` function to do this.

`[bbox,orientation] = hbtracker(I)` additionally returns the angle between the *x*-axis and the major axis of the ellipse that has the same second-order moments as the object. The returned angle is between –pi/2 and pi/2.

`[bbox,orientation,score] = hbtracker(I)` additionally returns the confidence score for the returned bounding box that contains the tracked object.

Input Arguments

`I` — Video frame

grayscale | 2-D feature map

Video frame, specified as grayscale or any 2-D feature map that distinguishes the object from the background. For example, I can be a hue channel of the HSV color space.

Output Arguments

`bbox` — Bounding box

[*x y width height*]

Bounding box, returned as a four-element vector in the format, [*x y width height*].

`orientation` — Orientation

angle

Orientation, returned as an angle between –pi/2 and pi/2. The angle is measured from the *x*-axis and the major axis of the ellipse that has the same second-order moments as the object.

`score` — Score

scalar

Score, returned as a scalar in the range [0 1]. A value of `1` corresponds to the maximum confidence. `1`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to vision.HistogramBasedTracker

initializeObject	Set object to track
initializeSearchWindow	Set initial search window

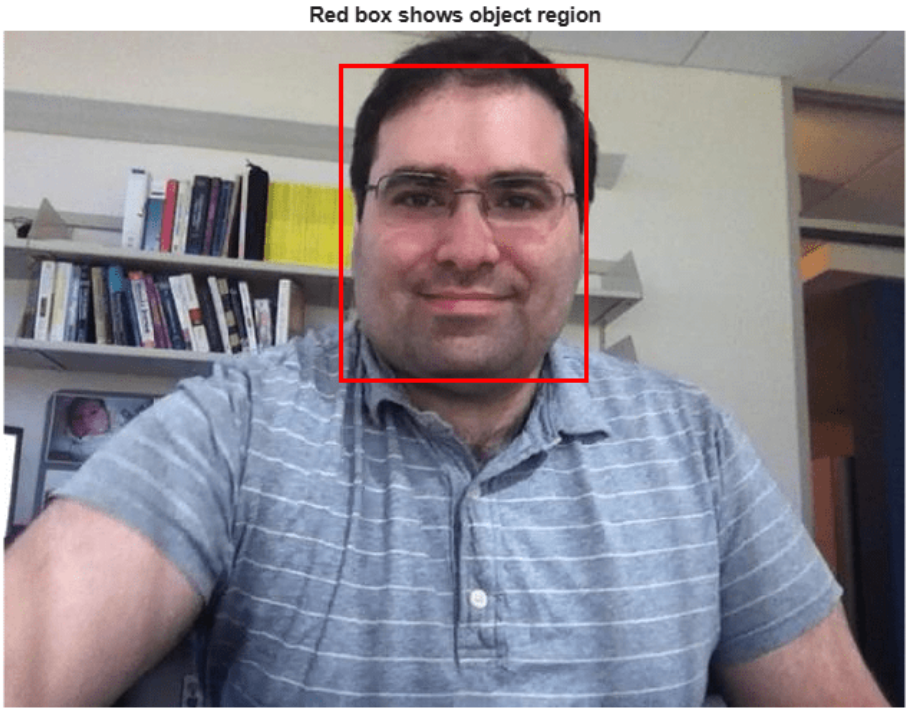
Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Track a Face

Track and display a face in each frame of an input video.



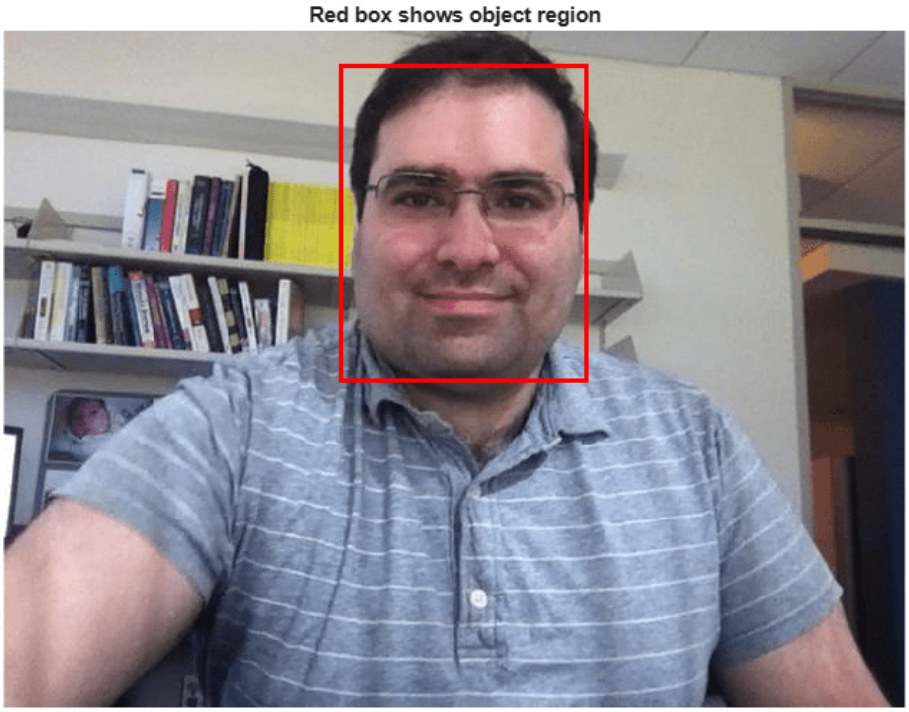
Load in the input video and create a System object displaying video.

```
videoReader = VideoReader("tilted_face.avi");
videoPlayer = vision.VideoPlayer();
```

Read the first video frame, which contains the object. Convert the image to HSV color space. Then define and display the object region.

```
objectFrame = im2single(readFrame(videoReader));
objectHSV = rgb2hsv(objectFrame);
objectRegion = [240, 25, 175, 225];
objectImage = insertShape(objectFrame,"rectangle",objectRegion,LineWidth=3,Color="red");

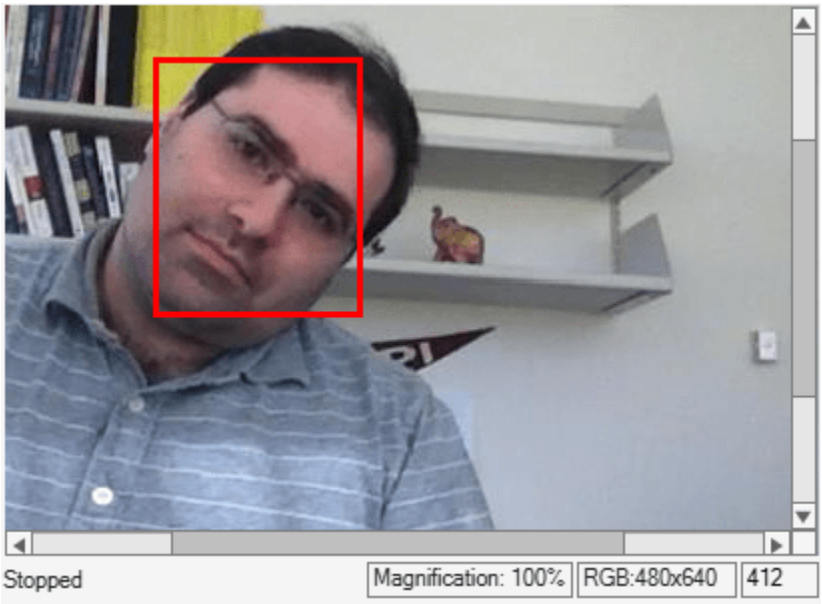
figure;
imshow(objectImage);
title("Red box shows object region")
```



Set the object, based on the hue channel of the first video frame.

```
tracker = vision.HistogramBasedTracker;
initializeObject(tracker, objectHSV(:,:,1),objectRegion);
```

Track and display the object in each video frame. The while loop reads each image frame, converts the image to HSV color space, then tracks the object in the hue channel where it is distinct from the background. Finally, the example draws a box around the object and displays the results.



```
while hasFrame(videoReader)
  frame = im2single(readFrame(videoReader));
  hsvFrame = rgb2hsv(frame);
  bbox = tracker(hsvFrame(:,:,1));
  out = insertShape(frame,"rectangle",bbox,LineWidth=3,Color="red");
  videoPlayer(out);
end
```

Release the video player.

```
release(videoPlayer);
```

integralKernel

Define filter for use with integral images

Description

An `integralKernel` object describes box filters for use with integral images.

Creation

Syntax

```
intKernel = integralKernel(bbox,weights)
intKernel = integralKernel(bbox,weights,orientation)
```

Description

`intKernel = integralKernel(bbox,weights)` creates an upright box filter from bounding boxes, `bbox`, and their corresponding weights, `weights`. The bounding boxes set the "BoundingBoxes" on page 2-0 property and the weights set the "Weights" on page 2-0 property.

For example, a conventional filter with the coefficients:

```
h    = [1  1  1  1;
        1  1  1  1;
       -1 -1 -1 -1;
       -1 -1 -1 -1]
```

and two regions:
region 1: x=1, y=1, width = 4, height = 2
region 2: x=1, y=3, width = 4, height = 2
can be specified as

```
boxH = integralKernel([1 1 4 2; 1 3 4 2],[1, -1])
```

`intKernel = integralKernel(bbox,weights,orientation)` creates a box filter with an upright or rotated orientation. The specified orientation sets the "Orientation" on page 2-0 property.

Properties

BoundingBoxes — Bounding boxes

4-element vector | *M*-by-4 matrix

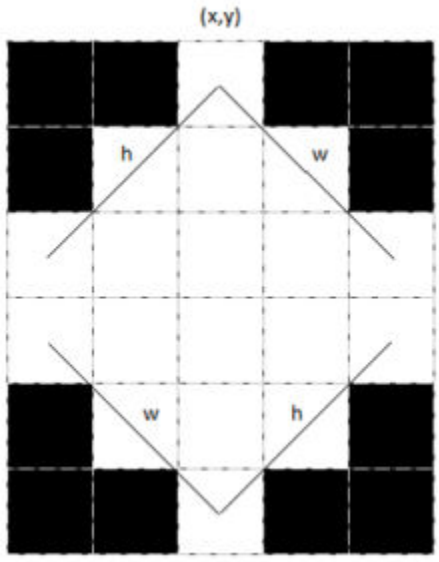
Bounding boxes, specified as a 4-element vector of the form [*x*,*y*,*width*, *height*] representing a single bounding box or an *M*-by-4 matrix representing *M* bounding boxes. The bounding boxes define the

filter. The (*x*,*y*) coordinates represent the top-most corner of the kernel. The (*width*, *height*) elements represent the width and height accordingly. Specifying the bounding boxes as an *M*-by-4 matrix is particularly useful for constructing Haar-like features composed of multiple rectangles.

Sums are computed over regions defined by `BoundingBoxes`. The bounding boxes can overlap. See “Define an 11-by-11 Average Filter” on page 2-917 for an example of how to specify a box filter.

`Weights` — Weights
numeric vector

Weights, specified as an *M*-element numeric vector containing a weight for each bounding box. The weights are used to define the coefficients of the filter.



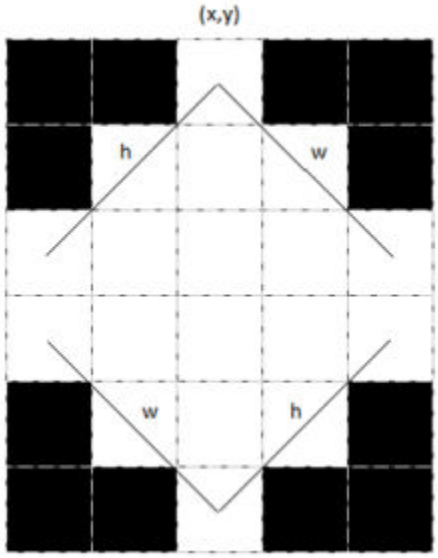
`Coefficients` — Filter coefficients
numeric

Filter coefficients, specified as a numeric value.

`Center` — Filter center
[*x*,*y*] coordinates

Filter center, specified as [*x*,*y*] coordinates. The filter center represents the center of the bounding rectangle. It is calculated by halving the dimensions of the rectangle. For even dimensional rectangles, the center is placed at subpixel locations. Hence, it is rounded up to the next integer.

For example, for this filter, the center is at [3,3].



These coordinates are in the kernel space, where the top-left corner is (1,1). To place the center in a different location, provide the appropriate bounding box specification. For this filter, the best workflow would be to construct the upright kernel and then call the `rot45` method to provide the rotated version.

`Size` — Filter size
2-element vector

Filter size, specified as a 2-element vector. The size of the kernel is computed to be the dimensions of the rectangle that bounds the kernel. For a single bounding box vector [*x*,*y*,*width*, *height*], the kernel is bounded within a rectangle of dimensions [(*width*+*height*) (*width*+*height*)-1].

For cascaded rectangles, the lowest corner of the bottom-most rectangle defines the size. For example, a filter with a bounding box specification of [3 1 3 3], with weights set to 1, produces a 6-by-5 filter with this kernel:

`Orientation` — Filter orientation
`'upright'` (default) | `'rotated'`

Filter orientation, specified as `'upright'` or `'rotated'`. When you specify the orientation as `'rotated'`, the (*x*,*y*) components refer to the location of the top-left corner of the bounding box. Also, the (*width*,*height*) components refer to a 45-degree line from the top-left corner of the bounding box.

More About

Computing an Integral Image and Using it for Filtering with Box Filters

The `integralImage` function together with the `integralKernel` object and `integralFilter` function complete the workflow for box filtering based on integral images. You can use this workflow for filtering with box filters.

- Use the `integralImage` function to compute the integral images
- Use the `integralFilter` function for filtering
- Use the `integralKernel` object to define box filters

The `integralKernel` object allows you to transpose the filter. You can use this to aim a directional filter. For example, you can turn a horizontal edge detector into vertical edge detector.

Object Functions

rot45	Rotate upright kernel clockwise by 45 degrees
transpose	Transpose integral kernel

Examples

Define an 11-by-11 Average Filter

```
avgH = integralKernel([1 1 11 11], 1/11^2);
```

Define a Filter to Approximate a Gaussian Second Order Partial Derivative in Y Direction

```
ydH = integralKernel([1,1,5,9;1,4,5,3], [1, -3]);
```

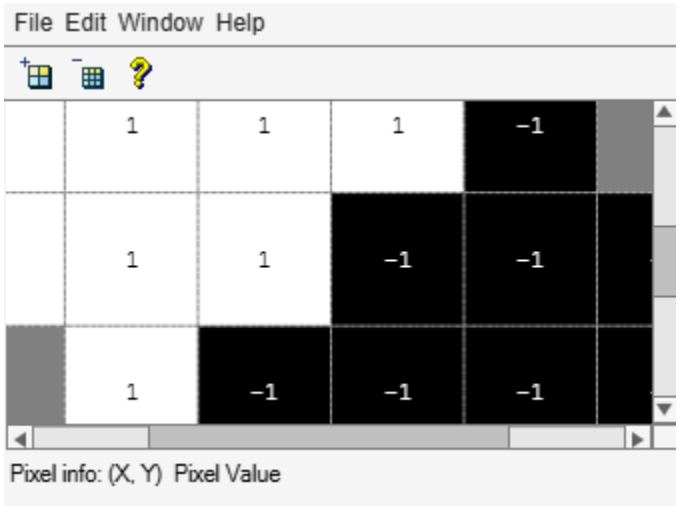
You can also define this filter as `integralKernel`([1,1,5,3;1,4,5,3;1,7,5,3], [1, -2, 1]);|. This filter definition is less efficient because it requires three bounding boxes.

Visualize the filter.

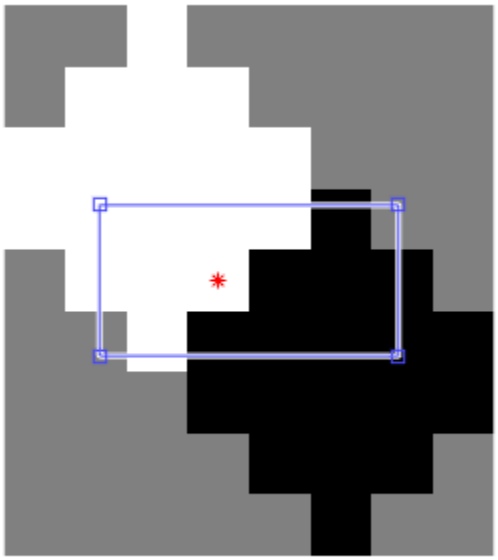
```
ydH.Coefficients
```

```
ans = 9×5

     1     1     1     1     1
     1     1     1     1     1
     1     1     1     1     1
    -2    -2    -2    -2    -2
    -2    -2    -2    -2    -2
    -2    -2    -2    -2    -2
     1     1     1     1     1
     1     1     1     1     1
     1     1     1     1     1
```



Create a Haar-like Wavelet to Detect 45-Degree Edges



Create the filter.

```
K = integralKernel([3,1,3,3;6 4 3 3], [1 -1], "rotated");
```

Visualize the filter and mark the center.

```
imshow(K.Coefficients, []);
hold on;
plot(K.Center(2),K.Center(1), "r*");
impixelregion;
```

Blur an Image Using an Average Filter

Read and display the input image.

```
I = imread('pout.tif');
imshow(I);
```

Compute the integral image.

```
intImage = integralImage(I);
```

Apply a 7-by-7 average filter.

```
avgH = integralKernel([1 1 7 7], 1/49);
J = integralFilter(intImage, avgH);
```

Cast the result back to the same class as the input image.

```
J = uint8(J);
figure
imshow(J);
```

transpose

Transpose integral kernel

Syntax

```
transposedKernel = transpose(intKernel)
```

Description

`transposedKernel = transpose(intKernel)` transposes the integral kernel. You can use this operation to change the direction of an oriented filter.

Examples

Construct Haar-like Wavelet Filters

Horizontal filter

```
horiH = integralKernel([1 1 4 3; 1 4 4 3], [-1, 1]);
```

Using the dot and apostrophe create a vertical filter.

```
vertH = horiH.';
```

Using the transpose method.

```
verticalH = transpose(horiH);
```

Input Arguments

`intKernel` — Integral kernel

`integralKernel` object

Integral kernel, specified as an `integralKernel` object.

Output Arguments

`transposedKernel` — Transposed integral kernel

`integralKernel` object

Transposed integral kernel, returned as an `integralKernel` object.

Version History

Introduced in R2012a

`rot45`

rot45

Rotate upright kernel clockwise by 45 degrees

Syntax

```
rotKernel = rot45(intKernel)
```

Description

`rotKernel = rot45(intKernel)` rotates upright kernel `intKernel` clockwise by 45 degrees.

Examples

Construct and Rotate a Haar-like Wavelet Filter

Create a horizontal filter.

```
H = integralKernel([1 1 4 3; 1 4 4 3], [-1, 1]);
```

Rotate the filter 45 degrees.

```
rotH = rot45(H);
```

Input Arguments

`intKernel` — Integral kernel

`integralKernel` object

Integral kernel, specified as an `integralKernel` object.

Output Arguments

`rotKernel` — Rotated integral kernel

`integralKernel` object

Rotated integral kernel, returned as an `integralKernel` object.

vision.KalmanFilter

Correction of measurement, state, and state estimation error covariance

Description

The Kalman filter object is designed for tracking. You can use it to predict a physical object's future location, to reduce noise in the detected location, or to help associate multiple physical objects with their corresponding tracks. A Kalman filter object can be configured for each physical object for multiple object tracking. To use the Kalman filter, the object must be moving at constant velocity or constant acceleration.

Creation

The Kalman filter algorithm involves two steps, prediction and correction (also known as the update step). The first step uses previous states to predict the current state. The second step uses the current measurement, such as object location, to correct the state. The Kalman filter implements a discrete time, linear State-Space System.

Note To make configuring a Kalman filter easier, you can use the `configureKalmanFilter` object to configure a Kalman filter. It sets up the filter for tracking a physical object in a Cartesian coordinate system, moving with constant velocity or constant acceleration. The statistics are the same along all dimensions. If you need to configure a Kalman filter with different assumptions, do not use the function, use this object directly.

In the state space system, the state transition model, A, and the measurement model, H, are set as follows:

Variable	Value
A	`[1 1 0 0; 0 1 0 0; 0 0 1 1; 0 0 0 1]`
H	`[1 0 0 0; 0 0 1 0]`

Syntax

```
kalmanFilter = vision.KalmanFilter
kalmanFilter = vision.KalmanFilter(StateTransitionModel,MeasurementModel)
kalmanFilter = vision.KalmanFilter(StateTransitionModel,MeasurementModel,
ControlModel,Name,Value)
```

Description

`kalmanFilter = vision.KalmanFilter` returns a kalman filter for a discrete time, constant velocity system.

`kalmanFilter = vision.KalmanFilter(StateTransitionModel,MeasurementModel)` additionally configures the control model, B.

`kalmanFilter = vision.KalmanFilter(StateTransitionModel,MeasurementModel, ControlModel,Name,Value)` configures the Kalman filter object properties, specified as one or more `Name,Value` pair arguments. Unspecified properties have default values.

Properties

`StateTransitionModel` — Model describing state transition between time steps (*A*)

`[1 1 0 0; 0 1 0 0; 0 0 1 1; 0 0 0 1]` (default) | *M*-by-*M* matrix

Model describing state transition between time steps (*A*), specified as an *M*-by-*M* matrix. After the object is constructed, this property cannot be changed. This property relates to the *A* variable in the state-space model.

`MeasurementModel` — Model describing state to measurement transformation (*H*)

`[1 0 0 0; 0 0 1 0]` (default) | *N*-by-*M* matrix

Model describing state to measurement transformation (*H*) , specified as an *N*-by-*M* matrix. After the object is constructed, this property cannot be changed. This property relates to the *H* variable in the state-space model.

`ControlModel` — Model describing control input to state transformation (*B*)

`[]` (default) | *M*-by-*L* matrix

Model describing control input to state transformation (*B*) , specified as an *M*-by-*L* matrix. After the object is constructed, this property cannot be changed. This property relates to the *B* variable in the state-space model.

`State` — State (*x*)

`[0]` (default) | scalar | *M*-element vector.

State (*x*), specified as a scalar or an *M*-element vector. If you specify `State` as a scalar, it will be extended to an *M*-element vector. This property relates to the *x* variable in the state-space model.

`StateCovariance` — State estimation error covariance (*P*)

`[1]` (default) | scalar | *M*-by-*M* matrix

State estimation error covariance (*P*), specified as a scalar or an *M*-by-*M* matrix. If you specify `StateCovariance` as a scalar it will be extended to an *M*-by-*M* diagonal matrix. This property relates to the *P* variable in the state-space system.

`ProcessNoise` — Process noise covariance (*Q*)

`[1]` (default) | scalar | *M*-by-*M* matrix

Process noise covariance (*Q*) , specified as a scalar or an *M*-by-*M* matrix. If you specify `ProcessNoise` as a scalar it will be extended to an *M*-by-*M* diagonal matrix. This property relates to the *Q* variable in the state-space model.

`MeasurementNoise` — Measurement noise covariance (*R*)

`[1]` (default) | scalar | *N*-by-*N* matrix

Measurement noise covariance (*R*) , specified as a scalar or an *N*-by-*N* matrix. If you specify `MeasurementNoise` as a scalar it will be extended to an *N*-by-*N* diagonal matrix. This property relates to the *R* variable in the state-space model.

Object Functions

Use the `predict` and `correct` functions based on detection results. Use the `distance` function to find the best matches.

- When the tracked object is detected, use the `predict` and `correct` functions with the Kalman filter object and the detection measurement. Call the functions in the following order:

  ```
  [...] = predict(kalmanFilter);
  [...] = correct(kalmanFilter,measurement);
  ```

- When the tracked object is not detected, call the `predict` function, but not the `correct` function. When the tracked object is missing or occluded, no measurement is available. Set the functions up with the following logic:

  ```
  [...] = predict(kalmanFilter);
  If measurement exists
      [...] = correct(kalmanFilter,measurement);
  end
  ```

- If the tracked object becomes available after missing for the past *t*-1 contiguous time steps, you can call the `predict` function *t* times. This syntax is particularly useful to process asynchronous video.. For example,

  ```
  for i = 1:k
    [...] = predict(kalmanFilter);
  end
  [...] = correct(kalmanFilter,measurement)
  ```

correct	Correction of measurement, state, and state estimation error covariance
predict	Prediction of measurement
distance	Confidence value of measurement

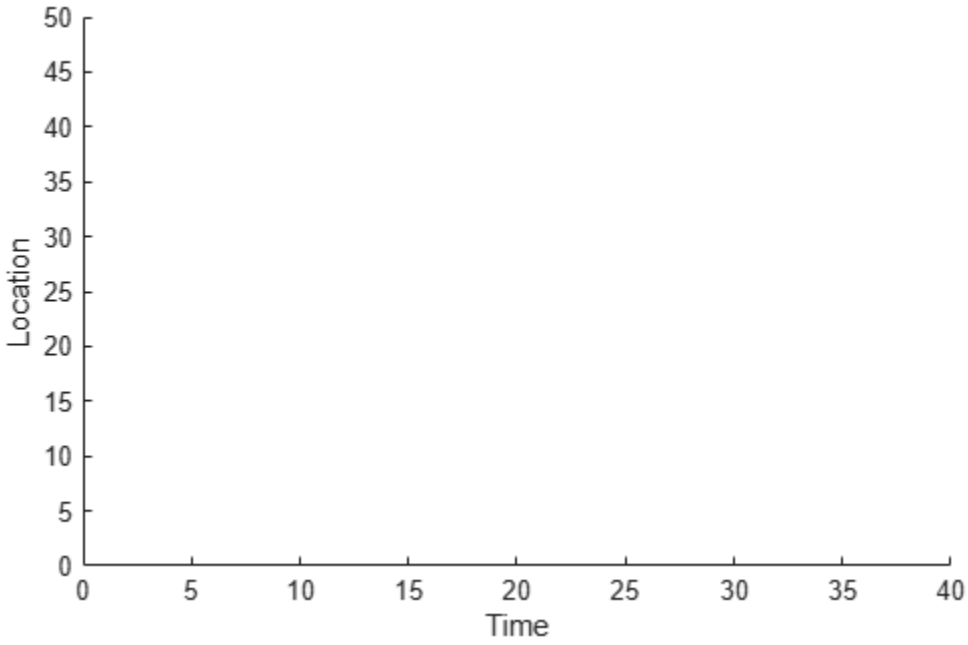
Examples

Track Location of An Object

Track the location of a physical object moving in one direction.

Generate synthetic data which mimics the 1-D location of a physical object moving at a constant speed.

```
detectedLocations = num2cell(2*randn(1,40) + (1:40));
```



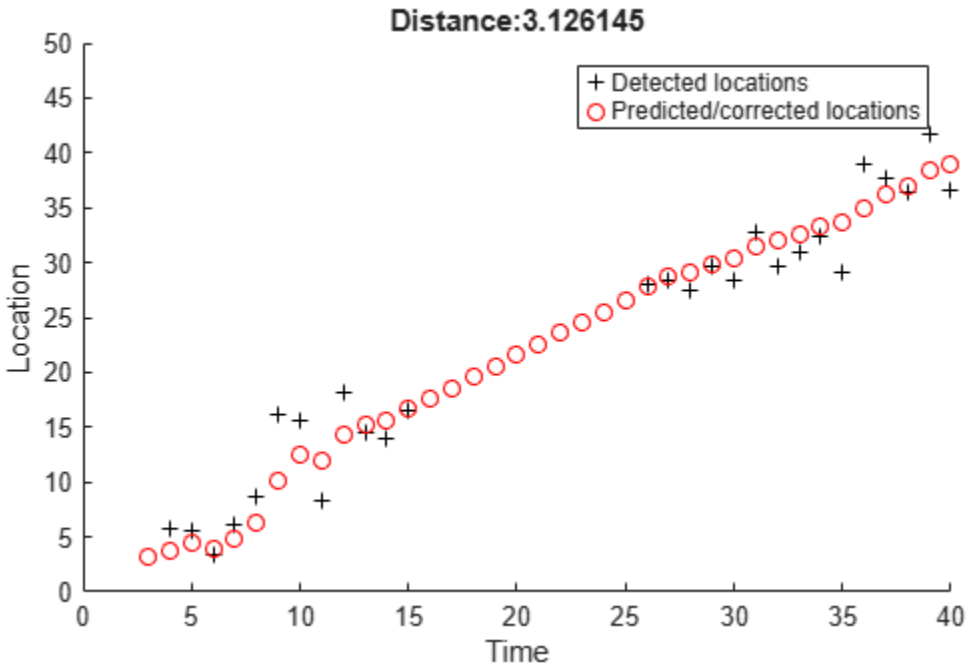
Simulate missing detections by setting some elements to empty.

```
detectedLocations{1} = [];
  for idx = 16: 25
      detectedLocations{idx} = [];
  end
```

Create a figure to show the location of detections and the results of using the Kalman filter for tracking.

```
figure;
hold on;
```

```
ylabel('Location');
ylim([0,50]);
xlabel('Time');
xlim([0,length(detectedLocations)]);
```



Create a 1-D, constant speed Kalman filter when the physical object is first detected. Predict the location of the object based on previous states. If the object is detected at the current time step, use its location to correct the states.

```
kalman = [];
for idx = 1: length(detectedLocations)
   location = detectedLocations{idx};
   if isempty(kalman)
     if ~isempty(location)

       stateModel = [1 1;0 1];
       measurementModel = [1 0];
       kalman = vision.KalmanFilter(stateModel,measurementModel,'ProcessNoise',1e-4,'MeasurementN
      kalman.State = [location, 0];
     end
   else
     trackedLocation = predict(kalman);
     if ~isempty(location)
       plot(idx, location,'k+');
      d = distance(kalman,location);
       title(sprintf('Distance:%f', d));
       trackedLocation = correct(kalman,location);
     else
       title('Missing detection');
     end
     pause(0.2);
     plot(idx,trackedLocation,'ro');
   end
```

```
 end
legend('Detected locations','Predicted/corrected locations');
```

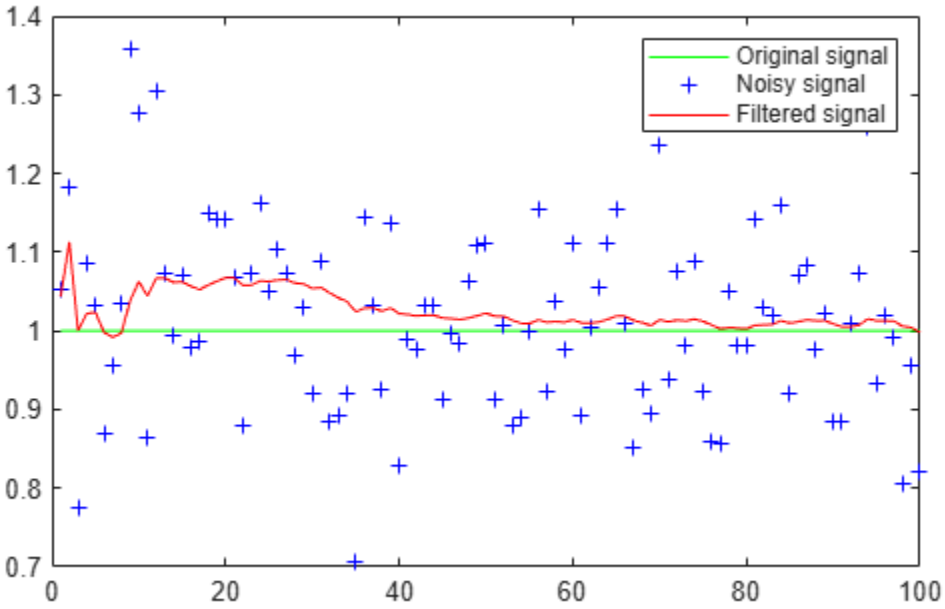
Remove Noise from a Signal

Use Kalman filter to remove noise from a random signal corrupted by a zero-mean Gaussian noise.

Synthesize a random signal that has value of 1 and is corrupted by a zero-mean Gaussian noise with standard deviation of 0.1.

```
x = 1;
len = 100;
z = x + 0.1 * randn(1,len);
```

Remove noise from the signal by using a Kalman filter. The state is expected to be constant, and the measurement is the same as state.



```
stateTransitionModel = 1;
measurementModel = 1;
obj = vision.KalmanFilter(stateTransitionModel,measurementModel,'StateCovariance',1,'ProcessNoise

z_corr = zeros(1,len);
for idx = 1: len
 predict(obj);
 z_corr(idx) = correct(obj,z(idx));
end
```

Plot results.

```
figure, plot(x * ones(1,len),'g-');
hold on;
```

```
plot(1:len,z,'b+',1:len,z_corr,'r-');
legend('Original signal','Noisy signal','Filtered signal');
```

Algorithms

State Space Model

This object implements a discrete time, linear state-space system, described by the following equations.

State equation:	$x(k) = Ax(k-1) + Bu(k-1) + w(k-1)$
Measurement equation:	$z(k) = Hx(k) + v(k)$

Variable Definition

Variable	Description	Dimension
k	Time.	Scalar
x	State. Gaussian vector with covariance P. [$x \sim N(\bar{x}, P)$]	M-element vector
P	State estimation error covariance.	M-by-M matrix
A	State transition model.	M-by-M matrix
B	Control model.	M-by-L matrix
u	Control input.	L-element vector
w	Process noise; Gaussian vector with zero mean and covariance Q. [$w \sim N(0, Q)$]	M-element vector
Q	Process noise covariance.	M-by-M matrix
z	Measurement. For example, location of detected object.	N-element vector
H	Measurement model.	N-by-M matrix
v	Measurement noise; Gaussian vector with zero mean and covariance R. [$v \sim N(0, R)$]	N-element vector
R	Measurement noise covariance.	N-by-N matrix

vision.LocalMaximaFinder

Namespace: `vision`

(Removed) Find local maxima in matrices

Note `vision.LocalMaximaFinder` function has been removed. Use the `imregionalmax` to find the local maxima, instead.

Description

To find local maxima in matrices.

1. Create the `vision.LocalMaximaFinder` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
LMaxFinder = vision.LocalMaximaFinder
LMaxFinder = vision.LocalMaximaFinder(maxnum,neighborsize)
LMaxFinder = vision.LocalMaximaFinder(Name,Value)
```

Description

`LMaxFinder = vision.LocalMaximaFinder` returns a local maxima finder System object, `H`, that finds local maxima in input matrices.

`LMaxFinder = vision.LocalMaximaFinder(maxnum,neighborsize)` returns a local maxima finder object with the `MaximumNumLocalMaxima` property set to `maxnum`, `NeighborhoodSize` property set to `neighborsize`, and other specified properties set to the specified values.

`LMaxFinder = vision.LocalMaximaFinder(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `LMaxFinder = vision.LocalMaximaFinder('ThresholdSource','Property')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`MaximumNumLocalMaxima` — Maximum number of maxima
`2` (default) | positive scalar integer

Maximum number of maxima to find, specified as a positive scalar integer.

`NeighborhoodSize` — Neighborhood size for zero-ing out values
`[5 7]` (default) | two-element vector

Neighborhood size for zero-ing out values, specified as a two-element vector

`ThresholdSource` — Source of threshold
`'Property'` (default) | `'Input port'`

Source of threshold, specified as `'Property'` or `'Input port'`.

`Threshold` — Value that all maxima should match or exceed
`10` (default) | built-in numeric data type

Value that all maxima should match or exceed, specified as a scalar of MATLAB built-in numeric data type. This property applies when you set the `ThresholdSource` property to `'Property'`.

Tunable: Yes

`HoughMatrixInput` — Indicator of Hough transform matrix input
`false` (default) | `true`

Indicator of Hough transform matrix input, specified as `true` or `false`. The block applies additional processing, specific to Hough transform on the right and left boundaries of the input matrix. Set this property to `true` if the input is antisymmetric about the rho axis and the theta value ranges from $-\frac{\pi}{2}$ to $\frac{\pi}{2}$ radians, which correspond to a Hough matrix.

`IndexDataType` — Data type of index values
`uint32` (default) | `double` | `single` | `uint8` | `uint16`

Data type of index values, specified as `double`, `single` , `uint8`, `uint16`, or `uint32`.

Usage

Syntax

```
idx = LMaxFinder(I)
idx = LMaxFinder(I,threshold)
```

Description

`idx = LMaxFinder(I)` returns [*x y*] coordinates of the local maxima in an *M*-by-2 matrix, `idx`. *M* represents the number of local maximas found. The maximum value of *M* may not exceed the value set in the `MaximumNumLocalMaxima` property.

`idx = LMaxFinder(I,threshold)` finds the local maxima in the input image `I`, using the threshold value `threshold`, when you set the `ThresholdSource` property to `'Input port'`.

Input Arguments

`I` — Video frame
grayscale | truecolor (RGB)

Video frame, specified as grayscale or truecolor (RGB).

`threshold` — Threshold
scalar

Value that all maxima should match or exceed, specified as a scalar of MATLAB built-in numeric data type.

Output Arguments

`idx` — Local maxima
M-by-2 matrix

Local maxima, returned as an *M*-by-2 matrix of one-based [*x* *y*] coordinates, where *M* represents the number of local maximas found.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to vision.LocalMaximaFinder

initialize	Initialize video frame and points to track

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Find Local Maxima of an Input

1 Create an example input.

```
I = [0 0 0 0 0 0 0 0 0 0 0 0; ...
     0 0 0 1 1 2 3 2 1 1 0 0; ...
     0 0 0 1 2 3 4 3 2 1 0 0; ...
     0 0 0 1 3 5 7 5 3 1 0 0; ...
     0 0 0 1 2 3 4 3 2 1 0 0; ...
     0 0 0 1 1 2 3 2 1 1 0 0; ...
     0 0 0 0 0 0 0 0 0 0 0 0];
```

2 Create a local maxima finder object.

```
hLocalMax = vision.LocalMaximaFinder('MaximumNumLocalMaxima',1, ...
                                     'NeighborhoodSize',[3,3], ...
                                     'Threshold',1);
```

3 Find local maxima.

```
location = hLocalMax(I)
```

```
location = 1x2 uint32 row vector

   7   4
```

Version History

Introduced in R2012b

R2024b: `vision.LocalMaximaFinder` function has been removed

Errors starting in R2024b

`vision.LocalMaximaFinder` function has been removed. Use the `imregionalmax` to find the local maxima, instead. For example,

```
I = [0 0 0 0 0 0 0 0 0 0 0 0; ...
     0 0 0 1 1 2 3 2 1 1 0 0; ...
     0 0 0 1 2 3 4 3 2 1 0 0; ...
     0 0 0 1 3 5 7 5 3 1 0 0; ...
     0 0 0 1 2 3 4 3 2 1 0 0; ...
     0 0 0 1 1 2 3 2 1 1 0 0; ...
     0 0 0 0 0 0 0 0 0 0 0 0];

BW = imregionalmax(I,8);
threshold = 1;
BW(I<threshold) = false;
BW = bwmorph(BW,"shrink",inf);
[row,col] = find(BW);
```

R2024a: `vision.LocalMaximaFinder` function will be removed

Warns starting in R2024a

`vision.LocalMaximaFinder` function will be removed in a future release. Use the `houghpeaks` or `max` functions to find the local maxima, instead.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Generates portable C code using a C++ compiler that links to OpenCV libraries. See “Portable C Code Generation for Functions That Use OpenCV Library”.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

`hough` | `houghpeaks` | `max` | `vision.Maximum`

vision.Maximum

Namespace: `vision`

(Removed) Find maximum values in input or sequence of inputs

Note `vision.Maximum` function has been removed. Use the `max` and `movmax` function to find maximum values, instead.

Description

Find maximum values in an input or sequence of inputs.

To track a set of points:

1. Create the `vision.Maximum` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
maxObj = vision.Maximum
maxObj = vision.Maximum(Name,Value)
```

Description

`maxObj = vision.Maximum` returns an object, `maxObj`, that computes the value and index of the maximum elements in an input or a sequence of inputs.

`maxObj = vision.Maximum(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `maxObj = vision.Maximum('RunningMaximum',false)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`ValueOutputPort` — Output maximum value
`true` (default) | `false`

Output maximum value, specified as `true` or `false`. Set this property to `true` to output the maximum value of the input. This property applies when you set the `RunningMaximum` property to `false`.

`RunningMaximum` — Calculate over single input or multiple inputs
`false` (default) | `true`

Calculate over single input or multiple inputs, specified as `true` or `false`. When you set this property to `true`, the object computes the maximum value over a sequence of inputs. When you set this property to `false`, the object computes the maximum value over the current input.

`IndexOutputPort` — Output the index of the maximum value
`true` (default) | `false`

Output the index of the maximum value, specified as `true` or `false`. This property applies only when you set the `RunningMaximum` property to `false`.

`ResetInputPort` — Additional input to enable resetting of running maximum
`false` (default) | `true`

Additional input to enable resetting of running maximum, specified as `true` or `false`. When you set this property to `true`, a reset input must be specified to reset the running maximum. This property applies only when you set the `RunningMaximum` property to `true`.

`ResetCondition` — Condition that triggers resetting of running maximum
`'Non-zero'` (default) | `'Rising edge'` | `'Falling edge'` | `'Either edge'`

Condition that triggers resetting of running maximum, specified as `'Rising edge'`, `'Falling edge'`, `'Either edge'`, or `'Non-zero'`. This property applies only when you set the `ResetInputPort` property to `true`.

`IndexBase` — Numbering base for index of maximum value
`'One'` (default) | `'Zero'`

Numbering base for index of maximum value, specified as `'One'` or `'Zero'`. This property applies only when you set the `IndexOutputPort` property to true.

`Dimension` — Dimension to operate along
`'Column'` (default) | `{'All'}` | `'Row'` | `'Custom'`

Dimension to operate along, specified as `{'All'}`, `'Row'`, `'Column'`, or `'Custom'`. This property applies only when you set the `RunningMaximum` property to `false`.

`CustomDimension` — Numerical dimension to calculate over
1 (default) | numerical scalar

Numerical dimension to calculate over, specified as a numerical scalar. This property only applies when you set the `Dimension` property to `'Custom'`.

`ROIProcessing` — Enable region-of-interest processing
`false` (default) | `true`

Enable region-of-interest processing, specified as `true` or `false`. This property applies when you set the `Dimension` property to `'All'` and the `RunningMaximum` property to `false`.

`ROIForm` — Type of ROI
`'Rectangles'` (default) | `Lines'` | `'Label matrix''Binary mask'`

Type of ROI, specified as `'Rectangles'`, `'Lines'`, `'Label matrix'`, or `'Binary mask'`. This property applies only when you set the `ROIProcessing` property to `true`.

`ROIPortion` — ROI or perimeter calculation
`'Entire ROI'` (default) | `'ROI perimeter'`

ROI or perimeter calculation, specified as `'Entire ROI'` or `'ROI perimeter'`. This property applies only when you set the `ROIForm` property to `'Rectangles'`.

`ROIStatistics` — Calculate statistics for each ROI or one for all ROIs
`'Individual statistics for each ROI'` (default) | `'Single statistic for all ROIs'`

Calculate statistics for each ROI or one for all ROIs, specified as `'Individual statistics for each ROI'` or `'Single statistic for all ROIs'`. This property applies only when you set the `'ROIForm'` property to `'Rectangles'`, `'Lines'`, or `'Label matrix'`.

`ValidityOutputPort` — Flag to indicate if any part of ROI is outside input image
`false` (default) | `true`

Flag to indicate if any part of ROI is outside input image, specified as `true` or `false`.

This applies when you set the `ROIForm` property to `'Lines'` or `'Rectangles'`.

Set this property to `true` to return the validity of the specified label numbers. This applies when you set the `ROIForm` property to `'Label matrix'`.

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest''Round'` | `'Simplest''Zero'`

Rounding method for fixed-point operations, specified as `'Floor'`, `'Ceiling'`, `'Convergent'`, `'Nearest'` , `'Round'` , `'Simplest'` , or `'Zero'`.

`OverflowAction` — Action to take when integer input is out-of-range
`'Wrap'` (default) | `'Saturate'`

Action to take when integer input is out-of-range, specified as `'Wrap'` or `'Saturate'`.

`ProductDataType` — Product data type
`'Same as input'` (default) | `'Custom'`

Product data type, specified as `'Same as input'` or `'Custom'`.

`CustomProductDataType` — Product word and fraction lengths
`numerictype(true,32,30)` (default) | scaled `numerictype` object

Product word and fraction lengths, specified as a scaled `numerictype` object. This property applies only when you set the `AccumulatorDataType` property to `'Custom'`.

`AccumulatorDataType` — Data type of accumulator
`'Same as product'` (default) | `'Same as input'` | `'Custom'`

Data type of accumulator, specified as `'Same as product'`, `'Same as input'`, or `'Custom'`.

`CustomAccumulatorDataType` — Accumulator word and fraction lengths
`numerictype(true,32,30)` (default) | scaled `numerictype` object

Accumulator word and fraction lengths, specified as a scaled `numerictype` object. This property applies only when you set the `AccumulatorDataType` property to `'Custom'`.

Usage

Syntax

```
[value,index] = maxObj(input)
index = maxObj(input)

[___] = maxObj(I,ROI)
[___,flag] = maxObj(I,ROI)

[___] = maxObj(I,label,labelNumbers)
[___,flag] = maxObj(I,label,labelNumbers)
```

Description

`[value,index] = maxObj(input)` returns the maximum value and index of the input.

`index = maxObj(input)` returns the one-based index of the maximum value when you set the `IndexOutputPort` property to `true` and the `ValueOutputPort` property to `false`. The `RunningMaximum` property must be set to `false`.

`[___] = maxObj(I,ROI)` returns the maximum value in the input image within the given region of interest.

`[___,flag] = maxObj(I,ROI)`additionally returns a flag to indicate whether the given ROI is within the bounds of the image.

`[___] = maxObj(I,label,labelNumbers)` returns the maximum of the input image for a region the labels specified in the `labelNumbers` vector. The regions are defined and labeled in the `label` matrix.

`[___,flag] = maxObj(I,label,labelNumbers)` additionally returns a flag to indicate whether the input label numbers are valid.

Input Arguments

`input` — Input data
vector | matrix | multidimensional array

Input data, specified as a vector, matrix, or multidimensional array.

`ROI` — Region of interest
four-element vector

Region of interest, specified as a four-element vector, [*x y width height*]. This option is available when you set the `ROIProcessing` property to `true` and the `ROIForm` property to `'Lines'`, `'Rectangles'`, or `'Binary Mask'`.

`label` — Label numbers
matrix

Label numbers, specified as a matrix. This option is available when you set the `ROIProcessing` property to `true` and the `ROIForm` property to `'Label matrix'`.

`labelNumbers` — Label numbers
vector

Label numbers, specified as a vector. This option is available when you set the `ROIProcessing` property to `true` and the `ROIForm` property to `'Label matrix'`.

Output Arguments

`value` — Maximum value
same as input

Maximum value, returned as the same data type as the input

`index` — Index to maximum value
one-based index

Index to maximum value, returned as a one-based index.

`flag` — Flag for valid data
`true` | `false`

Flag for valid data, returned as `true` or `false`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Find Index to Maximum Value in Grayscale Image

1 Read a color image.

```
img = imread('peppers.png');
```

2 Convert the image to grayscale.

```
img = im2single(im2gray(img));
```

3 Find the maximum.

```
hMax = vision.Maximum
```

```
hMax =
  vision.Maximum with properties:

    ValueOutputPort: true
     RunningMaximum: false
    IndexOutputPort: true
          Dimension: 'All'
      ROIProcessing: false

  Use get to show all properties
```

```
[m,ind] = hMax(img);
```

Version History

Introduced in R2012a

R2024b: `vision.Maximum` function has been removed
Errors starting in R2024b

`vision.Maximum` function has been removed. Use the `max` and `movmax` function to find maximum values, instead.

R2024a: `vision.Maximum` function will be removed
Warns starting in R2024a

`vision.Maximum` function will be removed in a future release. Use the `max` and `movmax` function to find maximum values, instead.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

vision.Mean

Namespace: `vision`

(Removed) Find mean values in input or sequence of inputs

Note `vision.Mean` function has been removed. Use the `mean` and `movmean` functions to find mean values, instead.

Description

Find the mean values in an input or sequence of inputs.

To track a set of points:

1. Create the `vision.Mean` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
minObj = vision.Mean
minObj = vision.Mean(Name,Value)
```

Description

`minObj = vision.Mean` returns an object, `minObj`, that computes the value and index of the maximum elements in an input or a sequence of inputs.

`minObj = vision.Mean(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `minObj = vision.Maximum('RunningMean',false)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`RunningMean` — Calculate over single input or multiple inputs

`false` (default) | `true`

Calculate over single input or multiple inputs, specified as `true` or `false`. When you set this property to `true`, the object computes the mean value over a sequence of inputs. When you set this property to `false`, the object computes the mean value over the current input.

`ResetInputPort` — Additional input to enable resetting of running mean
`false` (default) | `true`

Additional input to enable resetting of running mean, specified as `true` or `false`. When you set this property to `true`, a reset input must be specified to reset the running mean. This property applies only when you set the `RunningMean` property to `true`.

`ResetCondition` — Condition that triggers resetting of running mean
`'Non-zero'` (default) | `'Rising edge'` | `'Falling edge'` | `'Either edge'`

Condition that triggers resetting of running mean, specified as `'Rising edge'`, `'Falling edge'`, `'Either edge'`, or `'Non-zero'`. This property applies only when you set the `ResetInputPort` property to `true`.

`Dimension` — Dimension to operate along
`'Column'` (default) | `{'All'}` | `'Row'` | `'Custom'`

Dimension to operate along, specified as `{'All'}`, `'Row'`, `'Column'`, or `'Custom'`. This property applies only when you set the `RunningMean` property to `false`.

`CustomDimension` — Numerical dimension to calculate over
`1` (default) | numerical scalar

Numerical dimension to calculate over, specified as a numerical scalar. This property only applies when you set the `Dimension` property to `'Custom'`.

`ROIProcessing` — Enable region-of-interest processing
`false` (default) | `true`

Enable region-of-interest processing, specified as `true` or `false`. This property applies when you set the `Dimension` property to `'All'` and the `RunningMean` property to `false`.

`ROIForm` — Type of ROI
`'Rectangles'` (default) | `Lines'` | `'Label matrix''Binary mask'`

Type of ROI, specified as `'Rectangles'`, `'Lines'`, `'Label matrix'`, or `'Binary mask'`. This property applies only when you set the `ROIProcessing` property to `true`.

`ROIPortion` — ROI or perimeter calculation
`'Entire ROI'` (default) | `'ROI perimeter'`

ROI or perimeter calculation, specified as `'Entire ROI'` or `'ROI perimeter'`. This property applies only when you set the `ROIForm` property to `'Rectangles'`.

`ROIStatistics` — Calculate statistics for each ROI or one for all ROIs
`'Individual statistics for each ROI'` (default) | `'Single statistic for all ROIs'`

Calculate statistics for each ROI or one for all ROIs, specified as `'Individual statistics for each ROI'` or `'Single statistic for all ROIs'`. This property applies only when you set the `'ROIForm'` property to `'Rectangles'`, `'Lines'`, or `'Label matrix'`.

`ValidityOutputPort` — Flag to indicate if any part of ROI is outside input image
`false` (default) | `true`

Flag to indicate if any part of ROI is outside input image, specified as `true` or `false`.

This applies when you set the `ROIForm` property to `'Lines'` or `'Rectangles'`.

Set this property to `true` to return the validity of the specified label numbers. This applies when you set the `ROIForm` property to `'Label matrix'`.

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest''Round'` | `'Simplest''Zero'`

Rounding method for fixed-point operations, specified as `'Floor'`, `'Ceiling'`, `'Convergent'`, `'Nearest'` , `'Round'` , `'Simplest'` , or `'Zero'`.

`OverflowAction` — Action to take when integer input is out-of-range
`'Wrap'` (default) | `'Saturate'`

Action to take when integer input is out-of-range, specified as `'Wrap'` or `'Saturate'`.

`ProductDataType` — Product data type
`'Same as input'` (default) | `'Custom'`

Product data type, specified as `'Same as input'` or `'Custom'`.

`CustomProductDataType` — Product word and fraction lengths
`numerictype(true,32,30)` (default) | scaled `numerictype` object

Product word and fraction lengths, specified as a scaled `numerictype` object. This property applies only when you set the `AccumulatorDataType` property to `'Custom'`.

`AccumulatorDataType` — Data type of accumulator
`'Same as product'` (default) | `'Same as input'` | `'Custom'`

Data type of accumulator, specified as `'Same as product'`, `'Same as input'`, or `'Custom'`.

`CustomAccumulatorDataType` — Accumulator word and fraction lengths
`numerictype(true,32,30)` (default) | scaled `numerictype` object

Accumulator word and fraction lengths, specified as a scaled `numerictype` object. This property applies only when you set the `AccumulatorDataType` property to `'Custom'`.

Usage

Syntax

```
[value,index] = minObj(input)
index = minObj(input)

[___] = minObj(I,ROI)
[___,flag] = minObj(I,ROI)
```

```
[ ___ ] = minObj(I,label,labelNumbers)
[ ___ ,flag] = minObj(I,label,labelNumbers)
```

Description

`[value,index] = minObj(input)` returns the mean value and index of the input.

`index = minObj(input)` returns the one-based index of the mean value when you set the `IndexOutputPort` property to `true` and the `ValueOutputPort` property to `false`. The `RunningMean` property must be set to `false`.

`[ ___ ] = minObj(I,ROI)` returns the mean value in the input image within the given region of interest.

`[ ___ ,flag] = minObj(I,ROI)`additionally returns a flag to indicate whether the given ROI is within the bounds of the image.

`[ ___ ] = minObj(I,label,labelNumbers)` returns the mean of the input image for a region the labels specified in the `labelNumbers` vector. The regions are defined and labeled in the `label` matrix.

`[ ___ ,flag] = minObj(I,label,labelNumbers)` additionally returns a flag to indicate whether the input label numbers are valid.

Input Arguments

`input` — Input data
vector | matrix | multidimensional array

Input data, specified as a vector, matrix, or multidimensional array.

`ROI` — Region of interest
four-element vector

Region of interest, specified as a four-element vector, [*x y width height*]. This option is available when you set the `ROIProcessing` property to `true` and the `ROIForm` property to `'Lines'`, `'Rectangles'`, or `'Binary Mask'`.

`label` — Label numbers
matrix

Label numbers, specified as a matrix. This option is available when you set the `ROIProcessing` property to `true` and the `ROIForm` property to `'Label matrix'`.

`labelNumbers` — Label numbers
vector

Label numbers, specified as a vector. This option is available when you set the `ROIProcessing` property to `true` and the `ROIForm` property to `'Label matrix'`.

Output Arguments

`value` — Mean value
same as input

Mean value, returned as the same data type as the input

`index` — Index to mean value
one-based index

Index to mean value, returned as a one-based index.

`flag` — Flag for valid data
`true` | `false`

Flag for valid data, returned as `true` or `false`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Determine Mean Value in Grayscale Image

1 Read a color image.

```
img = imread('peppers.png');
```

2 Convert the image to grayscale.

```
img = im2single(im2gray(img));
```

3 Find the mean.

```
hMean = vision.Mean;
mean = hMean(img);
```

Version History

Introduced in R2012a

R2024b: `vision.Mean` function has been removed
Errors starting in R2024b

`vision.Mean` function has been removed. Use the `mean` and `movmean` functions to find mean values, instead.

R2024a: `vision.Mean` function will be removed
Warns starting in R2024a

vision.Median

Namespace: `vision`

(Removed) Find median values in input or sequence of inputs

Note `vision.Median` function has been removed. Use the `median` and `movmedian` functions to find median values, instead.

Description

Find the median values in an input or sequence of inputs.

To track a set of points:

1. Create the `vision.Median` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
medObj = vision.Median
medObj = vision.Median(Name,Value)
```

Description

`medObj = vision.Median` returns an object, `medObj`, that computes the value and index of the maximum elements in an input or a sequence of inputs.

`medObj = vision.Median(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `medObj = vision.Median('Dimension','Column')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`SortMethod` — Sort method

`'Quick sort'` | `'Insertion sort'`

Sort method for calculating the median value, specified as `'Quick sort'` or `'Insertion sort'`.

`Dimension` — Dimension to operate along
`'Column'` (default) | `{'All'}` | `'Row'` | `'Custom'`

Dimension to operate along, specified as `{'All'}`, `'Row'`, `'Column'`, or `'Custom'`. This property applies only when you set the `RunningMean` property to `false`.

`CustomDimension` — Numerical dimension to calculate over
1 (default) | numerical scalar

Numerical dimension to calculate over, specified as a numerical scalar. This property only applies when you set the `Dimension` property to `'Custom'`.

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest''Round'` | `'Simplest''Zero'`

Rounding method for fixed-point operations, specified as `'Floor'`, `'Ceiling'`, `'Convergent'`, `'Nearest'` , `'Round'` , `'Simplest'` , or `'Zero'`.

`OverflowAction` — Action to take when integer input is out-of-range
`'Wrap'` (default) | `'Saturate'`

Action to take when integer input is out-of-range, specified as `'Wrap'` or `'Saturate'`.

`ProductDataType` — Product data type
`'Same as input'` (default) | `'Custom'`

Product data type, specified as `'Same as input'` or `'Custom'`.

`CustomProductDataType` — Product word and fraction lengths
`numerictype(true,32,30)` (default) | scaled `numerictype` object

Product word and fraction lengths, specified as a scaled `numerictype` object. This property applies only when you set the `AccumulatorDataType` property to `'Custom'`.

`AccumulatorDataType` — Data type of accumulator
`'Same as product'` (default) | `'Same as input'` | `'Custom'`

Data type of accumulator, specified as `'Same as product'`, `'Same as input'`, or `'Custom'`.

`CustomAccumulatorDataType` — Accumulator word and fraction lengths
`numerictype(true,32,30)` (default) | scaled `numerictype` object

Accumulator word and fraction lengths, specified as a scaled `numerictype` object. This property applies only when you set the `AccumulatorDataType` property to `'Custom'`.

Usage

Syntax

```
[value,index] = medObj(input)
```

Description

`[value,index] = medObj(input)` returns the median value and index of the input.

Input Arguments

`input` — Input data

vector | matrix | multidimensional array

Input data, specified as a vector, matrix, or multidimensional array.

Output Arguments

`value` — Median value

same as input

Median value, returned as the same data type as the input

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm

vision.Minimum

Namespace: `vision`

(Removed) Find minimum values in input or sequence of inputs

Note `vision.Minimum` function has been removed. Use the `min` and `movmin` functions to find minimum values, instead.

Description

Find the minimum values in an input or sequence of inputs.

To track a set of points:

1. Create the `vision.Minimum` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
minObj = vision.Minimum
minObj = vision.Minimum(Name,Value)
```

Description

`minObj = vision.Minimum` returns an object, `minObj`, that computes the value and index of the maximum elements in an input or a sequence of inputs.

`minObj = vision.Minimum(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `minObj = vision.Maximum('RunningMinimum',false)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`ValueOutputPort` — Output Minimum value
`true` (default) | `false`

Output minimum value, specified as `true` or `false`. Set this property to `true` to output the Minimum value of the input. This property applies when you set the `RunningMinimum` property to `false`.

`RunningMinimum` — Calculate over single input or multiple inputs
`false` (default) | `true`

Calculate over single input or multiple inputs, specified as `true` or `false`. When you set this property to `true`, the object computes the minimum value over a sequence of inputs. When you set this property to `false`, the object computes the minimum value over the current input.

`IndexOutputPort` — Output the index of the minimum value
`true` (default) | `false`

Output the index of the minimum value, specified as `true` or `false`. This property applies only when you set the `RunningMinimum` property to `false`.

`ResetInputPort` — Additional input to enable resetting of running minimum
`false` (default) | `true`

Additional input to enable resetting of running minimum, specified as `true` or `false`. When you set this property to `true`, a reset input must be specified to reset the running minimum. This property applies only when you set the `RunningMinimum` property to `true`.

`ResetCondition` — Condition that triggers resetting of running minimum
`'Non-zero'` (default) | `'Rising edge'` | `'Falling edge'` | `'Either edge'`

Condition that triggers resetting of running minimum, specified as `'Rising edge'`, `'Falling edge'`, `'Either edge'`, or `'Non-zero'`. This property applies only when you set the `ResetInputPort` property to `true`.

`IndexBase` — Numbering base for index of minimum value
`'One'` (default) | `'Zero'`

Numbering base for index of minimum value, specified as `'One'` or `'Zero'`. This property applies only when you set the `IndexOutputPort` property to true.

`Dimension` — Dimension to operate along
`'Column'` (default) | `{'All'}` | `'Row'` | `'Custom'`

Dimension to operate along, specified as `{'All'}`, `'Row'`, `'Column'`, or `'Custom'`. This property applies only when you set the `RunningMinimum` property to `false`.

`CustomDimension` — Numerical dimension to calculate over
1 (default) | numerical scalar

Numerical dimension to calculate over, specified as a numerical scalar. This property only applies when you set the `Dimension` property to `'Custom'`.

`ROIProcessing` — Enable region-of-interest processing
`false` (default) | `true`

Enable region-of-interest processing, specified as `true` or `false`. This property applies when you set the `Dimension` property to `'All'` and the `RunningMinimum` property to `false`.

`ROIForm` — Type of ROI
`'Rectangles'` (default) | `Lines'` | `'Label matrix''Binary mask'`

Type of ROI, specified as `'Rectangles'`, `'Lines'`, `'Label matrix'`, or `'Binary mask'`. This property applies only when you set the `ROIProcessing` property to `true`.

`ROIPortion` — ROI or perimeter calculation
`'Entire ROI'` (default) | `'ROI perimeter'`

ROI or perimeter calculation, specified as `'Entire ROI'` or `'ROI perimeter'`. This property applies only when you set the `ROIForm` property to `'Rectangles'`.

`ROIStatistics` — Calculate statistics for each ROI or one for all ROIs
`'Individual statistics for each ROI'` (default) | `'Single statistic for all ROIs'`

Calculate statistics for each ROI or one for all ROIs, specified as `'Individual statistics for each ROI'` or `'Single statistic for all ROIs'`. This property applies only when you set the `'ROIForm'` property to `'Rectangles'`, `'Lines'`, or `'Label matrix'`.

`ValidityOutputPort` — Flag to indicate if any part of ROI is outside input image
`false` (default) | `true`

Flag to indicate if any part of ROI is outside input image, specified as `true` or `false`.

This applies when you set the `ROIForm` property to `'Lines'` or `'Rectangles'`.

Set this property to `true` to return the validity of the specified label numbers. This applies when you set the `ROIForm` property to `'Label matrix'`.

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest''Round'` | `'Simplest''Zero'`

Rounding method for fixed-point operations, specified as `'Floor'`, `'Ceiling'`, `'Convergent'`, `'Nearest'` , `'Round'` , `'Simplest'` , or `'Zero'`.

`OverflowAction` — Action to take when integer input is out-of-range
`'Wrap'` (default) | `'Saturate'`

Action to take when integer input is out-of-range, specified as `'Wrap'` or `'Saturate'`.

`ProductDataType` — Product data type
`'Same as input'` (default) | `'Custom'`

Product data type, specified as `'Same as input'` or `'Custom'`.

`CustomProductDataType` — Product word and fraction lengths
`numerictype(true,32,30)` (default) | scaled `numerictype` object

Product word and fraction lengths, specified as a scaled `numerictype` object. This property applies only when you set the `AccumulatorDataType` property to `'Custom'`.

`AccumulatorDataType` — Data type of accumulator
`'Same as product'` (default) | `'Same as input'` | `'Custom'`

Data type of accumulator, specified as `'Same as product'`, `'Same as input'`, or `'Custom'`.

`CustomAccumulatorDataType` — Accumulator word and fraction lengths
`numerictype(true,32,30)` (default) | scaled `numerictype` object

Accumulator word and fraction lengths, specified as a scaled `numerictype` object. This property applies only when you set the `AccumulatorDataType` property to `'Custom'`.

Usage

Syntax

```
[value,index] = minObj(input)
index = minObj(input)

[ ___ ] = minObj(I,ROI)
[ ___ ,flag] = minObj(I,ROI)

[ ___ ] = minObj(I,label,labelNumbers)
[ ___ ,flag] = minObj(I,label,labelNumbers)
```

Description

`[value,index] = minObj(input)` returns the minimum value and index of the input.

`index = minObj(input)` returns the one-based index of the minimum value when you set the `IndexOutputPort` property to `true` and the `ValueOutputPort` property to `false`. The `RunningMinimum` property must be set to `false`.

`[ ___ ] = minObj(I,ROI)` returns the minimum value in the input image within the given region of interest.

`[ ___ ,flag] = minObj(I,ROI)`additionally returns a flag to indicate whether the given ROI is within the bounds of the image.

`[ ___ ] = minObj(I,label,labelNumbers)` returns the minimum of the input image for a region the labels specified in the `labelNumbers` vector. The regions are defined and labeled in the `label` matrix.

`[ ___ ,flag] = minObj(I,label,labelNumbers)` additionally returns a flag to indicate whether the input label numbers are valid.

Input Arguments

`input` — Input data
vector | matrix | multidimensional array

Input data, specified as a vector, matrix, or multidimensional array.

`ROI` — Region of interest
four-element vector

Region of interest, specified as a four-element vector, [*x y width height*]. This option is available when you set the `ROIProcessing` property to `true` and the `ROIForm` property to `'Lines'`, `'Rectangles'`, or `'Binary Mask'`.

`label` — Label numbers
matrix

Label numbers, specified as a matrix. This option is available when you set the `ROIProcessing` property to `true` and the `ROIForm` property to `'Label matrix'`.

`labelNumbers` — Label numbers
vector

Label numbers, specified as a vector. This option is available when you set the `ROIProcessing` property to `true` and the `ROIForm` property to `'Label matrix'`.

Output Arguments

`value` — Minimum value
same as input

Minimum value, returned as the same data type as the input

`index` — Index to minimum value
one-based index

Index to minimum value, returned as a one-based index.

`flag` — Flag for valid data
`true` | `false`

Flag for valid data, returned as `true` or `false`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Find Index to Minimum Value in Grayscale Image

1. Read a color image.

```
img = imread('peppers.png');
```

2. Convert the image to grayscale.

```
img = im2single(im2gray(img));
```

3 Find the minimum.

```
hMin = vision.Minimum

hMin =
  vision.Minimum with properties:

    ValueOutputPort: true
     RunningMinimum: false
    IndexOutputPort: true
          Dimension: 'All'
      ROIProcessing: false

  Use get to show all properties

[m, ind] = hMin(img);
```

Version History

Introduced in R2012a

R2024b: `vision.Minimum` function has been removed

Errors starting in R2024b

`vision.Minimum` function has been removed. Use the `min` and `movmin` functions to find minimum values, instead.

R2024a: `vision.Minimum` function will be removed

Warns starting in R2024a

`vision.Minimum` function will be removed in a future release. Use the `min` and `movmin` functions to find minimum values, instead.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

`min` | `movmin`

vision.VideoFileReader

Namespace: `vision`

(To be removed) Read video frames and audio samples from video file

Note The `vision.VideoFileReader` system object will be removed in a future release. Use the `VideoReader` object instead to read video files or the `audioread` or `dsp.AudioFileReader` object to read audio files.

Description

The `VideoFileReader` object reads video frames, images, and audio samples from a video file. The object can also read image files.

Platforms	File Formats
All Platforms	AVI, including uncompressed, indexed, grayscale, and Motion JPEG-encoded video (`.avi`) Motion JPEG 2000 (`.mj2`) **Note** `VideoReader` does not support remote reading for formats exclusive to Microsoft DirectShow®.
All Windows	MPEG-1 (`.mpg`) Windows Media Video (`.wmv`, `.asf`) Any format supported by Microsoft DirectShow
Windows 7 or later	MPEG-4, including H.264 encoded video (`.mp4`, `.m4v`) Apple QuickTime Movie (`.mov`) Any format supported by Microsoft Media Foundation
Macintosh	Most formats supported by QuickTime Player, including: MPEG-1 (`.mpg`) MPEG-4, including H.264 encoded video (`.mp4`, `.m4v`) Apple QuickTime Movie (`.mov`) 3GPP 3GPP2 AVCHD DV **Note:** For OS X Yosemite (Version 10.10) and later, MPEG-4/H.264 files written using `VideoWriter`, play correctly, but display an inexact frame rate.

Platforms	File Formats
Linux	Any format supported by your installed plug-ins for GStreamer 1.0 or higher, as listed on https://gstreamer.freedesktop.org/documentation/plugins_doc.html, including Ogg Theora (`.ogg`).

To read a file:

1. Create the `vision.VideoFileReader` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
videoFReader = vision.VideoFileReader(Filename)
videoFReader = vision.VideoFileReader( ___ ,Name,Value)
```

Description

`videoFReader = vision.VideoFileReader(Filename)` returns a video file reader System object, `videoFReader`, that sequentially reads video frames or audio samples from an input file, `Filename`.

`videoFReader = vision.VideoFileReader( ___ ,Name,Value)` additionally sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `videoFReader = vision.VideoFileReader('PlayCount',1)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Filename` — File name

`vipmen.avi` (default) | character vector

File name, specified as a character vector. The full path for the file needs to be specified only if the file is not on the MATLAB path.

`PlayCount` — Number of times to play file

`1` (default) | positive integer | `inf`

Number of times to play file, specified as a positive integer.

`AudioOutputPort` — Output audio data
`false` (default) | `true`

Output audio data, specified as `true` or `false`. Use this property to control the audio output only when the input file contains audio and video streams.

`ImageColorSpace` — Image format
`RGB` (default) | `YCbCr 4:2:2` | intensity video

Image format, specified as `RGB`, `YCbCr 4:2:2`, or intensity video frames when the input file contains video.

`VideoOutputDataType` — Output video data type
`single` (default)

Output video data type, specified as one of the data types listed or `'inherit'`. This property applies when the input file contains video. When you set this property to `'inherit'`, the object sets the output data type to the native data type of the input video.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

`AudioOutputDataType` — Output audio samples data type
`int16` (default)

Output audio samples data type, specified as one of the data types listed and `inherit`. This property applies when the input file contains audio.

Data Types: `double` | `single` | `int16` | `uint8`

Usage

Syntax

```
I = videoFReader()
[Y,Cb,Cr] = videoFReader()
[___,audio] = videoFReader()
[___,EOF] = videoFReader()
```

Description

`I = videoFReader()` returns the next video frame.

`[Y,Cb,Cr] = videoFReader()` returns the next frame of `YCbCr 4:2:2` format video in the color components `Y`, `Cb`, and `Cr`. This syntax requires that you set the `'ImageColorSpace'` property to `'YCbCr 4:2:2'`

`[___,audio] = videoFReader()` also returns one frame of audio samples, `audio`. This syntax requires that you set the `AudioOutputPort` property to `true`.

`[___,EOF] = videoFReader()` also returns the end-of-file indicator, `EOF`. The object sets `EOF` to `true` each time the output contains the last audio sample and/or video frame.

Output Arguments

`I` — Video frame

truecolor | 2-D grayscale image

Video frame, returned as a truecolor or 2-D grayscale image.

`Y`, `Cb`, `Cr` — YCbCr color channels

numeric matrices

YCbCr color channels of a `YCbCr 4:2:2` format image, returned as numeric matrices.

`audio` — One frame of audio samples

`.wav` | `.mp3` | `.mp3` | `.mp4` | `.ogg` | `.flac` | `.au` | `.aiff` | `.aif` | `.aifc`

One frame of audio samples, returned in one of the following formats.

Platform	Supported File Name Extensions
All Platforms	AVI (`.avi`)
Windows	**Image**: `.jpg`,`.bmp`
	Video: MPEG (`.mpeg`) MPEG-2 (`.mp2`) MPEG-1`.mpg` MPEG-4, including H.264 encoded video (`.mp4`, `.m4v`) Motion JPEG 2000 (`.mj2`) Windows Media Video (`.wmv`,`.asf`, `.asx`, .asx) and any format supported by Microsoft DirectShow® 9.0 or higher.
	Audio: WAVE (`.wav`) Windows Media Audio File (`.wma`) Audio Interchange File Format (`.aif`, `.aiff`) Compressed Audio Interchange File Format(`.aifc`), MP3 (`.mp3`) Sun Audio (`.au`) Apple (`.snd`)
Macintosh	**Video**: `.avi` Motion JPEG 2000 (`.mj2`) MPEG-4, including H.264 encoded video (`.mp4`, `.m4v`) Apple QuickTime Movie (.mov) and any format supported by QuickTime as listed on http://support.apple.com/kb/HT3775.
	Audio: Uncompressed `.avi`
Linux	Motion JPEG 2000 (`.mj2`) Any format supported by your installed plug-ins for GStreamer 0.1 or higher, as listed on https://gstreamer.freedesktop.org/documentation/plugins_doc.html?gi-language=c, including Ogg Theora (.ogg).

Windows XP and Windows 7 x64 platform ships with a limited set of 64-bit video and audio codecs. If a compressed multimedia file fails to play, try saving the multimedia file to a supported file format listed in the table above.

If you use Windows, use Windows Media player Version 11 or later.

Note MJ2 files with bit depth higher than 8-bits are not supported by `vision.VideoFileReader`. Use `VideoReader` and `VideoWriter` for higher bit depths.

Reading audio from compressed MP4 files with video and audio is not supported by `vision.VideoFileReader`.

EOF — End-of-file

`true` | `false`

End-of-file indicator, returned as `true` or `false`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to vision.VideoFileReader

info	Information about specified video file
isDone	End-of-file status (logical)

Common to All System Objects

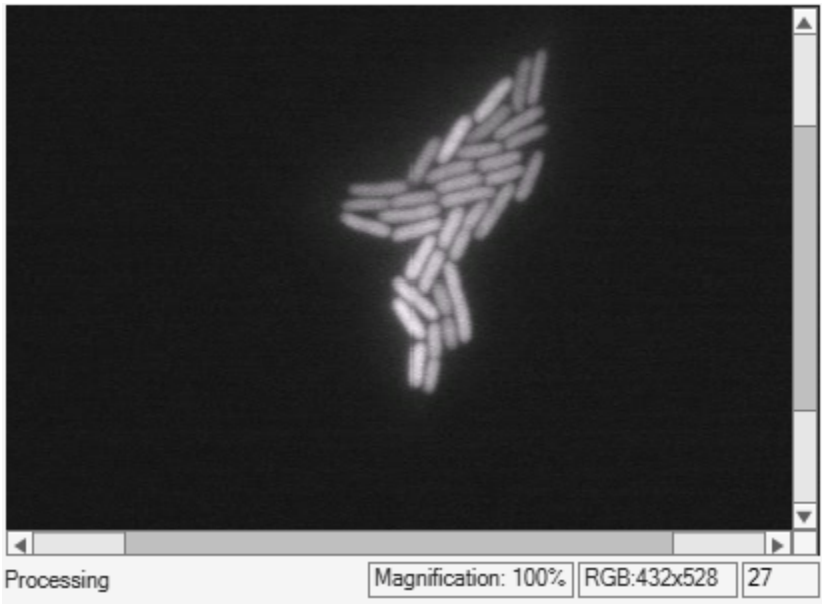
step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Read and Play a Video File

Load the video using a video reader object.

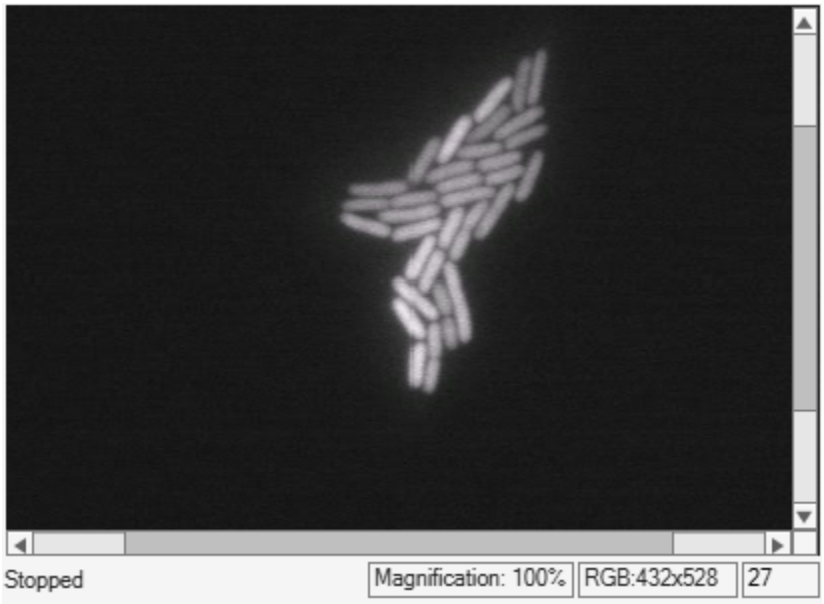
```
vidReader = VideoReader('ecolicells.avi');
```



Create a video player object to play the video file.

```
videoPlayer = vision.VideoPlayer;
```

Use a while loop to read and play the video frames. Pause for 0.1 seconds after displaying each frame.



```
while hasFrame(vidReader)
```

```
    videoFrame = readFrame(vidReader);
    videoPlayer(videoFrame);
    pause(0.1)
end
```

Release the objects.

```
release(videoPlayer);
```

Tips

- Video Reading Performance on Windows Systems:To achieve better video reader performance on Windows for MP4 and MOV files, MATLAB uses the system's graphics hardware for decoding.

However, in some cases using the graphics card for decoding can result in poorer performance depending on the specific graphics hardware on the system. If you notice slower video reader performance on your system, turn off the hardware acceleration by typing:

```
matlab.video.read.UseHardwareAcceleration('off')
```

Hardware acceleration can be reenabled by typing:

```
matlab.video.read.UseHardwareAcceleration('on')
```

Version History

Introduced in R2012a

R2022b: `vision.VideoFileReader` system object will be removed in future release
Warns starting in R2022b

The `vision.VideoFileReader` system object will be removed in a future release. Use the `VideoReader` object instead.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Generated code for this function uses a precompiled platform-specific shared library.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

Topics

“Video Display in a Custom User Interface”

vision.VideoFileWriter

Namespace: `vision`

Write video frames and audio samples to video file

Description

The `VideoFileWriter` object writes video frames and audio samples to a video file. The video and audio can be compressed. The available compression types depend on the encoders installed on the platform.

Note This block supports code generation for platforms that have file I/O available. You cannot use this block with Simulink Desktop Real-Time software, because that product does not support file I/O.

This object performs best on platforms with Version 11 or later of Windows Media Player software. This object supports only uncompressed RGB24 AVI files on Linux and Mac platforms.

The generated code for this object relies on prebuilt library files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra library files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See `packNGo` for more information.

To run an executable file that was generated from an object, you may need to add precompiled shared library files to your system path. See “MATLAB Coder” and “Simulink Shared Library Dependencies” for details.

Creation

Syntax

```
videoFWriter = vision.VideoFileWriter
videoFWriter = vision.VideoFileWriter(Filename)
videoFWriter = vision.VideoFileWriter( ___ ,Name,Value)
```

Description

`videoFWriter = vision.VideoFileWriter` returns a video file writer System object, `videoFWriter`. It writes video frames to an uncompressed '`output.avi`' video file. Every call to the `step` method writes a video frame.

`videoFWriter = vision.VideoFileWriter(Filename)` returns a video file writer object, `videoFWriter` that writes video to a file, `Filename`. The file type can be `.avi`, `.mj2`, `.mp4`, and `.m4v` specified by the `FileFormat` property.

`videoFWriter = vision.VideoFileWriter( ___ ,Name,Value)` configures the video file writer properties, specified as one or more name-value pair arguments. Unspecified properties have default values.

`Name` is a property name and `Value` is the corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `videoFWriter = vision.VideoFileWriter('myFile.avi','FrameRate',... videoFReader.info.VideoFrameRate);`

Properties

`Filename` — Video output file name

`output.avi` (default) | character vector

Video output file name, specified as a character vector. The file extension you give for `Filename` must match the `FileFormat`.

`FileFormat` — Output file format

`'AVI'` (default) | `'MJ2000'` | `'MPEG4'`

Output file format, specified as one of the supported file formats shown in the table.

File Format	Description	File Extension	Supported Platform
`'AVI'`	Audio-Video Interleave file	`.avi`	All platforms
`'MJ2000'`	Motion JPEG 2000 file	`.mj2`	All platforms
`'MPEG4'`	MPEG-4/H.264 Video	`.mp4` , `.m4v`	Windows and Mac

`AudioInputPort` — Write audio data

`false` (default) | `true`

Write audio data, specified as `false` or `true`. Use this property to control whether the object writes audio samples to the video file. Set this value to `true` to write audio data. To write audio and video to a file, you must use the `.avi` format.

`FrameRate` — Video frame rate

`30` (default) | positive numeric scalar

Video frame rate in frames per second, specified as a positive numeric scalar. For videos which also contain audio data, the rate of the audio data will be determined as the rate of the video multiplied by the number of audio samples passed in. For example, if you use a frame rate of `30`, and pass 1470 audio samples, the object sets the audio sample to `44100`, (`1470 x 30 = 44100`).

`AudioCompressor` — Audio compression encoder

`None (uncompressed)` (default) | system compressors

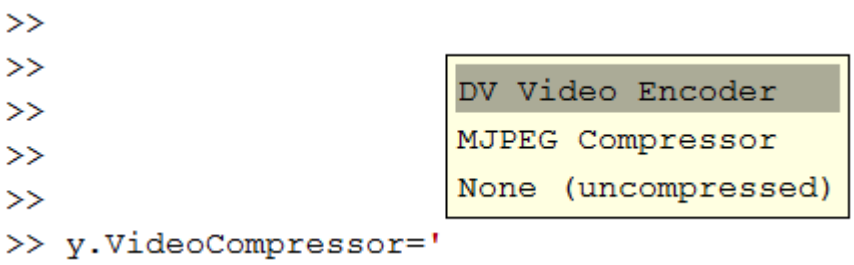
Specify the type of compression algorithm to implement for audio data. This compression reduces the size of the video file. Choose `None (uncompressed)` to save uncompressed audio data to the video file. The other options reflect the available audio compression algorithms installed on your system. This property applies only when writing `AVI` files on Windows platforms.

`VideoCompressor` — Video compression encoder

`None (uncompressed)` (default) | system compressors

Specify the type of compression algorithm to use to compress the video data. This compression reduces the size of the video file. Choose `None (uncompressed)` to save uncompressed video data

to the video file. The `VideoCompressor` property can also be set to one of the compressors available on your system. To obtain a list of available video compressors, you can use tab completion. Follow these steps:



1. Instantiate the object:

   ```
   y = vision.VideoFileWriter
   ```

2. To launch the tab completion functionality, type the following up to the open quote.

   ```
   y.VideoCompressor='
   ```

   A list of compressors available on your system will appear after you press the `Tab` key. For example:

This property applies only when writing `AVI` files on Windows platforms.

`AudioDataType` — Uncompressed audio data type
`WAV` (default)

Specify the compressed output audio data type. This property only applies when you write uncompressed `WAV` files.

`FileColorSpace` — Color space for output file
`RGB` (default) | `YCbCr 4:2:2`

Color space for output AVI file, specified as `RGB` or `YCbCr 4:2:2`. This property applies when you set the `FileFormat` property to `AVI` and only on Windows platforms.

`Quality` — Control size of output video file
`75` (default) | integer

Control size of output video file, specified as an integer in the range `[0,100]`. Increase this value for greater video quality. However, doing so increases the file size. Decrease the value to lower video quality with a smaller file size.

The `Quality` property only applies when you are writing MPEG4 video files (on Windows or Mac) or when you are writing MJPEG-AVI video only files on a Mac or Linux.

`CompressionFactor` — Target ratio between number of bytes in input image and compressed image
`10` (default) | integer

Target ratio between number of bytes in input image and compressed image, specified as an integer greater than `1`. The `CompressionFactor` indicates the target ratio between the number of bytes in the input image and the compressed image. The data is compressed as much as possible, up to the specified target. This property applies only when writing Lossy MJ2000 files.

Usage

Syntax

```
Filename = videoFWriter(videoFrame)
Filename = videoFWriter(videoFrame,audio)
Filename = videoFWriter(videoFrame,Y,Cb,Cr,audio)
```

Description

`Filename = videoFWriter(videoFrame)` writes one frame of video, `videoFrame`, to the output file. The input video can be an *M*-by-*N*-by-3 truecolor RGB video frame, or an *M*-by-*N* grayscale video frame..

`Filename = videoFWriter(videoFrame,audio)` writes one frame of the input video, `videoFrame`, and one frame of audio samples, `audio`, to the output file. This applies when you set the `AudioInputPort` property to `true`.

`Filename = videoFWriter(videoFrame,Y,Cb,Cr,audio)` writes one frame of YCbCr 4:2:2 video, and one frame of audio samples, `audio`, to the output file. This applies when you set the `AudioInputPort` to `true` and the `FileColorSpace` property to '`YCbCr 4:2:2`'. The width of Cb and Cr color components must be half of the width of Y.

Input Arguments

`videoFrame` — Video frame

truecolor | 2-D grayscale image

Video frame, returned as a truecolor or 2-D grayscale image.

`Y,Cb,Cr` — YCbCr color format

`'YCbCr 4:2:2'`

YCbCr color format, returned in the `YCbCr 4:2:2` format.

`audio` — One frame of audio samples

`.wav` | `.mp3` | `.mp3` | `.mp4` | `.ogg` | `.flac` | `.au` | `.aiff` | `.aif` | `.aifc`

One frame of audio samples, returned in one of the following formats.

Platform	Supported File Name Extensions
All Platforms	AVI (`.avi`)
Windows	**Image**: `.jpg`,`.bmp`
	Video: MPEG (`.mpeg`) MPEG-2 (`.mp2`) MPEG-1`.mpg` MPEG-4, including H.264 encoded video (`.mp4`, `.m4v`) Motion JPEG 2000 (`.mj2`) Windows Media Video (`.wmv`,`.asf`, `.asx`, .asx) and any format supported by Microsoft DirectShow® 9.0 or higher.

Platform	Supported File Name Extensions
	Audio: WAVE (`.wav`) Windows Media Audio File (`.wma`) Audio Interchange File Format (`.aif`, `.aiff`) Compressed Audio Interchange File Format(`.aifc`), MP3 (`.mp3`) Sun Audio (`.au`) Apple (`.snd`)
Macintosh	**Video**: `.avi` Motion JPEG 2000 (`.mj2`) MPEG-4, including H.264 encoded video (`.mp4`, `.m4v`) Apple QuickTime Movie (.mov) and any format supported by QuickTime as listed on http://support.apple.com/kb/HT3775.
	Audio: Uncompressed `.avi`
Linux	Motion JPEG 2000 (`.mj2`) Any format supported by your installed plug-ins for GStreamer 0.1 or higher, as listed on http://gstreamer.freedesktop.org/documentation/plugins.html, including Ogg Theora (.ogg).

Windows XP and Windows 7 x64 platform ships with a limited set of 64-bit video and audio codecs. If a compressed multimedia file fails to play, try saving the multimedia file to a supported file format listed in the table above.

If you use Windows, use Windows Media player Version 11 or later.

Note Use `VideoReader` and `VideoWriter` for higher bit depths.

Output Arguments

`Filename` — Video output file name
`'.avi'` (default) | `'.mj2'` | `'.mp4'` | `'.m4v'`

Video output file name, specified as `'.avi'`, `'.mj2'`, `'.mp4'`, and `'.m4v'`. The file extension you give for `Filename` must match the `FileFormat`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to vision.VideoFileWriter

info Information about specified video file

isDone End-of-file status (logical)

Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

Write a Video to an AVI File

Load a video file and write the file to a writer object.

```
vidReader = VideoReader('viplanedeparture.mp4');
videoFWriter = vision.VideoFileWriter('myFile.avi', ...
    'FrameRate',vidReader.FrameRate);
```

Write the first 50 frames from original file into a newly created `myFile.avi` file.

```
for i=1:50
  videoFrame = readFrame(vidReader);
  videoFWriter(videoFrame);
end
```

Close the input and output files.

```
release(videoFWriter);
```

`VideoWriter` | `VideoReader` | `vision.VideoPlayer`

ocrText

Store OCR results

Description

The `ocrText` object contains recognized text and metadata collected during optical character recognition (OCR). You can locate text that matches a specific pattern with the `locateText` function.

Creation

Create an `ocrText` object or array using the `ocr` function.

Properties

`Text` — Text recognized by OCR
cell array of characters

Text recognized by OCR, specified as a cell array of characters. The text includes white space and new line characters.

`CharacterBoundingBoxes` — Character bounding box locations and sizes
M-by-4 matrix

Character bounding box locations and sizes, specified as an *M*-by-4 matrix. Each row of the matrix is of the form, [*x y width height*]. The [*x y*] elements correspond to the upper-left corner of the bounding box. The [*width height*] elements correspond to the horizontal and vertical size, respectively, of the rectangular region in pixels. The bounding boxes enclose the text found in an image by the `ocr` function. Widths and heights of bounding boxes that correspond to new line characters have values of zero. Bounding boxes for character modifiers found in languages such as Hindi, Tamil, and Bengali, also have values of zero.

`CharacterConfidences` — Character recognition confidences
array

Character recognition confidence, specified as an array. Confidence values are in the range [0, 1]. Interpret each confidence value set by the `ocr` function, as a probability. The `ocr` function sets confidence values for spaces between words and new line characters to `NaN`, as OCR does not explicitly recognize spaces and new line characters. You can use the confidence values to identify the location of misclassified text within the image by extracting characters with low confidence.

`Words` — Recognized words
cell array of character vectors

Recognized words, specified as a cell array of character vectors.

`WordBoundingBoxes` — Word bounding box location and size of words
N-by-4 matrix

Word bounding box locations and sizes, specified as an *N*-by-4 matrix. Each row of the matrix is of the form, [*x y width height*], and specifies the upper-left corner position and size of a rectangular region in pixels.

`WordConfidences` — Word recognition confidences
vector

Word recognition confidences, specified as a vector of probability values in the range [0,1]. The `ocr` function sets confidence values for spaces between words and new line characters to `NaN`, as OCR does not explicitly recognize spaces and new line characters. You can use confidence values to identify the location of misclassified text within the image by extracting words with low confidence.

`TextLines` — Recognized text lines
cell array of character vectors

Recognized text lines, specified as a cell array of character vectors.

`TextLineBoundingBoxes` — Text line bounding box location and size
N-by-4 matrix

Text line bounding box location and size, specified as an *N*-by-4 matrix. Each row of the matrix is of the form, [*x y width height*], and specifies the upper-left corner position and size of a rectangular region in pixels.

`TextLineConfidences` — Text line confidences
vector

Text line confidences, specified as a vector of probability values in the range [0,1]. Use confidence values to identify the location of misclassified text lines within the image by extracting text lines with low confidence.

Object Functions

locateText Locate text pattern

Examples

Find and Highlight Text in Image

Load an image containing text into the workspace.

```
businessCard = imread("businessCard.png");
ocrResults = ocr(businessCard);
bboxes = locateText(ocrResults,"Math",IgnoreCase=true);
Iocr = insertShape(businessCard,"FilledRectangle",bboxes);
figure
imshow(Iocr)
```

Find Text Using Regular Expressions

Load an image containing text into the workspace.

```
businessCard = imread("businessCard.png");
ocrResults   = ocr(businessCard);
bboxes = locateText(ocrResults, "www.*com","UseRegexp", true);
img    = insertShape(businessCard, "FilledRectangle", bboxes);
figure
imshow(img)
```

Version History

Introduced in R2014a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use in a MATLAB Function block is not supported.
- The `Words` property cannot be accessed in code generation. Use the `Text` property in place of the `Words` property to access the OCR results.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.
