locateText

Locate text pattern

Syntax

```
bboxes = locateText(ocrText,pattern)
bboxes = locateText(ocrText,pattern,Name=Value)
```

Description

`bboxes = locateText(ocrText,pattern)` returns the location and size of bounding boxes stored in the `ocrText` object. The `locateText` function returns only the locations of bounding boxes which correspond to text within an image that exactly match the input `pattern`.

`bboxes = locateText(ocrText,pattern,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `IgnoreCase=true` specifies case-insensitive text locations.

Examples

Find and Highlight Text in Image

Load an image containing text into the workspace.

```
businessCard = imread("businessCard.png");
ocrResults = ocr(businessCard);
bboxes = locateText(ocrResults,"Math",IgnoreCase=true);
Iocr = insertShape(businessCard,"FilledRectangle",bboxes);
figure
imshow(Iocr)
```

Find Text Using Regular Expressions

Load an image containing text into the workspace.

```
businessCard = imread("businessCard.png");
ocrResults   = ocr(businessCard);
bboxes = locateText(ocrResults, "www.*com","UseRegexp", true);
img    = insertShape(businessCard, "FilledRectangle", bboxes);
figure
imshow(img)
```

Input Arguments

`ocrText` — Object containing OCR results

`ocrText` object

Recognized text and metrics, returned as an `ocrText` object. The object contains the recognized text, the location of the recognized text within the input image, and the metrics indicating the confidence of the results. The confidence values, representing the probabilities, range between `0` and `1`. When you specify an *M*-by-4 `roi`, the function returns `ocrText` as an *M*-by-1 array of `ocrText` objects.

`pattern` — OCR character vector pattern

single character vector | cell array of character vectors | string scalar | string array

OCR character vector pattern, specified as a single character vector, string scalar, cell array of character vectors, or a string array. The object function returns only the locations of bounding boxes which correspond to text within an image that exactly match the input `pattern`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `IgnoreCase=true` specifies case-insensitive text locations

`UseRegexp` — Logical to treat pattern as regular expression

`false` (default) | logical scalar

Logical to treat pattern as regular expression, specified as a logical scalar. When you set this property to `true`, the object function treats the pattern as a regular expression. For more information about regular expressions, see `regexp`.

`IgnoreCase` — Case sensitivity
`false` (default) | logical scalar

Case sensitivity, specified as a logical scalar. When you set this property to `true`, the object function performs case-insensitive text location.

Output Arguments

`bboxes` — Text bounding boxes
M-by-4 matrix

Text bounding boxes, returned as an *M*-by-4 matrix. Each row of the matrix contains a four-element vector, [*x y width height*]. The [*x y*] elements correspond to the upper-left corner of the bounding box. The [*width height*] elements correspond to the size of the rectangular region in pixels. The bounding boxes enclose text found in an image using the `ocr` function. The `ocr` function stores OCR results in the `ocrText` object.

Version History

Introduced in R2014a

pointCloud

Object for storing 3-D point cloud

Description

The `pointCloud` object creates point cloud data from a set of points in 3-D coordinate system. The points generally represent the *x*,*y*, and *z* geometric coordinates for samples on a surface or of an environment. Each point can also be represented with additional information, such as the RGB color. The point cloud data is stored as an object with the properties listed in “Properties” on page 2-984. Use “Object Functions” on page 2-985 to retrieve, select, and remove desired points from the point cloud data.

Creation

Syntax

```
ptCloud = pointCloud(xyzPoints)
ptCloud = pointCloud( ___ ,Name=Value)
```

Description

`ptCloud = pointCloud(xyzPoints)` returns a point cloud object with coordinates specified by `xyzPoints`.

`ptCloud = pointCloud( ___ ,Name=Value)` sets options using one or more name-value arguments in addition to the previous syntax. For example, `Color=[1 0 0]` sets the color of the point cloud to red.

Input Arguments

`xyzPoints` — 3-D coordinate points
M-by-3 list of points | *M*-by-*N*-by-3 array for organized point cloud

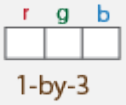
3-D coordinate points, specified as an *M*-by-3 list of points or an *M*-by-*N*-by-3 array for an organized point cloud. The 3-D coordinate points specify the *x*, *y*, and *z* positions of a point in the 3-D coordinate space. The first two dimensions of an organized point cloud correspond to the scanning order from sensors such as RGBD or lidar. This argument sets the `Location` property.

Data Types: `single` | `double`

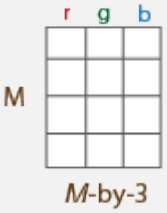
Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

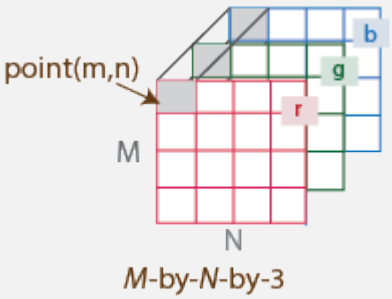
Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*



Example: `Color=[1 0 0]` sets the color of the point cloud to red.



`Color` — Point cloud color



`[ ]` (default) | color string | 1-by-3 vector | *M*-by-3 matrix | *M*-by-*N*-by-3 array

Point cloud color, specified as an RGB value as one of, a color string, a 1-by-3 vector, or an *M*-by-3 or *M*-by-*N*-by-3 array. *M*-by- *N* specifies the dimensions of the point cloud. Each entry specifies the RGB color of a point in the point cloud data. Therefore, you can specify the same color for all points or a different color for each point.

- For `single` or `double` datatype, the `Color` RGB value must be specified in the range [0, 1].
- For `uint8` datatype, the `Color` RGB value must be specified in the range [0, 255].
- For `uint16` datatype, the `Color` RGB value must be specified in the range [0, 65535].
- The function stores the `Color` value as either an *M*-by-3 or *M*-by-*N*-by-3. If you specify the color as a string or a 1-by-3 vector, the function converts it to one of these dimensions.

Color	Format	Example
Specify one color for all points	string scalar or character vector	`"r"` `"red"`
	1-by-3 vector	 `[255 0 0]`

Specify a color for each point	*M*-by-3 matrix, as a list of RGB values	`255 0 0`
		`255 0 0`
		`0 255 255`
		

	M-by-*N*-by-3 array for an organized point cloud containing RGB values for each point, where *M*-by-*N* is the dimension of the point cloud.	

Data Types: `uint8` | `uint16` | `single` | `double`

`Normal` — Surface normals

`[ ]` (default) | *M*-by-3 array | *M*-by-*N*-by-3 array

Surface normals, specified as a *M*-by-3 or *M*-by-*N*-by-3 array. Use this property to specify the normal vector with respect to each point in the point cloud. Each entry in the surface normals specifies the *x*, *y*, and *z* component of a normal vector.

Coordinates	Surface Normals
M-by-3 array	*M*-by-3 array, where each row contains a corresponding normal vector.
M-by-*N*-by-3 array	*M*-by-*N*-by-3 array containing a 1-by-1-by-3 normal vector for each point.

Data Types: `single` | `double`

`Intensity` — Grayscale intensities
`[ ]` (default) | *M*-by-1 vector | *M*-by-*N* matrix

Grayscale intensities at each point, specified as a *M*-by-1 vector or *M*-by-*N* matrix. The function maps each intensity value to a color value in the current colormap.

Coordinates	Intensity
M-by-3 array	*M*-by-1 vector, where each row contains a corresponding intensity value.
M-by-*N*-by-3 array	*M*-by-*N* matrix containing intensity value for each point.

Data Types: `single` | `double` | `uint8` | `uint16`

Output Arguments

`ptCloud` — Point cloud
`pointCloud` object

Point cloud, returned as a `pointCloud` object with the properties listed in “Properties” on page 2-984.

Properties

`Location` — Position of the points in 3-D coordinate space
M-by-3 array | *M*-by-*N*-by-3 array

This property is read-only.

Position of the points in 3-D coordinate space or geographic coordinate space, represented as an *M*-by-3 or *M*-by-*N*-by-3 array. Each entry specifies the coordinates of a point, which can be either:

The `xyzPoints` input argument sets this property. To reduce memory use, you can store point locations as a `single` data type.

- For unorganized point clouds, `Location` must be specified as an *M*-by-3 array, where *M* is the total number of points, and the array provides the coordinates for each point.
- For organized point clouds, `Location` must be specified as an *M*-by-*N*-by-3 array, where *M***N* is the total number of points, and the array provides the coordinates for each point. Points obtained from a projective camera, such as Kinect or a lidar sensor, are stored as an organized point cloud. An organized point cloud is laid out as a 2-D array of points that resemble an image-like structure.

Data Types: `single` | `double`

`Count` — Number of points
positive integer

This property is read-only.

Number of points in the point cloud, represented as a positive integer.

`XLimits` — Range of *x* coordinates
2-element vector

This property is read-only.

Range of coordinates along *x*-axis, represented as a 2-element vector.

`YLimits` — Range of *y* coordinates
2-element vector

This property is read-only.

Range of coordinates along *y*-axis, represented as a 2-element vector.

`ZLimits` — Range of *z* coordinates
2-element vector

This property is read-only.

Range of coordinates along *z*-axis, represented as a 2-element vector.

Object Functions

findNearestNeighbors	Find nearest neighbors of query points in point cloud
findNeighborsInRadius	Find neighbors within radius for query points in point cloud
findPointsInROI	Find points within a region of interest in the point cloud
findPointsInCylinder	Find points within a cylindrical region in a point cloud
removeInvalidPoints	Remove invalid points from point cloud
select	Select points in point cloud
copy	Copy array of point cloud objects

Examples

Create a Point Cloud Object and Modify Properties

Read the 3-D coordinate points into the workspace.

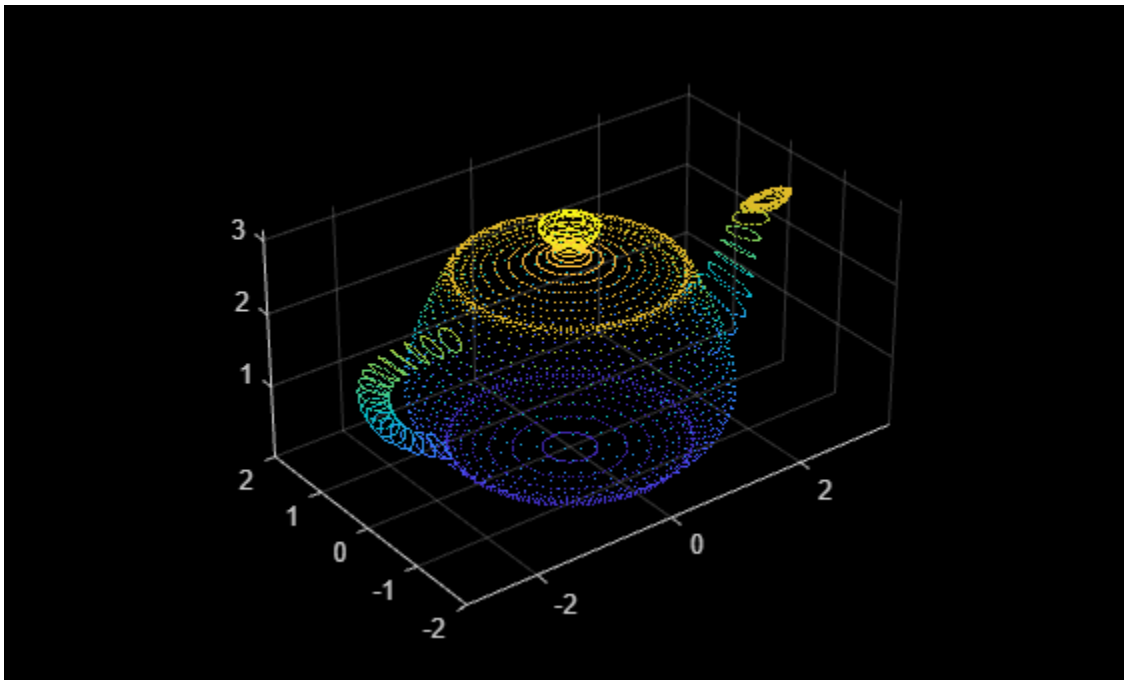
```
load("xyzPoints");
```

Create a point cloud object from the input point coordinates.

```
ptCloud = pointCloud(xyzPoints);
```

Inspect the properties of the point cloud object.

```
ptCloud
```



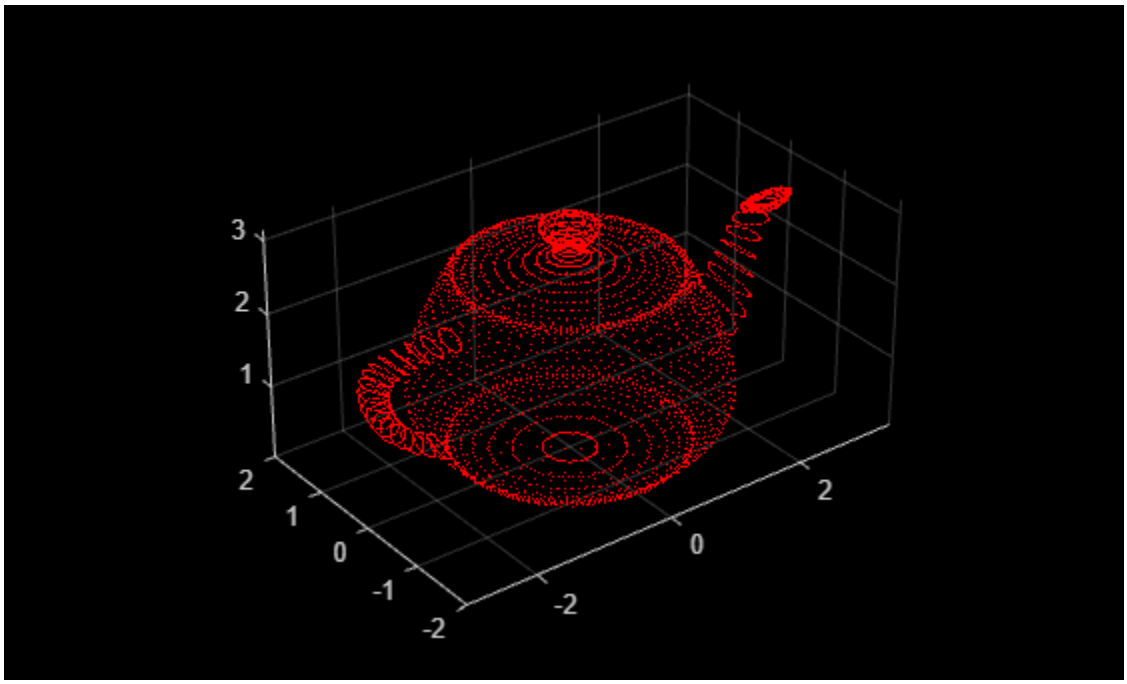
```
ptCloud =
  pointCloud with properties:

     Location: [5184×3 single]
        Count: 5184
      XLimits: [-3 3.4338]
```

```
      YLimits: [-2 2]
      ZLimits: [0.0016 3.1437]
        Color: []
       Normal: []
    Intensity: []
```

Display the point cloud by using `pcshow`.

```
pcshow(ptCloud)
```



Modify Color of Point Cloud Data

Create an RGB color array of size same as the size of the point cloud data. Set the point colors to Red.

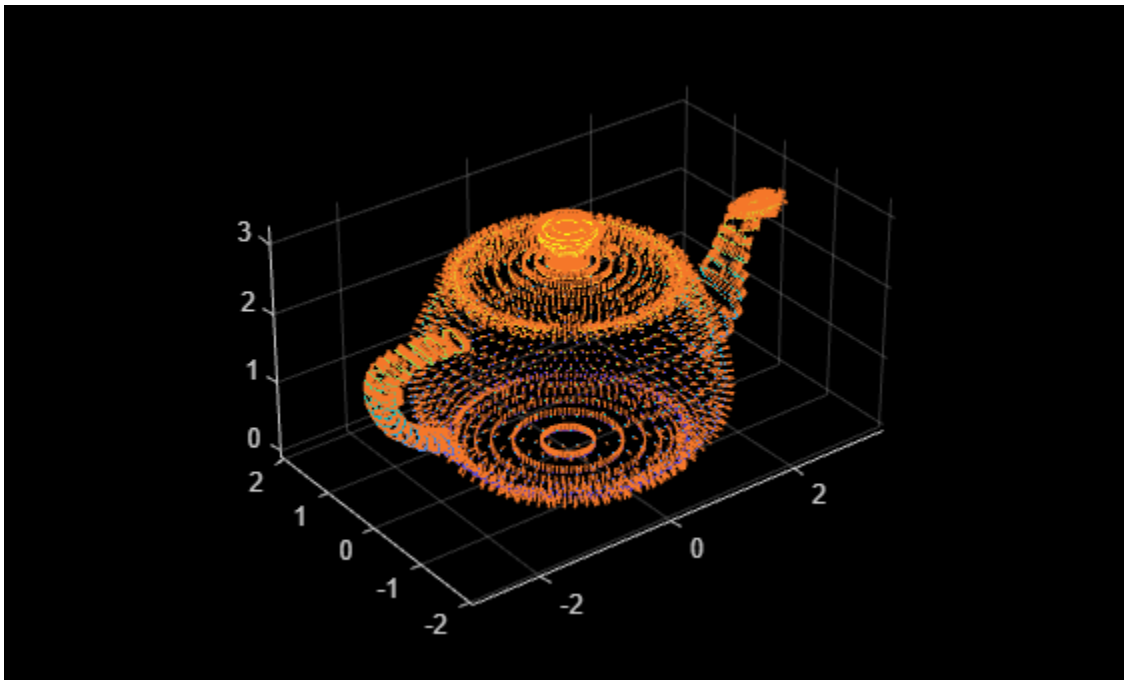
```
cmatrix = ones(size(ptCloud.Location)).*[1 0 0];
```

Create the point cloud object with the color property set to the RGB color array.

```
ptCloud = pointCloud(xyzPoints,Color=cmatrix);
pcshow(ptCloud)
```

Add Surface Normals to Point Cloud Data

Compute surface normals corresponding to the point cloud data using `pcnormals`.



```
normals = pcnormals(ptCloud);
```

Create point cloud object from input point coordinates. Add the computed surface normals to point cloud object.

```
ptCloud = pointCloud(xyzPoints,Normal=normals);
```

Display the point cloud and plot the surface normals.

```
pcshow(ptCloud)
x = ptCloud.Location(:,1);
y = ptCloud.Location(:,2);
z = ptCloud.Location(:,3);
u = normals(:,1);
v = normals(:,2);
w = normals(:,3);
hold on
quiver3(x,y,z,u,v,w);
hold off
```

Tips

The `pointCloud` object is a `handle` object. If you want to create a separate copy of a point cloud, you can use the MATLAB `copy` method.
`ptCloudB = copy(ptCloudA)`

If you want to preserve a single copy of a point cloud, which can be modified by point cloud functions, use the same point cloud variable name for the input and output.
`ptCloud = pcFunction(ptCloud)`

Version History

Introduced in R2015a

R2022b: Color support `uint16` datatype

`uint16` datatype support for the `Color` property

R2026a: Store `Color` property using `single` or `double` data type

The object now supports storing the `Color` property using the `single` or `double` data type.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- GPU code generation for variable input sizes is not optimized. Consider using constant size inputs for an optimized code generation.
- GPU code generation supports the `Color`, `Normal`, and `Intensity` name-value pairs.
- GPU code generation supports the `findNearestNeighbors`, `findNeighborsInRadius`, `findPointsInROI`, `removeInvalidPoints`, and `select` methods.
- For very large inputs, the memory requirements of the algorithm may exceed the GPU device limits. In such cases, consider reducing the input size to proceed with code generation.

findNearestNeighbors

Find nearest neighbors of query points in point cloud

Syntax

```
[indices,dists] = findNearestNeighbors(ptCloud,points,K)
[indices,dists] = findNearestNeighbors(ptCloud,points,K,camMatrix)
[indices,dists] = findNearestNeighbors( ___ ,Name,Value)
```

Description

`[indices,dists] = findNearestNeighbors(ptCloud,points,K)` returns the `indices` for the K-nearest neighbors of one or more query points in the input point cloud. `ptCloud` can be an unorganized or organized point cloud. The K-nearest neighbors of the query points are computed by using the Kd-tree based search algorithm.

`[indices,dists] = findNearestNeighbors(ptCloud,points,K,camMatrix)` returns the K-nearest neighbors of one or more query points in the input point cloud. The input point cloud is an organized point cloud generated by a depth camera. The K-nearest neighbors of the query points are determined using fast approximate K-nearest neighbor search algorithm.

The function uses the camera projection matrix `camMatrix` to know the relationship between adjacent points and hence, speeds up the nearest neighbor search. However, the results have lower accuracy as compared to the Kd-tree based approach.

Note

- This syntax only supports organized point cloud data produced by RGB-D sensors.
- You can use `estimateCameraMatrix` to estimate camera projection matrix for the given point cloud data.

`[indices,dists] = findNearestNeighbors( ___ ,Name,Value)` specifies options using one or more name-value arguments in addition to the input arguments in the preceding syntaxes.

Examples

Find K-Nearest Neighbors in Point Cloud

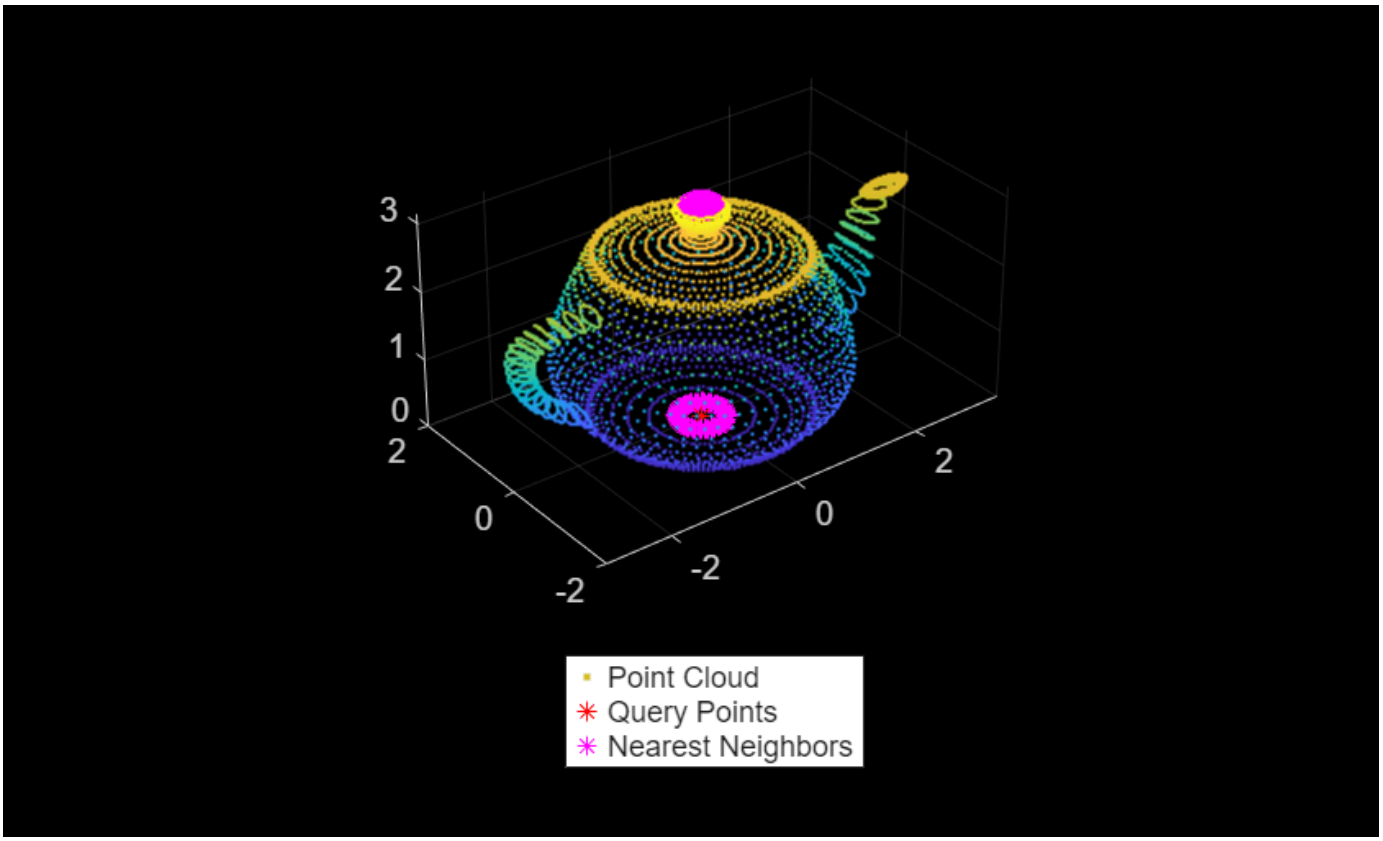
Load a set of 3-D coordinate points into the workspace.

```
load("xyzPoints.mat");
```

Create a point cloud object.

```
ptCloud = pointCloud(xyzPoints);
```

Specify two query points and the number of nearest neighbors to identify.



```
points = [0 0 0; 0 0 3];
K = 70;
```

Get the indices and the distances of the K nearest neighbors for each query point.

```
[indices,dists] = findNearestNeighbors(ptCloud,points,K);
```

Display the point cloud. Plot the query points and their nearest neighbors.

```
figure
pcshow(ptCloud)
hold on
plot3(points(:,1),points(:,1),points(:,3),"*r")
plot3(ptCloud.Location(indices,1), ...
    ptCloud.Location(indices,2), ...
    ptCloud.Location(indices,3),"*m")
legend("Point Cloud","Query Points", ...
    "Nearest Neighbors", ...
    Location="southoutside", ...
    Color=[1 1 1])
hold off
```

Find K-Nearest Neighbors in Organized Point Cloud

Find the K-nearest neighbors of a query point in the organized point cloud data by using the camera projection matrix. Compute the camera projection matrix from sampled point cloud data points and their corresponding image point coordinates.

Load an organized point cloud data into the workspace. The point cloud is generated by using the Kinect depth sensor.

```
ld = load('object3d.mat');
ptCloud = ld.ptCloud;
```

Specify the step size for sampling the point cloud data.

```
stepSize = 100;
```

Sample the input point cloud and store the sampled 3-D point coordinates as a point cloud object.

```
indices = 1:stepSize:ptCloud.Count;
tempPtCloud = select(ptCloud,indices);
```

Remove invalid points from the sampled point cloud.

```
[tempPtCloud,validIndices] = removeInvalidPoints(tempPtCloud);
```

Define the 3-D world point coordinates of input point cloud.

```
worldPoints = tempPtCloud.Location;
```

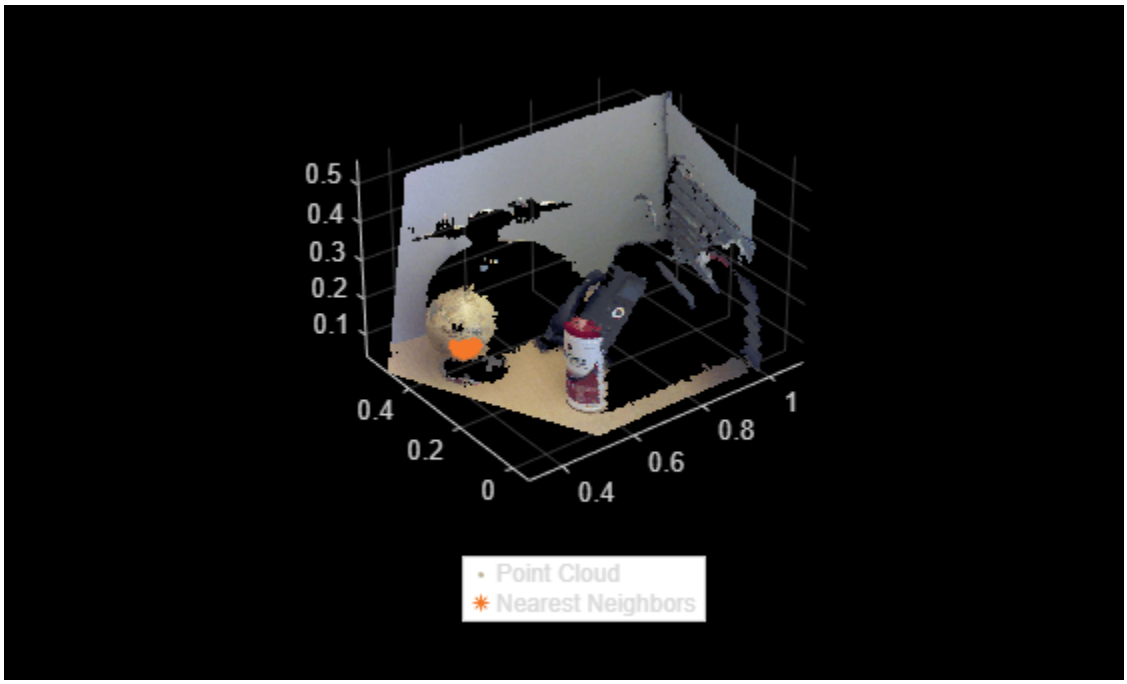
Find the 2-D image coordinates corresponding to the 3-D point coordinates of input point cloud.

```
[Y,X] = ind2sub([size(ptCloud.Location,1),size(ptCloud.Location,2)],indices);
imagePoints = [X(validIndices)' Y(validIndices)'];
```

Estimate camera projection matrix from the image and the world point coordinates.

```
camMatrix = estimateCameraMatrix(imagePoints,worldPoints);
```

Specify a query point and the number of nearest neighbors to be identified.



```
point = [0.4 0.3 0.2];
K = 1000;
```

Find the indices and distances of K nearest neighboring points by using the camera projection matrix. Use the point cloud method `select` to get the point cloud data of nearest neighbors.

```
[indices,dists] = findNearestNeighbors(ptCloud,point,K,camMatrix);
ptCloudB = select(ptCloud,indices);
```

Display the point cloud and the nearest neighbors of the query point.

```
figure
pcshow(ptCloud)
hold on
plot3(ptCloudB.Location(:,1),ptCloudB.Location(:,2),ptCloudB.Location(:,3),'*')
legend('Point Cloud','Nearest Neighbors','Location','southoutside','Color',[1 1 1])
hold off
```

Input Arguments

`ptCloud` — Point cloud

`pointCloud` object

Point cloud, specified as a `pointCloud` object.

Note The function supports organized point cloud data generated only from RGB-D sensors.

`points` — Query points

1-by-3 vector | *N*-by-3 matrix

Query points, specified as a 1-by-3 vector or *N*-by-3 matrix.

- To find the nearest neighbors of a single query point, specify its coordinates as a 1-by-3 vector of the form `[x y z]`.
- To find the nearest neighbors of multiple query points, specify them as an *N*-by-3 matrix. *N* is the number of query points. Each row of the matrix is of the form `[x y z]`, representing the coordinates of a query point.

`K` — Number of nearest neighbors

positive integer

Number of nearest neighbors, specified as a positive integer.

`camMatrix` — Camera projection matrix

4-by-3 matrix

Camera projection matrix, specified as a 4-by-3 matrix that maps 3-D world points to 2-D image points. You can compute the `camMatrix` by using the `estimateCameraMatrix` function.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `findNearestNeighbors(ptCloud,point,k,'Sort',true)`

`Sort` — Sort indices

`false` (default) | `true`

Sort indices, specified as a comma-separated pair of `'Sort'` and a logical scalar. When you set `Sort` to `true`, the returned indices are sorted in the ascending order based on the distance from a query point. To turn off sorting, set `Sort` to `false`.

`MaxLeafChecks` — Number of leaf nodes to check

`Inf` (default) | integer

Number of leaf nodes to check, specified as a comma-separated pair consisting of `'MaxLeafChecks'` and an integer. When you set this value to `Inf`, the entire tree is searched. When the entire tree is searched, it produces exact search results. Increasing the number of leaf nodes to check increases accuracy, but reduces efficiency.

Note The name-value argument `'MaxLeafChecks'` is valid only with Kd-tree based search method.

Output Arguments

`indices` — Indices of nearest neighbor points

K-by-1 vector | *K*-by-*N* matrix

Indices of nearest neighbor points, returned as a *K*-by-1 vector or *K*-by-*N* matrix. *K* is the number of nearest neighbors.

- For a single query point, the function returns linear indices of the *K* nearest neighbors as a *K*-by-1 vector.
- For multiple query points, the function returns a *K*-by-*N* matrix. *K* is the number of nearest neighbors and *N* is the number of query points. Each column of the matrix contains the linear indices of the *K* nearest neighbors of the query point specified by the corresponding row of the `points` input argument.

`dists` — Distances between query points and their nearest neighbors

K-by-1 vector | *K*-by-*N* matrix

Distances between query points and their nearest neighbors, returned as a *K*-by-1 vector or *K*-by-*N* matrix. *K* is the number of nearest neighbors.

- For a single query point, the function returns a *K*-by-1 vector. The vector contains the Euclidean distances between the query point and its *K* nearest neighbors.

- For multiple query points, the function returns a *K*-by-*N* matrix. *K* is the number of nearest neighbors and *N* is the number of query points. Each column of the matrix contains the Euclidean distances to the *K* nearest neighbors of a query point. This query point is specified by the corresponding row in the `points` input argument.

Version History

Introduced in R2015a

R2025a: Find nearest neighbors of multiple query points in point cloud

Starting in R2025a, the `points` input argument value supports an *N*-by-3 matrix. Using an *N*-by-3 matrix enables you to simultaneously find the nearest neighbors of multiple query points in the input point cloud. To find the nearest neighbors of a single query point, specify the `points` argument as a 1-by-3 vector.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- For code generation in non-host platforms, the value for `'MaxLeafChecks'` must be set to the default value `Inf`. If you specify values other than `Inf`, the function generates a warning and automatically assigns the default value for `'MaxLeafChecks'`.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- For GPU code generation, the `camMatrix` input argument is ignored.
- For GPU code generation, the `'MaxLeafChecks'` name-value pair option is ignored.

`pointCloud` | `findNeighborsInRadius` | `estimateCameraMatrix` | `cameraMatrix`

findNeighborsInRadius

Find neighbors within radius for query points in point cloud

Syntax

```
[indices,dists,numNeighbors] = findNeighborsInRadius(ptCloud,points,radius)
[indices,dists,numNeighbors] = findNeighborsInRadius(ptCloud,points,radius,
camMatrix)
[indices,dists,numNeighbors] = findNeighborsInRadius( ___ ,Name,Value)
```

Description

`[indices,dists,numNeighbors] = findNeighborsInRadius(ptCloud,points,radius)` returns the `indices` of neighbors within a radius of one or more query points in the input point cloud. `ptCloud` can be an unorganized or organized point cloud. The neighbors within a radius of the query points are computed by using the Kd-tree based search algorithm.

`[indices,dists,numNeighbors] = findNeighborsInRadius(ptCloud,points,radius, camMatrix)` returns the neighbors within a radius of one or more query points in the input point cloud. The input point cloud is an organized point cloud generated by a depth camera. The neighbors within a radius of the query points are determined using fast approximate neighbor search algorithm.

The function uses the camera projection matrix `camMatrix` to know the relationship between adjacent points and hence, speeds up the search. However, the results have lower accuracy as compared to the Kd-tree based approach.

Note

- This syntax only supports organized point cloud data produced by RGB-D sensors.
- You can use `estimateCameraMatrix` to estimate camera projection matrix for the given point cloud data.

`[indices,dists,numNeighbors] = findNeighborsInRadius( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the preceding syntaxes.

Examples

Find Radial Neighbors in Point Cloud

Load a set of 3-D coordinate points into the workspace.

```
load("xyzPoints.mat")
```

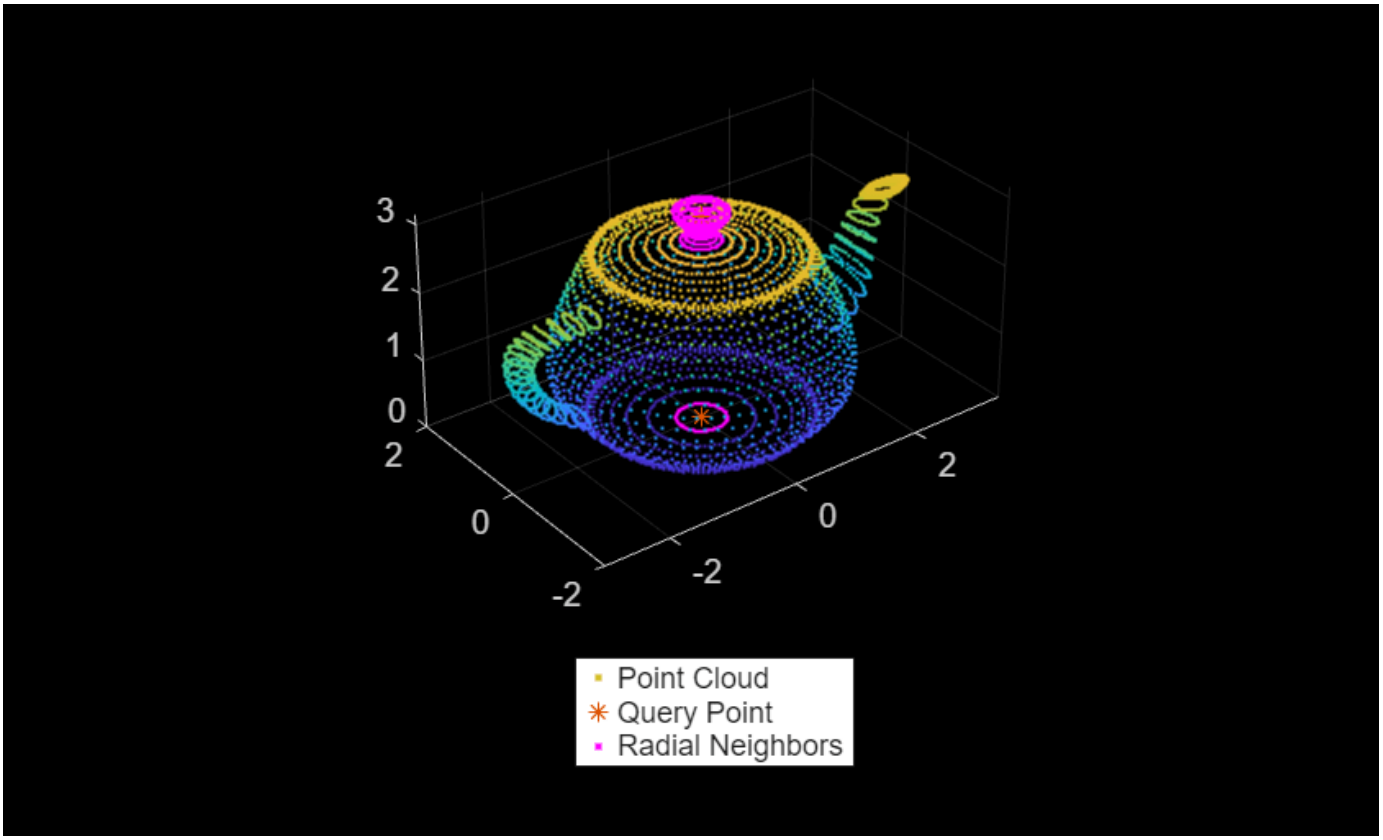
Create a point cloud object.

```
ptCloud = pointCloud(xyzPoints);
```

Specify two query points and a search radius.

```
points = [0 0 0; 0 0 3];
radius = 0.5;
```

For each query point, find the neighbors within the specified radius.



```
[indices,dists,numNeighbors] = findNeighborsInRadius(ptCloud,points,radius);
```

Convert the cell array of indices to an ordinary array. Then, select radial neighbors using these indices from the input point cloud.

```
indices = cell2mat(indices);
ptCloudB = select(ptCloud,indices);
```

Display the point cloud and overlay the query points and radial neighbors.

```
figure
pcshow(ptCloud)
hold on
plot3(points(:,1),points(:,2),points(:,3),"*")
pcshow(ptCloudB.Location,"m")
legend("Point Cloud", ...
    "Query Point", ...
    "Radial Neighbors", ...
    Location="southoutside", ...
    Color=[1 1 1])
hold off
```

Find Radial Neighbors in Organized Point Cloud

Find radial neighbors of a query point in the organized point cloud data by using the camera projection matrix. Compute the camera projection matrix from sampled point cloud data points and their corresponding image point coordinates.

Load an organized point cloud data into the workspace. The point cloud is generated by using the Kinect depth sensor.

```
ld = load('object3d.mat');
ptCloud = ld.ptCloud;
```

Specify the step size for sampling the point cloud data.

```
stepSize = 100;
```

Sample the input point cloud and store the sampled 3-D point coordinates as a point cloud object.

```
indices = 1:stepSize:ptCloud.Count;
tempPtCloud = select(ptCloud,indices);
```

Remove invalid points from the sampled point cloud.

```
[tempPtCloud,validIndices] = removeInvalidPoints(tempPtCloud);
```

Define the 3-D world point coordinates of input point cloud.

```
worldPoints = tempPtCloud.Location;
```

Find the 2-D image coordinates corresponding to the 3-D point coordinates of input point cloud.

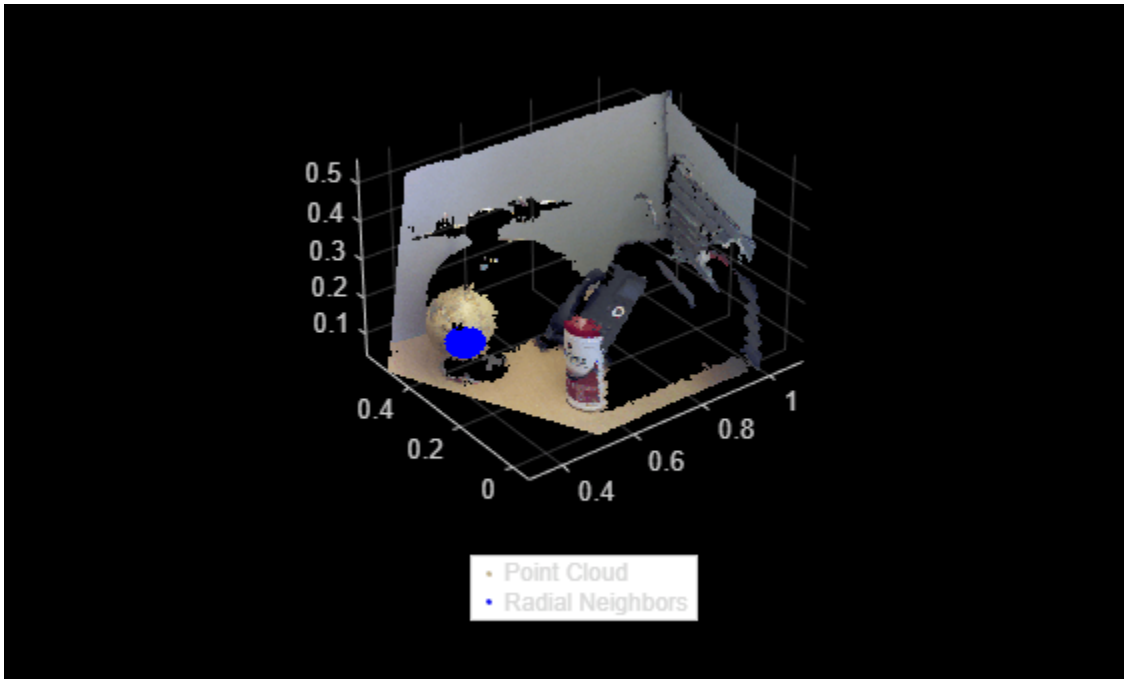
```
[Y,X] = ind2sub([size(ptCloud.Location,1),size(ptCloud.Location,2)],indices);
imagePoints = [X(validIndices)' Y(validIndices)'];
```

Estimate camera projection matrix from the image and the world point coordinates.

```
camMatrix = estimateCameraMatrix(imagePoints,worldPoints);
```

Specify a query point and the radius within which the neighbors are to be identified.

```
point = [0.4 0.3 0.2];
radius = 0.05;
```



Get the indices and the distances of radial neighbors. Use the point cloud method `select` to get the point cloud data of neighboring points.

```
[indices,dists] = findNeighborsInRadius(ptCloud,point,radius,camMatrix);
ptCloudB = select(ptCloud,indices);
```

Display the point cloud and the radial neighbors found around a query point.

```
figure
pcshow(ptCloud);
hold on;
pcshow(ptCloudB.Location, 'b');
```

```
legend('Point Cloud','Radial Neighbors','Location','southoutside','Color',[1 1 1] )
hold off;
```

Input Arguments

`ptCloud` — Point cloud

`pointCloud` object

Point cloud, specified as a `pointCloud` object.

`points` — Query points

1-by-3 vector | *N*-by-3 matrix

Query points, specified as a 1-by-3 vector or *N*-by-3 matrix.

- To find the neighbors within a radius for a single query point, specify its coordinates as a 1-by-3 vector of the form `[x y z]`.
- To find the neighbors within a radius for multiple query points, specify them as an *N*-by-3 matrix. *N* is the number of query points. Each row of the matrix is of the form `[x y z]`, representing the coordinates of a query point.

`radius` — Search radius

scalar

Search radius, specified as a scalar. The function finds the neighbors within the specified `radius` around a query point in the input point cloud.

`camMatrix` — Camera projection matrix

4-by-3 matrix

Camera projection matrix, specified as a 4-by-3 matrix that maps 3-D world points to 2-D image points. You can find `camMatrix` by using the `estimateCameraMatrix` function.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `findNeighborsInRadius(ptCloud,point,radius,'Sort',true)`

`Sort` — Sort indices

`false` (default) | `true`

Sort indices, specified as a comma-separated pair of `'Sort'` and a logical scalar. When you set `Sort` to `true`, the returned indices are sorted in the ascending order based on the distance from a query point. To turn off sorting, set `Sort` to `false`.

`MaxLeafChecks` — Number of leaf nodes

`Inf` (default) | integer

Number of leaf nodes, specified as a comma-separated pair consisting of `'MaxLeafChecks'` and an integer. When you set this value to `Inf`, the entire tree is searched. When the entire tree is searched, it produces exact search results. Increasing the number of leaf nodes to check increases accuracy, but reduces efficiency.

Output Arguments

`indices` — Indices of stored points

M-by-1 vector | *N*-by-1 cell array

Indices of stored points, returned as an *M*-by-1 vector or *N*-by-1 cell array.

- For a single query point, the function returns linear indices of *M* radial neighbors as an *M*-by-1 vector.
- For multiple query points, the function returns an *N*-by-1 cell array. *N* is the number of query points. Each cell contains an *M*-by-1 column vector of linear indices for the radial neighbors of a query point. *M* is the number of radial neighbors for that query point.

`dists` — Distances between query points and their radial neighbors

M-by-1 vector | *N*-by-1 cell array

Distances between query points and their radial neighbors, returned as an *M*-by-1 vector or *N*-by-1 cell array.

- For a single query point, the function returns an *M*-by-1 vector. The vector contains the Euclidean distances between the query point and its *M* radial neighbors.
- For multiple query points, the function returns an *N*-by-1 cell array. *N* is the number of query points. Each cell contains an *M*-by-1 column vector of the Euclidean distances between the query point and its *M* radial neighbors.

`numNeighbors` — Number of identified radial neighbors
nonnegative integer | *N*-by-1 vector

Number of identified radial neighbors, returned as a nonnegative integer for a single query point or an *N*-by-1 vector of nonnegative integers for *N* query points.

Version History

Introduced in R2015a

R2025a: Find neighbors within radius for multiple query points in point cloud

Starting in R2025a, the `points` input argument value supports an *N*-by-3 matrix. Using an *N*-by-3 matrix enables you to simultaneously find the radial neighbors of multiple query points in the input point cloud. To find the radial neighbors of a single query point, specify the `points` argument as a 1-by-3 vector.

The function now also returns a `numNeighbors` argument, which indicates the number of neighbors found within the specified radius of each query point.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- For code generation in non-host platforms, the value for `'MaxLeafChecks'` must be set to the default value `Inf`. If you specify values other than `Inf`, the function generates a warning and automatically assigns the default value for `'MaxLeafChecks'`.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- For GPU code generation, the `camMatrix` input argument is ignored.
- For GPU code generation, the `'MaxLeafChecks'` name-value pair option is ignored.

`pointCloud` | `findNearestNeighbors` | `estimateCameraMatrix` | `cameraMatrix`

findPointsInROI

Find points within a region of interest in the point cloud

Syntax

```
indices = findPointsInROI(ptCloud,roi)
indices = findPointsInROI(ptCloud,roi,camMatrix)
```

Description

`indices = findPointsInROI(ptCloud,roi)` returns the points within a region of interest (ROI) in the input point cloud. The points within the specified ROI are obtained using a Kd-tree based search algorithm.

`indices = findPointsInROI(ptCloud,roi,camMatrix)` returns the points within the ROI area of the input point cloud. The input point cloud is an organized point cloud generated by a depth camera. The points within the specified ROI are obtained using fast approximate neighbor search algorithm.

The function uses the camera projection matrix `camMatrix` to know the relationship between adjacent points and hence, speeds up the search. However, the results have lower accuracy as compared to the Kd-tree based approach.

Note

- This syntax only supports organized point cloud data produced by RGB-D sensors.
- You can use `estimateCameraMatrix` to estimate camera projection matrix for the given point cloud data.

Examples

Find Points Within a Cuboid ROI in Point Cloud

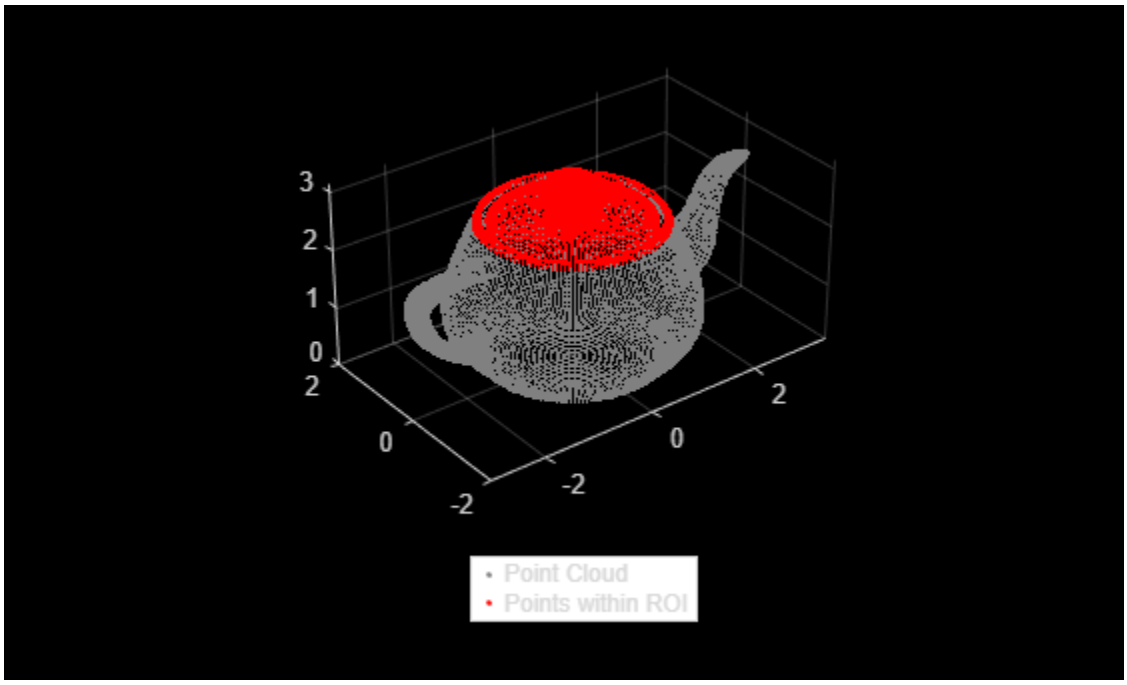
Read a point cloud data into the workspace.

```
ptCloud = pcread('teapot.ply');
```

Define a cuboid ROI within the range of the *x*, *y* and *z* coordinates of the input point cloud.

```
roi = [-2 2 -2 2 2.4 3.5];
```

Find the indices of the points that lie within the cuboid ROI.



```
indices = findPointsInROI(ptCloud,roi);
```

Select the points that lie within the cuboid ROI and store as a point cloud object.

```
ptCloudB = select(ptCloud,indices);
```

Display the input point cloud and the point cloud within the specified ROI.

```
figure
pcshow(ptCloud.Location,[0.5 0.5 0.5])
hold on
pcshow(ptCloudB.Location,'r');
legend('Point Cloud','Points within ROI','Location','southoutside','Color',[1 1 1])
hold off
```

Find Points Within a Cuboid ROI in Organized Point Cloud

Find points within a cuboid ROI in the organized point cloud data by using the camera projection matrix. Compute the camera projection matrix from sampled point cloud data points and their corresponding image point coordinates.

Load an organized point cloud data into the workspace. The point cloud is generated by using the Kinect depth sensor.

```
ld = load('object3d.mat');
ptCloud = ld.ptCloud;
```

Specify the step size for sampling the point cloud data.

```
stepSize = 100;
```

Sample the input point cloud and store the sampled 3-D point coordinates as a point cloud object.

```
indices = 1:stepSize:ptCloud.Count;
tempPtCloud = select(ptCloud,indices);
```

Remove invalid points from the sampled point cloud.

```
[tempPtCloud,validIndices] = removeInvalidPoints(tempPtCloud);
```

Get the 3-D world point coordinates from input point cloud.

```
worldPoints = tempPtCloud.Location;
```

Find the 2-D image coordinates corresponding to the 3-D point coordinates of input point cloud.

```
[Y,X] = ind2sub([size(ptCloud.Location,1),size(ptCloud.Location,2)],indices);
imagePoints = [X(validIndices)' Y(validIndices)'];
```

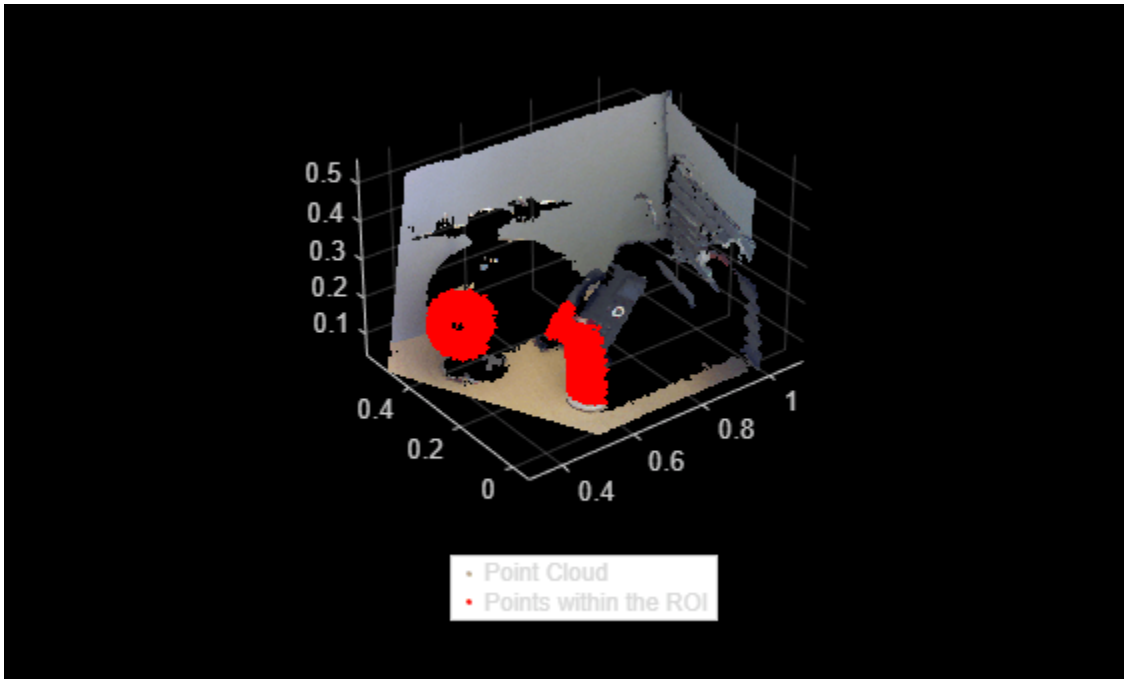
Estimate camera projection matrix from the image and the world point coordinates.

```
camMatrix = estimateCameraMatrix(imagePoints,worldPoints);
```

Specify a cuboid ROI within the range of the *x*, *y* and *z* coordinates of the input point cloud.

```
roi = [0.3 0.7 0 0.4 0.1 0.3];
```

Find the indices of the point cloud data that lie within the cuboid ROI.



```
indices = findPointsInROI(ptCloud,roi,camMatrix);
```

Use the point cloud method `select` to get the point cloud data of points within the ROI.

```
ptCloudB = select(ptCloud,indices);
```

Display the input point cloud and the points within the cuboid ROI.

```
figure
pcshow(ptCloud)
hold on
pcshow(ptCloudB.Location,'r');
legend('Point Cloud','Points within the ROI','Location','southoutside','Color',[1 1 1])
hold off
```

Input Arguments

`ptCloud` — Point cloud

`pointCloud` object

Point cloud, specified as a `pointCloud` object.

`roi` — Region of interest

six-element vector

Region of interest, specified as a six-element vector of form [*xmin*, *xmax*, *ymin*, *ymax*, *zmin*, *zmax*], where:

- *xmin* and *xmax* are the minimum and the maximum limits along the *x*-axis respectively.
- *ymin* and *ymax* are the minimum and the maximum limits along the *y*-axis respectively.
- *zmin* and *zmax* are the minimum and the maximum limits along the *z*-axis respectively.

`camMatrix` — Camera projection matrix

4-by-3 matrix

Camera projection matrix, specified as a 4-by-3 matrix that maps 3-D world points to 2-D image points. You can find `camMatrix` by using the `estimateCameraMatrix` function.

Output Arguments

`indices` — Indices of stored points

column vector

Indices of stored points, returned as a column vector. The vector contains the linear indices of the ROI points stored in the point cloud.

findPointsInCylinder

Find points within a cylindrical region in a point cloud

Syntax

```
indices = findPointsInCylinder(ptCloud,radius)
indices = findPointsInCylinder( ___ ,Name=Value)
```

Description

`indices = findPointsInCylinder(ptCloud,radius)` finds the points within a cylindrical neighborhood of the specified `radius` in a point cloud, ptCloud.

`indices = findPointsInCylinder( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to the previous syntax. For example, `Height=10`, sets the height of the cylinder to 10.

Examples

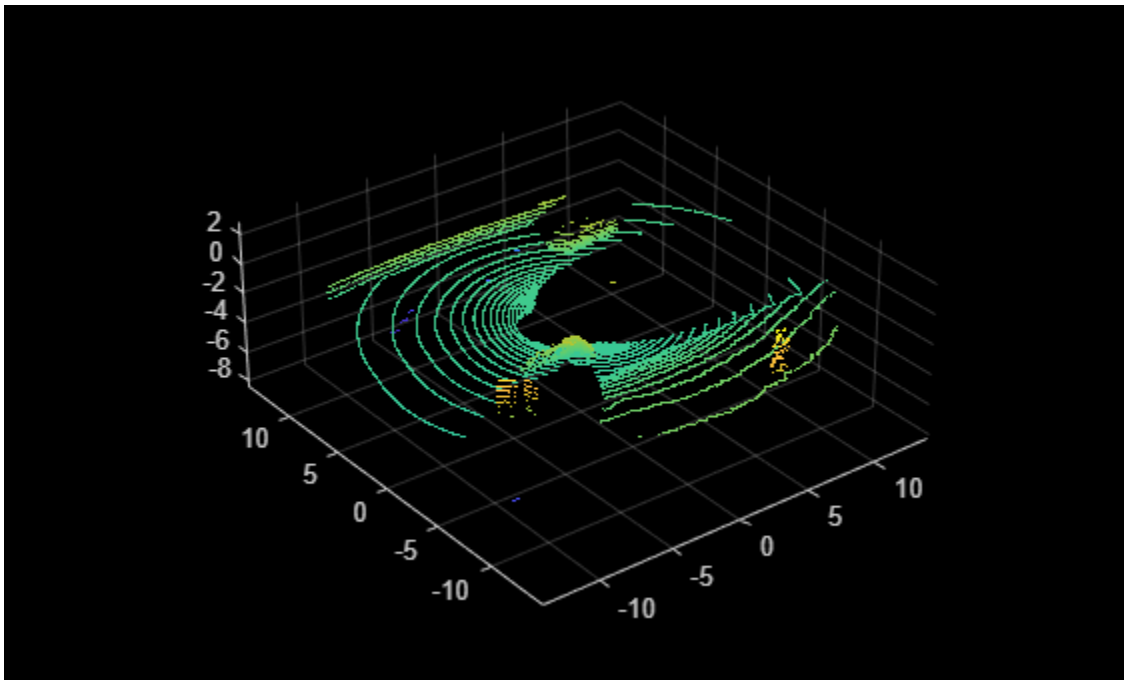
Find Points in Hollow Cylinder

Load a point cloud from a saved MAT file.

```
load("drivingLidarPoints.mat","ptCloud")
```

Specify a hollow cylindrical neighborhood with an inner radius of 2 meters and an outer radius of 15 meters, and find the points in the point cloud within the neighborhood.

```
minRadius = 2;
maxRadius = 15;



indices = findPointsInCylinder(ptCloud,[minRadius maxRadius]);
```

Select the cylindrical neighborhood in the point cloud, preserving the organized format.

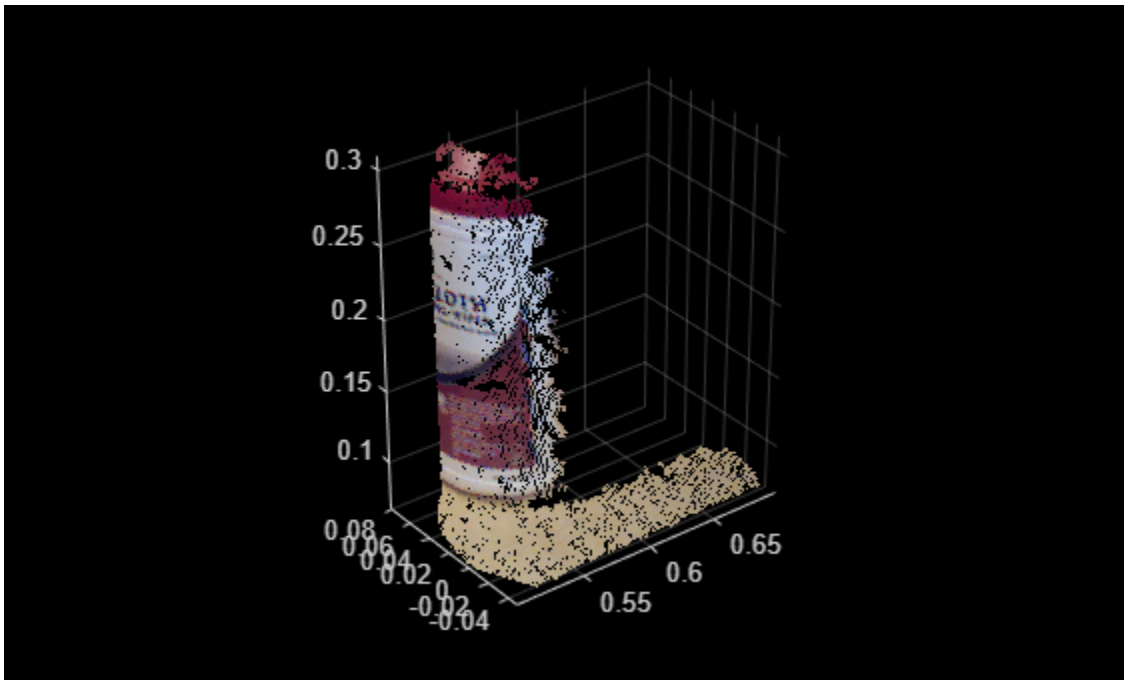
```
ptCloudCylinder = select(ptCloud,indices,OutputSize="full");
```

Visualize the selected points.

```
figure
pcshow(ptCloudCylinder)
```

Apply Solid Cylindrical Filter Centered Around Point of Interest

Load a point cloud from a saved MAT file.



```
load("object3d.mat","ptCloud")
maxRadius = 0.1;
cylinderHeight = 0.5;
```

Offset the center of the cylinder 0.6 units in the *X*-direction and 0.2 units in the *Z*-direction. Then, find and select the points of the point cloud within the cylinder.

```
shiftedCenter = [0.6 0 0.2];
indices = findPointsInCylinder(ptCloud,maxRadius,Height=cylinderHeight,Center=shiftedCenter,Verti
ptCloudCylinder = select(ptCloud,indices);
```

Visualize the selected points.

```
figure
pcshow(ptCloudCylinder)
```

Input Arguments

`ptCloud` — Point cloud

`pointCloud` object

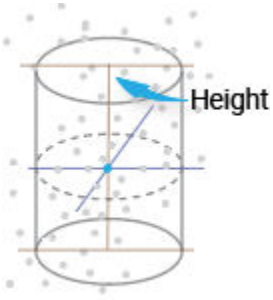
Point cloud, specified as a `pointCloud` object.

`radius` — Cylinder radius

scalar | 2-element vector

Cylinder radius, specified as a scalar or a 2-element vector of the form [*minRadius maxRadius*] that specifies the inner and outer radii of the cylindrical neighborhood. The radius is along the Z-axis of the point cloud and with `[0 0 0]` as its origin. The function finds the neighbors within the specified `radius` along the defined `VerticalAxis` with its origin at the `Center` of the cylinder.

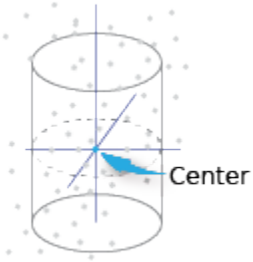
Name-Value Pair Arguments



Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `Height=10` sets the height of the cylinder to 10.

`Height` — Total height of cylinder



`Inf` (default) | positive scalar

Total height of cylinder, specified as a positive scalar. The height is measured along the cylinder's vertical axis, `VerticalAxis`. The cylinder is centered at its midpoint, the `Center`, with half of the height extending in one direction along the vertical axis and the other half extending in the opposite direction.

`Center` — Center of cylinder
`[0 0 0]` (default) | 3-element vector

Center of the cylinder, specified as a 3-element vector of the form [*x y z*] in Cartesian coordinates. The center point is halfway between the top and bottom of the cylinder, and the axis of the cylinder passes through it.

`VerticalAxis` — Vertical axis of cylinder
`"Z"` (default) | `"X"` | `"Y"`

Vertical axis of the cylinder, specified as `"X"`, `"Y"`, or `"Z"`.

Output Arguments

`indices` — Logical indices of points within cylindrical neighborhood
column vector | matrix

Logical indices of the points within a cylindrical neighborhood, returned as a column vector for unorganized point clouds or a matrix for organized point clouds. For organized point clouds. `indices` is the same size as the input point cloud, and each element with a value of `1` (true) indicates that the corresponding index of the input point cloud references a point inside the specified cylindrical neighborhood.

Functions
`findPointsInROI` | `pcfitcylinder`

Objects
`pointCloud`

removeInvalidPoints

Remove invalid points from point cloud

Syntax

```
[ptCloudOut,indices] = removeInvalidPoints(ptCloud)
```

Description

`[ptCloudOut,indices] = removeInvalidPoints(ptCloud)` removes points with `Inf` or `NaN` coordinate values from point cloud and returns the indices of valid points.

Note The output is always an unorganized (*X*-by-3) point cloud. If the input `ptCloud` is an organized point cloud (*M*-by-*N*-by-3), the function returns the output as an unorganized point cloud.

Examples

Remove Invalid Points from Point Cloud

Create a point cloud object with `NaN` and `Inf` values.

```
xyzpoints = abs(randn(10,3)).*100;
xyzpoints(1:2:4,:) = nan('single');
xyzpoints(6:2:10,:) = inf('single');
ptCloud = pointCloud(xyzpoints);
```

Inspect the `Location` property of point cloud data to verify the occurrence of `NaN` and `Inf` values.

```
ptCloud.Location
```

```
ans = 10×3

       NaN       NaN       NaN
  183.3885  303.4923  120.7487
       NaN       NaN       NaN
   86.2173    6.3055  163.0235
   31.8765   71.4743   48.8894
       Inf       Inf       Inf
   43.3592   12.4144   72.6885
       Inf       Inf       Inf
  357.8397  140.9034   29.3871
       Inf       Inf       Inf
```

Remove points with `NaN` and `Inf` values from the point cloud.

```
ptCloudOut = removeInvalidPoints(ptCloud);
```

Inspect the `Location` property of point cloud data to verify that the invalid points are removed.

```
ptCloudOut.Location

ans = 5×3

  183.3885  303.4923  120.7487
   86.2173    6.3055  163.0235
   31.8765   71.4743   48.8894
   43.3592   12.4144   72.6885
  357.8397  140.9034   29.3871
```

Input Arguments

`ptCloud` — Point cloud

`pointCloud` object

Point cloud, specified as a `pointCloud` object.

Output Arguments

`ptCloudOut` — Point cloud with points removed

`pointCloud` object

Point cloud, returned as a `pointCloud` object with `Inf` or `NaN` coordinates removed.

Note The output is always an unorganized (*X*-by-3) point cloud. If the input `ptCloud` is an organized point cloud (*M*-by-*N*-by-3), the function returns the output as an unorganized point cloud.

`indices` — Indices of valid points

vector

Indices of valid points in the point cloud, specified as a vector.

Version History

Introduced in R2015a

select

Select points in point cloud

Syntax

```
ptCloudOut = select(ptCloud,indices)
ptCloudOut = select(ptCloud,row,column)
ptCloudOut = select( ___ ,OutputSize=outputSize)
```

Description

`ptCloudOut = select(ptCloud,indices)` returns a `pointCloud` object containing only the points that are selected using linear or logical indices.

`ptCloudOut = select(ptCloud,row,column)` returns a `pointCloud` object containing only the points that are selected using row and column subscripts. This syntax applies only if the input is an organized point cloud data of size *M*-by-*N*-by-3.

`ptCloudOut = select( ___ ,OutputSize=outputSize)` returns the selected points as a `pointCloud` object of size specified by `outputSize`.

Examples

Select Points from Point Cloud

Read a point cloud data into the workspace.

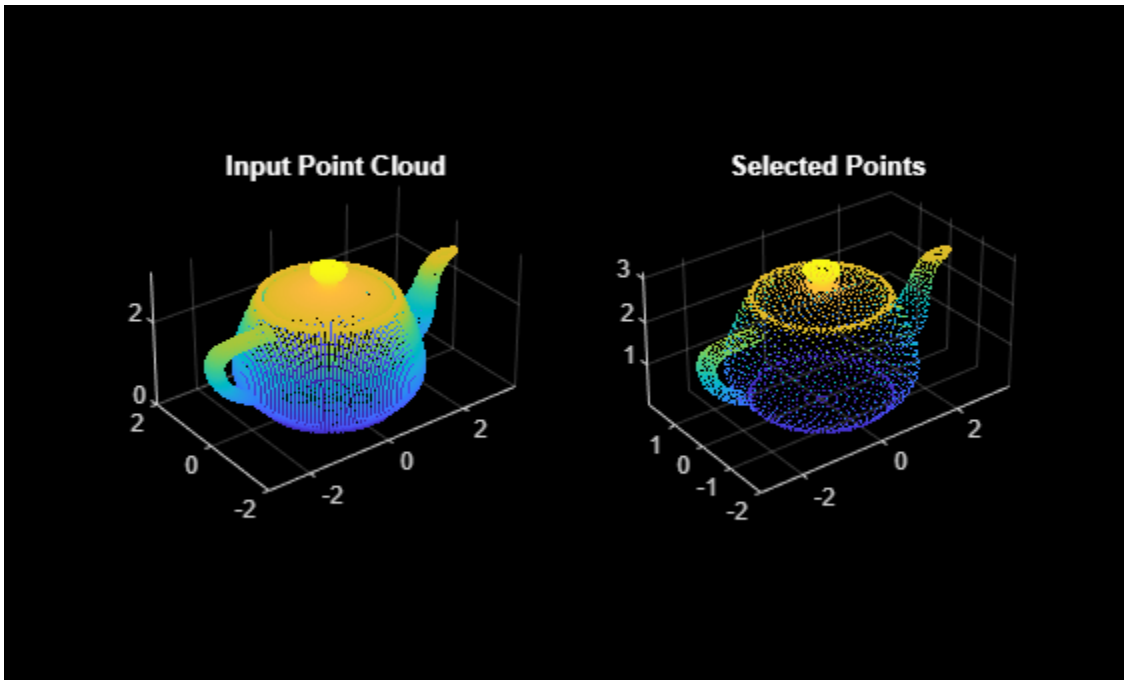
```
ptCloud = pcread("teapot.ply");
```

Read the number of points in the point cloud data.

```
Length = ptCloud.Count;
```

Select indices within the range [1, `Length`].

```
stepSize = 10;
indices = 1:stepSize:Length;
```



Select points specified by the indices from input point cloud. This selection of points downsamples the input point cloud by a factor of `stepSize`.

```
ptCloudB = select(ptCloud,indices);
```

Display the input and the selected point cloud data.

```
figure
subplot(1,2,1)
pcshow(ptCloud)
title("Input Point Cloud",Color=[1 1 1]);
subplot(1,2,2)
```

```
pcshow(ptCloudB)
title("Selected Points",Color=[1 1 1]);
```

Input Arguments

`ptCloud` — Point cloud

`pointCloud` object

Point cloud, specified as a `pointCloud` object.

`indices` — Linear or logical indices of selected points

vector | matrix

Linear or logical indices of selected points, specified as a vector or a matrix. For organized point clouds, `indices` (linear or logical), refer only to the first two dimensions of the "Location" on page 2-0 property.

`row` — Row indices

vector

Row indices, specified as a vector. This argument applies only if the input is an organized point cloud with the "Location" on page 2-0 data of size *M*-by-*N*-by-3.

`column` — Column indices

vector

Column indices, specified as a vector. This argument applies only if the input is an organized point cloud with the "Location" on page 2-0 data of size *M*-by-*N*-by-3.

`outputSize` — Size of output point cloud

`"selected"` (default) | `"full"`

Size of the output point cloud, `ptCloudOut`, specified as `"selected"` or `"full"`.

- If the size is `"selected"`, then the output contains only the selected points from the input point cloud, `ptCloud`.
- If the size is `"full"`, then the output is same size as the input point cloud `ptCloud`. Cleared points are filled with `NaN` and the color is set to [0 0 0].
- When working with organized point clouds and to return an organized point cloud, set `outputSize` to `"full"`.

Output Arguments

`ptCloudOut` — Selected point cloud
`pointCloud` object

Point cloud, returned as a `pointCloud` object.

Version History

Introduced in R2015a

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

The input argument `outputSize` must be compile-time constant. For example,

```
outputSize = coder.Constant('full');
```

If you use the coder app, you can choose the `outputSize` by right-clicking on it and selecting **Use constant**.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

`pointCloud` | `pcread`

copy

Copy array of point cloud objects

Syntax

```
ptCloudOut = copy(ptCloudIn)
```

Description

`ptCloudOut = copy(ptCloudIn)` copies an array of point cloud objects at the input to the new array `ptCloudOut`.

Examples

Create Copy of Point Cloud

- `pointCloudOut = copy(ptCloudIn)`

Input Arguments

`ptCloudIn` — Input point cloud data

`pointCloud` object

Input point cloud data, specified as a `pointCloud` object or an array of `pointCloud` objects.

Output Arguments

`ptCloudOut` — Output point cloud data

`pointCloud` object

Output point cloud data, returned as a `pointCloud` object or an array of `pointCloud` objects. The output data contains a copy of the input point cloud data.

Version History

Introduced in R2015a

Extended Capabilities

cylinderModel

Parametric cylinder model

Description

The `cylinderModel` object stores a parametric cylinder model.

Creation

Syntax

```
model = cylinderModel(parameters)
```

Description

`model = cylinderModel(parameters)` constructs a parametric cylinder model from the specified `parameters`. The `parameters` argument is a 1-by-7 numeric vector that determines the value of the `Parameters` property.

Input Arguments

`parameters` — Cylinder parameters

1-by-7 numeric vector

Cylinder parameters, specified as a 1-by-7 numeric vector. This input specifies the “Parameters” on page 2-0 property. The vector is of the form [*x1 y1 z1 x2 y2 z2 r*].

- [*x1 y1 z1*] and [*x2 y2 z2*] are the 3-D centers of each end-cap surface of the cylinder.
- *r* is the radius of the cylinder.

Properties

`Parameters` — Cylinder model parameters

1-by-7 numeric vector

This property is read-only.

Cylinder model parameters, stored as a 1-by-7 numeric vector. The vector is of the form [*x1 y1 z1 x2 y2 z2 r*].

- [*x1 y1 z1*] and [*x2 y2 z2*] are the 3-D centers of each end-cap surface of the cylinder.
- *r* is the radius of the cylinder.

`Center` — Center of cylinder

1-by-3 numeric vector

This property is read-only.

Center of the cylinder, stored as a 1-by-3 numeric vector representing the x-, y-, and z-coordinates.

`Height` — Height of cylinder
scalar

This property is read-only.

Height of the cylinder, stored as a scalar.

`Radius` — Radius of cylinder
scalar

This property is read-only.

Radius of the cylinder, stored as a scalar.

`Orientation` — Orientation of cylinder
1-by-3 vector

This property is read-only.

Orientation of the cylinder, stored as a 1-by-3 vector. The orientation vector points from one center [*x1*,*y1*,*z1*] of the cylinder end-cap to the center [*x2*,*y2*,*z2*] of the other end-cap.

Object Functions

plot	Plot parametric model
findPointsInModel	Find points in or on surface of geometric model

Examples

Detect Cylinder in Point Cloud

Load a MAT file containing a point cloud into the workspace.

```
load("object3d.mat");
```

Display the point cloud.

```
figure
pcshow(ptCloud)
title("Detect a Cylinder in a Point Cloud")
```

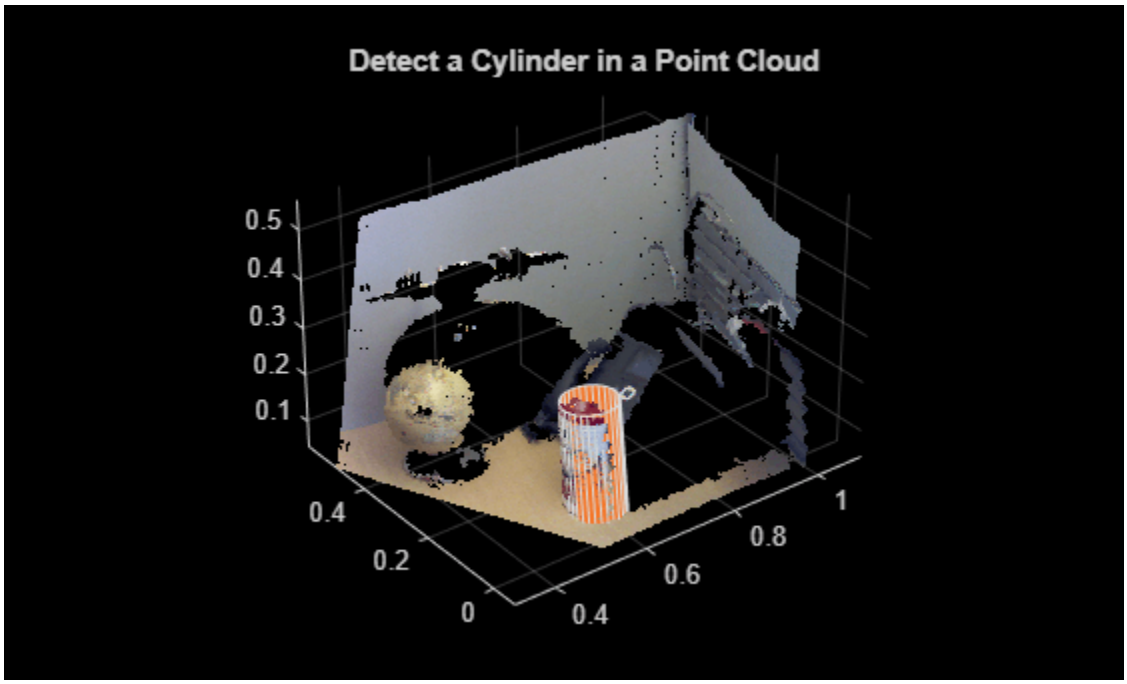
Set the maximum point-to-cylinder distance for cylinder fitting to 5mm.

```
maxDistance = 0.005;
```

Specify a region of interest (ROI) to constrain the fitting function.

```
roi = [0.4 0.6; -inf 0.2; 0.1 inf];
sampleIndices = findPointsInROI(ptCloud,roi);
```

Set the orientation constraint for the fitting function



```
referenceVector = [0 0 1];
```

Detect the cylinder in the specified ROI of the point cloud and extract it.

```
model = pcfitcylinder(ptCloud,maxDistance,referenceVector, ...
        SampleIndices=sampleIndices);
```

Plot the model of the detected cylinder.

```
hold on
plot(model)
```

planeModel

Object for storing parametric plane model

Description

Construct and store a parametric plane model based on parameters that describe a plane.

Creation

Syntax

```
model = planeModel(parameters)
```

Description

`model = planeModel(parameters)` constructs a parametric plane model from the 1-by-4 `Parameters` input vector that describes a plane.

Input Arguments

`parameters` — Plane parameters
1-by-4 scalar vector

Plane parameters, specified as a 1-by-4 vector. This input specifies the `Parameters` property. The four parameters [a,b,c,d] describe the equation for a plane:

$$ax + by + cz + d = 0$$

Properties

These properties are read-only.

`Parameters` — Plane model parameters
1-by-4 vector

Plane model parameters, stored as a 1-by-4 vector. These parameters are specified by the parameters on page 2-0 input argument.

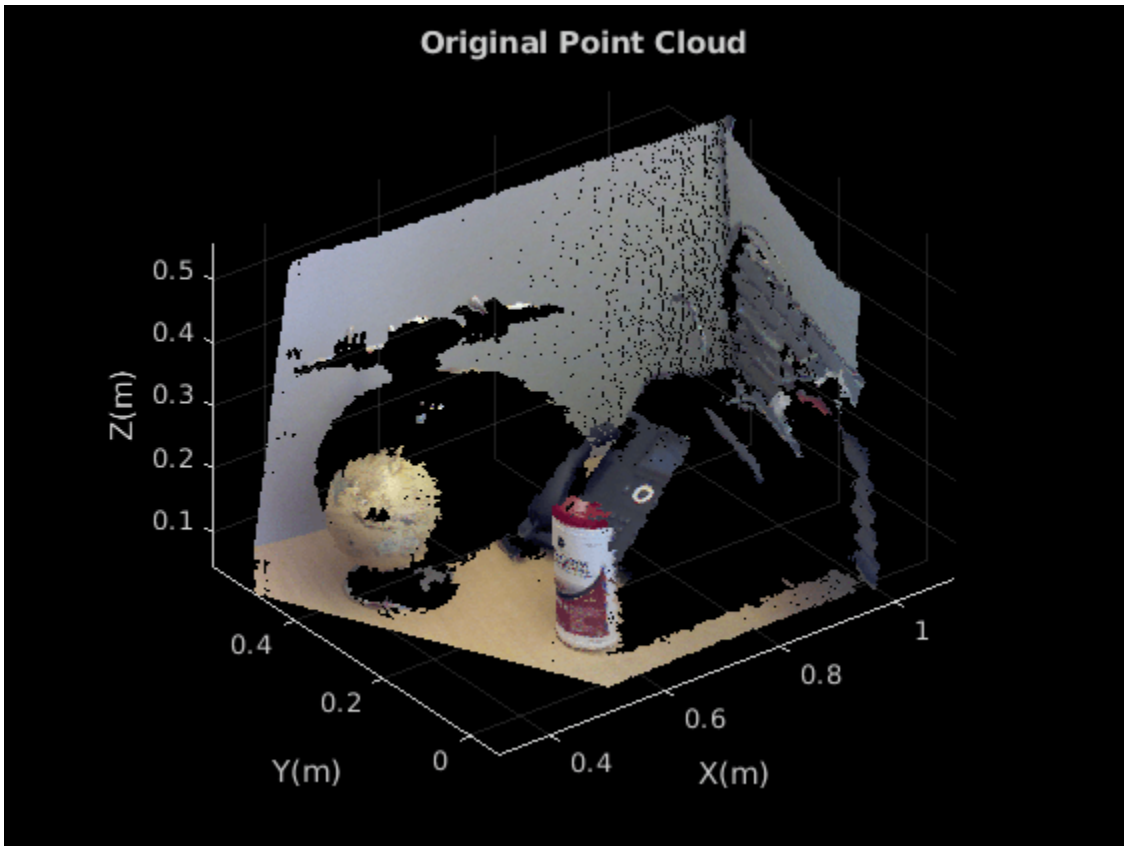
`Normal` — Normal vector of the plane
1-by-3 vector

Normal vector of the plane, stored as a 1-by-3 vector. The [a,b,c] vector specifies the unnormalized normal vector of the plane.

Object Functions

plot	Plot parametric model
normalRotation	Compute transform for rotation of normal to plane

Examples



Detect Multiple Planes from Point Cloud

Load the point cloud.

```
load("object3d.mat")
```

Display the point cloud and label the figure.

```
figure
pcshow(ptCloud)
xlabel("X(m)")
ylabel("Y(m)")
zlabel("Z(m)")
title("Original Point Cloud")
```

Set the maximum point-to-plane distance (2cm) for plane fitting.

```
maxDistance = 0.02;
```

Set the normal vector of the plane.

```
referenceVector = [0,0,1];
```

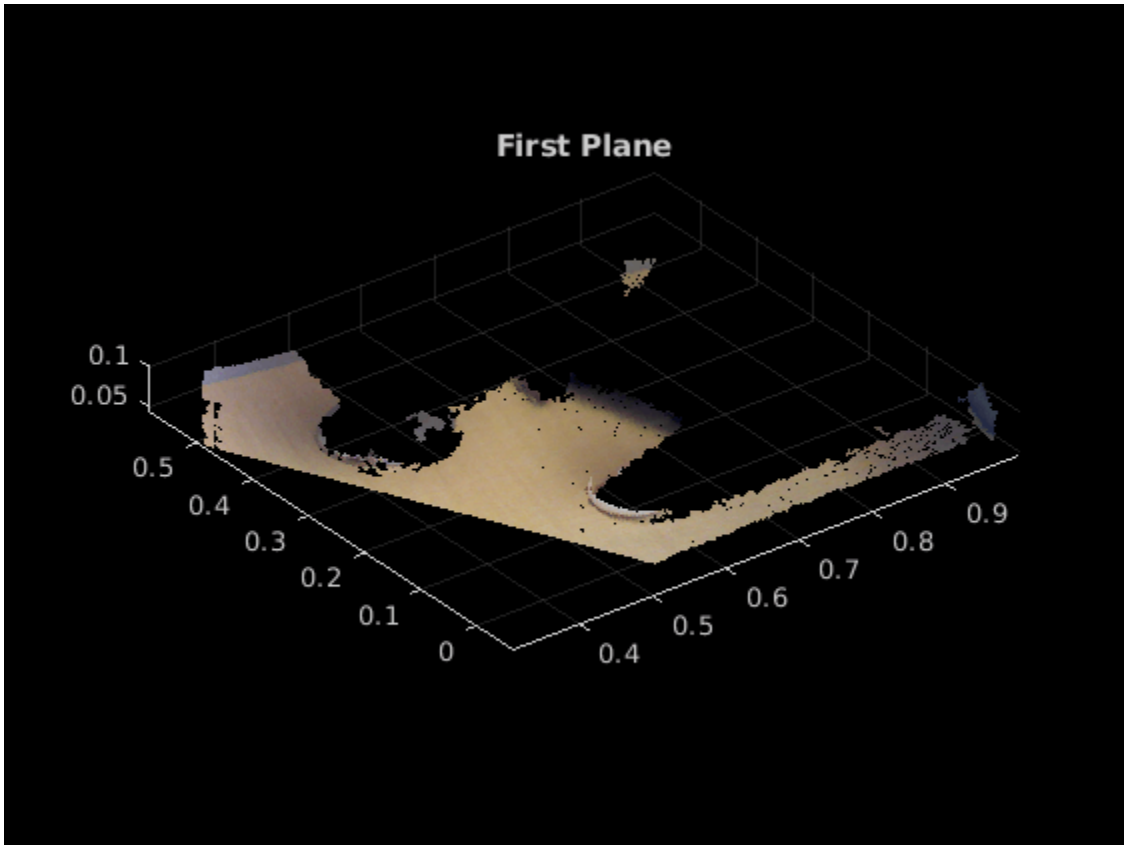
Set the maximum angular distance to 5 degrees.

```
maxAngularDistance = 5;
```

Detect the first plane, the table, and extract it from the point cloud.

```
[model1,inlierIndices,outlierIndices] = pcfitplane(ptCloud,...
           maxDistance,referenceVector,maxAngularDistance);
plane1 = select(ptCloud,inlierIndices);
remainPtCloud = select(ptCloud,outlierIndices);
```

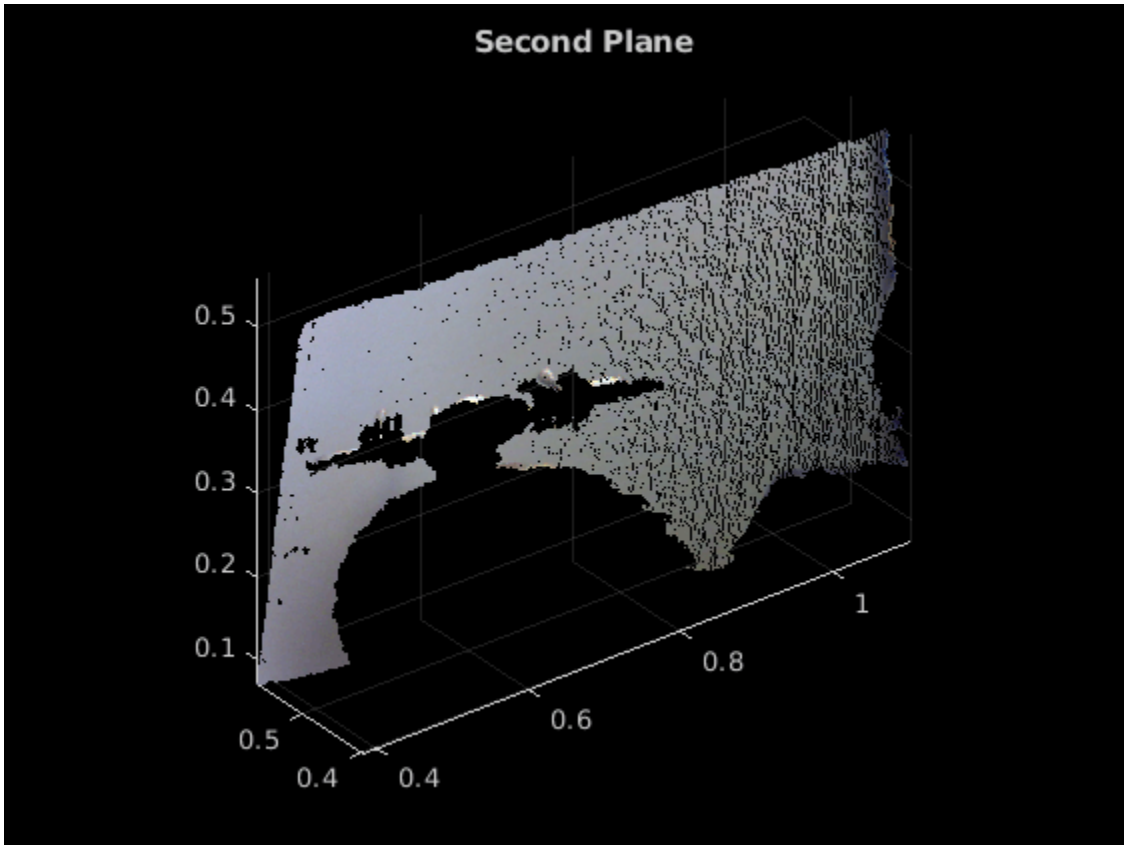
Set the region of interest to constrain the search for the second plane, left wall.



```
roi = [-inf,inf;0.4,inf;-inf,inf];
sampleIndices = findPointsInROI(remainPtCloud,roi);
```

Detect the left wall and extract it from the remaining point cloud.

```
[model2,inlierIndices,outlierIndices] = pcfitplane(remainPtCloud,...
           maxDistance,SampleIndices=sampleIndices);
plane2 = select(remainPtCloud,inlierIndices);
remainPtCloud = select(remainPtCloud,outlierIndices);
```



Plot the two planes and the remaining points.

```
figure

sphereModel

Object for storing a parametric sphere model

Description

The `sphereModel` object stores a parametric sphere model.

Creation

Syntax

```
model = sphereModel(parameters)
```

Description

`model = sphereModel(parameters)` constructs a parametric sphere model from the specified parameters. The `parameters` argument is a 1-by-4 numeric vector that determines the value of the `Parameters` property.

Input Arguments

`parameters` — Sphere parameters

1-by-4 scalar vector

Sphere parameters, specified as a 1-by-4 vector. This input specifies the `Parameters` property. The four parameters [*a b c d*] satisfy this equation for a sphere:

$$(x-a)^2+(y-b)^2+(z-c)^2=d^2$$

Properties

`Parameters` — Sphere model parameters

1-by-4 numeric vector

This property is read-only.

Sphere model parameters, stored as a 1-by-4 numeric vector. This property is set by the “parameters” on page 2-0 input. The four parameters [*a b c d*] satisfy this equation for a sphere:

$$(x-a)^2+(y-b)^2+(z-c)^2=d^2$$

`Center` — Center of sphere

1-by-3 vector

This property is read-only.

Center of the sphere, stored as a 1-by-3 vector of form [*xc yc zc*]. The elements *xc*,*yc*,*zc* specify the x-, y-, and z-coordinates of the center coordinates of the sphere, respectively.

Radius — Radius of sphere

scalar

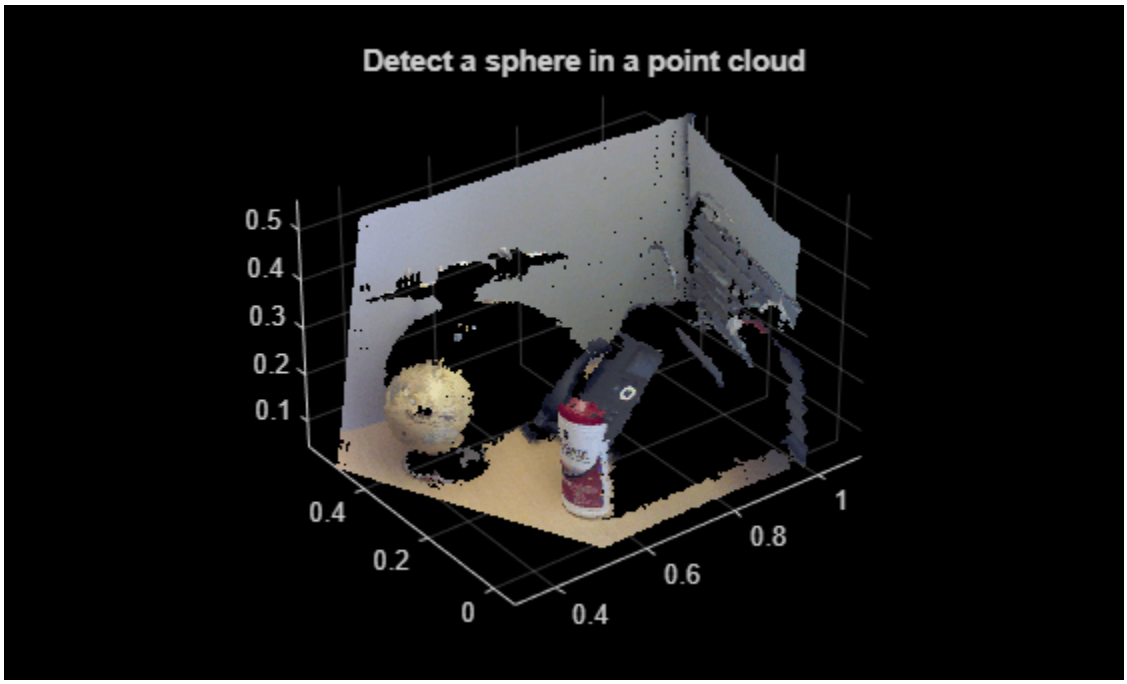
This property is read-only.

Radius of the sphere, stored as a scalar value.

Object Functions

plot	Plot parametric model
findPointsInModel	Find points in or on surface of geometric model

Examples



Detect Sphere in Point Cloud

Load a point cloud into the workspace.

```
load("object3d.mat");
```

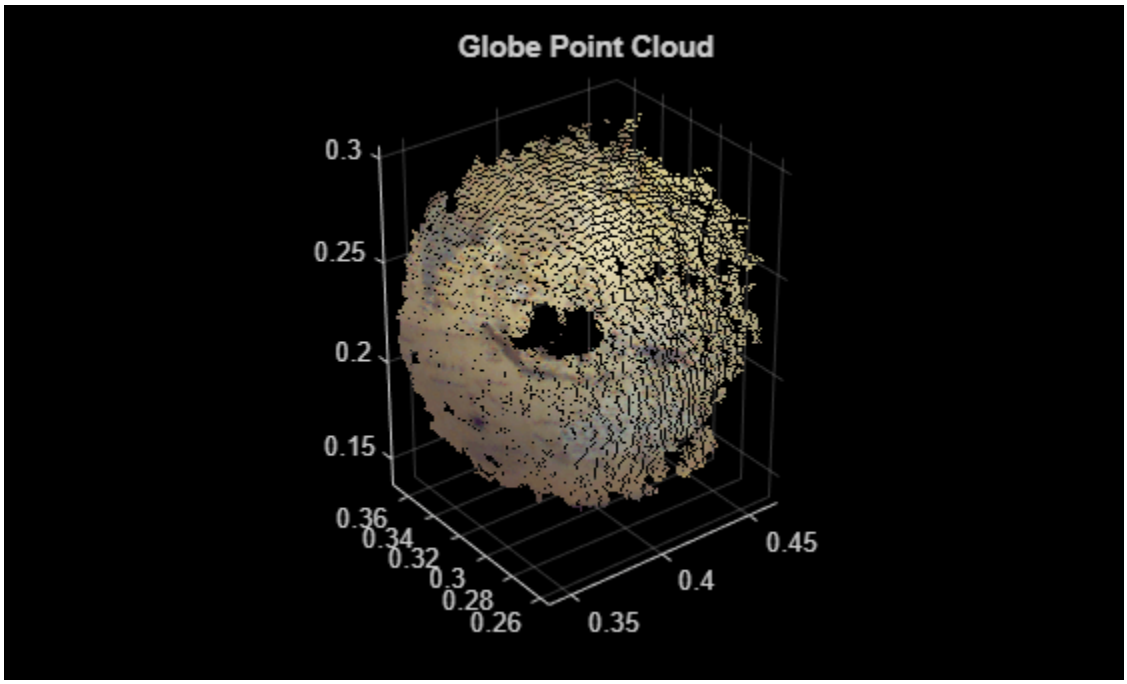
Display the point cloud and label the figure.

```
figure
pcshow(ptCloud)
title("Detect a sphere in a point cloud")
```

Set the maximum point-to-sphere distance for sphere fitting to 1cm.

```
maxDistance = 0.01;
```

Set the region of interest to constrain the search.



```
roi = [-inf,0.5;0.2,0.4;0.1,inf];
sampleIndices = findPointsInROI(ptCloud,roi);
```

Detect the globe in the point cloud and extract it.

```
[model,inlierIndices] = pcfitsphere(ptCloud,maxDistance,SampleIndices=sampleIndices);
globe = select(ptCloud,inlierIndices);
```

Plot the extracted globe.

```
figure
pcshow(globe)
title("Globe Point Cloud")
```

findPointsInModel

Find points in or on surface of geometric model

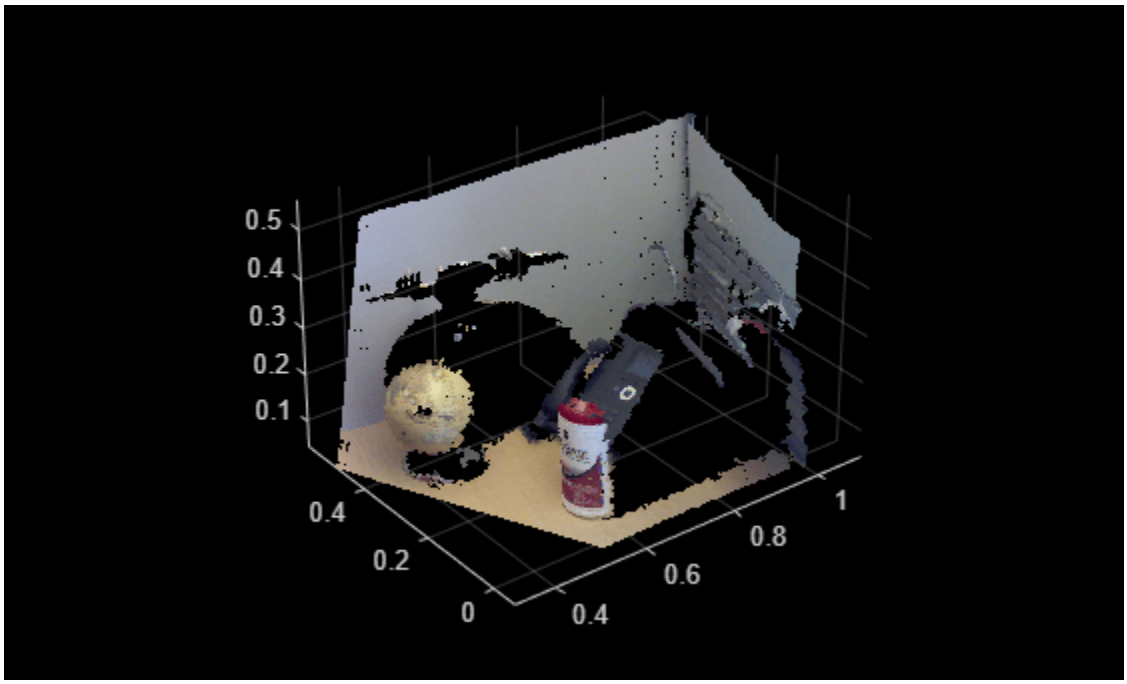
Syntax

```
indices = findPointsInModel(model,ptCloud)
```

Description

`indices = findPointsInModel(model,ptCloud)` finds the points in the point cloud `ptCloud` that are located inside or on the surface of the geometric shape specified by `model`, and returns their linear `indices`.

Examples



Find Points of Cylinder Model in Point Cloud

Load a MAT file containing point cloud data into the workspace.

```
load("object3d.mat")
```

Visualize the point cloud.

```
figure
pcshow(ptCloud)
```

Define a region of interest (ROI) in the point cloud in which to detect a cylinder model.

```
roi = [0.4 0.7; -0.1 0.2; 0 0.4];
sampleIndices = findPointsInROI(ptCloud,roi);
```

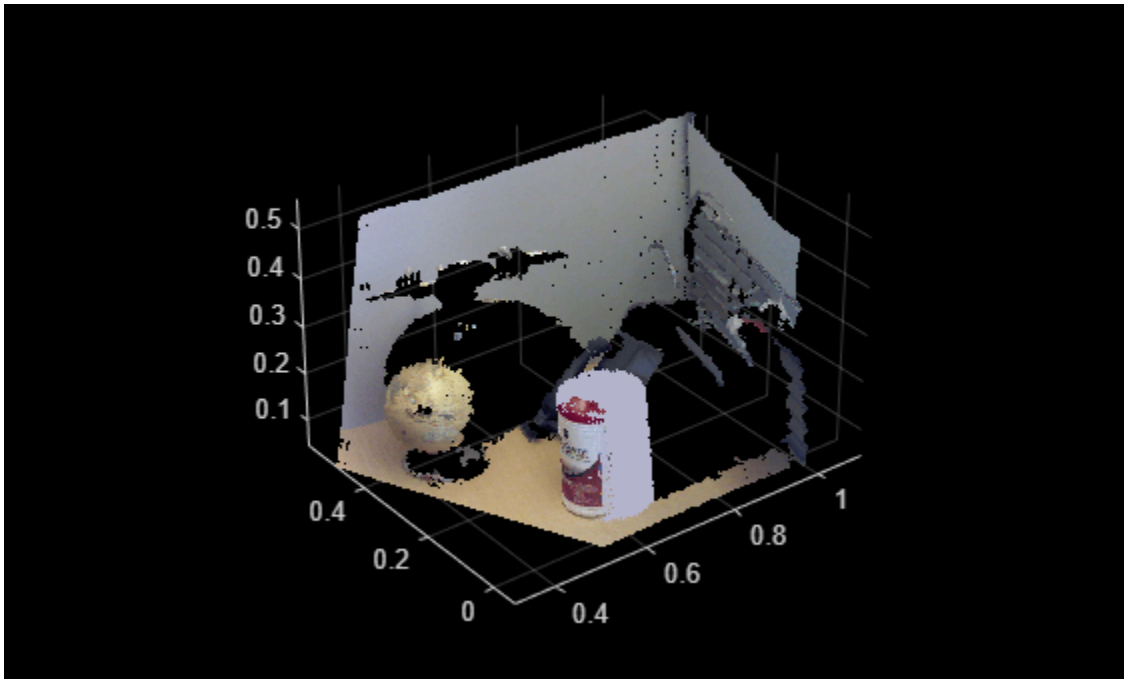
Set a maximum point-to-cylinder distance of 5 mm for cylinder fitting and the orientation constraint.

```
maxDistance = 0.005;
referenceVector = [0 0 1];
```

Detect a cylinder in the point cloud.

```
 model = pcfitcylinder(ptCloud,maxDistance,referenceVector, ...
        SampleIndices=sampleIndices);
```

Create a synthetic point cloud that is evenly distributed and covers the region of interest.



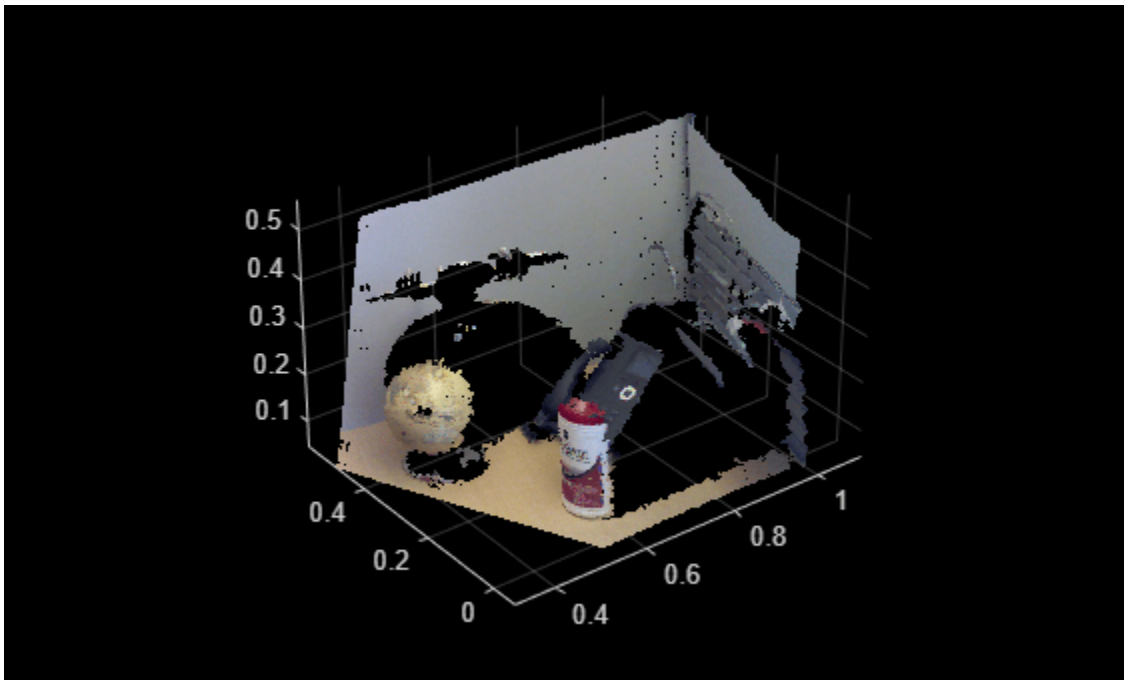
```
gridStep = 0.005;
[x,y,z] = meshgrid(roi(1,1):gridStep:roi(1,2),roi(2,1):gridStep:roi(2,2), ...
roi(3,1):gridStep:roi(3,2));
syntheticPtCloud = pointCloud([x(:) y(:) z(:)],Color=[0.7 0.7 0.8]);
```

Find the points in the synthetic point cloud that are in the cylinder.

```
idx = findPointsInModel(model,syntheticPtCloud);
cylinderPtCloud = select(syntheticPtCloud,idx);
```

Visualize the resulting point cloud, with the synthetic points in the cylinder modeling the object on the table.

```
figure
pcshow(cylinderPtCloud)
hold on
pcshow(ptCloud)
```



Find Points of Sphere Model in Point Cloud

Load a MAT file containing a point cloud into the workspace.

```
load("object3d.mat")
```

Visualize the point cloud.

```
figure
pcshow(ptCloud)
```

Define a region of interest (ROI) in the point cloud in which to detect a sphere model.

```
roi = [0.2 0.55; 0.2 0.5; 0 0.5];
sampleIndices = findPointsInROI(ptCloud,roi);
```

Set a maximum point-to-sphere distance of 5mm for sphere fitting.

```
maxDistance = 0.005;
```

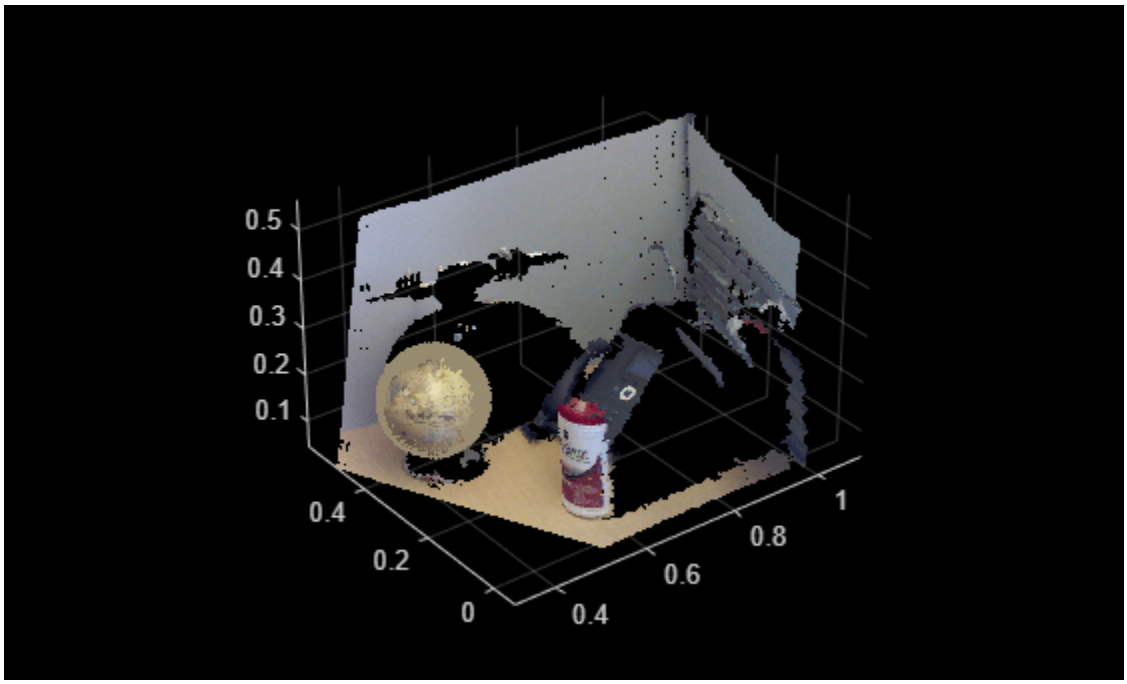
Detect the sphere in the point cloud.

```
[model,inlierIdx] = pcfitsphere(ptCloud,maxDistance,SampleIndices=sampleIndices);
```

Find one of the colors in the detected sphere, to use for the synthetic point cloud.

```
inlierPtCloud = select(ptCloud,inlierIdx);
color = median(inlierPtCloud.Color);
```

Create a synthetic point cloud that is evenly distributed and covers the region of interest.



```
gridStep = 0.005;
[x,y,z] = meshgrid(roi(1,1):gridStep:roi(1,2),roi(2,1):gridStep:roi(2,2), ...
roi(3,1):gridStep:roi(3,2));
syntheticPtCloud = pointCloud([x(:) y(:) z(:)],Color=color);
```

Find the points in the synthetic point cloud that are in the sphere.

```
idx = findPointsInModel(model,syntheticPtCloud);
spherePtCloud = select(syntheticPtCloud,idx);
```

Visualize the resulting point cloud, with the synthetic points in the sphere modeling the object on the table.

```
figure
pcshow(spherePtCloud)
hold on
pcshow(ptCloud)
```

Input Arguments

`model` — Parametric model
`cylinderModel` object | `sphereModel` object

Parametric model, specified as a `cylinderModel` or `sphereModel` object.

`ptCloud` — Point cloud
`pointCloud` object

Point cloud in the sensor coordinate system, specified as a `pointCloud` object.

Output Arguments

`indices` — Linear indices of point cloud points
column vector

Linear indices of the point cloud points that are located inside or on the surface of the model, returned as a column vector.

opticalFlow

Object for storing optical flow matrices

Description

The `opticalFlow` object stores the direction and speed of a moving object from one image or video frame to another. Use the object function `plot` to plot the optical flow vectors.

Creation

Syntax

```
flow = opticalFlow
flow = opticalFlow(Vx,Vy)
```

Description

`flow = opticalFlow` creates an optical flow object with default property values.

`flow = opticalFlow(Vx,Vy)` creates an optical flow object from two equal-sized matrices `Vx` and `Vy`. The matrices `Vx` and `Vy` are the *x* and *y* components of velocity respectively. The input velocity components set the “Properties” on page 2-1035 of optical flow object.

Input Arguments

Vx — *x* component of velocity

M-by-*N* matrix

x component of velocity in pixels per frame, specified as an *M*-by-*N* matrix.

Data Types: `single` | `double`

Vy — *y* component of velocity

M-by-*N* matrix

y component of velocity in pixels per frame, specified as an *M*-by-*N* matrix.

Data Types: `single` | `double`

Note `Vx` and `Vy` must be of the same size and data type.

Properties

Vx — *x* component of velocity

0-by-1 empty matrix (default) | *M*-by-*N* matrix

x component of velocity in pixels per frame, specified as an *M*-by-*N* matrix. If the input `Vx` is not specified, the default value of this property is set to a 0-by-1 empty matrix.

Data Types: `single` | `double`

`Vy` — *y* component of velocity

0-by-1 empty matrix (default) | *M*-by-*N* matrix

y component of velocity in pixels per frame, specified as an *M*-by-*N* matrix. If the input `Vy` is not specified, the default value of this property is set to a 0-by-1 empty matrix.

Data Types: `single` | `double`

`Orientation` — Phase angles of optical flow

0-by-1 empty matrix (default) | *M*-by-*N* matrix

This property is read-only.

Phase angles of optical flow in radians, specified as an *M*-by-*N* matrix of the same size and data type as the components of velocity. The phase angles of optical flow is calculated from the *x* and *y* components of velocity. If the inputs `Vx` and `Vy` are not specified, the default value of this property is set to 0-by-1 empty matrix.

Data Types: `single` | `double`

`Magnitude` — Magnitude of optical flow

0-by-1 empty matrix (default) | *M*-by-*N* matrix

This property is read-only.

Magnitude of optical flow in pixels per frame, specified as an *M*-by-*N* matrix of the same size and data type as the components of velocity. The magnitude of optical flow is calculated from the *x* and *y* components of velocity. If the inputs `Vx` and `Vy` are not specified, the default value of this property is set to 0-by-1 empty matrix.

Data Types: `single` | `double`

Object Functions

plot Plot optical flow vectors

Examples

Create Optical Flow Object

Create an optical flow object and view its properties.

```
flow = opticalFlow
```

```
flow =

  opticalFlow with properties:

            Vx: [0×1 double]
            Vy: [0×1 double]
    Orientation: [0×1 double]
      Magnitude: [0×1 double]
```

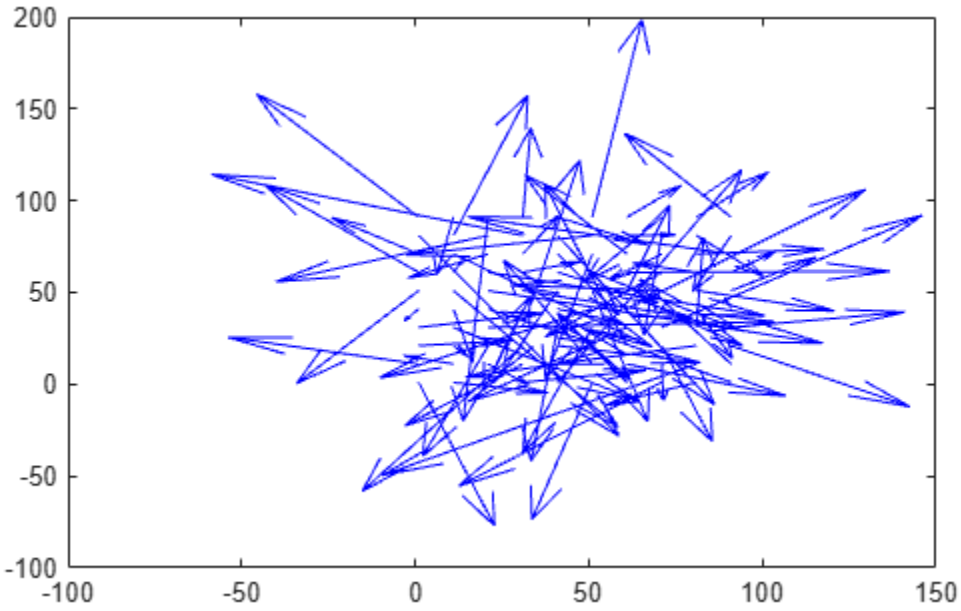
The default values of the properties are returned as an empty matrix of size 0-by-1 and data type `double`.

Create an Optical Flow Object and Plot Its Velocity

Create an optical flow object from two equal-sized velocity matrices.

```
Vx = randn(100,100);
Vy = randn(100,100);
opflow = opticalFlow(Vx,Vy);
```

Inspect the properties of the optical flow object. The orientation and the magnitude are computed from the velocity matrices.



```
opflow
```

```
opflow =
  opticalFlow with properties:

            Vx: [100×100 double]
            Vy: [100×100 double]
   Orientation: [100×100 double]
     Magnitude: [100×100 double]
```

Plot the velocity of the object as a quiver plot.

```
plot(opflow,DecimationFactor=[10 10],ScaleFactor=10);
```

plot

Plot optical flow vectors

Syntax

```
plot(flow)
plot(flow,Name=Value)
```

Description

`plot(flow)` plots the optical flow vectors.

`plot(flow,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `plot(flow,Color="red")` plots the optical flow with red flow vectors.

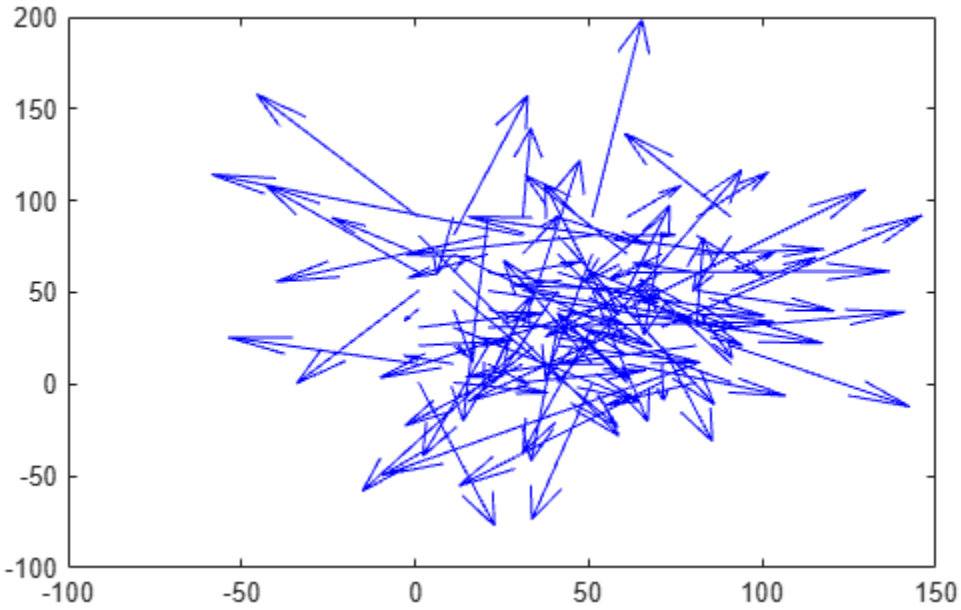
Examples

Create an Optical Flow Object and Plot Its Velocity

Create an optical flow object from two equal-sized velocity matrices.

```
Vx = randn(100,100);
Vy = randn(100,100);
opflow = opticalFlow(Vx,Vy);
```

Inspect the properties of the optical flow object. The orientation and the magnitude are computed from the velocity matrices.



```
opflow
```

```
opflow =
  opticalFlow with properties:

            Vx: [100×100 double]
            Vy: [100×100 double]
    Orientation: [100×100 double]
      Magnitude: [100×100 double]
```

Plot the velocity of the object as a quiver plot.

```
plot(opflow,DecimationFactor=[10 10],ScaleFactor=10);
```

Input Arguments

`flow` — Object containing optical flow matrices

`opticalFlow` object

Object containing optical flow velocity matrices, specified as an `opticalFlow` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `plot(flow,Color="red")` plots the optical flow with red flow vectors.

`DecimationFactor` — Decimation factor of velocity vectors

`[1 1]` (default) | two-element vector

Decimation factor of velocity vectors, specified as a two-element vector. The two-element vector is of form [*XDecimFactor YDecimFactor*] and specifies the decimation factor for velocity vectors along the *x* and *y* directions respectively. *XDecimFactor* and *YDecimFactor* are positive scalar integers. Increase the value of this property to get a less cluttered quiver plot.

`ScaleFactor` — Scaling factor for velocity vector display

1 (default) | positive integer-valued scalar

Scaling factor for velocity vector display, specified as a positive integer-valued scalar. Increase this value to display longer vectors.

`Parent` — Figure axes
`gca` handle

Figure axes, specified as an axes object. The default is set to the current axes handle, `gca`.

`Color` — Color of optical flow vectors
"blue" (default) | RGB triplet | long or short color name

Color of optical flow vectors, specified as a 1-by-3 RGB triplet in the range [0,1] or a long or short color name.

opticalFlowHS

Object for estimating optical flow using Horn-Schunck method

Description

Create an optical flow object for estimating the direction and speed of a moving object using the Horn-Schunck method. Use the object function `estimateFlow` to estimate the optical flow vectors. Using the `reset` object function, you can reset the internal state of the optical flow object.

Creation

Syntax

```
opticFlow = opticalFlowHS
opticFlow = opticalFlowHS(Name,Value)
```

Description

`opticFlow = opticalFlowHS` returns an optical flow object that you can use to estimate the direction and speed of the moving objects in a video. The optical flow is estimated using the Horn-Schunck method.

`opticFlow = opticalFlowHS(Name,Value)` returns an optical flow object with properties specified as one or more `Name,Value` pair arguments. Any unspecified properties have default values. Enclose each property name in quotes.

For example, `opticalFlowHS('Smoothness',1.5)`

Properties

`Smoothness` — Expected smoothness
`1` (default) | positive scalar

Expected smoothness of optical flow, specified as a positive scalar. Increase this value when there is increased motion between consecutive frames. A typical value for `'Smoothness'` is around `1`.

`MaxIteration` — Maximum number of iterations
`10` (default) | positive integer-valued scalar

Maximum number of iterations, specified as a positive integer-valued scalar. Increase this value to estimate the optical flow of objects with low velocity.

The iterative computation stops when the number of iterations equals the value of `'MaxIteration'` or when the algorithm reaches the value set for `'VelocityDifference'`. To stop computation only by using `'MaxIteration'`, set the value of `'VelocityDifference'` to `0`.

`VelocityDifference` — Minimum absolute velocity difference
`0` (default) | positive scalar

Minimum absolute velocity difference, specified as a positive scalar. This value depends on the input data type. Decrease this value to estimate the optical flow of objects that have low velocity.

The iterative computation stops when the algorithm reaches the value set for `'VelocityDifference'` or the number of iterations equals `'MaxIteration'`. To use only `'VelocityDifference'` to stop computation, set `'MaxIteration'` to `Inf`.

Object Functions

estimateFlow	Estimate optical flow
reset	Reset the internal state of the optical flow estimation object

Examples

Estimate Optical Flow Using Horn-Schunck Method

Create a `VideoReader` object for the input video file, `visiontraffic.avi`. Specify the timestamp of the frame to read as 11.

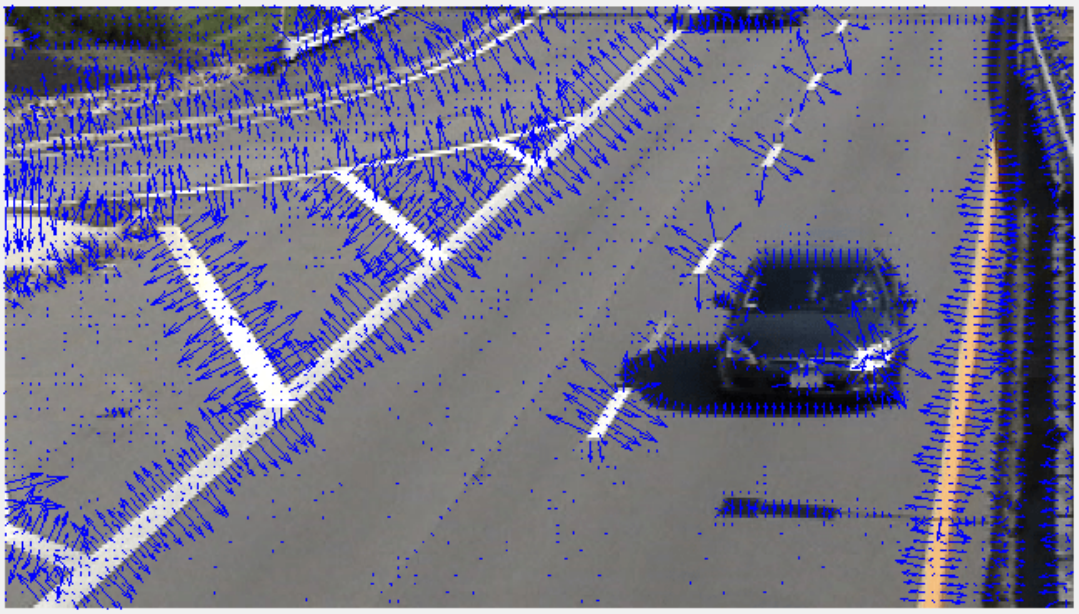
```
vidReader = VideoReader('visiontraffic.avi',CurrentTime=11);
```

Specify the optical flow estimation method as `opticalFlowHS`. The output is an object specifying the optical flow estimation method and its properties.

```
opticFlow = opticalFlowHS
```

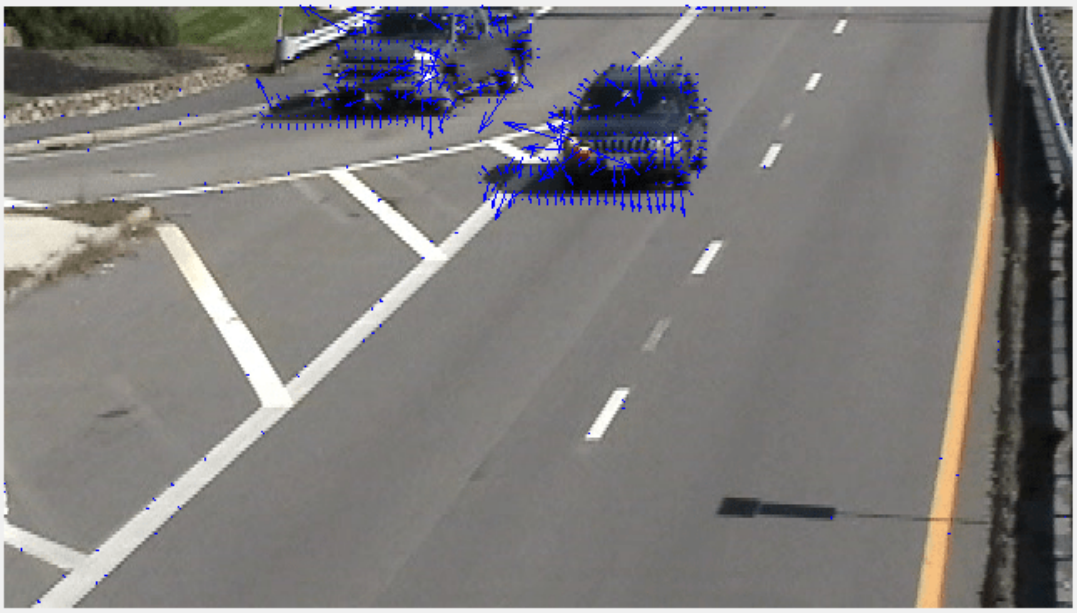
```
opticFlow =
  opticalFlowHS with properties:

            Smoothness: 1
          MaxIteration: 10
    VelocityDifference: 0
```



Create a custom figure window to visualize the optical flow vectors.

```
h = figure;
movegui(h);
hViewPanel = uipanel(h,Position=[0 0 1 1],Title="Plot of Optical Flow Vectors");
hPlot = axes(hViewPanel);
```



Read image frames from the `VideoReader` object and convert to grayscale images. Estimate the optical flow from consecutive image frames. Display the current image frame and plot the optical flow vectors as quiver plot.

```
while hasFrame(vidReader)
    frameRGB = readFrame(vidReader);
    frameGray = im2gray(frameRGB);
    flow = estimateFlow(opticFlow,frameGray);
    imshow(frameRGB)
    hold on
    plot(flow,DecimationFactor=[5 5],ScaleFactor=5,Parent=hPlot);
    hold off
    pause(10^-3)
end
```

Plot of Optical Flow Vectors

Plot of Optical Flow Vectors

Algorithms

To compute the optical flow between two images, you must solve this optical flow constraint equation:

$$I_x u + I_y v + I_t = 0$$

.

- I_x, I_y, and I_t are the spatiotemporal image brightness derivatives.
- u is the horizontal optical flow.
- v is the vertical optical flow.

Horn-Schunck Method

By assuming that the optical flow is smooth across the entire image, the Horn-Schunck method estimates a velocity field, $[u\ v]^T$, that minimizes this equation:

$$E = \iint (I_x u + I_y v + I_t)^2 dx dy + \alpha \iint \left\{ \left(\frac{\partial u}{\partial x}\right)^2 + \left(\frac{\partial u}{\partial y}\right)^2 + \left(\frac{\partial v}{\partial x}\right)^2 + \left(\frac{\partial v}{\partial y}\right)^2 \right\} dx dy$$

.

In this equation, $\frac{\partial u}{\partial x}$ and $\frac{\partial u}{\partial y}$ are the spatial derivatives of the optical velocity component, u, and α scales the global smoothness term. The Horn-Schunck method minimizes the previous equation to obtain the velocity field, $[u\ v]$, for each pixel in the image. This method is given by the following equations:

$$u_{x,y}^{k+1} = \bar{u}_{x,y}^{k} - \frac{I_x [I_x \bar{u}^k_{x,y} + I_y \bar{v}^k_{x,y} + I_t]}{\alpha^2 + I_x^2 + I_y^2}$$

$$v_{x,y}^{k+1} = \bar{v}_{x,y}^{k} - \frac{I_y [I_x \bar{u}^k_{x,y} + I_y \bar{v}^k_{x,y} + I_t]}{\alpha^2 + I_x^2 + I_y^2}$$

.

In these equations, $\left[u_{x,y}^k\ v_{x,y}^k\right]$ is the velocity estimate for the pixel at (x,y), and $\left[\bar{u}_{x,y}^k\ \bar{v}_{x,y}^k\right]$ is the neighborhood average of $\left[u_{x,y}^k\ v_{x,y}^k\right]$. For $k = 0$, the initial velocity is 0.

To solve u and v using the Horn-Schunck method:

1. Compute I_x and I_y by using the Sobel convolution kernel, $[-1\ -2\ -1;\ 0\ 0\ 0;\ 1\ 2\ 1]$, and its transposed form for each pixel in the first image.
2. Compute I_t between images 1 and 2 using the $[-1\ 1]$ kernel.
3. Assume the previous velocity to be 0, and compute the average velocity for each pixel using $[0\ 1\ 0;\ 1\ 0\ 1;\ 0\ 1\ 0]$ as a convolution kernel.
4. Iteratively solve for u and v.

“What Is Optical Flow?”

opticalFlowLK

Object for estimating optical flow using Lucas-Kanade method

Description

Create an optical flow object for estimating the direction and speed of a moving object using the Lucas-Kanade method. Use the object function `estimateFlow` to estimate the optical flow vectors. Using the `reset` object function, you can reset the internal state of the optical flow object.

Creation

Syntax

```
opticFlow = opticalFlowLK
opticFlow = opticalFlowLK('NoiseThreshold',threshold)
```

Description

`opticFlow = opticalFlowLK` returns an optical flow object that you can use to estimate the direction and speed of the moving objects in a video. The optical flow is estimated using the Lucas-Kanade method.

`opticFlow = opticalFlowLK('NoiseThreshold',threshold)` returns an optical flow object with the property `'NoiseThreshold'` specified as a `Name,Value` pair. Enclose the property name in quotes.

For example, `opticalFlowLK('NoiseThreshold',0.05)`

Properties

`NoiseThreshold` — Threshold for noise reduction

`0.0039` (default) | positive scalar

Threshold for noise reduction, specified as a positive scalar. As you increase this number, the movement of the objects has less impact on optical flow calculation.

Object Functions

estimateFlow	Estimate optical flow
reset	Reset the internal state of the optical flow estimation object

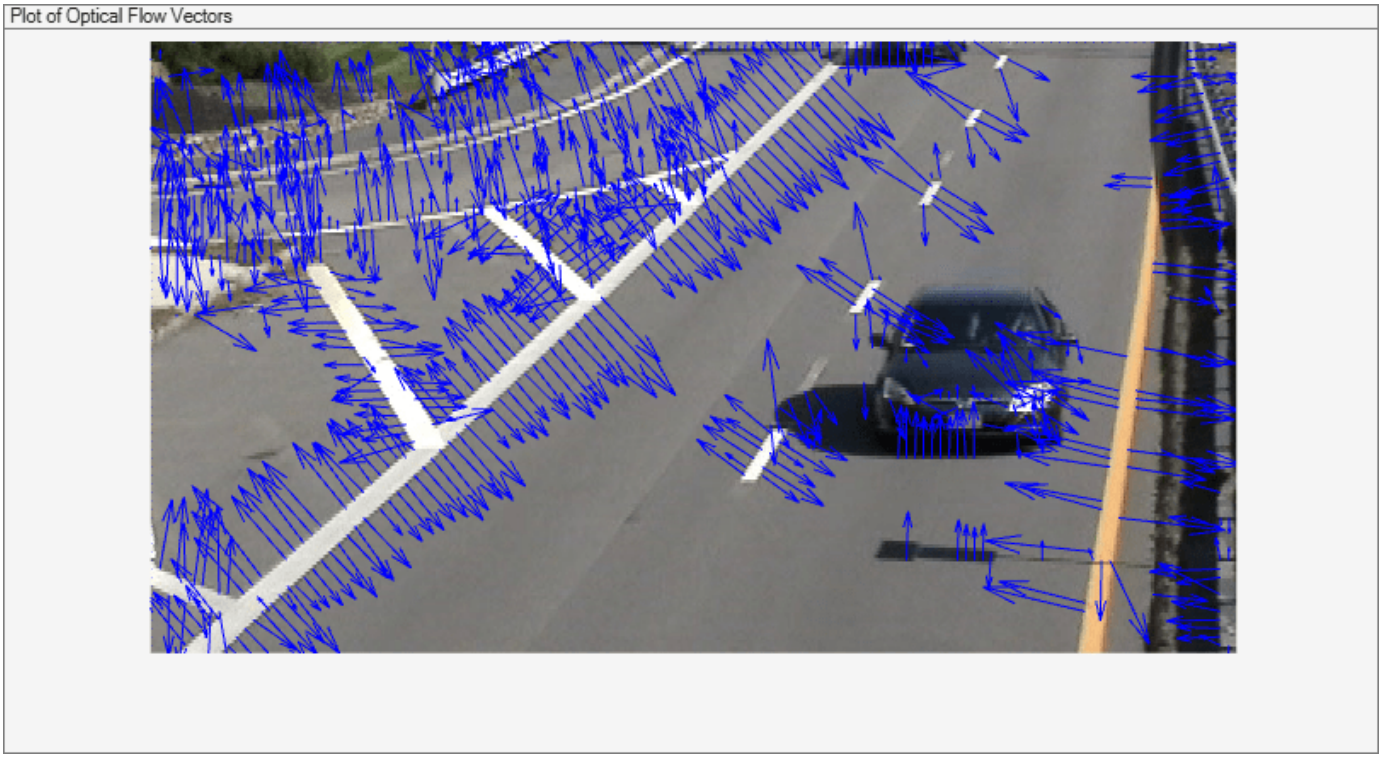
Examples

Compute Optical Flow Using Lucas-Kanade Algorithm

Read a video file. Specify the timestamp of the frame to be read.

```
vidReader = VideoReader('visiontraffic.avi','CurrentTime',11);
```

Create an optical flow object for estimating the optical flow using Lucas-Kanade method. Specify the threshold for noise reduction. The output is an optical flow object specifying the optical flow estimation method and its properties.



```
opticFlow = opticalFlowLK('NoiseThreshold',0.009);
```

Create a custom figure window to visualize the optical flow vectors.

```
h = figure;
movegui(h);
hViewPanel = uipanel(h,'Position',[0 0 1 1],'Title','Plot of Optical Flow Vectors');
hPlot = axes(hViewPanel);
```

Read the image frames and convert to grayscale images. Estimate the optical flow from consecutive image frames. Display the current image frame and plot the optical flow vectors as quiver plot.

```
while hasFrame(vidReader)
    frameRGB = readFrame(vidReader);
    frameGray = im2gray(frameRGB);
    flow = estimateFlow(opticFlow,frameGray);
    imshow(frameRGB)
    hold on
    plot(flow,'DecimationFactor',[5 5],'ScaleFactor',10,'Parent',hPlot);
    hold off
    pause(10^-3)
end
```

Algorithms

To compute the optical flow between two images, you must solve this optical flow constraint equation:

$$I_x u + I_y v + I_t = 0$$

.

- I_x, I_y, and I_t are the spatiotemporal image brightness derivatives.
- u is the horizontal optical flow.
- v is the vertical optical flow.

Lucas-Kanade Method

To solve the optical flow constraint equation for u and v, the Lucas-Kanade method divides the original image into smaller sections and assumes a constant velocity in each section. Then it performs a weighted, least-square fit of the optical flow constraint equation to a constant model for $[u\ v]^T$ in each section Ω. The method achieves this fit by minimizing this equation:

$$\sum_{x \in \Omega} W^2 [I_x u + I_y v + I_t]^2$$

W is a window function that emphasizes the constraints at the center of each section. The solution to the minimization problem is

$$\begin{bmatrix} \sum W^2 I_x^2 & \sum W^2 I_x I_y \\ \sum W^2 I_y I_x & \sum W^2 I_y^2 \end{bmatrix} \begin{bmatrix} u \\ v \end{bmatrix} = - \begin{bmatrix} \sum W^2 I_x I_t \\ \sum W^2 I_y I_t \end{bmatrix}$$

.

The Lucas-Kanade method computes I_t using a difference filter, `[-1 1]`.

u and v are solved as follows:

1. Compute I_x and I_y using the kernel $[-1\ 8\ 0\ -8\ 1]/12$ and its transposed form.
2. Compute I_t between images 1 and 2 using the $[-1\ 1]$ kernel.
3. Smooth the gradient components, I_x, I_y, and I_t, using a separable and isotropic 5-by-5 element kernel whose effective 1-D coefficients are $[1\ 4\ 6\ 4\ 1]/16$.
4. Solve the 2-by-2 linear equations for each pixel using the following method:

   - If $A = \begin{bmatrix} a & b \\ b & c \end{bmatrix} = \begin{bmatrix} \sum W^2 I_x^2 & \sum W^2 I_x I_y \\ \sum W^2 I_y I_x & \sum W^2 I_y^2 \end{bmatrix}$

     Then the eigenvalues of A are $\lambda_i = \frac{a+c}{2} \pm \frac{\sqrt{4b^2 + (a-c)^2}}{2}; i = 1, 2$

   - The eigenvalues are compared to the threshold, τ, that corresponds to the value you enter for the threshold for noise reduction. The results fall into one of the following cases:

     Case 1: $\lambda_1 \geq \tau$ and $\lambda_2 \geq \tau$

     A is nonsingular, the system of equations are solved using Cramer's rule.

     Case 2: $\lambda_1 \geq \tau$ and $\lambda_2 < \tau$

     A is singular (noninvertible), the gradient flow is normalized to calculate u and v.

     Case 3: $\lambda_1 < \tau$ and $\lambda_2 < \tau$

     The optical flow, u and v, is 0.

Topics

“What Is Optical Flow?”

opticalFlowLKDoG

Object for estimating optical flow using Lucas-Kanade derivative of Gaussian method

Description

Create an optical flow object for estimating the direction and speed of moving objects using the Lucas-Kanade derivative of Gaussian (DoG) method. Use the object function `estimateFlow` to estimate the optical flow vectors. Using the `reset` object function, you can reset the internal state of the optical flow object.

Creation

Syntax

```
opticFlow = opticalFlowLKDoG
opticFlow = opticalFlowLKDoG(Name,Value)
```

Description

`opticFlow = opticalFlowLKDoG` returns an optical flow object that you can use to estimate the direction and speed of the moving objects in a video. The optical flow is estimated using the Lucas-Kanade derivative of Gaussian (DoG) method.

`opticFlow = opticalFlowLKDoG(Name,Value)` returns an optical flow object with properties specified as one or more `Name,Value` pair arguments. Any unspecified properties have default values. Enclose each property name in quotes.

For example, `opticalFlowLKDoG('NumFrames',3)`

Properties

`NumFrames` — Number of buffered frames
3 (default) | positive integer-valued scalar

Number of buffered frames for temporal smoothing, specified as a positive integer-valued scalar. As you increase this number, the optical flow estimation method becomes less robust to abrupt changes in the trajectory of the moving objects. The amount of delay in flow estimation depends on the value of `NumFrames`. The output flow corresponds to the image at $t_{flow} = t_{current} - 0.5(NumFrames\text{-}1)$, where $t_{current}$ is the time of the current image.

`ImageFilterSigma` — Standard deviation for image smoothing filter
`1.5` | positive scalar

Standard deviation for image smoothing filter, specified as a positive scalar.

`GradientFilterSigma` — Standard deviation for gradient smoothing filter
1 | positive scalar

Standard deviation for gradient smoothing filter, specified as a positive scalar.

`NoiseThreshold` — Threshold for noise reduction
`0.0039` (default) | positive scalar

Threshold for noise reduction, specified as a positive scalar. As you increase this number, the movement of the objects has less impact on optical flow calculation.

Object Functions

estimateFlow	Estimate optical flow
reset	Reset the internal state of the optical flow estimation object

Examples

Compute Optical Flow Using Lucas-Kanade DoG Method

Read a video file. Specify the timestamp of the frame to be read.

```
vidReader = VideoReader('visiontraffic.avi',CurrentTime=11);
```

Create an optical flow object for estimating the optical flow using Lucas-Kanade DoG method. Specify the threshold for noise reduction. The output is an optical flow object specifying the optical flow estimation method and its properties.

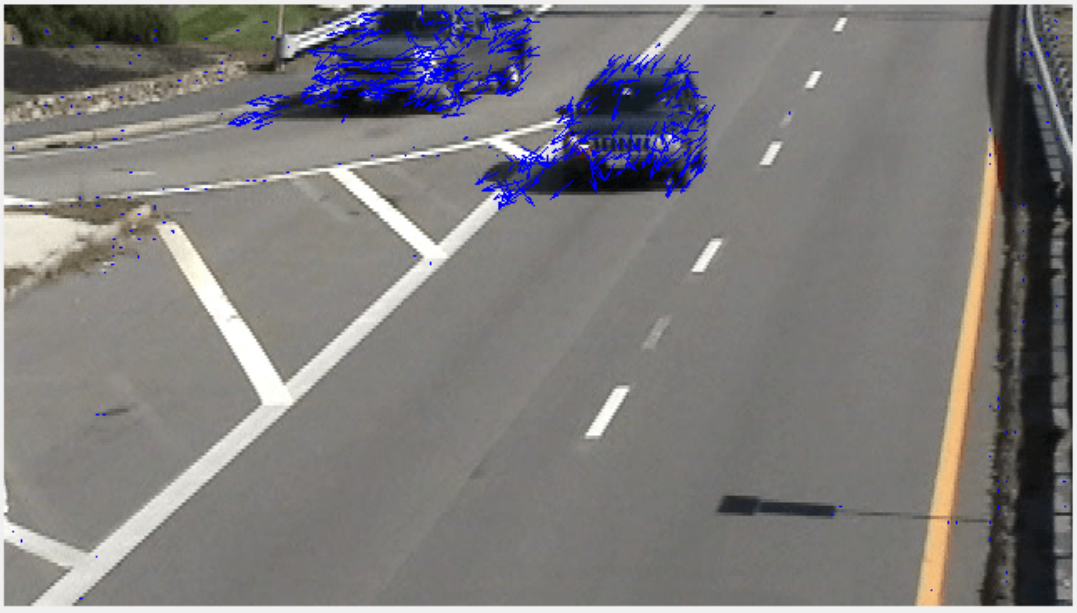
```
opticFlow = opticalFlowLKDoG(NoiseThreshold=0.0005)
```

```
opticFlow =
  opticalFlowLKDoG with properties:

              NumFrames: 3
       ImageFilterSigma: 1.5000
    GradientFilterSigma: 1
         NoiseThreshold: 5.0000e-04
```

Create a custom figure window to visualize the optical flow vectors.

```
h = figure;
movegui(h);
hViewPanel = uipanel(h,Position=[0 0 1 1],Title="Plot of Optical Flow Vectors");
hPlot = axes(hViewPanel);
```



Read the image frames and convert to grayscale images. Estimate the optical flow from consecutive image frames. Display the current image frame and plot the optical flow vectors as quiver plot.

```
while hasFrame(vidReader)
    frameRGB = readFrame(vidReader);
    frameGray = im2gray(frameRGB);
    flow = estimateFlow(opticFlow,frameGray);
    imshow(frameRGB)
    hold on
    plot(flow,DecimationFactor=[5 5],ScaleFactor=5,Parent=hPlot);
    hold off
    pause(10^-3)
end
```

Plot of Optical Flow Vectors

Plot of Optical Flow Vectors

Algorithms

To compute the optical flow between two images, you must solve this optical flow constraint equation:

$$I_x u + I_y v + I_t = 0$$

.

- I_x, I_y, and I_t are the spatiotemporal image brightness derivatives.
- u is the horizontal optical flow.
- v is the vertical optical flow.

Lucas-Kanade Derivative of Gaussian Method

The Lucas-Kanade method computes I_t using a derivative of Gaussian filter.

To solve the optical flow constraint equation for u and v:

1. Compute I_x and I_y using the following steps:
   a. Use a Gaussian filter to perform temporal filtering. Specify the temporal filter characteristics such as the standard deviation and number of filter coefficients using the `NumFrames` property.
   b. Use a Gaussian filter and the derivative of a Gaussian filter to smooth the image using spatial filtering. Specify the standard deviation and length of the image smoothing filter using the `ImageFilterSigma` property.
2. Compute I_t between images 1 and 2 using the following steps:
   a. Use the derivative of a Gaussian filter to perform temporal filtering. Specify the temporal filter characteristics such as the standard deviation and number of filter coefficients using the `NumFrames` property.
   b. Use the filter described in step 1b to perform spatial filtering on the output of the temporal filter.
3. Smooth the gradient components, I_x, I_y, and I_t, using a gradient smoothing filter. Use the `GradientFilterSigma` property to specify the standard deviation and the number of filter coefficients for the gradient smoothing filter.
4. Solve the 2-by-2 linear equations for each pixel using the following method:
   - If $A = \begin{bmatrix} a & b \\ b & c \end{bmatrix} = \begin{bmatrix} \sum W^2 I_x^2 & \sum W^2 I_x I_y \\ \sum W^2 I_y I_x & \sum W^2 I_y^2 \end{bmatrix}$

     Then the eigenvalues of A are $\lambda_i = \frac{a+c}{2} \pm \frac{\sqrt{4b^2 + (a-c)^2}}{2}; i = 1, 2$
   - When the algorithm finds the eigenvalues, it compares them to the threshold, τ, that corresponds to the value you enter for the `NoiseThreshold` property. The results fall into one of the following cases:

     Case 1: $\lambda_1 \geq \tau$ and $\lambda_2 \geq \tau$

     A is nonsingular, so the algorithm solves the system of equations using Cramer's rule.

Case 2: $\lambda_1 \geq \tau$ and $\lambda_2 < \tau$

A is singular (noninvertible), so the algorithm normalizes the gradient flow to calculate u and v.

Case 3: $\lambda_1 < \tau$ and $\lambda_2 < \tau$

The optical flow, u and v, is 0.

Topics

"What Is Optical Flow?"

opticalFlowFarneback

Object for estimating optical flow using Farneback method

Description

Create an optical flow object for estimating the direction and speed of moving objects using the Farneback method. Use the object function `estimateFlow` to estimate the optical flow vectors. Using the `reset` object function, you can reset the internal state of the optical flow object.

Creation

Syntax

```
opticFlow = opticalFlowFarneback
opticFlow = opticalFlowFarneback(Name,Value)
```

Description

`opticFlow = opticalFlowFarneback` returns an optical flow object that you can use to estimate the direction and speed of the moving objects in a video. The optical flow is estimated using the Farneback method.

`opticFlow = opticalFlowFarneback(Name,Value)` returns an optical flow object with properties specified as one or more `Name,Value` pair arguments. Any unspecified properties have default values. Enclose each property name in quotes.

For example, `opticalFlowFarneback('NumPyramidLevels',3)`

Properties

`NumPyramidLevels` — Number of pyramid layers
3 (default) | positive scalar

Number of pyramid layers, specified as a positive scalar. The value includes the initial image as one of the layers. When you set this value to `1`, the function estimates optical flow only from the original image frame and does not perform pyramid decomposition. The recommended values are between `1` and `4`.

`PyramidScale` — Image scale
`0.5` (default) | positive scalar in the range (0,1)

Image scale, specified as a positive scalar in the range (0,1). The value specifies the rate of downsampling at each pyramid level. A value of `0.5` creates a classical pyramid, where the resolution of the pyramid reduces by a factor of two at each level. The lowest level in the pyramid has the highest resolution.

`NumIterations` — Number of search iterations per pyramid level
3 (default) | positive integer

Number of search iterations per pyramid level, specified as a positive integer. The Farneback algorithm performs an iterative search for the key points at each pyramid level, until convergence.

`NeighborhoodSize` — Size of the pixel neighborhood
5 (default) | positive integer

Size of the pixel neighborhood, specified as a positive integer. Increase the neighborhood size to increase blurred motion. The blur motion yields a more robust estimation of optical flow. A typical value for `NeighborhoodSize` is 5 or 7.

`FilterSize` — Averaging filter size
15 (default) | positive integer in the range [2, Inf)

Averaging filter size, specified as a positive integer in the range [2, Inf). After the algorithm computes the displacement (flow), the averaging over neighborhoods is done using a Gaussian filter of size (`FilterSize` * `FilterSize`). Also, the pixels close to the borders are given a reduced weight because the algorithm assumes that the polynomial expansion coefficients are less reliable there. Increasing the filter size increases the robustness of the algorithm to image noise. The larger the filter size, the greater the algorithm handles image noise and fast motion detection, making it more robust.

Object Functions

estimateFlow	Estimate optical flow
reset	Reset the internal state of the optical flow estimation object

Examples

Estimate Optical Flow Using Farneback Method

Read a video file. Specify the timestamp of the frame to be read.

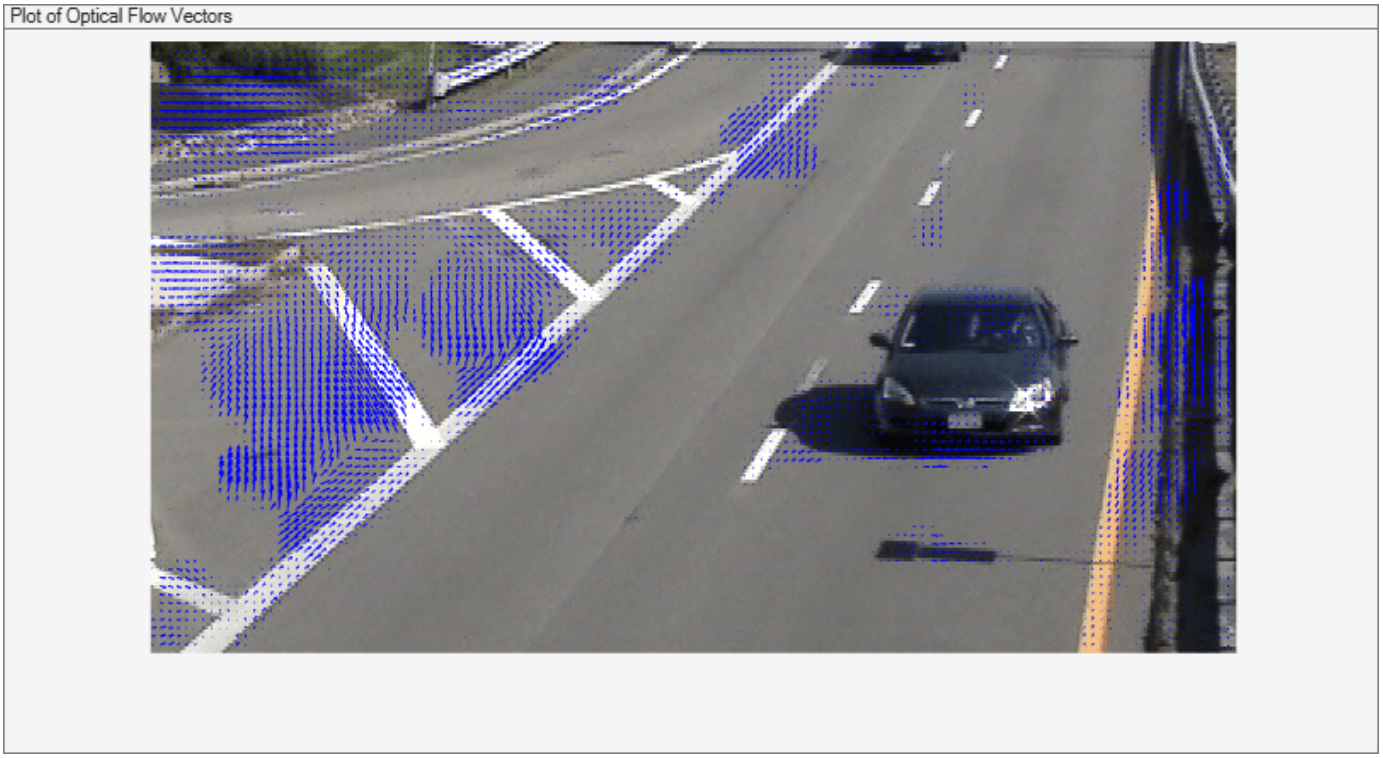
```
vidReader = VideoReader('visiontraffic.avi','CurrentTime',11);
```

Create an optical flow object for estimating the optical flow using Farneback method. The output is an object specifying the optical flow estimation method and its properties.

```
opticFlow = opticalFlowFarneback
```

```
opticFlow =
  opticalFlowFarneback with properties:

    NumPyramidLevels: 3
        PyramidScale: 0.5000
       NumIterations: 3
    NeighborhoodSize: 5
          FilterSize: 15
```



Create a custom figure window to visualize the optical flow vectors.

```
h = figure;
movegui(h);
hViewPanel = uipanel(h,'Position',[0 0 1 1],'Title','Plot of Optical Flow Vectors');
hPlot = axes(hViewPanel);
```

Read the image frames and convert to grayscale images. Estimate the optical flow from consecutive image frames. Display the current image frame and plot the optical flow vectors as quiver plot.

```
while hasFrame(vidReader)
    frameRGB = readFrame(vidReader);
    frameGray = im2gray(frameRGB);
    flow = estimateFlow(opticFlow,frameGray);

    imshow(frameRGB)
    hold on
    plot(flow,'DecimationFactor',[5 5],'ScaleFactor',2,'Parent',hPlot);
    hold off
    pause(10^-3)
end
```

Algorithms

The Farneback algorithm generates an image pyramid, where each level has a lower resolution compared to the previous level. When you select a pyramid level greater than 1, the algorithm can track the points at multiple levels of resolution, starting at the lowest level. Increasing the number of pyramid levels enables the algorithm to handle larger displacements of points between frames. However, the number of computations also increases. The diagram shows an image pyramid with three levels.

The tracking begins in the lowest resolution level, and continues until convergence. The point locations detected at a level are propagated as keypoints for the succeeding level. In this way, the algorithm refines the tracking with each level. The pyramid decomposition enables the algorithm to handle large pixel motions, which can be distances greater than the neighborhood size.

“What Is Optical Flow?”

estimateFlow

Estimate optical flow

Syntax

```
flow = estimateFlow(opticFlow,I)
```

Description

`flow = estimateFlow(opticFlow,I)` estimates optical flow between two consecutive video frames.

Examples

Estimate Optical Flow Using Horn-Schunck Method

Create a `VideoReader` object for the input video file, `visiontraffic.avi`. Specify the timestamp of the frame to read as 11.

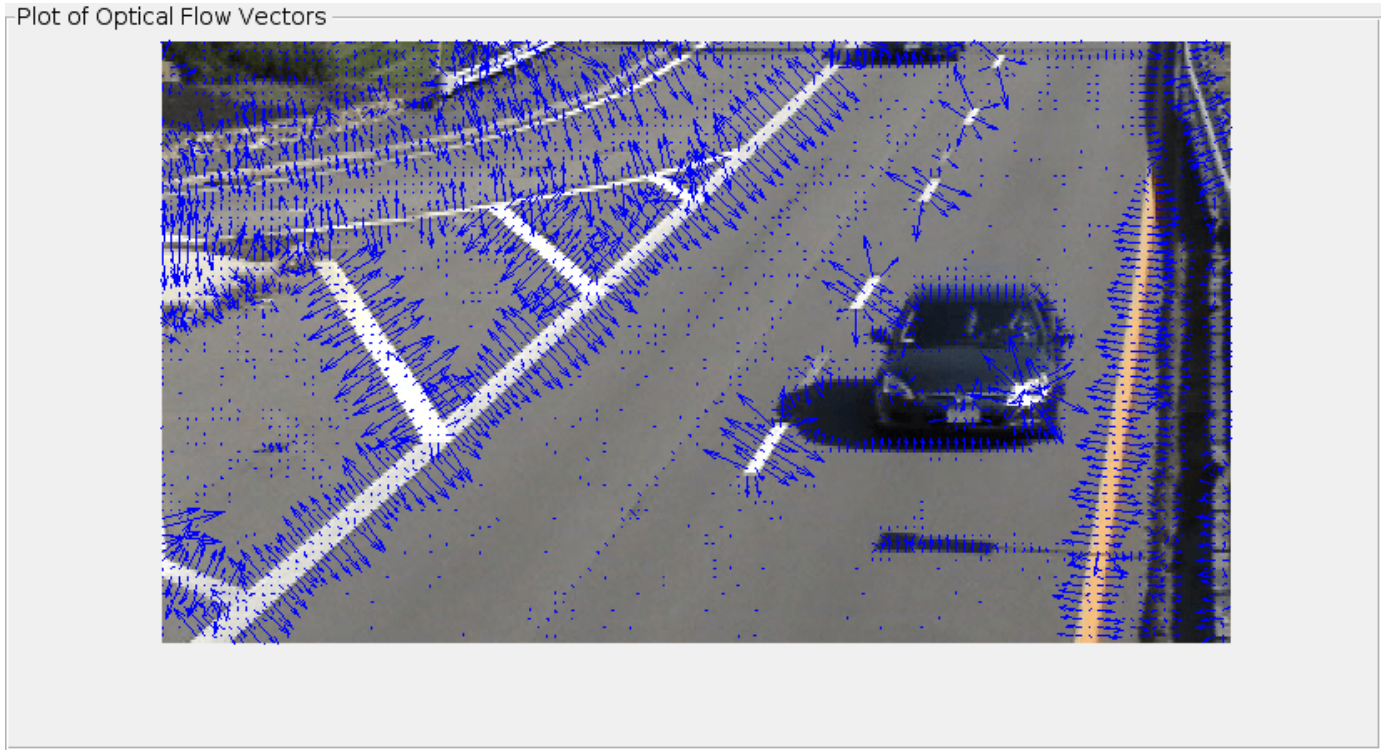
```
vidReader = VideoReader('visiontraffic.avi',CurrentTime=11);
```

Specify the optical flow estimation method as `opticalFlowHS`. The output is an object specifying the optical flow estimation method and its properties.

```
opticFlow = opticalFlowHS
```

```
opticFlow =
  opticalFlowHS with properties:

           Smoothness: 1
         MaxIteration: 10
    VelocityDifference: 0
```



Create a custom figure window to visualize the optical flow vectors.

```
h = figure;
movegui(h);
hViewPanel = uipanel(h,Position=[0 0 1 1],Title="Plot of Optical Flow Vectors");
hPlot = axes(hViewPanel);
```

Read image frames from the `VideoReader` object and convert to grayscale images. Estimate the optical flow from consecutive image frames. Display the current image frame and plot the optical flow vectors as quiver plot.

```
while hasFrame(vidReader)
    frameRGB = readFrame(vidReader);
    frameGray = im2gray(frameRGB);
    flow = estimateFlow(opticFlow,frameGray);
    imshow(frameRGB)
    hold on
```

```
    plot(flow,DecimationFactor=[5 5],ScaleFactor=5,Parent=hPlot);
    hold off
    pause(10^-3)
end
```

Input Arguments

`opticFlow` — Object for optical flow estimation

`opticalFlowFarneback` object | `opticalFlowHS` | object | `opticalFlowLK` object | `opticalFlowLKDoG` object

Object for optical flow estimation, specified as one of the following:

- `opticalFlowFarneback` object
- `opticalFlowHS` object
- `opticalFlowLK` object
- `opticalFlowLKDoG` object
- `opticalFlowRAFT` object

The input `opticFlow` defines the optical flow estimation method and its properties used for estimating the optical flow velocity matrices.

`I` — Current video frame

2-D grayscale image

Current video frame, specified as a 2-D grayscale image of size *m*-by-*n*. The input image is generated from the current video frame read using the `VideoReader` object. The video frames in RGB format must be converted to 2-D grayscale images for estimating the optical flow.

Output Arguments

`flow` — Object for storing optical flow velocity matrices
`opticalFlow` object

Object for storing optical flow velocity matrices, returned as an `opticalFlow` object.

Algorithms

The function estimates optical flow of the input video using the method specified by the input object `opticFlow`. The optical flow is estimated as the motion between two consecutive video frames. The video frame *T* at the given instant $t_{current}$ is referred as current frame and the video frame *T-1* is referred as previous frame. The initial value of the previous frame at time $t_{current} = 0$ is set as a uniform image of grayscale value 0.

Note If you specify `opticFlow` as `opticalFlowLKDoG` object, then the estimation delays by an amount relative to the number of video frames. The amount of delay depends on the value of `NumFrames` defined in `opticalFlowLKDoG` object. The optic flow estimated for a video frame at $t_{current}$ corresponds to the video frame at time $t_{flow} = (t_{current} - (NumFrames - 1)/2)$. $t_{current}$ is the time of the current video frame.

`reset`

reset

Reset the internal state of the optical flow estimation object

Syntax

```
reset(opticFlow)
```

Description

`reset(opticFlow)` resets the internal state of the optical flow estimation object. The previous frame is reset to its initial value which is a uniform image of intensity value 0.

Input Arguments

`opticFlow` — Object for optical flow estimation

`opticalFlowFarneback` object | `opticalFlowHS` | object | `opticalFlowLK` object | `opticalFlowLKDoG` object

Object for optical flow estimation, specified as one of the following:

- `opticalFlowFarneback` object
- `opticalFlowHS` object
- `opticalFlowLK` object
- `opticalFlowLKDoG` object

The input `opticFlow` defines the optical flow estimation method and its properties used for estimating the optical flow velocity matrices.

`estimateFlow`

vision.PeopleDetector

(Removed) Detect upright people using HOG features

Note `vision.PeopleDetector` function has been removed. Use the `peopleDetectorACF` function to detect people, instead.

Description

The people detector object detects people in an input image using the Histogram of Oriented Gradient (HOG) features and a trained Support Vector Machine (SVM) classifier. The object detects unoccluded people in an upright position.

To detect people in an image:

1. Create the `vision.PeopleDetector` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
peopleDetector = vision.PeopleDetector
peopleDetector = vision.PeopleDetector(model)
peopleDetector = vision.PeopleDetector(Name,Value)
```

Description

`peopleDetector = vision.PeopleDetector` returns a people detector object, `peopleDetector`, that tracks a set of points in a video.

`peopleDetector = vision.PeopleDetector(model)` creates a people detector object and sets the `ClassificationModel` property to `model`.

`peopleDetector = vision.PeopleDetector(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `peopleDetector = vision.PeopleDetector('ClassificationModel','UprightPeople_128x64')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`ClassificationModel` — Name of classification model
`'UprightPeople_128x64'` (default) | `'UprightPeople_96x48'`

Name of classification model, specified as `'UprightPeople_128x64'` or `'UprightPeople_96x48'`. The pixel dimensions indicate the image size used for training.

The images used to train the models include background pixels around the person. Therefore, the actual size of a detected person is smaller than the training image size.

`ClassificationThreshold` — People classification threshold
1 (default) | nonnegative scalar value

People classification threshold, specified as a nonnegative scalar value. Use this threshold to control the classification of individual image subregions during multiscale detection. The threshold controls whether a subregion gets classified as a person. You can increase this value when there are many false detections. The higher the threshold value, the more stringent the requirements are for the classification. Vary the threshold over a range of values to find the optimum value for your data set. Typical values range from `0` to `4`.

Tunable: Yes

`MinSize` — Smallest region containing a person
`[]` (default) | two-element vector

Smallest region containing a person, specified in pixels as a two-element vector, [*height width*]. Set this property to the minimum size region containing a person. You can reduce computation time when you set this property. To do so, set this property to a value larger than the image size used to train the classification model. When you do not specify this property, the detector sets it to the image size used to train the classification model.

Tunable: Yes

`MaxSize` — Largest region containing a person
`[]` (default) | two-element vector

Largest region that contains a person, specified in pixels as a two-element vector, [*height width*]. Set this property to the largest region containing a person. You can reduce computation time when you set this property. To do so, set this property to a value smaller than the size of the input image. When you do not specify this property, the detector sets it to the input image size. This property is tunable.

`ScaleFactor` — Multiscale object detection scaling
`1.05` (default) | numeric value greater than `1.0001`

Multiscale object detection scaling, specified as a value greater than `1.0001`. The scale factor incrementally scales the detection resolution between `MinSize` and `MaxSize`. You can set the scale factor to an ideal value using:
`size(I)/(size(I)-0.5)`
The object calculates the detection resolution at each increment.

`round(`*TrainingSize*`*(ScaleFactor`^{N}`))`

In this case, the *TrainingSize* is `[128 64]` for the `'UprightPeople_128x64'` model and `[96 48]` for the `'UprightPeople_96x48'` model. *N* is the increment. Decreasing the scale factor can

increase the detection accuracy. However, doing so increases the computation time. This property is tunable.

`WindowStride` — Detection window stride
`[8 8]` (default) | scalar | two-element vector

Detection window stride in pixels, specified as a scalar or a two-element vector, [*x y*]. The detector uses the window stride to slide the detection window across the image. When you specify this value as a vector, the first and second elements are the stride size in the *x* and *y* directions. When you specify this value as a scalar, the stride is the same for both *x* and *y*. Decreasing the window stride can increase the detection accuracy. However, doing so increases computation time. Increasing the window stride beyond `[8 8]` can lead to a greater number of missed detections. This property is tunable.

`MergeDetections` — Merge detection control
`true` | `false`

Merge detection control, specified as `true` or `false`. This property controls whether similar detections are merged. Set this property to `true` to merge bounding boxes using a mean-shift based algorithm. Set this property to `false` to output the unmerged bounding boxes.

For more flexibility and control of merging parameters, you can use the `selectStrongestBbox` function in place of the `MergeDetections` algorithm. To do this, set the `MergeDetections` property to `false`. See the “Tracking Pedestrians from a Moving Car” example, which shows the use of the people detector and the `selectStrongestBbox` function.

`UseROI` — Use region of interest
`false` (default) | `true`

Use region of interest, specified as `true` or `false`. Set this property to `true` to detect objects within a rectangular region of interest within the input image.

Usage

Syntax

```
bboxes = peopleDetector(I)
[bboxes, scores] = peopleDetector(I)
[ ___ ] = peopleDetector(I,roi)
```

Description

`bboxes = peopleDetector(I)` performs multiscale object detection on the input image, `I` and returns an *M*-by-4 matrix defining *M* bounding boxes. *M* represents the number of detected people. Each row of the output matrix, `BBOXES`, contains a four-element vector, [*x y* width height]. This vector specifies, in pixels, the upper-left corner and size, of a bounding box. When no people are detected, the object returns an empty vector. The input image, `I`, must be a grayscale or truecolor (RGB) image.

`[bboxes, scores] = peopleDetector(I)` additionally returns a confidence value for the detections.

`[ ___ ] = peopleDetector(I,roi)` detects people within the rectangular search region, `roi`.

Input Arguments

`I` — Input image
grayscale | truecolor (RGB)

Input image, specified as grayscale or truecolor (RGB).

`roi` — Rectangular region of interest
four-element vector (default)

Rectangular region of interest within image `I`, specified as a four-element vector, [*x y width height*].

`model` — Classification model
`'UprightPeople_128x64'` (default) | `'UprightPeople_96x48'`

Classification model, specified as `'UprightPeople_128x64'` or `'UprightPeople_96x48'`.

Output Arguments

`peopleDetector` — People detector
object (default)

People detector object, returned as an object. The detector detects people in an input image using the Histogram of Oriented Gradient (HOG) features and a trained SVM classifier. The object detects unoccluded people in an upright position.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

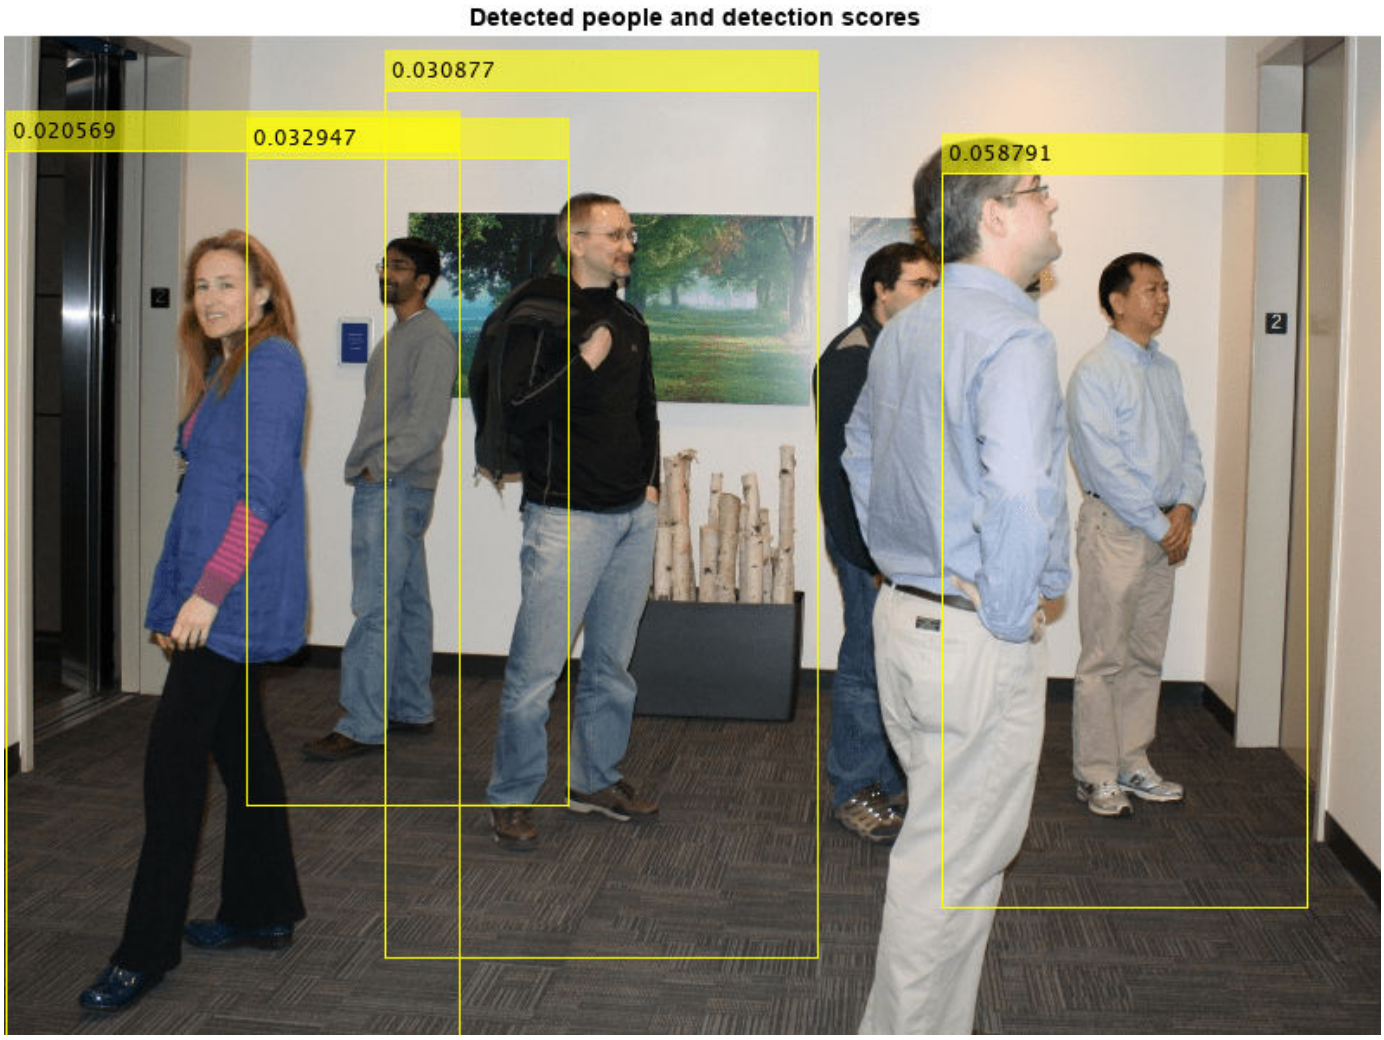
Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Detect People

1. Create a people detector and load the input image.



```
peopleDetector = vision.PeopleDetector;
I = imread('visionteam1.jpg');
```

2. Detect people using the people detector object.

```
[bboxes,scores] = peopleDetector(I);
```

3. Annotate detected people.

```
I = insertObjectAnnotation(I,'rectangle',bboxes,scores);
figure, imshow(I)
title('Detected people and detection scores');
```

Version History

Introduced in R2012b

R2024b: `vision.PeopleDetector` function has been removed

Errors starting in R2024b

`vision.PeopleDetector` function has been removed. Use the `peopleDetectorACF` function to detect people, instead.

R2024a: `vision.PeopleDetector` function will be removed

Warns starting in R2024a

`vision.PeopleDetector` function will be removed in a future release. Use the `peopleDetectorACF` function to detect people, instead.

instanceSegmentationMetrics

Instance segmentation quality metrics

Description

Use the `instanceSegmentationMetrics` object and its object functions to evaluate the quality of instance segmentation results.

An `instanceSegmentationMetrics` object stores instance segmentation quality metrics for a set of images, such as the average precision (AP) and precision and recall, computed per class and per image. To compute the AP and precision recall metrics, pass the `instanceSegmentationMetrics` object to the `averagePrecision` or the `precisionRecall` object functions, respectively. To compute the confusion matrix, pass the `instanceSegmentationMetrics` object to the `confusionMatrix` object function. Evaluate the summary of all metrics across all classes and all images in the data set using the `summarize` object function.

Creation

Create an `instanceSegmentationMetrics` object using the `evaluateInstanceSegmentation` function.

Properties

`ClassMetrics` — Metrics per class
table

This property is read-only.

Metrics per class, specified as a table with *C* rows, where *C* is the number of classes in the instance segmentation. `ClassMetrics` has these columns, corresponding to these instance segmentation metrics:

- `mAP` — Mean average precision calculated by averaging over all thresholds specified in the `threshold` argument for a class.
- `AP` — Average precision calculated for a class at each overlap threshold in `OverlapThreshold`, returned as a *numThresh*-by-1 array, where *numThresh* is the number of overlap thresholds.
- `Precision` — Precision values, returned as a *numThresh*-by-(*numPredictions*+1) matrix, where *numPredictions* is the number of predicted object masks. Precision is the ratio of the number of true positives (*TP*) and the total number of predicted positives.
  Precision = *TP* / (*TP* + *FP*)

  FP is the number of false positives, or misclassified pixels that comprise object instances. Larger precision scores imply that most object instance classes match ground truth objects.
- `Recall` — Recall values, returned as a *numThresh*-by-(*numPredictions*+1) matrix, where *numPredictions* is the number of predicted object masks. Recall is the ratio of the number of true positives (*TP*) and the total number of ground truth positives.

Recall = *TP* / (*TP* + *FN*)

FN is the number of false negatives, or the number of pixels that comprise instances that have been misclassified as background pixels. Larger recall scores imply that most ground truth objects are detected.

`ImageMetrics` — Metrics for each image
table

This property is read-only.

Metrics for each image in the data set, specified as a table with *numImages* rows, where *numImages* is the number of images in the data set. `ImageMetrics` has these columns, corresponding to these instance segmentation metrics:

- `NumObjects` — Number of objects in the ground truth data in each image, stored as a positive integer.
- `mAP` — Mean average precision (mAP), calculated by averaging the average precision (AP) across all classes at each overlap threshold in the `OverlapThreshold` property, stored as a *numThresh*-by-1 numeric vector. *numThresh* is the number of overlap thresholds. Specify the overlap thresholds for an image using the `threshold` argument.
- `mAPOverlapAvg` — Mean average precision (mAP), calculated by averaging the AP across all classes and all overlap thresholds specified by the `OverlapThreshold` property, stored as a numeric scalar.

`ClassNames` — Class names
array of strings | cell array of character vectors

Class names of segmented objects, specified as an array of strings.

Example: `["sky" "grass" "building" "sidewalk"]`

`OverlapThreshold` — Overlap threshold
numeric scalar | numeric vector

Overlap threshold, specified as a numeric scalar or numeric vector. When the intersection over union (IoU) of the pixels in the predicted object mask and ground truth object mask is equal to or greater than the overlap threshold, the prediction is considered a true positive.

IoU, or the Jaccard Index, is the number of pixels in the intersection of the binary masks divided by the number of pixels in the union of the masks. In other words, IoU is the ratio of correctly classified pixels to the total number of pixels that are assigned that class by the ground truth and the predictor.

Object Functions

averagePrecision	Evaluate average precision metric of instance segmentation results
confusionMatrix	Compute confusion matrix of instance segmentation results
precisionRecall	Get precision recall metrics of instance segmentation results
summarize	Summarize instance segmentation performance metrics at data set and class level
metricsByArea	Evaluate instance segmentation across object mask size ranges

Version History

Introduced in R2022b

R2024b: `ConfusionMatrix`, `NormalizedConfusionMatrix`, and `DatasetMetrics` properties have been removed
Not recommended starting in R2024b

The `ConfusionMatrix`, `NormalizedConfusionMatrix`, and `DatasetMetrics` properties of the `instanceSegmentationMetrics` object have been removed.

To update your code to compute the confusion matrix, replace instances of the `ConfusionMatrix` and `NormalizedConfusionMatrix` properties with the `confusionMatrix` object function.

To compute the summary of the instance segmentation quality metrics over the entire data set or over each class, use the `summarize` object function.

To compute precision, recall, and confidence scores for all classes in the data set, or at specified classes and overlap thresholds, use the `precisionRecall` object function.

To compute average precision (AP) for all classes and overlap thresholds in the data set, or specify the classes and overlap thresholds for which to compute AP, use the `averagePrecision` object function.

For an example that uses the new `instanceSegmentationMetrics` object functions to evaluate instance segmentation results, see the “Perform Instance Segmentation Using SOLOv2” example.

R2024b: Table columns in `ClassMetrics` and `ImageMetrics` properties have been renamed
Behavior change in future release

These table columns of the `ClassMetrics` and `ImageMetrics` properties have been renamed.

`instanceSegmentationMetrics` Property	Renamed Columns
`ClassMetrics`	• `mAP`, or the average precision (AP) averaged over all overlap thresholds for each class, has been renamed to `APOverlapAvg`. • `mLAMR`, or the log-average miss rate for each class averaged over all specified overlap thresholds, has been renamed to `LAMROverlapAvg`. • `mAOS`, or the average orientation similarity for each class averaged over all the specified overlap thresholds, has been renamed to `AOSOverlapAvg`.

instanceSegmentationMetrics Property	Renamed Columns
ImageMetrics	• AP, or the AP across all classes at each overlap threshold, has been renamed to mAP. • mAP, or the AP averaged across all classes and all overlap thresholds, has been renamed to mAPOverlapAvg. • mLAMR, or the log-average miss rate for each class averaged over all specified overlap thresholds, has been renamed to LAMROverlapAvg. • mAOS, or the average orientation similarity for each class averaged over all the specified overlap thresholds, has been renamed to AOSOverlapAvg.

metricsByArea

Evaluate instance segmentation across object mask size ranges

Syntax

```
areaMetrics = metricsByArea(metrics,objectAreaRanges)
areaMetrics = metricsByArea(metrics,objectAreaRanges,ClassNames)
```

Description

`areaMetrics = metricsByArea(metrics,objectAreaRanges)` evaluates the instance segmentation metrics detection performance for the object size range or ranges, specified as bounding box areas, `objectAreaRanges`. The function evaluates the specified bounding box size range within the existing instance segmentation `metrics`.

`areaMetrics = metricsByArea(metrics,objectAreaRanges,ClassNames)` also specifies the names of the classes for which to evaluate area-based metrics.

Input Arguments

`metrics` — Instance segmentation metrics

M-by-4 numeric matrix | vector

Instance segmentation metrics, specified as an `instanceSegmentationMetrics` object.

`objectAreaRanges` — Area of rectangular bounding boxes

M-by-2 numeric matrix | vector

Area of rectangular bounding boxes which are axis-aligned and surround the object mask, specified as one of the following:

- An *M*-by-2 numeric matrix, with each row specifying the upper (exclusive) and lower (inclusive) limits of an box area range in evaluation. For example, if the input is $[x_1\ x_2;\ x_3\ x_4]$. The evaluated bounding box area ranges are $x_1 \leq$ area $< x_2$ and $x_3 \leq$ area $< x_4$.
- A vector with $M+1$ elements, specifying the edge values of M contiguous area ranges. Each range is inclusive in the lower limit, and exclusive in the upper limit. For example, if the input is $[x_1\ x_2\ x_3]$, the area ranges evaluated are $x_1 \leq$ area $< x_2$ and $x_2 \leq$ area $< x_3$.

`ClassNames` — Names of classes

`''` (default) | string scalar | vector

Names of the classes for which to evaluate area-based metrics. If multiple classes are specified, the function computes averaged metrics across the classes. By default, all classes will be considered and the returned metrics will be the average of all classes.

Output Arguments

`areaMetrics` — Metrics by area

table

Metrics by area, returned as a table with *M* rows. Each row contains metrics using objects within an area range (for a total of *M* area ranges). The columns are specified by these table variables.

- `AreaRange`: The upper and lower limits of each area range, returned as a two-element row vector.
- `NumObjects`: The number of objects falling within each area range, returned as a positive integer.
- `mAP`: Mean average precision (mAP), or average precision averaged over all classes, computed at all overlap thresholds specified by the `OverlapThreshold` property, returned as a *numThresh*-by-1 numeric vector. *numThresh* is the number of overlap thresholds.
- `mAPOverlapAvg`: Mean average precision (mAP) averaged over all thresholds specified by the `OverlapThreshold` property, returned as a numeric scalar.

Introduced in R2023b

See Also

`instanceSegmentationMetrics` | `evaluateInstanceSegmentation`

averagePrecision

Evaluate average precision metric of instance segmentation results

Syntax

```
ap = averagePrecision(metrics)
ap = averagePrecision(metrics,Name=Value)
```

Description

`ap = averagePrecision(metrics)` evaluates the average precision (AP) for all classes and overlap thresholds of `metrics`.

AP aggregates the precision across different recall levels, providing a single metric to assess the overall ability of an object detector to identify objects accurately while minimizing false detections.

`ap = averagePrecision(metrics,Name=Value)` specifies options for the average precision evaluation using one or more name-value arguments. For example, `ClassNames=["cars" "people"]` specifies to evaluate the average precision metric for the cars and people classes.

Input Arguments

`metrics` — Instance segmentation performance metrics

`instanceSegmentationMetrics` object

Instance segmentation performance metrics, specified as an `instanceSegmentationMetrics` object.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `averagePrecision(metrics,ClassNames=[cars people])` specifies to evaluate the average precision metric for the cars and people classes.

`ClassNames` — Class names

string array | cell array of character vectors

Class names of segmented objects, specified as an array of strings or a cell array of character vectors. By default, the `averagePrecision` function returns the average precision metrics for all classes specified by the `ClassNames` property of the `instanceSegmentationMetrics` object `metrics`.

`OverlapThreshold` — Overlap threshold

numeric scalar | numeric vector

Overlap threshold to use for evaluating the average precision, specified as a numeric scalar or numeric vector of box overlap threshold values. To evaluate multiple overlap thresholds, specify this argument as a numeric vector. By default, the `averagePrecision` object function returns the

average precision metrics for all overlap thresholds specified by the `OverlapThreshold` property of the `instanceSegmentationMetrics` object `metrics`.

Output Arguments

ap — Average precision

M-by-*N* matrix

Average precision (AP) for specified classes and overlap thresholds, specified as an *M*-by-*N* matrix. *M* is the number of classes in the `ClassNames` property and *N* is the number of specified overlap thresholds `OverlapThreshold`.

The AP metric evaluates instance segmentation performance by quantifying the accuracy of the model in identifying object instances across different confidence thresholds, enabling you to assess both the precision (correctness of detections) and recall (completeness of detections).

`instanceSegmentationMetrics` | `evaluateInstanceSegmentation`

Topics

“Perform Instance Segmentation Using SOLOv2”

confusionMatrix

Compute confusion matrix of instance segmentation results

Syntax

```
[confMat,confusionClassNames] = confusionMatrix(metrics)
[confMat,confusionClassNames] = confusionMatrix(metrics,Name=Value)
```

Description

`[confMat,confusionClassNames] = confusionMatrix(metrics)` computes the confusion matrix for all overlap thresholds in the `OverlapThreshold` property of `metrics`, and returns the confusion matrix and the class names. The function considers all segmentations to compute the confusion matrix.

`[confMat,confusionClassNames] = confusionMatrix(metrics,Name=Value)` specifies one or more name-value arguments. For example, `ScoreThreshold=0.3` specifies to disregard segmentations with a confidence score value below `0.3` when computing the confusion matrix.

Input Arguments

`metrics` — Instance segmentation metrics

`instanceSegmentationMetrics` object

Instance segmentation performance metrics, specified as an `instanceSegmentationMetrics` object.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `confusionMatrix(metrics,ScoreThreshold=0.3)` specifies segmentations with a confidence score value below `0.3` to be disregarded when computing the confusion matrix.

`ScoreThreshold` — Confidence score threshold values

`0` (default) | numeric scalar in range `[0, 1]` | numeric vector

Confidence score threshold values to use for computing the confusion matrix, specified as a numeric scalar in the range `[0, 1]` or a numeric vector of values in the range `[0, 1]`. The function filters out predictions with confidence scores less than the threshold value when evaluating the confusion matrix.

Increase this value to reduce the number of false positives, at the possible expense of missing some true positives.

`OverlapThreshold` — Overlap threshold values

numeric scalar | numeric vector

Overlap threshold values to use for computing the confusion matrix, specified as a numeric scalar or numeric vector. Each overlap threshold value must be an element of the `OverlapThreshold` property of the `instanceSegmentationMetrics` object. By default, the function returns the confusion matrix computed at all the overlap thresholds specified by the `OverlapThreshold` property.

`Normalize` — Confusion matrix normalization
`false` or `0` (default) | `true` or `1`

Confusion matrix normalization option, specified as a numeric or logical `0` (or `false`) or `1` (or `true`). If you specify `Normalize` as `true`, the function normalizes the elements of the confusion matrix in the `confMat` argument by the number of objects known to belong to each class. For each overlap threshold, each element (*i*, *j*) in the normalized confusion matrix is the count of objects known to belong to class *i*, but predicted to belong to class *j*, divided by the total number of objects predicted in class *j*.

For other normalization options, see “Tips” on page 2-1082.

Output Arguments

`confMat` — Confusion matrix
M-by-*N* cell array

Confusion matrix, returned as an *M*-by-*N* cell array. *M* is the number of confidence score thresholds specified by the `ScoreThreshold` argument, and *N* is the number of overlap thresholds specified by the `OverlapThreshold` argument.

Each element of the `confMat` cell array is a square numeric matrix of size (*C*+1)-by-(*C*+1), where *C* is the number of classes. Each element (*i*, *j*) of the matrix is the count of *matched* bounding boxes predicted to belong to class *j*, but that have a ground truth annotation class of *i*.

Row and column *C*+1 in the confusion matrix correspond to these *unmatched* conditions:

- Column *C*+1 — Undetected objects, or *false negative* predictions. Each element in this column is the number of ground truth annotations of the corresponding class unmatched with any predicted bounding box.
- Row *C*+1 — Incorrect predictions, or *false positive* predictions. Each element in this row is the number of predicted bounding boxes of the corresponding class unmatched with any ground truth annotation.

`confusionClassNames` — Class names
string array

Class names corresponding to the returned confusion matrices, returned as a string array of size *C* +1. The elements of the string array correspond to the classes stored in the `ClassNames` property of the `instanceSegmentationMetrics` object `metrics` and an extra background class. The background class, `"background"`, corresponds to the row and column *C*+1 of the confusion matrix, which count the false positives and false negatives.

Tips

Normalize the confusion matrix output of the `confusionMatrix` function in these ways:

- Specify the `Normalize` name-value argument as `true` to divide each entry of the confusion matrix, `confMat`, by the sum of the corresponding column, so each value represents the proportion of predicted bounding boxes for a given class.
- For additional normalization options, use the `confusionchart` function. Pass the confusion matrix, `confMat`, to the `confusionchart` function, and specify the `Normalization` name-value argument. You can use this option to normalize the confusion matrix by row or by the total number of detected bounding boxes, in addition to column normalization.

objectDetectionMetrics

Object detection quality metrics

Description

Use the `objectDetectionMetrics` object and its object functions to evaluate the quality of object detection results.

An `objectDetectionMetrics` object stores object detection quality metrics, such as the average precision (AP) and precision recall, computed per class. To compute the AP and precision recall metrics, pass the `objectDetectionMetrics` object to the `averagePrecision` or the `precisionRecall` object functions, respectively. To compute the confusion matrix, pass the `objectDetectionMetrics` object to the `confusionMatrix` object function. Evaluate the summary of all metrics across all classes and all images in the data set using the `summarize` object function.

To get started with evaluating object detector performance using the performance metrics, see "Evaluate Object Detector Performance".

Creation

Create an `objectDetectionMetrics` object by using the `evaluateObjectDetection` function.

Properties

`ClassMetrics` — Metrics per class
table

This property is read-only.

Metrics per class, stored as a table with *C* rows, where *C* is the number of classes in the object detection. If additional metrics are not specified through the `AdditionalMetrics` argument of the `evaluateObjectDetection` function, the `ClassMetrics` table has five columns, corresponding to these object detection metrics.

- `NumObjects` — Number of objects in the ground truth data for a class.
- `AP` — Average precision (AP) for each class at each overlap threshold in `OverlapThreshold`, stored as a *numThresh*-by-1 array, where *numThresh* is the number of overlap thresholds.
- `APOverlapAvg` — AP averaged over all overlap thresholds. Specify the overlap thresholds for a class using the `threshold` argument.
- `Precision` — Precision values, stored as a *numThresh*-by-(*numPredictions*+1) matrix, where *numPredictions* is the number of predicted bounding boxes. Precision is the ratio of the number of true positives (*TP*) and the total number of predicted positives.
  Precision = *TP* / (*TP* + *FP*)

  FP is the number of false positives. Larger precision scores imply that most detected objects match ground truth objects.

- `Recall` — Recall values, stored as a *numThresh*-by-(*numPredictions*+1) matrix, where *numPredictions* is the number of predicted boxes. Recall is the ratio of the number of true positives (*TP*) and the number of groundtruths – the sum of true positives (*TP*) and false negatives (*FN*).
  Recall = *TP* / (*TP* + *FN*)

  FN is the number of false negatives. Larger recall scores indicate that more of ground truth objects are detected.

  Note For each overlap threshold (row in the `Recall` matrix), the recall values (columns of the `Recall` matrix) are sorted in the order of decreasing confidence score associated with each detection.

For information on optional additional metrics for this table, see the `AdditionalMetrics` argument of the `evaluateObjectDetection` function.

`ClassNames` — Class names
array of strings | cell array of character vectors

Class names of detected objects, stored as an array of strings or a cell array of character vectors.

Example: `{"sky"} {"grass"} {"building"} {"sidewalk"}`

`OverlapThreshold` — Overlap threshold
numeric scalar | numeric vector

Overlap threshold, stored as a numeric scalar or numeric vector of box overlap threshold values over which the mean average precision is computed. When the intersection over union (IoU) of the pixels in the ground truth bounding box and the predicted bounding box is equal to or greater than the overlap threshold, the detection is considered a match to the ground truth (true positive). The IoU is the number of pixels in the intersection of the bounding boxes divided by the number of pixels in the union of the bounding boxes.

`NumClasses` — Number of classes in data set
non-negative integer

This property is read-only.

Number of classes in the data set, specified as a non-negative integer.

`NumImages` — Number of images in data set
non-negative integer

This property is read-only.

Number of images in the data set, specified as a non-negative integer.

Object Functions

imageMetrics	Evaluate per-image object detection performance metrics
averagePrecision	Evaluate average precision metric of object detection results
confusionMatrix	Compute confusion matrix of object detection results
precisionRecall	Get precision recall metrics of object detection results
summarize	Summarize object detection performance metrics at data set and class level

metricsByArea Evaluate detection performance across object size ranges

Examples

Plot Precision-Recall Curve for Object Detection

Load a table containing images and ground truth bounding box labels. The first column contains the images, and the remaining columns contain the labeled bounding boxes.

```
data = load("vehicleTrainingData.mat");
trainingData = data.vehicleTrainingData;
```

Set the value of the `dataDir` variable as the location where the `vehicleTrainingData.mat` file is located. Load the test data into a local vehicle data folder.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata");
trainingData.imageFilename = fullfile(dataDir,trainingData.imageFilename);
```

Create an `imageDatastore` using the files from the table.

```
imds = imageDatastore(trainingData.imageFilename);
```

Display the first 5 rows of the training data table.

```
disp(trainingData(1:5,:))
```

```
                                imageFilename                                    vehicle
    ____________________________________________________________________    _______________

    "B:\runnable\matlab\toolbox\vision\visiondata\vehicles\image_00001.jpg"    {[126 78 20 16]}
    "B:\runnable\matlab\toolbox\vision\visiondata\vehicles\image_00002.jpg"    {[100 72 35 26]}
    "B:\runnable\matlab\toolbox\vision\visiondata\vehicles\image_00003.jpg"    {[ 62 69 26 19]}
    "B:\runnable\matlab\toolbox\vision\visiondata\vehicles\image_00004.jpg"    {[ 71 64 22 21]}
    "B:\runnable\matlab\toolbox\vision\visiondata\vehicles\image_00005.jpg"    {[147 71 25 18]}
```

Create a `boxLabelDatastore` using the label columns from the table.

```
blds = boxLabelDatastore(trainingData(:,2:end));
```

Load Pretrained Object Detector

Load a pretrained YOLO v2 object detector trained to detect vehicles into the workspace.

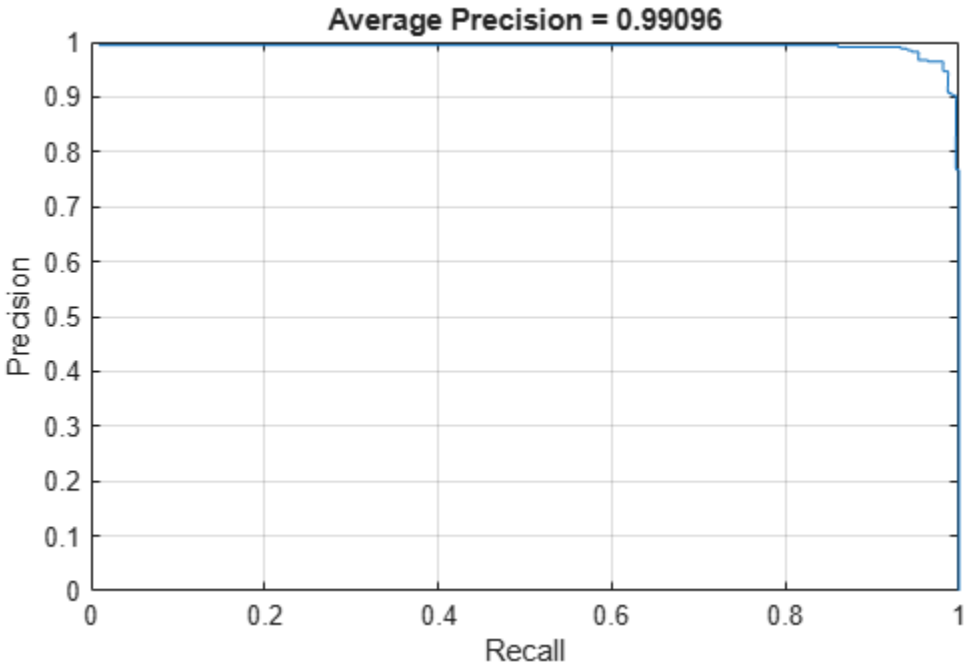
```
vehicleDetector = load("yolov2VehicleDetector.mat");
detector = vehicleDetector.detector;
```

Evaluate and Plot Object Detection Metrics

Run the detector on the test images. Set the detection threshold to a low value to detect as many objects as possible. This helps you evaluate the detector precision across the full range of recall values.

```
results = detect(detector,imds,Threshold=0.01);
```

Use `evaluateObjectDetection` to compute metrics for evaluating the performance of an object detector.



```
metrics = evaluateObjectDetection(results,blds);
```

Return the precision and recall metrics for the vehicle class using the `precisionRecall` object function.

```
[recall,precision,scores] = precisionRecall(metrics);
ap = averagePrecision(metrics);
```

Plot the precision-recall curve for the vehicle class, the only class in the data set. Compute the average precision (AP) using the `averagePrecision` object function.

```
figure
plot(recall{1},precision{1})
grid on
title("Average Precision = " + ap);
xlabel("Recall");
ylabel("Precision");
```

Compute the summary of the object detection metrics for the data set using the `summarize` object function.

```
[summaryDataset,summaryClass] = summarize(metrics);
disp(summaryDataset)
```

NumObjects	mAPOverlapAvg	mAP0.5
336	0.99096	0.99096

Version History

Introduced in R2023b

R2026a: Evaluate per-image object detection metrics

To evaluate the per-image object detection metrics for all images or a subset of images in the data set, use the `imageMetrics` object function.

To update your code to compute per-image metrics, replace instances of the `ImageMetrics` property with the `imageMetrics` object function. For an example, see the “Multiclass Object Detection Using YOLO v2 Deep Learning” example.

R2024b: `ConfusionMatrix`, `NormalizedConfusionMatrix`, and `DatasetMetrics` properties have been removed
Not recommended starting in R2024b

The `ConfusionMatrix`, `NormalizedConfusionMatrix`, and `DatasetMetrics` properties of the `objectDetectionMetrics` object have been removed.

To update your code to compute the confusion matrix, replace instances of the `ConfusionMatrix` and `NormalizedConfusionMatrix` properties with the `confusionMatrix` object function. For an example, see the "Evaluate Detector Errors Using Confusion Matrix" section of the “Multiclass Object Detection Using YOLO v2 Deep Learning” example.

To compute the summary of the object detection metrics over the entire data set or over each class, use the `summarize` object function.

To compute precision, recall, and confidence scores for all classes in the data set, or at specified classes and overlap thresholds, use the `precisionRecall` object function.

To compute average precision (AP) for all classes and overlap thresholds in the data set, or specify the classes and overlap thresholds for which to compute AP, use the `averagePrecision` object function.

R2024b: Table columns in `ClassMetrics` and `ImageMetrics` properties have been renamed
Behavior change in future release

These table columns of the `ClassMetrics` and `ImageMetrics` properties have been renamed.

`objectDetectionMetrics` property	Renamed Columns
`ClassMetrics`	• `mAP`, or the average precision (AP) averaged over all overlap thresholds for each class, has been renamed to `APOverlapAvg`. • `mLAMR`, or the log-average miss rate for each class averaged over all specified overlap thresholds, has been renamed to `LAMROverlapAvg`. • `mAOS`, or the average orientation similarity for each class averaged over all the specified overlap thresholds, has been renamed to `AOSOverlapAvg`.

objectDetectionMetrics property	Renamed Columns
ImageMetrics	• AP, or the AP across all classes at each overlap threshold, has been renamed to mAP. • mAP, or the AP averaged across all classes and all overlap thresholds, has been renamed to mAPOverlapAvg. • mLAMR, or the log-average miss rate for each class averaged over all specified overlap thresholds, has been renamed to LAMROverlapAvg. • mAOS, or the average orientation similarity for each class averaged over all the specified overlap thresholds, has been renamed to AOSOverlapAvg.

precisionRecall

Get precision recall metrics of instance segmentation results

Syntax

```
[precision,recall,scores] = precisionRecall(metrics)
[precision,recall,scores] = precisionRecall(metrics,Name=Value)
```

Description

`[precision,recall,scores] = precisionRecall(metrics)` gets the precision, recall, and prediction score values for all classes in the `ClassNames` property and all overlap thresholds in the `OverlapThreshold` property of the `instanceSegmentationMetrics` object `metrics`.

`[precision,recall,scores] = precisionRecall(metrics,Name=Value)` specifies precision and recall evaluation options using one or more name-value arguments. For example, `ClassNames=["cars" "people"]` specifies to get the precision recall metrics for the cars and people classes.

Input Arguments

`metrics` — instance segmentation performance metrics

`instanceSegmentationMetrics` object

instance segmentation performance metrics, specified as an `instanceSegmentationMetrics` object.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `[precision,recall,scores]=precisionRecall(metrics,ClassNames=[cars people])` specifies the precision recall metric to be evaluated for the cars and people classes.

`ClassNames` — Class names

string array | cell array of character vectors

Class names of detected objects, specified as an array of strings or a cell array of character vectors. By default, the `precisionRecall` function returns the precision recall metrics for all classes specified by the `ClassNames` property of the `instanceSegmentationMetrics` object.

`OverlapThresholds` — Overlap threshold

numeric scalar | numeric vector

Overlap threshold, or Intersection over Union (IoU) threshold, for which to get the precision recall metrics, specified as a numeric scalar or numeric vector of box overlap threshold values. By default, the `precisionRecall` object function returns the precision and recall metrics for all overlap

thresholds specified by the `OverlapThreshold` property of the `instanceSegmentationMetrics` object. To learn more about how to use overlap thresholds to evaluate instance segmentation results, see “Evaluate Network Performance Using Precision Recall at Multiple Overlap Thresholds” on page 2-1091.

Output Arguments

`precision` — Precision

M-by-*N* cell array

Precision, returned as an *M*-by-*N* cell array. *M* is the number of classes in the `ClassNames` property, and *N* is the number of overlap thresholds in the `OverlapThreshold` property of the `instanceSegmentationMetrics` object `metrics`. Each element of the cell array contains a (*numPredictions*+1)-element numeric vector of precision values, sorted in descending order of prediction confidence scores. *numPredictions* is the number of predicted object masks.

Precision is the ratio of the number of true positives (TP) and the total number of predicted positives. Larger precision scores indicate that more predicted object masks match ground truth objects. To learn more about the precision metric, see “Compute Precision and Recall” on page 2-1092.

`recall` — Recall

M-by-*N* cell array

Recall, returned as an *M*-by-*N* cell array. *M* is the number of classes in the `ClassNames` property, and *N* is the number of overlap thresholds in the `OverlapThreshold` property of the `instanceSegmentationMetrics` object `metrics`. Each element of the cell array contains a (*numPredictions*+1)-element numeric vector of recall values, sorted in order of prediction confidence scores. *numPredictions* is the number of predicted object masks.

Recall is the ratio of true positives (TP) to the sum of true positives and false negatives (FN), where false negatives represent instances in the image that the model incorrectly classified as background or missed entirely. Larger recall scores indicate that the instance segmentation model is effectively identifying most of the actual instances within the images. To learn more about the recall metric, see “Compute Precision and Recall” on page 2-1092.

`scores` — Confidence score

M-by-1 cell array

Confidence score for each instance segmentation, returned as an *M*-by-1 cell array. *M* is the number of classes in the `ClassNames` property. Each element of the array is a (*numPredictions*+1)-element numeric vector. *numPredictions* is the number of predicted object masks.

More About

Evaluate Network Performance Using Precision Recall at Multiple Overlap Thresholds

To evaluate how precisely a network can localize object instances, plot the precision recall curve for a range of overlap thresholds.

At higher overlap thresholds, the criteria for how well the object masks and ground truth masks must overlap to be a true positive (TP) are stricter. Therefore, average precision is lower at higher overlap thresholds, which corresponds to a decrease in the area under the precision-recall curve, which plots

the recall against precision. Plotting the precision-recall curves across different overlap thresholds can help you evaluate the instance segmentation network in these ways.

- Evaluate how well the network identifies object classes at higher overlap thresholds.
- Identify specific overlap thresholds where network performance is significantly lower, highlighting areas for model improvement.
- Choose an overlap threshold that balances the tradeoff between identifying as many object instances as possible (high recall) and ensuring high accuracy in those detections (high precision).
- Use precision-recall curves at different overlap thresholds for a more granular comparison between instance segmentation models than single metric evaluations. Nuances in performance can be obscured when considering only one overlap threshold or when relying solely on aggregated metrics such as mean average precision.

Algorithms

Compute Precision and Recall

Precision recall is a powerful tool you can use to evaluate instance segmentation network performance. The `precisionRecall` function computes the precision and recall in these steps.

1. Sorts object instances in descending order based on their confidence scores. Higher confidence scores indicate that the model is more certain that the instance segmentation is correct.
2. Identifies true positives (TP) and false positives (FP) according to the specified overlap threshold criteria. A segmentation is considered a TP if its IoU is greater to or equal to the specified overlap threshold. A segmentation is considered an FP if it does not match any ground truth object or if it matches a ground truth object but the IoU is below the specified overlap threshold.
3. Starting with the instance segmentation with the highest confidence score, the `precisionRecall` function iterates through each instance and calculates the cumulative number of TPs and FPs at each step. This step-by-step process enables the calculation of precision and recall at every confidence level. At each score, the function calculates the precision and recall.

   Precision measures the accuracy of positive predictions, consisting of the proportion of correctly detected instances from all object instances.
   $$\text{Precision} = TP / (TP + FP)$$

   Recall measures the ability of the network to detect all object instances, consisting of the proportion of actual instances that the network correctly identifies. False negatives (FNs) are ground truth objects the network misses or detects with a confidence score below the specified threshold.
   $$\text{Recall} = TP / (TP + FN)$$
4. For each instance segmentation, the set of TPs, FPs, and FNs changes, which enables you to recalculate precision and recall at each confidence level.

To visualize the tradeoff between precision and recall for different confidence thresholds, plot the calculated precision and recall values. For an example, see “Perform Instance Segmentation Using SOLOv2”.

Summarize instance segmentation performance metrics at data set and class level

Syntax

```
[summaryDataset,summaryClass] = summarize(metrics)
[summaryDataset,summaryClass] = summarize(metrics,MetricName=metricName)
```

Description

`[summaryDataset,summaryClass] = summarize(metrics)` summarizes the object detection evaluation metrics across all classes of the data set `summaryDataset`, and for each class in the data set `summaryClass`.

`[summaryDataset,summaryClass] = summarize(metrics,MetricName=metricName)` specifies the metrics category to return in the metrics summary.

Input Arguments

`metrics` — Instance segmentation performance metrics
`instanceSegmentationMetrics` object

instance segmentation performance metrics, specified as an `instanceSegmentationMetrics` object.

`metricName` — Metrics category to return
`"all"` (default) | `"AP"` | `"LAMR""AOS"`

Metrics category to return in the metrics summary, specified as one of these options.

- `"all"` – Returns the average precision and mean average precision metric values, aggregated over each overlap threshold, along with all additional metrics.
- `"AP"` – Returns only the average precision across all classes at each overlap threshold as a *numThresh*-by-1 numeric vector, and the mean average precision (mAP) computed across all overlap thresholds. *numThresh* is the number of overlap thresholds specified by the `OverlapThreshold` property of the `instanceSegmentationMetrics` object.
- `"LAMR"` – Returns only the log-average miss rate (LAMR) computed at each overlap threshold as a *numThresh*-by-1 numeric vector, and the mean of the log-average miss rate (mLAMR) computed across all overlap thresholds.
- `"AOS"` – Returns only the average orientation similarity (AOS) computed at each overlap threshold as a *numThresh*-by-1 array, and the mean of the average orientation similarity (mAOS) computed across all overlap thresholds.

  To specify `"AOS"` as the metric to return, your input data must contain rotated bounding boxes.
- `"AOS"` – Return only the average orientation similarity (AOS) computed at each overlap threshold as a *numThresh*-by-1 array, and the mean of the average orientation (mAOS) similarity computed across all overlap thresholds as a numeric scalar.

  To specify `"AOS"` as the metric to return, your input data must contain rotated bounding boxes.

Output Arguments

`summaryDataset` — Metrics summary over data set

table

Metric summary over the data set, returned as a 1-by-*numMetrics* table, where *numMetrics* is the number of specified metrics.

The columns of the table depend on the value of the `metricName` argument.

- `"all"` —

`NumObjects`	`mAPOverlapAvg`	`mAP`	`mLAMROverlapAvg`	`mLAMR`	`mAOSOverlapAvg`	`mAOS`
Number of object instances in the ground truth data, returned as a positive integer.	Mean average precision (mAP) averaged over all thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a numeric scalar.	Mean average precision (mAP), or average precision averaged over all classes, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector. *numThresh* is the number of overlap thresholds.	Mean log-average miss rate (mLAMR) averaged over all classes and all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a numeric scalar.	Mean log-average miss rate (mLAMR) averaged over all classes, computed at all overlap thresholds, specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector.	Mean average orientation similarity (mAOS) averaged over all classes, and averaged over all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a numeric scalar.	Mean average orientation similarity (mAOS) averaged over all classes, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector.

  To return the `"mAOSOverlapAvg"` and `"mAOS"` columns, your input data must contain rotated bounding boxes.

- `"AP"` —

NumObjects	mAPOverlapAvg	mAP
Number of object instances in the ground truth data, returned as a positive integer.	Mean average precision (mAP) averaged over all thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a numeric scalar.	Mean average precision (mAP), or average precision averaged over all classes, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector. *numThresh* is the number of overlap thresholds.

- `"LAMR"` —

mLAMROverlapAvg	mLAMR
Mean log-average miss rate (mLAMR) averaged over all classes and all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a positive scalar.	Mean log-average miss rate (mLAMR) averaged over all classes, computed at all overlap thresholds, specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector.

- `"AOS"` —

mAOSOverlapAvg	mAOS
Mean average orientation similarity (mAOS) averaged over all classes and all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a numeric scalar.	Mean average orientation similarity (mAOS) averaged over all classes, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector.

`summaryClass` — Metrics summary per class
table

Metrics summary per class, returned as a *numClasses*-by-*numMetrics* table, where *numClasses* is the number of classes, and *numMetrics* is the number of specified metrics.

The columns of the table depend on the value of the `metricName` argument.

- `"all"` —

NumObjects	APOverlapAvg	AP	LAMROverlapAvg	LAMR	AOSOverlapAvg	AOS
Number of object instances in the ground truth data for each class, returned as a positive integer.	Average precision (AP) for each class averaged over all thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a numeric scalar.	Average precision (AP) for each class, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector. *numThresh* is the number of overlap thresholds.	Log-average miss rate (LAMR) for each class, averaged over all overlap thresholds specified by the `OverlapThreshold` property of `metrics`.	Log-average miss rate (LAMR) for each class, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector.	Average orientation similarity (AOS) for each class, averaged over all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a numeric scalar.	Average orientation similarity (AOS) for each class, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector.

To return the `"AOSOverlapAvg"` and `"AOS"` columns, your input data must contain rotated bounding boxes.

- `"AP"` —

NumObjects	APOverlapAvg	AP
Number of object instances in the ground truth data for each class, returned as a positive integer.	Average precision (AP) for each class averaged over all thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a numeric scalar.	Average precision (AP) for each class, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector. *numThresh* is the number of overlap thresholds.

- `"LAMR"` —

LAMROverlapAvg	LAMR
Log-average miss rate (LAMR) for each class, averaged over all overlap thresholds specified by the `OverlapThreshold` property of `metrics`.	Log-average miss rate (LAMR) for each class, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector.

- `"AOS"` —

AOSOverlapAvg	AOS
Average orientation similarity (AOS) for each class, averaged over all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a numeric scalar.	Average orientation similarity (AOS) for each class, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector.

averagePrecision

Evaluate average precision metric of object detection results

Syntax

```
ap = averagePrecision(metrics)
ap = averagePrecision(metrics,Name=Value)
```

Description

`ap = averagePrecision(metrics)` evaluates the average precision (AP) for all classes and overlap thresholds of `metrics`.

AP aggregates the precision across different recall levels, providing a single metric to assess the overall ability of an object detector to identify objects accurately while minimizing false detections.

`ap = averagePrecision(metrics,Name=Value)` specifies options for the average precision evaluation using one or more name-value arguments. For example, `ClassNames=["cars" "people"]` specifies to evaluate the average precision metric for the cars and people classes.

Examples

Evaluate Average Precision

Load a table containing image filenames and ground truth bounding box labels into the workspace. The first column contains the images, and the remaining columns contain the labeled bounding boxes.

```
data = load("vehicleTrainingData.mat");
trainingData = data.vehicleTrainingData;
```

Set the value of the `dataDir` variable as the location where the `vehicleTrainingData.mat` file is located. Load the test data into a local vehicle data folder.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata");
trainingData.imageFilename = fullfile(dataDir,trainingData.imageFilename);
```

Create an `imageDatastore` using the files from the table.

```
imds = imageDatastore(trainingData.imageFilename);
```

Create a `boxLabelDatastore` using the label column from the table.

```
blds = boxLabelDatastore(trainingData(:,2:end));
```

Load a pretrained YOLO v2 object detector, trained to detect vehicles, into the workspace.

```
vehicleDetector = load("yolov2VehicleDetector.mat");
detector = vehicleDetector.detector;
```

Compute Average Precision Metric

Run the detector on the test images. Set the detection threshold to a low value to detect as many objects as possible. This enables you to evaluate the detector precision across the full range of recall values.

```
results = detect(detector,imds,Threshold=0.01);
```

Compute the metrics for evaluating the performance of the object detector.

```
metrics = evaluateObjectDetection(results,blds);
```

Evaluate the average precision for all classes. The high AP across all classes indicates that the object detection model demonstrates near-perfect precision in identifying objects correctly, while also achieving comprehensive recall, missing very few actual objects across all evaluated classes.

```
ap = averagePrecision(metrics)
```

```
ap =
0.9910
```

Input Arguments

`metrics` — Object detection performance metrics

`objectDetectionMetrics` object

Object detection performance metrics, specified as an `objectDetectionMetrics` object.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `averagePrecision(metrics,ClassNames=[cars people])` specifies to evaluate the average precision metric for the cars and people classes.

`ClassNames` — Class names

string array | cell array of character vectors

Class names of detected objects, specified as an array of strings or a cell array of character vectors. By default, the `averagePrecision` function returns the average precision metrics for all classes specified by the `ClassNames` property of the `objectDetectionMetrics` object `metrics`.

`OverlapThreshold` — Overlap threshold

numeric scalar | numeric vector

Overlap threshold to use for evaluating the average precision, specified as a numeric scalar or numeric vector of box overlap threshold values. To evaluate multiple overlap thresholds, specify this argument as a numeric vector. By default, the `averagePrecision` object function returns the average precision metrics for all overlap thresholds specified by the `OverlapThreshold` property of the `objectDetectionMetrics` object `metrics`.

Output Arguments

ap — Average precision

M-by-*N* matrix

Average precision (AP) for specified classes and overlap thresholds, specified as an *M*-by-*N* matrix. *M* is the number of classes in the `ClassNames` property and *N* is the number of specified overlap thresholds `OverlapThreshold`.

The AP metric evaluates object detection performance by quantifying the accuracy of the model in identifying objects across different confidence thresholds, enabling you to assess both the precision (correctness of detections) and recall (completeness of detections).

confusionMatrix

Compute confusion matrix of object detection results

Syntax

```
[confMat,confusionClassNames] = confusionMatrix(metrics)
[confMat,confusionClassNames] = confusionMatrix(metrics,Name=Value)
```

Description

`[confMat,confusionClassNames] = confusionMatrix(metrics)` computes the confusion matrix for all overlap thresholds in the `OverlapThreshold` property of `metrics`, and returns the confusion matrix and the class names. The function considers all detections to compute the confusion matrix.

`[confMat,confusionClassNames] = confusionMatrix(metrics,Name=Value)` specifies one or more name-value arguments. For example, `ScoreThreshold=0.3` specifies to disregard detections with a confidence score value below `0.3` when computing the confusion matrix.

Input Arguments

`metrics` — Object detection performance metrics

`objectDetectionMetrics` object

Object detection performance metrics, specified as an `objectDetectionMetrics` object.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `confusionMatrix(metrics,ScoreThreshold=0.3)` specifies detections with a confidence score value below `0.3` to be disregarded when computing the confusion matrix.

`ScoreThreshold` — Confidence score threshold values

`0` (default) | numeric scalar in range `[0, 1]` | numeric vector

Confidence score threshold values to use for computing the confusion matrix, specified as a numeric scalar in the range `[0, 1]` or a numeric vector of values in the range `[0, 1]`. The function filters out predictions with confidence scores less than the threshold value when evaluating the confusion matrix.

Increase this value to reduce the number of false positives, at the possible expense of missing some true positives.

`OverlapThreshold` — Overlap threshold values

numeric scalar | numeric vector

Overlap threshold values to use for computing the confusion matrix, specified as a numeric scalar or numeric vector. Each overlap threshold value must be an element of the `OverlapThreshold` property of the `objectDetectionMetrics` object `metrics`. By default, the function returns the confusion matrix computed at all the overlap thresholds specified by the `OverlapThreshold` property.

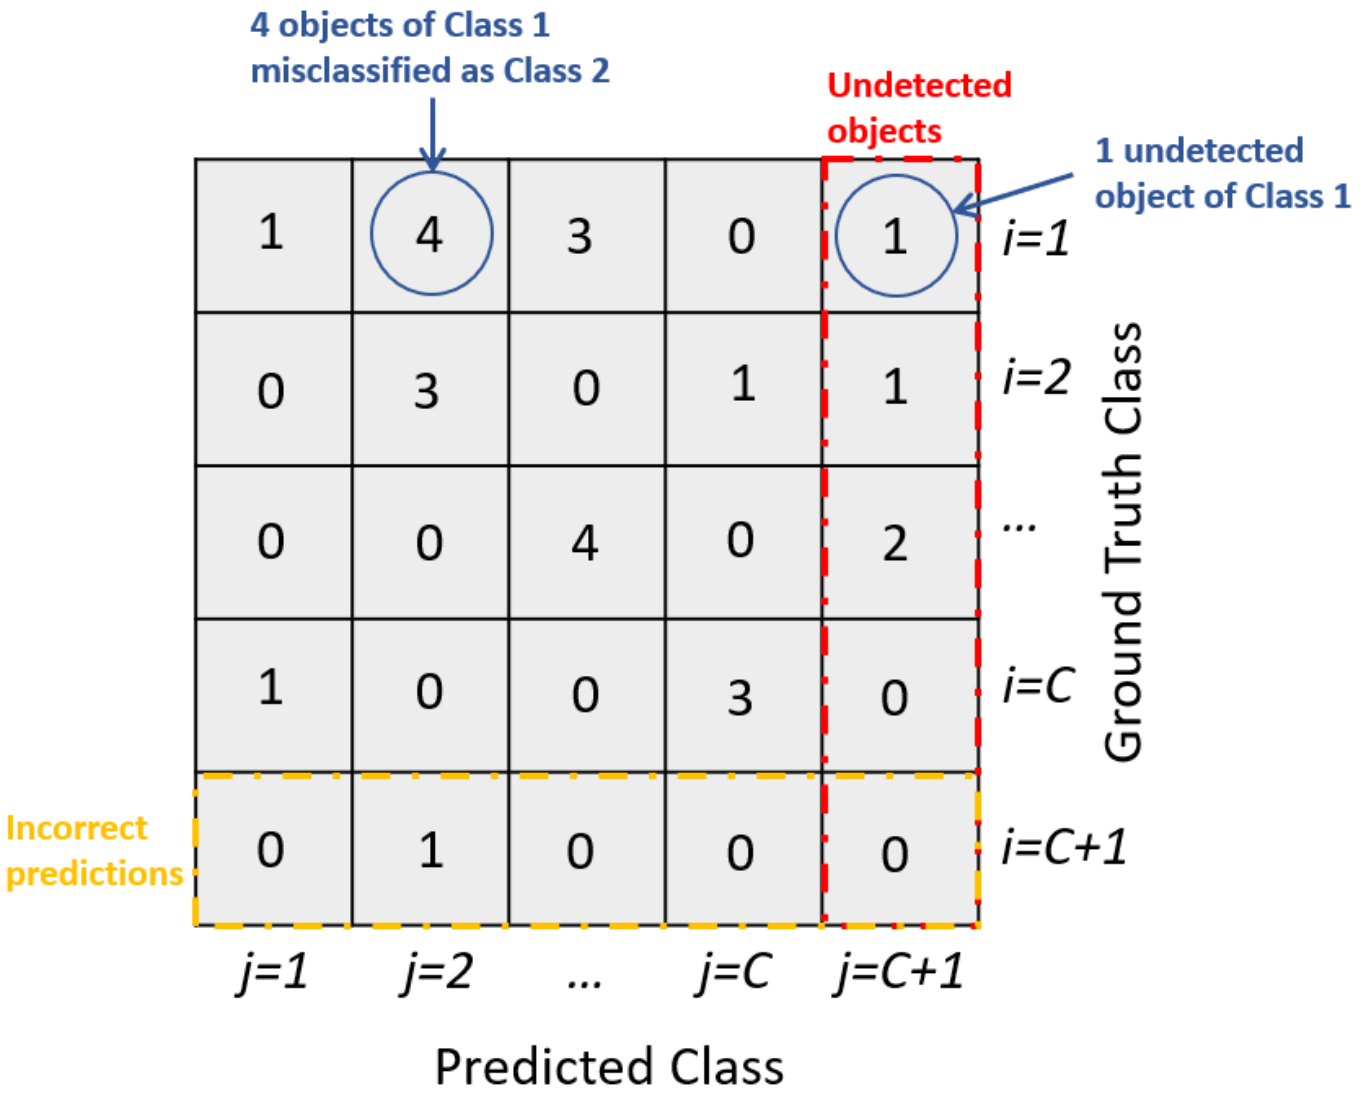
`Normalize` — Confusion matrix normalization
`false` or `0` (default) | `true` or `1`

Confusion matrix normalization option, specified as a numeric or logical `0` (or `false`) or `1` (or `true`). If you specify `Normalize` as `true`, the function normalizes the elements of the confusion matrix in the `confMat` argument by the number of bounding boxes known to belong to each class. For each overlap threshold, each element (*i*, *j*) in the normalized confusion matrix is the count of ground truth bounding boxes that belong to class *i*, but are predicted to belong to class *j*, divided by the total number of bounding boxes predicted in class *j*.

For other normalization options, see “Tips” on page 2-1104.

Output Arguments

`confMat` — Confusion matrix
M-by-*N* cell array



Confusion matrix, returned as an *M*-by-*N* cell array. *M* is the number of confidence score thresholds specified by the `ScoreThreshold` argument, and *N* is the number of overlap thresholds specified by the `OverlapThreshold` argument.

Each element of the `confMat` cell array is a square numeric matrix of size (*C*+1)-by-(*C*+1), where *C* is the number of classes. Each element (*i*, *j*) of the matrix is the count of *matched* bounding boxes predicted to belong to class *j*, but that have a ground truth annotation class of *i*.

Row and column *C*+1 in the confusion matrix correspond to these *unmatched* conditions:

- Column *C*+1 — Undetected objects, or *false negative* predictions. Each element in this column is the number of ground truth annotations of the corresponding class unmatched with any predicted bounding box.
- Row *C*+1 — Incorrect predictions, or *false positive* predictions. Each element in this row is the number of predicted bounding boxes of the corresponding class unmatched with any ground truth annotation.

This image shows the structure of a sample confusion matrix, displayed as a confusion chart. Each element of the matrix contains the number of predictions that fall into a matched or unmatched category. The sum of values in each class row is the total number of ground truth bounding boxes that belong to the corresponding class. The sum of values in each class column is the total number of predicted bounding boxes that belong to the corresponding class.

Confusion Matrix

`confusionClassNames` — Class names
string array

Class names corresponding to the returned confusion matrices, returned as a string array of size $C+1$. The elements of the string array correspond to the classes stored in the `ClassNames` property of the `objectDetectionMetrics` object `metrics` and an extra background class. The background class, `"background"`, corresponds to the row and column $C+1$ of the confusion matrix, which count the false positives and false negatives.

Tips

Normalize the confusion matrix output of the `confusionMatrix` function in these ways:

- Specify the `Normalize` name-value argument as `true` to divide each entry of the confusion matrix, `confMat`, by the sum of the corresponding column, so each value represents the proportion of predicted bounding boxes for a given class.
- For additional normalization options, use the `confusionchart` function. Pass the confusion matrix, `confMat`, to the `confusionchart` function, and specify the `Normalization` name-value argument. You can use this option to normalize the confusion matrix by row or by the total number of detected bounding boxes, in addition to column normalization.

precisionRecall

Get precision recall metrics of object detection results

Syntax

```
[precision,recall,scores] = precisionRecall(metrics)
[precision,recall,scores] = precisionRecall(metrics,Name=Value)
```

Description

`[precision,recall,scores] = precisionRecall(metrics)` gets the precision, recall, and prediction score values for all classes in the `ClassNames` property and all overlap thresholds in the `OverlapThreshold` property of the `objectDetectionMetrics` object `metrics`.

`[precision,recall,scores] = precisionRecall(metrics,Name=Value)` specifies precision and recall evaluation options using one or more name-value arguments. For example, `ClassNames=["cars" "people"]` specifies to get the precision recall metrics for the cars and people classes.

Examples

Plot Precision-Recall Curve

Load a table containing image file names and ground truth bounding box labels into the workspace. The first column contains the image file names, and the remaining columns contain the labeled bounding boxes.

```
data = load("vehicleTrainingData.mat");
trainingData = data.vehicleTrainingData;
```

Set the value of the `dataDir` variable as the location where the `vehicleTrainingData.mat` file is located. Load the test data into a local vehicle data folder.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata");
trainingData.imageFilename = fullfile(dataDir,trainingData.imageFilename);
```

Create an `imageDatastore` using the files from the table.

```
imds = imageDatastore(trainingData.imageFilename);
```

Create a `boxLabelDatastore` using the label column from the table.

```
blds = boxLabelDatastore(trainingData(:,2:end));
```

Load a pretrained YOLO v2 object detector, trained to detect vehicles, into the workspace.

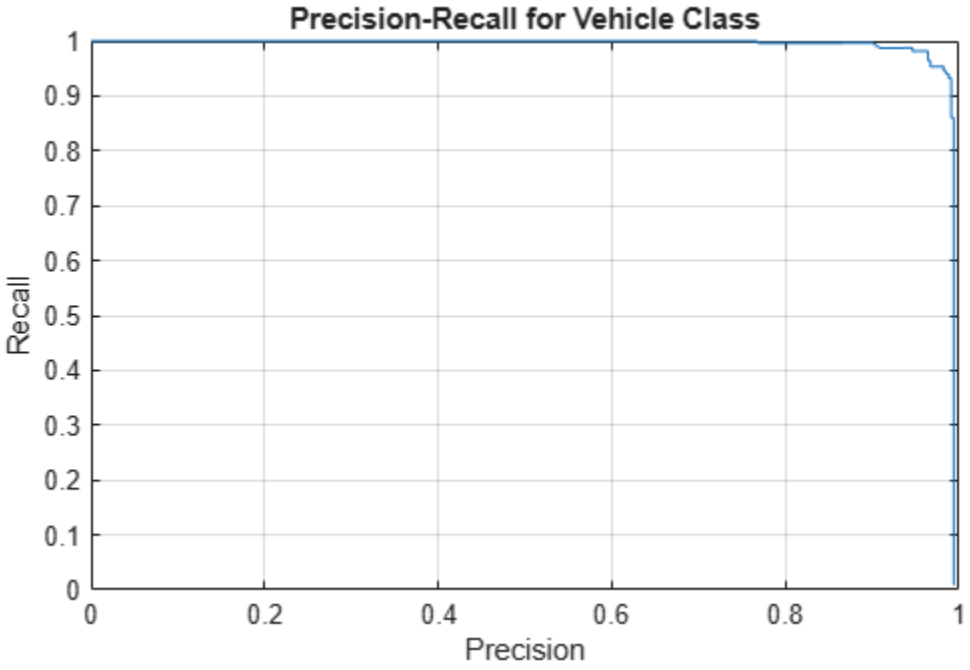
```
vehicleDetector = load("yolov2VehicleDetector.mat");
detector = vehicleDetector.detector;
```

Plot Precision-Recall Curve

Run the detector on the test images. Set the detection threshold to a low value to detect as many objects as possible. This enables you to evaluate the detector precision across the full range of recall values.

```
results = detect(detector,imds,Threshold=0.01);
```

Compute metrics for evaluating the performance of the object detector.



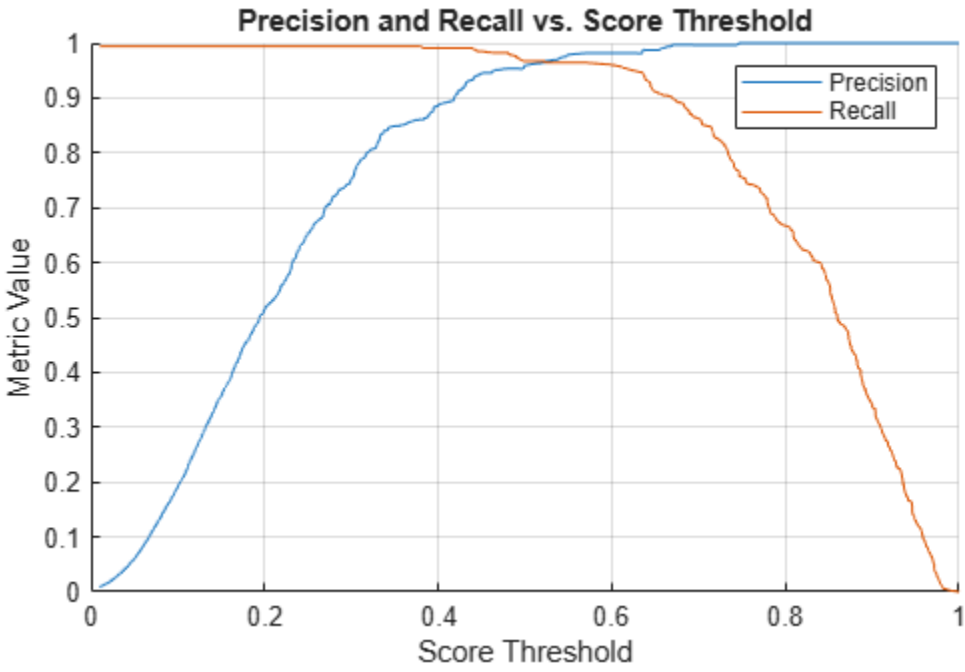
```
metrics = evaluateObjectDetection(results,blds);
```

Get the precision, recall, and confidence scores for the vehicle class using the `precisionRecall` object function.

```
[precision,recall,scores] = precisionRecall(metrics);
```

Plot the precision-recall curve.

```
figure
plot(recall{1},precision{1})
grid on
title("Precision-Recall for Vehicle Class")
xlabel("Precision")
ylabel("Recall")
```



Display the confidence score thresholds and the corresponding values of precision and recall for each point on the precision-recall curve.

```
figure
hold on

plot(scores{1}, precision{1}, DisplayName="Precision");
```

```
plot(scores{1}, recall{1}, DisplayName="Recall");

xlabel("Score Threshold");
ylabel("Metric Value");
title("Precision and Recall vs. Score Threshold");
legend("show")
grid on
hold off
```

Input Arguments

`metrics` — Object detection performance metrics

`objectDetectionMetrics` object

Object detection performance metrics, specified as an `objectDetectionMetrics` object.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `[precision,recall,scores]=precisionRecall(metrics,ClassNames=[cars people])` specifies the precision recall metric to be evaluated for the cars and people classes.

`ClassNames` — Class names

string array | cell array of character vectors

Class names of detected objects, specified as an array of strings or a cell array of character vectors. By default, the `precisionRecall` function returns the precision recall metrics for all classes specified by the `ClassNames` property of the `objectDetectionMetrics` object `metrics`.

`OverlapThresholds` — Overlap threshold

numeric scalar | numeric vector

Overlap threshold, or Intersection over Union (IoU) threshold, for which to get the precision recall metrics, specified as a numeric scalar or numeric vector of box overlap threshold values. By default, the `precisionRecall` object function returns the precision recall metrics for all overlap thresholds specified by the `OverlapThreshold` property of the `objectDetectionMetrics` object `metrics`. To learn more about how to use overlap thresholds in object detection evaluation, see “Evaluate Detector Performance Using Precision Recall at Multiple Overlap Thresholds” on page 2-1109.

Output Arguments

`precision` — Precision

M-by-*N* cell array

Precision, returned as an *M*-by-*N* cell array. *M* is the number of classes in the `ClassNames` property, and *N* is the number of overlap thresholds in the `OverlapThreshold` property of the `objectDetectionMetrics` object `metrics`. Each element of the cell array contains a (*numPredictions*+1)-element numeric vector of precision values for the bounding boxes, sorted in descending order of bounding box confidence scores. *numPredictions* is the number of predicted bounding boxes.

Precision is the ratio of the number of true positives (TP) and the total number of predicted positives. Larger precision scores indicate that more detected objects match ground truth objects. To learn more about the precision metric, see “Compute Precision and Recall” on page 2-1110.

`recall` — Recall

M-by-*N* cell array

Recall, returned as an *M*-by-*N* cell array. *M* is the number of classes in the `ClassNames` property, and *N* is the number of overlap thresholds in the `OverlapThreshold` property of the `objectDetectionMetrics` object `metrics`. Each element of the cell array contains a (*numPredictions*+1)-element numeric vector of recall values, sorted in descending order of bounding box confidence scores. *numPredictions* is the number of predicted bounding boxes.

Recall is the ratio of the number of true positives (*TP*) and the total number of ground truth. Larger recall scores indicate that more detected objects match ground truth objects. To learn more about the recall metric, see “Compute Precision and Recall” on page 2-1110.

`scores` — Confidence score

M-by-1 cell array

Confidence score for each detection, returned as an *M*-by-1 cell array. *M* is the number of classes in the `ClassNames` property. Each element of the array is a (*numPredictions*+1)-element numeric vector. *numPredictions* is the number of predicted objects.

More About

Evaluate Detector Performance Using Precision Recall at Multiple Overlap Thresholds

To evaluate how precisely a detector can localize bounding boxes, plot the precision recall curve for a range of overlap thresholds.

At higher overlap thresholds, the criteria for how well the bounding boxes of the detection and ground truth must overlap to be a true positive (TP) are stricter. Therefore, average precision is lower at higher overlap thresholds, which corresponds to a decrease in the area under the precision-recall curve, which plots the recall against precision. Plotting the precision-recall curves across different overlap thresholds can help you evaluate the detector in these ways.

- Evaluate how well the detector can generate detection at higher overlap thresholds.
- Identify specific overlap thresholds where a detector's performance significantly drops, highlighting areas for model improvement.
- Choose an optimal overlap threshold that balances the tradeoff between detecting as many objects as possible (high recall) and ensuring high accuracy in these detections (high precision).
- Use precision-recall curves at different overlap thresholds for a more granular comparison between object detection models than single metric evaluations. Nuances in performance can be obscured when considering only one overlap threshold or when relying solely on aggregated metrics such as mean average precision.

Algorithms

Compute Precision and Recall

Precision recall is a powerful tool you can use to evaluate object detector performance. The `precisionRecall` function computes the precision and recall in these steps.

1. Sorts the detections which satisfy the criteria specified by the `ClassNames` and `OverlapThresholds` name-value arguments in descending order based on their confidence scores. Higher confidence scores indicate that the model is more certain that the detection is correct.
2. Identifies true positives (TP) and false positives (FP) according to the specified overlap threshold criteria. A detection is considered a TP if its IoU is greater to or equal to the specified overlap threshold. A detection is considered an FP if it does not match any ground truth object or if it matches a ground truth object but the IoU is below the specified overlap threshold.
3. Starting with the detection with the highest confidence score, the `precisionRecall` function iterates through each detection and calculates the cumulative number of TPs and FPs at each step. This step-by-step process enables the calculation of precision and recall at every confidence level. At each score, the function calculates the precision and recall.

   Precision measures the accuracy of positive predictions, i.e., the proportion of detections that are correctly identified from all detections made.
   $\text{Precision} = TP / (TP + FP)$

   Recall measures the ability of the detector to detect all object instances, i.e. the proportion of actual positives that are correctly identified. False negatives (FNs) are ground truth objects that haven't been detected or have been detected with a confidence score below the current threshold being considered.
   $\text{Recall} = TP / (TP + FN)$
4. For each detection, the set of TPs, FPs, and FNs changes, which enables you to recalculate precision and recall at each confidence level.

To visualize the tradeoff between precision and recall for different confidence thresholds, plot the calculated precision and recall values. For an example, see “Plot Precision-Recall Curve” on page 2-1106.

summarize

Summarize object detection performance metrics at data set and class level

Syntax

```
[summaryDataset,summaryClass] = summarize(metrics)
[summaryDataset,summaryClass] = summarize(metrics,MetricName=metricName)
```

Description

`[summaryDataset,summaryClass] = summarize(metrics)` summarizes the object detection evaluation metrics across all classes of the data set `summaryDataset`, and for each class in the data set `summaryClass`.

`[summaryDataset,summaryClass] = summarize(metrics,MetricName=metricName)` specifies the metrics category to return in the metrics summary.

Examples

Summarize Object Detection Metrics

Load a table containing image file names and ground truth bounding box labels into the workspace. The first column contains the image file names, and the remaining columns contain the labeled bounding boxes.

```
data = load("vehicleTrainingData.mat");
trainingData = data.vehicleTrainingData;
```

Set the value of the `dataDir` variable as the location where the `vehicleTrainingData.mat` file is located. Load the test data into a local vehicle data folder.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata");
trainingData.imageFilename = fullfile(dataDir,trainingData.imageFilename);
```

Create an `imageDatastore` using the files from the table.

```
imds = imageDatastore(trainingData.imageFilename);
```

Create a `boxLabelDatastore` using the label column from the table.

```
blds = boxLabelDatastore(trainingData(:,2:end));
```

Load a pretrained YOLO v2 object detector, trained to detect vehicles, into the workspace.

```
vehicleDetector = load("yolov2VehicleDetector.mat");
detector = vehicleDetector.detector;
```

Run the detector on the test images. Set the detection threshold to a low value to detect as many objects as possible. This enables you to evaluate the detector precision across the full range of recall values.

```
results = detect(detector,imds,Threshold=0.01);
```

Compute metrics for evaluating the performance of the object detector.

```
metrics = evaluateObjectDetection(results,blds);
```

Summarize the object detection metrics for the vehicle class using the `summarize` object function.

```
[summaryDataset,summaryClass] = summarize(metrics);
summaryClass
```

```
summaryClass=1×3 table
               NumObjects    APOverlapAvg     AP0.5
               __________    ____________    _______

    vehicle       336          0.99096       0.99096
```

Input Arguments

`metrics` — Object detection performance metrics

`objectDetectionMetrics` object

Object detection performance metrics, specified as an `objectDetectionMetrics` object.

`metricName` — Metrics category to return

`"all"` (default) | `"AP"` | `"LAMR"` | `"AOS"`

Metrics category to return in the metrics summary, specified as one of these options.

- `"all"` – Returns the average precision and mean average precision metric values, aggregated over each overlap threshold, along with all additional metrics.
- `"AP"` – Returns only the average precision across all classes at each overlap threshold as a *numThresh*-by-1 numeric vector, and the mean average precision (mAP) computed across all overlap thresholds. *numThresh* is the number of overlap thresholds specified by the `OverlapThreshold` property of the `objectDetectionMetrics` object.
- `"LAMR"` – Returns only the log-average miss rate (LAMR) computed at each overlap threshold as a *numThresh*-by-1 numeric vector, and the mean of the log-average miss rate (mLAMR) computed across all overlap thresholds.
- `"AOS"` – Returns only the average orientation similarity (AOS) computed at each overlap threshold as a *numThresh*-by-1 array, and the mean of the average orientation similarity (mAOS) computed across all overlap thresholds.

  To specify `"AOS"` as the metric to return, your input data must contain rotated bounding boxes.

Output Arguments

`summaryDataset` — Metrics summary over data set

table

Metric summary over the data set, returned as a 1-by-*numMetrics* table, where *numMetrics* is the number of specified metrics.

The columns of the table depend on the value of the `metricName` argument.

- `"all"` —

NumObjects	mAPOverlapAvg	mAP	mLAMROverlapAvg	mLAMR	mAOSOverlapAvg	mAOS
Number of objects in the ground truth data, returned as a positive integer.	Mean average precision (mAP) averaged over all thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a numeric scalar.	Mean average precision (mAP), or average precision averaged over all classes, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector. *numThresh* is the number of overlap thresholds.	Mean log-average miss rate (mLAMR) averaged over all classes and all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a numeric scalar.	Mean log-average miss rate (mLAMR) averaged over all classes, computed at all overlap thresholds, specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector.	Mean average orientation similarity (mAOS) averaged over all classes, and averaged over all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a numeric scalar.	Mean average orientation similarity (mAOS) averaged over all classes, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector.

  To return the `"mAOSOverlapAvg"` and `"mAOS"` columns, your input data must contain rotated bounding boxes.

- `"AP"` —

NumObjects	mAPOverlapAvg	mAP
Number of objects in the ground truth data, returned as a positive integer.	Mean average precision (mAP) averaged over all thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a numeric scalar.	Mean average precision (mAP), or average precision averaged over all classes, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector. *numThresh* is the number of overlap thresholds.

- `"LAMR"` —

mLAMROverlapAvg	mLAMR
Mean log-average miss rate (mLAMR) averaged over all classes and all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a positive scalar.	Mean log-average miss rate (mLAMR) averaged over all classes, computed at all overlap thresholds, specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector.

- `"AOS"` —

mAOSOverlapAvg	mAOS
Mean average orientation similarity (mAOS) averaged over all classes and all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a numeric scalar.	Mean average orientation similarity (mAOS) averaged over all classes, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector.

`summaryClass` — Metrics summary per class
table

Metrics summary per class, returned as a *numClasses*-by-*numMetrics* table, where *numClasses* is the number of classes, and *numMetrics* is the number of specified metrics.

The columns of the table depend on the value of the `metricName` argument.

- `"all"` —

NumObjects	APOverlapAvg	AP	LAMROverlapAvg	LAMR	AOSOverlapAvg	AOS
Number of objects in the ground truth data for each class, returned as a positive integer.	Average precision (AP) for each class averaged over all thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a numeric scalar.	Average precision (AP) for each class, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector. *numThresh* is the number of overlap thresholds.	Log-average miss rate (LAMR) for each class, averaged over all overlap thresholds specified by the `OverlapThreshold` property of `metrics`.	Log-average miss rate (LAMR) for each class, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector.	Average orientation similarity (AOS) for each class, averaged over all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a numeric scalar.	Average orientation similarity (AOS) for each class, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector.

To return the `"AOSOverlapAvg"` and `"AOS"` columns, your input data must contain rotated bounding boxes.

- `"AP"` —

NumObjects	APOverlapAvg	AP
Number of objects in the ground truth data for each class, returned as a positive integer.	Average precision (AP) for each class averaged over all thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a numeric scalar.	Average precision (AP) for each class, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector. *numThresh* is the number of overlap thresholds.

- `"LAMR"` —

LAMROverlapAvg	LAMR
Log-average miss rate (LAMR) for each class, averaged over all overlap thresholds specified by the `OverlapThreshold` property of `metrics`.	Log-average miss rate (LAMR) for each class, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector.

- `"AOS"` —

AOSOverlapAvg	AOS
Average orientation similarity (AOS) for each class, averaged over all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a numeric scalar.	Average orientation similarity (AOS) for each class, computed at all overlap thresholds specified by the `OverlapThreshold` property of `metrics`, returned as a *numThresh*-by-1 numeric vector.

Object Detector Analyzer

Functions

`objectDetectionMetrics` | `evaluateObjectDetection`

Topics

“Evaluate Object Detector Performance”
“Multiclass Object Detection Using YOLO v2 Deep Learning”

metricsByArea

Evaluate detection performance across object size ranges

Syntax

```
areaMetrics = metricsByArea(metrics,objectAreaRanges)
areaMetrics = metricsByArea(metrics,objectAreaRanges,ClassNames)
```

Description

`areaMetrics = metricsByArea(metrics,objectAreaRanges)` evaluates object detection metrics for the object size range or ranges, specified as bounding box areas, `objectAreaRanges`. The function evaluates the specified bounding box size range within the existing object detection `metrics`.

`areaMetrics = metricsByArea(metrics,objectAreaRanges,ClassNames)` also specifies the names of the classes for which to evaluate area-based metrics.

Examples

Evaluate Detection Metrics Across Object Size Ranges

Load a table containing images and ground truth bounding box labels. The first column contains the images, and the remaining columns contain the labeled bounding boxes.

```
data = load("vehicleTrainingData.mat");
trainingData = data.vehicleTrainingData;
```

Set the value of the `dataDir` variable as the location where the `vehicleTrainingData.mat` file is located. Load the test data into a local vehicle data folder.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata");
trainingData.imageFilename = fullfile(dataDir,trainingData.imageFilename);
```

Create an `imageDatastore` using the files from the table.

```
imds = imageDatastore(trainingData.imageFilename);
```

Create a `boxLabelDatastore` using the label columns from the table.

```
blds = boxLabelDatastore(trainingData(:,2:end));
```

Load a pretrained YOLO v2 object detector trained to detect vehicles into the workspace.

```
vehicleDetector = load("yolov2VehicleDetector.mat");
detector = vehicleDetector.detector;
```

Compute Object Detection Performance Metrics

Run the detector on the test images. Set the detection threshold to a low value to detect as many objects as possible. This helps you evaluate the detector precision across the full range of recall values.

```
results = detect(detector,imds,Threshold=0.01);
```

Compute metrics for evaluating the performance of an object detector using the `evaluateObjectDetection` function.

```
metrics = evaluateObjectDetection(results,blds);
```

Evaluate Metrics Across Object Size Ranges

Extract the anchor boxes from the detector, calculate their areas, and sort the areas.

```
areas = prod(detector.AnchorBoxes,2);
sortedAreas = sort(areas);
```

Define area range limits using the calculated areas. The upper limit for the last range is set to three times the size of the largest area, which is sufficient for the objects in this data set.

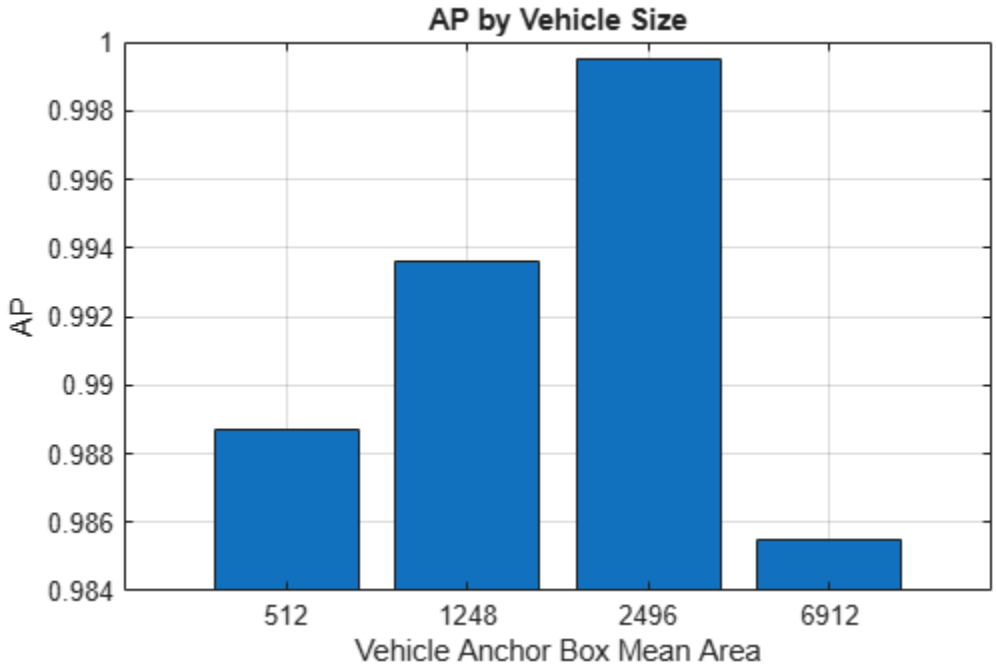
```
lowerLimit = sortedAreas;
upperLimit = [sortedAreas(2:end);3*sortedAreas(end)];
areaRanges = [lowerLimit upperLimit]
```

```
areaRanges = 4×2

          64         960
         960        1536
        1536        3456
        3456       10368
```

Evaluate detector performance across vehicle size ranges using the `metricsByArea` object function. Specify the object size ranges using the bounding box area ranges. The number of vehicles falling into each area range is computed in the `NumObjects` column.

```
areaMetrics = metricsByArea(metrics,areaRanges,ClassName="vehicle");
disp(areaMetrics(:,1:3))
```



```
      AreaRange      NumObjects    APOverlapAvg
    _____________    __________    ____________

      64      960       119           0.9887
     960     1536        12          0.99359
    1536     3456        45          0.99952
    3456    10368       141          0.98551
```

Plot the average precision (AP) metric, averaged across all overlap thresholds, as a function of the mean object size per vehicle size range.

```
figure
bar(categorical(mean(areaRanges,2)),areaMetrics.APOverlapAvg)
title("AP by Vehicle Size")
xlabel("Vehicle Anchor Box Mean Area")
ylabel("AP")
```

```
ylim([0.984 1])
grid on
```

Input Arguments

`metrics` — Object detection metrics

M-by-4 numeric matrix | vector

Object detection metrics, specified as an `objectDetectionMetrics` object.

`objectAreaRanges` — Bounding box area ranges

M-by-2 numeric matrix | vector

Bounding box area ranges (object size ranges), specified as one of the following:

- An *M*-by-2 numeric matrix, with each row specifying the upper (exclusive) and lower (inclusive) limits of an object area range in evaluation. For example, if the input is $[x_1\ x_2;\ x_3\ x_4]$. The evaluated bounding box area ranges are $x_1 \leq$ area $< x_2$ and $x_3 \leq$ area $< x_4$.
- A vector with *M*+1 elements, specifying the edge values of *M* contiguous area ranges. Each range is inclusive in the lower limit, and exclusive in the upper limit. For example, if the input is $[x_1\ x_2\ x_3]$, the area ranges evaluated are $x_1 \leq$ area $< x_2$ and $x_2 \leq$ area $< x_3$.

`ClassNames` — Names of classes

`''` (default) | string scalar | vector

Names of the classes for which to evaluate area-based metrics. If multiple classes are specified, the function computes averaged metrics across the classes. By default, all classes will be considered and the returned metrics will be the average of all classes.

Output Arguments

`areaMetrics` — Metrics by area

table

Metrics by area, returned as a table with *M* rows. Each row contains metrics using objects within an area range (for a total of *M* area ranges). The columns are specified by these table variables.

- `AreaRange`: The upper and lower limits of each area range, returned as a two-element row vector.
- `NumObjects`: The number of objects falling within each area range, returned as a positive integer.
- `mAP`: Mean average precision (mAP), or average precision averaged over all classes, computed at all overlap thresholds specified by the `OverlapThreshold` property, returned as a *numThresh*-by-1 numeric vector. *numThresh* is the number of overlap thresholds.
- `mAPOverlapAvg`: Mean average precision (mAP) averaged over all thresholds specified by the `OverlapThreshold` property, returned as a numeric scalar.

semanticSegmentationMetrics

Semantic segmentation quality metrics

Description

A `semanticSegmentationMetrics` object encapsulates semantic segmentation quality metrics for a set of images.

Creation

Create a `semanticSegmentationMetrics` object using the `evaluateSemanticSegmentation` function.

Properties

`ConfusionMatrix` — Confusion matrix
table

This property is read-only.

Confusion matrix, specified as a table with C rows and columns, where C is the number of classes in the semantic segmentation. Each table element (i,j) is the count of pixels known to belong to class i but predicted to belong to class j.

`NormalizedConfusionMatrix` — Normalized confusion matrix
table

This property is read-only.

Normalized confusion matrix, specified as a table with C rows and columns, where C is the number of classes in the semantic segmentation. The `NormalizedConfusionMatrx` represents a confusion matrix normalized by the number of pixels known to belong to each class. Each table element (i,j) is the count of pixels known to belong to class i but predicted to belong to class j, divided by the total number of pixels predicted in class i. Elements are in the range [0, 1].

`DataSetMetrics` — Data set metrics
table

This property is read-only.

Semantic segmentation metrics aggregated over the data set, specified as a table with one row. `DataSetMetrics` has up to five columns, corresponding to the metrics that were specified by the `'Metrics'` name-value pair used with `evaluateSemanticSegmentation`:

- `GlobalAccuracy` — Ratio of correctly classified pixels to total pixels, regardless of class.
- `MeanAccuracy` — Ratio of correctly classified pixels in each class to total pixels, averaged over all classes. The value is equal to the mean of `ClassMetrics.Accuracy`.

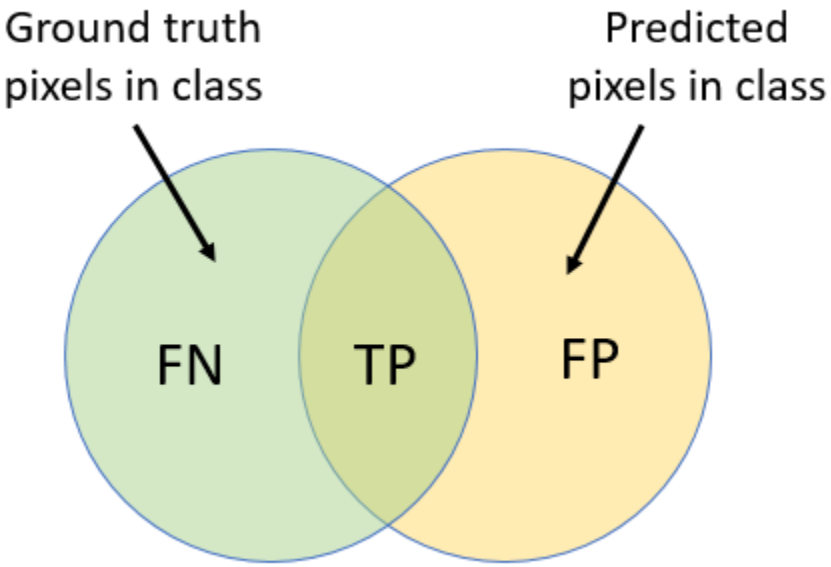
- `MeanIoU` — Average intersection over union (IoU) of all classes. The value is equal to the mean of `ClassMetrics.IoU`.
- `WeightedIoU` — Average IoU of all classes, weighted by the number of pixels in the class.
- `MeanBFScore` — Average boundary F1 (BF) score of all images. The value is equal to the mean of `ImageMetrics.BFScore`. This metric is not available when you create a `semanticSegmentationMetrics` object by using a confusion matrix as the input to `evaluateSemanticSegmentation`.

Note A value of `NaN` in the dataset, class, or image metrics, indicates that one or more classes were missing during the computation of the metrics when using the `evaluateSemanticSegmentation` function. In this case, the software was unable to accurately compute the metrics.

The missing classes can be found by looking at the `ClassMetrics` property, which provides the metrics for each class. To more accurately evaluate your network, augment your ground truth with more data that includes the missing classes.

`ClassMetrics` — Class metrics

table



This property is read-only.

Semantic segmentation metrics for each class, specified as a table with *C* rows, where *C* is the number of classes in the semantic segmentation. `ClassMetrics` has up to three columns, corresponding to the metrics that were specified by the `'Metrics'` name-value pair used with `evaluateSemanticSegmentation`:

- `Accuracy` — Ratio of correctly classified pixels in each class to the total number of pixels belonging to that class according to the ground truth. Accuracy can be expressed as:
  `Accuracy` = (TP + TN) / (TP + TN + FP + FN)

	Positive	**Negative**
Positive	TP: True Positive	FN: False Negative
Negative	FP: False Positive	TN: True Negative

  TP: True positives and FN is the number of false negatives.
- `IoU` — Ratio of correctly classified pixels to the total number of pixels that are assigned that class by the ground truth and the predictor. IoU can be expressed as:
  `IoU` = TP / (TP + FP + FN)
  The image describes the true positives (TP), false positives (FP), and false negatives (FN).

- `MeanBFScore` — Boundary F1 score for each class, averaged over all images. This metric is not available when you create a `semanticSegmentationMetrics` object by using a confusion matrix as the input to `evaluateSemanticSegmentation`.

`ImageMetrics` — Image metrics
table

This property is read-only.

Semantic segmentation metrics for each image in the data set, specified as a table with *N* rows, where *N* is the number of images in the data set. `ImageMetrics` has up to five columns, corresponding to the metrics that were specified by the `'Metrics'` name-value pair used with `evaluateSemanticSegmentation`:

- `GlobalAccuracy` — Ratio of correctly classified pixels to total pixels, regardless of class.
- `MeanAccuracy` — Ratio of correctly classified pixels to total pixels, averaged over all classes in the image.
- `MeanIoU` — Average IoU of all classes in the image.
- `WeightedIoU` — Average IoU of all classes in the image, weighted by the number of pixels in each class.
- `MeanBFScore` — Average BF score of each class in the image. This metric is not available when you create a `semanticSegmentationMetrics` object by using a confusion matrix as the input to `evaluateSemanticSegmentation`.

Each image metric returns a vector, with one element for each image in the data set. The order of the rows matches the order of the images defined by the input `PixelLabelDatastore` objects representing the data set.

Examples

Evaluate Semantic Segmentation Results

The `triangleImages` data set has 100 test images with ground truth labels. Define the location of the data set.

```
dataSetDir = fullfile(toolboxdir("vision"),"visiondata","triangleImages");
```

Define the location of the test images and ground truth labels.

```
testImagesDir = fullfile(dataSetDir,"testImages");
testLabelsDir = fullfile(dataSetDir,"testLabels");
```

Create an `imageDatastore` holding the test images.

```
imds = imageDatastore(testImagesDir);
```

Define the class names and their associated label IDs.

```
classNames = ["triangle" "background"];
labelIDs   = [255 0];
```

Create a `pixelLabelDatastore` holding the ground truth pixel labels for the test images.

```
pxdsTruth = pixelLabelDatastore(testLabelsDir,classNames,labelIDs);
```

Load a semantic segmentation network that has been trained on the training images of `triangleImages`.

```
net = load("triangleSegmentationNetwork");
net = net.net;
```

Run the network on the test images. Predicted labels are written to disk in a temporary directory and returned as a `pixelLabelDatastore`.

```
pxdsResults = semanticseg(imds,net,Classes=classNames,WriteLocation=tempdir);
```

```
Running semantic segmentation network
-------------------------------------
* Processed 100 images.
```

Evaluate the prediction results against the ground truth.

```
metrics = evaluateSemanticSegmentation(pxdsResults,pxdsTruth);
```

```
Evaluating semantic segmentation results
----------------------------------------
* Selected metrics: global accuracy, class accuracy, IoU, weighted IoU, BF score.
* Processed 100 images.
* Finalizing... Done.
* Data set metrics:

    GlobalAccuracy    MeanAccuracy    MeanIoU    WeightedIoU    MeanBFScore
    ______________    ____________    _______    ___________    ___________

mAPObjectDetectionMetric

Mean average precision (mAP) metric for object detection

Description

Use an `mAPObjectDetectionMetric` object to track the mean average precision (mAP) metric when you train an object detector.

You can specify metrics options for training by using these arguments of the `trainingOptions` function:

- `Metrics` — Specify which metrics to use during training.
- `Plots` — To plot metrics during training, specify as `"training-progress"`.
- `ValidationData` — Specify this argument to additionally plot and record the metric values for the validation data.
- `Verbose` — To output the metric values to the Command Window, specify as true.

Creation

Syntax

```
metric = mAPObjectDetectionMetric
metric = mAPObjectDetectionMetric(Name=Value)
```

Description

`metric = mAPObjectDetectionMetric` creates a default mean average precision (mAP) metric to use when training an object detector.

When specified to the `Metrics` argument of the `trainingOptions` function, the default `mAPObjectDetectionMetric` object is equivalent to specifying `Metrics` as `"mAP50"`.

`metric = mAPObjectDetectionMetric(Name=Value)` specifies the `Name` and `OverlapThreshold` properties, used for metric calculation, using name-value arguments.

For example, `Name="mAP50"` sets the mean average precision as the metric to calculate.

Properties

`Name` — Metric name
`"mAP50"` (default) | string scalar | character vector

Metric name, specified as a string scalar or character vector. The metric name appears in the training plot and the verbose output.

Data Types: `char` | `string`

`OverlapThreshold` — Overlap threshold
`0.5` (default) | numeric scalar

Overlap threshold, specified as a numeric scalar in the range `[0, 1]`, which `mAPObjectDetectionMetric` uses to compute the mAP metric. When the intersection over union (IoU) of the pixels in the ground truth bounding box and the predicted bounding box is equal to or greater than the overlap threshold, the `trainingOptions` function considers the detection to be a match to the ground truth. The IoU is the number of pixels in the intersection of the bounding boxes divided by the number of pixels in the union of the bounding boxes.

vision.StandardDeviation

Namespace: `vision`

(Removed) Find standard deviation values in input or sequence of inputs

Note `vision.StandardDeviation` function has been removed. Use the `std` and `movstd` functions to find standard deviation values, instead.

Description

Find the standard deviation values in an input or sequence of inputs.

To track a set of points:

1. Create the `vision.StandardDeviation` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
stdDev = vision.StandardDeviation
stdDev = vision.StandardDeviation(Name,Value)
```

Description

`stdDev = vision.StandardDeviation` returns an object, `stdDev`, that computes the value and index of the maximum elements in an input or a sequence of inputs.

`stdDev = vision.StandardDeviation(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `stdDev = vision.Maximum('RunningStandardDeviation',false)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`ValueOutputPort` — Output Minimum value
`true` (default) | `false`

Output standard deviation value, specified as `true` or `false`. Set this property to `true` to output the Minimum value of the input. This property applies when you set the `RunningStandardDeviation` property to `false`.

`RunningStandardDeviation` — Calculate over single input or multiple inputs
`false` (default) | `true`

Calculate over single input or multiple inputs, specified as `true` or `false`. When you set this property to `true`, the object computes the standard deviation value over a sequence of inputs. When you set this property to `false`, the object computes the standard deviation value over the current input.

`ResetInputPort` — Additional input to enable resetting of running standard deviation
`false` (default) | `true`

Additional input to enable resetting of running standard deviation, specified as `true` or `false`. When you set this property to `true`, a reset input must be specified to reset the running standard deviation. This property applies only when you set the `RunningStandardDeviation` property to `true`.

`ResetCondition` — Condition that triggers resetting of running standard deviation
`'Non-zero'` (default) | `'Rising edge'` | `'Falling edge'` | `'Either edge'`

Condition that triggers resetting of running standard deviation, specified as `'Rising edge'`, `'Falling edge'`, `'Either edge'`, or `'Non-zero'`. This property applies only when you set the `ResetInputPort` property to `true`.

`Dimension` — Dimension to operate along
`'Column'` (default) | `{'All'}` | `'Row'` | `'Custom'`

Dimension to operate along, specified as `{'All'}`, `'Row'`, `'Column'`, or `'Custom'`. This property applies only when you set the `RunningStandardDeviation` property to `false`.

`CustomDimension` — Numerical dimension to calculate over
`1` (default) | numerical scalar

Numerical dimension to calculate over, specified as a numerical scalar. This property only applies when you set the `Dimension` property to `'Custom'`.

`ROIProcessing` — Enable region-of-interest processing
`false` (default) | `true`

Enable region-of-interest processing, specified as `true` or `false`. This property applies when you set the `Dimension` property to `'All'` and the `RunningStandardDeviation` property to `false`.

`ROIForm` — Type of ROI
`'Rectangles'` (default) | `Lines'` | `'Label matrix''Binary mask'`

Type of ROI, specified as `'Rectangles'`,`'Lines'`, `'Label matrix'`, or `'Binary mask'`. This property applies only when you set the `ROIProcessing` property to `true`.

`ROIPortion` — ROI or perimeter calculation
`'Entire ROI'` (default) | `'ROI perimeter'`

ROI or perimeter calculation, specified as `'Entire ROI'` or `'ROI perimeter'`. This property applies only when you set the `ROIForm` property to `'Rectangles'`.

`ROIStatistics` — Calculate statistics for each ROI or one for all ROIs
`'Individual statistics for each ROI'` (default) | `'Single statistic for all ROIs'`

Calculate statistics for each ROI or one for all ROIs, specified as `'Individual statistics for each ROI'` or `'Single statistic for all ROIs'`. This property applies only when you set the `'ROIForm'` property to `'Rectangles'`, `'Lines'`, or `'Label matrix'`.

`ValidityOutputPort` — Flag to indicate if any part of ROI is outside input image
`false` (default) | `true`

Flag to indicate if any part of ROI is outside input image, specified as `true` or `false`.

This applies when you set the `ROIForm` property to `'Lines'` or `'Rectangles'`.

Set this property to `true` to return the validity of the specified label numbers. This applies when you set the `ROIForm` property to `'Label matrix'`.

Usage

Syntax

```
[value,index] = stdDev(input)
index = stdDev(input)

[ ___ ] = stdDev(I,ROI)
[ ___ ,flag] = stdDev(I,ROI)

[ ___ ] = stdDev(I,label,labelNumbers)
[ ___ ,flag] = stdDev(I,label,labelNumbers)
```

Description

`[value,index] = stdDev(input)` returns the standard deviation value and index of the input.

`index = stdDev(input)` returns the one-based index of the standard deviation value when you set the `IndexOutputPort` property to `true` and the `ValueOutputPort` property to `false`. The `RunningStandardDeviation` property must be set to `false`.

`[ ___ ] = stdDev(I,ROI)` returns the standard deviation value in the input image within the given region of interest.

`[ ___ ,flag] = stdDev(I,ROI)`additionally returns a flag to indicate whether the given ROI is within the bounds of the image.

`[ ___ ] = stdDev(I,label,labelNumbers)` returns the standard deviation of the input image for a region the labels specified in the `labelNumbers` vector. The regions are defined and labeled in the `label` matrix.

`[ ___ ,flag] = stdDev(I,label,labelNumbers)` additionally returns a flag to indicate whether the input label numbers are valid.

Input Arguments

`input` — Input data
vector | matrix | multidimensional array

Input data, specified as a vector, matrix, or multidimensional array.

`ROI` — Region of interest
four-element vector

Region of interest, specified as a four-element vector, [*x y width height*]. This option is available when you set the `ROIProcessing` property to `true` and the `ROIForm` property to `'Lines'`, `'Rectangles'`, or `'Binary Mask'`.

`label` — Label numbers
matrix

Label numbers, specified as a matrix. This option is available when you set the `ROIProcessing` property to `true` and the `ROIForm` property to `'Label matrix'`.

`labelNumbers` — Label numbers
vector

Label numbers, specified as a vector. This option is available when you set the `ROIProcessing` property to `true` and the `ROIForm` property to `'Label matrix'`.

Output Arguments

`value` — Minimum value
same as input

Minimum value, returned as the same data type as the input

`index` — Index to standard deviation value
one-based index

Index to standard deviation value, returned as a one-based index.

`flag` — Flag for valid data
`true` | `false`

Flag for valid data, returned as `true` or `false`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

Examples

Determine Standard Deviation in Grayscale Image

1. Read a color image.

```
img = imread('peppers.png');
```

2. Convert the image to grayscale.

```
img = im2single(rgb2gray(img));
```

3. Find the standard deviation.

```
stdDev = vision.StandardDeviation;
stdDevValue = stdDev(img);
```

Version History

Introduced in R2012a

R2024b: `vision.StandardDeviation` function has been removed

Errors starting in R2024b

`vision.StandardDeviation` function has been removed. Use the `std` and `movstd` functions to find standard deviation values, instead.

R2024a: `vision.StandardDeviation` function will be removed

Warns starting in R2024a

`vision.StandardDeviation` function will be removed in a future release. Use the `std` and `movstd` functions to find standard deviation values, instead.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

stereoParameters

Object for storing stereo camera system parameters

Description

The `stereoParameters` object stores the intrinsic and extrinsic parameters of two cameras and their geometric relationship.

Creation

You can create a `stereoParameters` object using the `stereoParameters` function described here. You can also create a `stereoParameters` object by using the `estimateCameraParameters` with an *M*-by-2-by-*numImages*-by-2 array of input image points, where *M* is the number of keypoint coordinates in each pattern.

Syntax

```
stereoParams = stereoParameters(cameraParameters1,cameraParameters2,
poseCamera2)
stereoParams = stereoParameters(paramStruct)
```

Description

`stereoParams = stereoParameters(cameraParameters1,cameraParameters2, poseCamera2)` returns a stereo camera system parameters object using the camera parameters from two cameras and the pose of camera 2. `cameraParameters1` and `cameraParameters2` are `cameraParameters` or `cameraIntrinsics` objects that contain the intrinsics of camera 1 and camera 2, respectively. The three input arguments set the CameraParameters1, CameraParameters2, and PoseCamera2 properties, respectively.

`stereoParams = stereoParameters(paramStruct)` creates an identical `stereoParameters` object from an existing `stereoParameters` object with parameters stored in `paramStruct`.

Input Arguments

`paramStruct` — Stereo parameters
struct

Stereo parameters, specified as a stereo parameters struct. To get a `paramStruct` from an existing `stereoParameters` object, use the `toStruct` function.

Properties

Intrinsic and extrinsic parameters of the two cameras

`CameraParameters1` — Parameters of camera 1
`cameraParameters` object

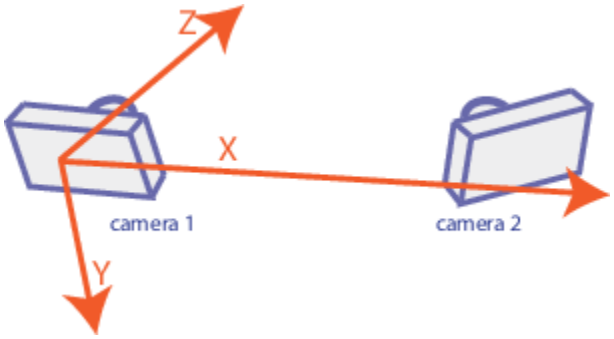
Parameters of camera 1, specified as a `cameraParameters` object. The object contains the intrinsic, extrinsic, and lens distortion parameters of a camera.

`CameraParameters2` — Parameters of camera 2

`cameraParameters` object

Parameters of camera 2, specified as a `cameraParameters` object. The object contains the intrinsic, extrinsic, and lens distortion parameters of a camera.

Geometric relationship between the two cameras



`PoseCamera2` — Relative pose of second camera

`rigidtform3d` object

Relative pose of the second camera, specified as a `rigidtform3d` object. The `R` and the `Translation` properties of the object represent the relative rotation and translation between camera 1 and camera 2, respectively. They convert camera 2 coordinates back to camera 1 coordinates using:

```
orientation1 = orientation2 * R
location1 = orientation2 * Translation + location2
```

`orientation1` and `location1` represent the absolute pose of camera 1, and `orientation2` and `location2` represent the absolute pose of camera 2.

You cannot set the value of `PoseCamera2` after you create the `stereoParameters` object.

`FundamentalMatrix` — Fundamental matrix

3-by-3 matrix

Fundamental matrix, stored as a 3-by-3 matrix. The fundamental matrix relates the two stereo cameras, such that the following equation must be true:

$$[P_1 \ 1] * FundamentalMatrix * \begin{bmatrix} P_2 \\ 1 \end{bmatrix} = 0$$

P_1, the point in image 1, corresponds to the point, P_2, in image 2. Both points are expressed in pixel coordinates.

`EssentialMatrix` — Essential matrix

3-by-3 matrix

Essential matrix, stored as a 3-by-3 matrix. The essential matrix relates the two stereo cameras, such that the following equation must be true:

$$[P_1\ 1] * EssentialMatrix * \begin{bmatrix} P_2 \\ 1 \end{bmatrix} = 0$$

P_1, the point in image 1, corresponds to P_2, the point in image 2. Both points are expressed in normalized image coordinates, where the origin is at the camera's optical center. The x and y pixel coordinates are normalized by the focal length f_x and f_y.

Accuracy of estimated parameters

`MeanReprojectionError` — Average Euclidean distance
number of pixels

Average Euclidean distance between reprojected points and detected points over all image pairs, specified in pixels.

Settings for camera parameter estimation

`NumPatterns` — Number of calibrated patterns
integer

Number of calibration patterns that estimate the extrinsics of the two cameras, stored as an integer.

`WorldPoints` — World coordinates
M-by-2 array

World coordinates of key points in the calibration pattern, specified as an *M*-by-2 array. *M* represents the number of key points in the pattern.

`WorldUnits` — World points units
`'mm'` (default) | character vector

World points units, specified as a character vector. The character vector describes the units of measure.

Object Functions

toStruct Convert a stereo parameters object into a struct

Examples

Perform Stereo Camera Calibration

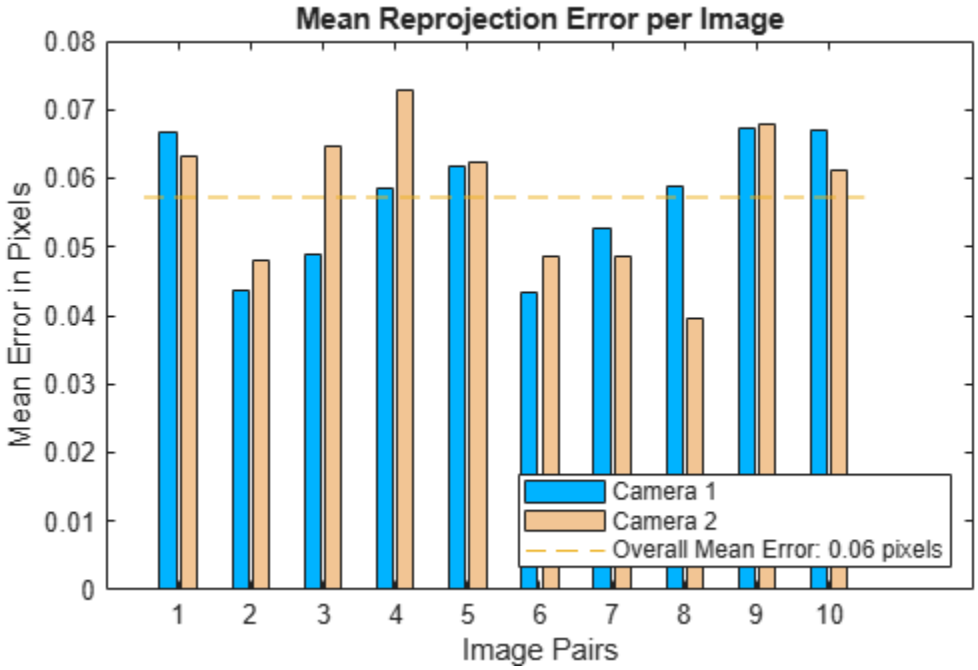
Specify calibration images.

```
leftImages = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
    "calibration","stereo","left"));
rightImages = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
    "calibration","stereo","right"));
```

Detect the checkerboards.

```
[imagePoints,patternDims] = ...
  detectCheckerboardPoints(leftImages.Files,rightImages.Files);
```

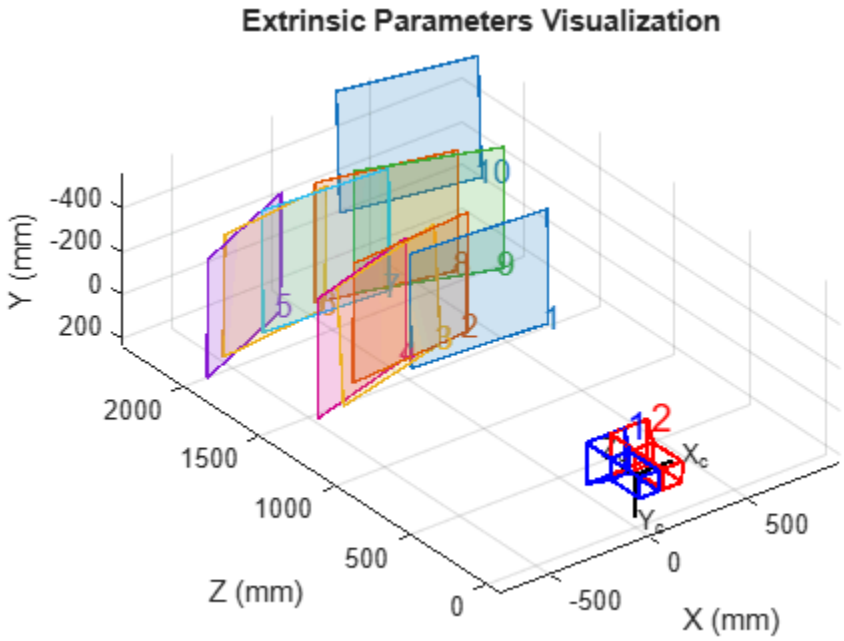
Specify the world coordinates of the checkerboard keypoints. Square size is in millimeters.



```
squareSize = 108; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Calibrate the stereo camera system. Both cameras have the same resolution.

```
I = readimage(leftImages,1);
imageSize = size(I,1:2);
params = estimateCameraParameters(imagePoints,worldPoints,ImageSize=imageSize);
```



Visualize the calibration accuracy.

```
showReprojectionErrors(params)
```

Visualize camera extrinsics.

```
figure
showExtrinsics(params)
```

Convert to structure.

```
paramsStruct = toStruct(params)
```

```
paramsStruct = struct with fields:
       CameraParameters1: [1×1 struct]
       CameraParameters2: [1×1 struct]
       RotationOfCamera2: [3×3 double]
    TranslationOfCamera2: [-119.8720 -0.4005 -0.0258]
                 Version: [1×1 struct]
     RectificationParams: [1×1 struct]
```

Version History

Introduced in R2014a

R2022b: Supports premultiply matrix convention
Behavior changed in R2022b

Starting in R2022b, many Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, some input arguments and properties of `stereoParameters` object have changed to support the premultiply convention.

- You can now specify the `tformOfCamera2` argument as a `rigidtform3d` object, which uses the premultiply convention. Although you can still specify `tformOfCamera2` as a `rigid3d` object, this object uses the postmultiply convention and is not recommended.
- The new `PoseCamera2` property replaces the old `RotationOfCamera2` and `TranslationOfCamera2` properties. You can access the rotation matrix and translation vector by querying the `R` and `Translation` properties of the `rigidtform3d` object stored in the `PoseCamera2` property. The value of the `R` property is the transpose of `RotationOfCamera2`.

For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

toStruct

Convert a stereo parameters object into a struct

Syntax

```
paramStruct = toStruct(stereoParams)
```

Description

`paramStruct = toStruct(stereoParams)` returns a struct containing the stereo parameters in the `stereoParams` input object. You can use the struct to create an identical `stereoParameters` object. Use the struct for C code generation. You can call `toStruct`, and then pass the resulting structure into the generated code, which recreates the `stereoParameters` object.

Examples

Perform Stereo Camera Calibration

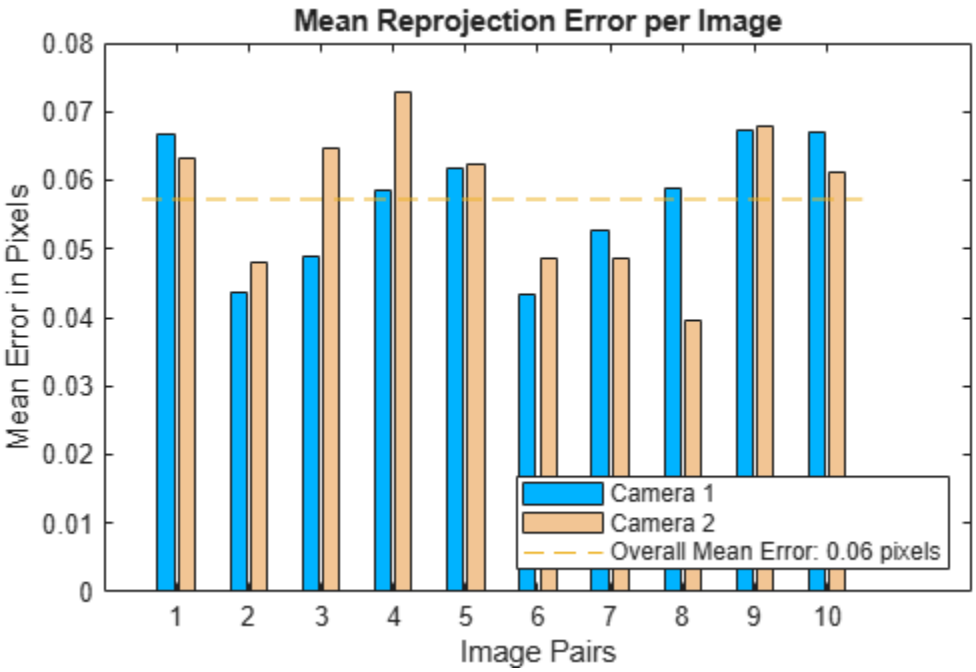
Specify calibration images.

```
leftImages = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
    "calibration","stereo","left"));
rightImages = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
    "calibration","stereo","right"));
```

Detect the checkerboards.

```
[imagePoints,patternDims] = ...
  detectCheckerboardPoints(leftImages.Files,rightImages.Files);
```

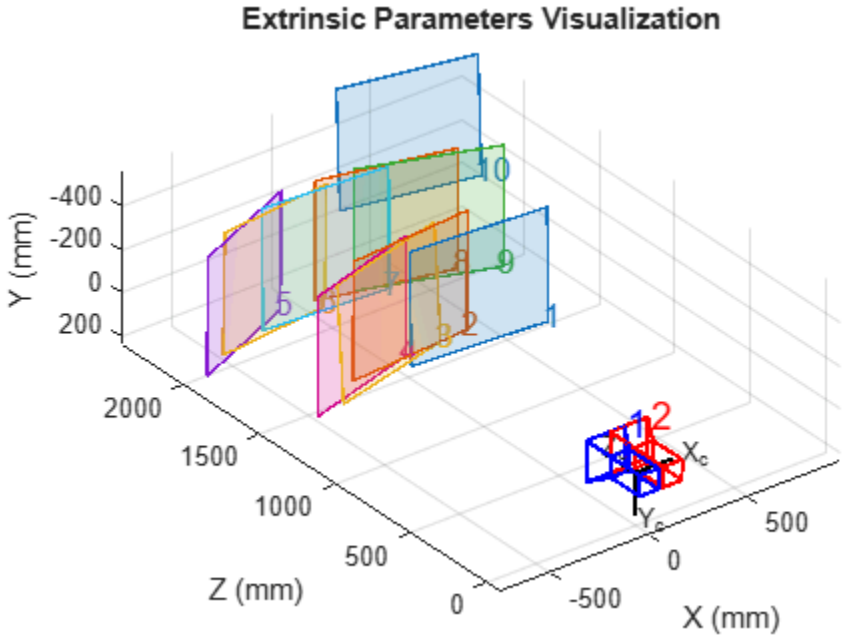
Specify the world coordinates of the checkerboard keypoints. Square size is in millimeters.



```
squareSize = 108; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Calibrate the stereo camera system. Both cameras have the same resolution.

```
I = readimage(leftImages,1);
imageSize = size(I,1:2);
params = estimateCameraParameters(imagePoints,worldPoints,ImageSize=imageSize);
```



Visualize the calibration accuracy.

```
showReprojectionErrors(params)
```

Visualize camera extrinsics.

```
figure
showExtrinsics(params)
```

Convert to structure.

```
paramsStruct = toStruct(params)
```

```
paramsStruct = struct with fields:
       CameraParameters1: [1×1 struct]
       CameraParameters2: [1×1 struct]
       RotationOfCamera2: [3×3 double]
    TranslationOfCamera2: [-119.8720 -0.4005 -0.0258]
                 Version: [1×1 struct]
     RectificationParams: [1×1 struct]
```

Input Arguments

`stereoParams` — Stereo parameters

`stereoParameters` object

Stereo parameters, specified as a `stereoParameters` object. The object contains the parameters of the stereo camera system.

Output Arguments

`paramStruct` — Stereo parameters

struct

Stereo parameters, returned as a stereo parameters struct.

Version History

Introduced in R2015a

toStruct

Convert a camera parameters object into a struct

Syntax

```
paramStruct = toStruct(cameraParams)
```

Description

`paramStruct = toStruct(cameraParams)` returns a struct containing the camera parameters in the `cameraParams` input object. You can use the struct to create an identical `cameraParameters` object. Use the struct for C code generation. You can call `toStruct`, and then pass the resulting structure into the generated code, which re-creates the `cameraParameters` object.

Examples

Remove Distortion from an Image Using Camera Parameters Object

Use the camera calibration functions to remove distortion from an image. This example creates a `cameraParameters` object manually, but in practice, you would use the `estimateCameraParameters` or the **Camera Calibrator** app to derive the object.

Create a `cameraParameters` object manually.

```
k = [715.2699 0 565.6995; 0 711.5281 355.3466; 0 0 1];
radialDistortion = [-0.3361 0.0921];
cameraParams = cameraParameters("K",k,"RadialDistortion",radialDistortion)
```

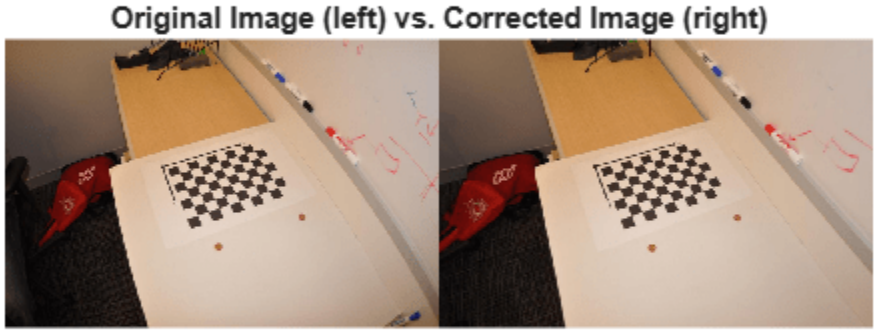
```
cameraParams =
  cameraParameters with properties:

   Camera Intrinsics
                        Intrinsics: [0×0 cameraIntrinsics]

   Camera Extrinsics
                PatternExtrinsics: [0×0 rigidtform3d]

   Accuracy of Estimation
             MeanReprojectionError: NaN
                ReprojectionErrors: [0×2 double]
                 ReprojectedPoints: [0×2×0×0 double]

   Calibration Settings
                           NumViews: 0
                       PatternCount: 0
                  DetectedKeypoints: [0×2 double]
                        WorldPoints: [0×2 double]
                         WorldUnits: 'mm'
                       EstimateSkew: 0
    NumRadialDistortionCoefficients: 2
```



```
        EstimateTangentialDistortion: 0
```

Remove distortion from the images.

```
I = imread(fullfile(matlabroot,"toolbox","vision","visiondata","calibration","mono","image01.jpg
J = undistortImage(I,cameraParams);
```

Display the original and the undistorted images.

```
montage({I,J})
title("Original Image (left) vs. Corrected Image (right)")
```

Input Arguments

`cameraParams` — Camera parameters

`cameraParameters` object

Camera parameters, specified as a `cameraParameters` object. The object contains the parameters for the camera.

Output Arguments

`paramStruct` — Camera parameters

struct

Camera parameters, returned as a camera parameters struct.

vision.TemplateMatcher

Namespace: `vision`

Locate template in image

Description

To locate a template in an image.

1. Create the `vision.TemplateMatcher` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
tMatcher = vision.TemplateMatcher
tMatcher = vision.TemplateMatcher(Name,Value)
```

Description

`tMatcher = vision.TemplateMatcher` returns a template matcher object, `tMatcher`. This object performs template matching by shifting a template in single-pixel increments throughout the interior of an image.

`tMatcher = vision.TemplateMatcher(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `tMatcher = vision.TemplateMatcher('Metric','Sum of absolute differences')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Metric` — Metric used for template matching source
`'Sum of absolute differences'` (default) | `'Sum of squared differences'` | `'Maximum absolute difference'`

Metric used for template matching, specified as `'Sum of absolute differences'`, `'Sum of squared differences'`, or `'Maximum absolute difference'`.

`OutputValue` — Type of output
`'Best match location'` (default) | `'Metric matrix'`

Type of output, specified as `'Metric matrix'` or `'Best match location'`.

`SearchMethod` — Specify search criteria to find minimum difference between two inputs
`'Exhaustive'` (default) | `'Three-step'`

Specify search criteria to find minimum difference between two inputs, specified as `'Exhaustive'` or `'Three-step'`. If you set this property to `'Exhaustive'`, the object searches for the minimum difference pixel by pixel. If you set this property to `'Three-step'`, the object searches for the minimum difference using a steadily decreasing step size. The `'Three-step'` method is computationally less expensive than the `'Exhaustive'` method, but sometimes does not find the optimal solution. This property applies when you set the `OutputValue` property to `'Best match location'`.

`BestMatchNeighborhoodOutputPort` — Enable metric values output
`false` (default) | `true`

Enable metric values output, specified as `true` or `false`. This property applies when you set the `OutputValue` property to `'Best match location'`.

`NeighborhoodSize` — Size of the metric values
3 (default) | odd number

Size of the metric values, specified as an odd number. The size *N*, of the *N*-by-*N* matrix of metric values as an odd number. For example, if the matrix size is 3-by-3 set this property to 3. This property applies when you set the `OutputValue` property to `'Best match location'` and the `BestMatchNeighborhoodOutputPort` property to `true`.

`ROIInputPort` — Enable ROI specification through input
`false` (default) | `true`

Enable ROI specification through input, specified as `true` or `false`. Set this property to `true` to define the Region of Interest (ROI) over which to perform the template matching. If you set this property to `true`, the ROI must be specified. Otherwise the entire input image is used.

`ROIValidityOutputPort` — Enable output of a flag indicating if any part of ROI is outside input image
`false` (default) | `true`

Enable output of a flag indicating if any part of ROI is outside input image, specified as `true` or `false`. When you set this property to `true`, the object returns an ROI flag. The flag, when set to `false`, indicates a part of the ROI is outside of the input image. This property applies when you set the `ROIInputPort` property to `true`

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Rounding method for fixed-point operations, specified as `'Floor'`, `'Ceiling'`, `'Convergent'`, `'Nearest'` , `'Round'` , `'Simplest'` , or `'Zero'`.

`OverflowAction` — Action to take when integer input is out-of-range
`'Wrap'` (default) | `'Saturate'`

Action to take when integer input is out-of-range, specified as `'Wrap'` or `'Saturate'`.

`ProductDataType` — Product data type
`'Same as input'` (default) | `'Custom'`

Product data type, specified as `'Same as input'` or `'Custom'`.

`CustomProductDataType` — Product word and fraction lengths
`numerictype(true,32,30)` (default) | scaled `numerictype` object

Product word and fraction lengths, specified as a scaled `numerictype` object. This property applies only when you set the `AccumulatorDataType` property to `'Custom'`.

`AccumulatorDataType` — Data type of accumulator
`'Same as product'` (default) | `'Same as input'` | `'Custom'`

Data type of accumulator, specified as `'Same as product'`, `'Same as input'`, or `'Custom'`.

`CustomAccumulatorDataType` — Accumulator word and fraction lengths
`numerictype(true,32,30)` (default) | scaled `numerictype` object

Accumulator word and fraction lengths, specified as a scaled `numerictype` object. This property applies only when you set the `AccumulatorDataType` property to `'Custom'`.

Usage

Syntax

```
location = tMatcher(I,T)

[location,numberOfValues,numValid] = tMatcher(I,T,ROI)
[location,numberOfValues,numValid,ROIvalid] = tMatcher(I,T,ROI)
[location,ROIvalid] = tMatcher(I,T,ROI)
```

Description

`location = tMatcher(I,T)` returns the [*x* *y*] location coordinates of the best template match relative to the top left corner of the image between the image matrix, `I`, and the template matrix, `T`. The object computes the location by shifting the template in single-pixel increments throughout the interior of the image.

`[location,numberOfValues,numValid] = tMatcher(I,T,ROI)`returns the location of the best template match `location`, the metric values around the best match `numberOfValues`, and a logical flag `numValid`. This applies when you set the `OutputValue` property to `'Best match location'` and the `BestMatchNeighborhoodOutputPort` property to `true`.

`[location,numberOfValues,numValid,ROIvalid] = tMatcher(I,T,ROI)` also returns a logical flag, `ROIvalid` to indicate whether the `ROI` is outside the bounds of the input image `I`. This applies when you set the `OutputValue` property to `'Best match location'`, and the `BestMatchNeighborhoodOutputPort`, `ROIInputPort`, and `ROIValidityOutputPort` properties to `true`.

`[location,ROIvalid] = tMatcher(I,T,ROI)` also returns a logical flag `ROIvalid` indicating if the specified `ROI` is outside the bounds of the input image `I`. This applies when you set the `OutputValue` property to `'Best match location'`, and both the `ROIInputPort` and `ROIValidityOutputPort` properties to `true`.

Input Arguments

`I` — Input image

M-by-*N* 2-D grayscale image

Input image, specified as a 2-D grayscale image. Performance of the `TemplateMatcher` object can depend on the input type. For example, using datatype `double` inputs can result in faster performance.

`T` — Template

binary image | *M*-by-*N* 2-D grayscale image

Input template, specified as 2-D grayscale image.

`ROI` — Input ROI

four-element vector

Input ROI, specified as a four-element vector, [*x y width height*], where the first two elements represent the coordinates of the upper-left corner of the rectangular ROI.

Output Arguments

`location` — Location of best template match

vector

Location of best template match, returned as a vector in the format (*x*,*y*). The coordinates indicate the center of the template relative to the top-left corner of the image. For more details, see “Algorithms” on page 2-1152

`numberOfValues` — Metric value

matrix

Metric value matrix , returned as a matrix. A `false` value for `numValid` indicates that the neighborhood around the best match extended outside the borders of the metric value matrix `numberOfValues`.

`numValid` — Valid neighborhood

`true` | `false`

Valid neighborhood, returned as `true` or `false`. A `false` value for `numValid` indicates that the neighborhood around the best match extended outside the borders of the metric value matrix `numberOfValues`.

`ROIvalid` — Valid ROI

`true` | `false`

Valid ROI neighborhood, returned as `true` or `false`. A `false` value for `ROIvalid` indicates that the ROI is outside the bounds of the input image.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Video Stabilization

This example shows how to remove the effect of camera motion from a video stream.

Introduction

In this example we first define the target to track. In this case, it is the back of a car and the license plate. We also establish a dynamic search region, whose position is determined by the last known target location. We then search for the target only within this search region, which reduces the number of computations required to find the target. In each subsequent video frame, we determine how much the target has moved relative to the previous frame. We use this information to remove unwanted translational camera motions and generate a stabilized video.

Initialization

Create a System object™ to read video from a multimedia file. We set the output to be of intensity only video.

```
% Input video file which needs to be stabilized.
filename = "shaky_car.avi";

hVideoSource = VideoReader(filename);
```

Create a template matcher System object to compute the location of the best match of the target in the video frame. We use this location to find translation between successive video frames.

```
hTM = vision.TemplateMatcher("ROIInputPort", true, ...
                             "BestMatchNeighborhoodOutputPort", true);
```

Create a System object to display the original video and the stabilized video.

```
hVideoOut = vision.VideoPlayer("Name", "Video Stabilization");
hVideoOut.Position(1) = round(0.4*hVideoOut.Position(1));
hVideoOut.Position(2) = round(1.5*(hVideoOut.Position(2)));
hVideoOut.Position(3:4) = [650 350];
```

Here we initialize some variables used in the processing loop.

```
pos.template_orig = [109 100]; % [x y] upper left corner
pos.template_size = [22 18];   % [width height]
```

```
pos.search_border = [15 10];   % max horizontal and vertical displacement
pos.template_center = floor((pos.template_size-1)/2);
pos.template_center_pos = (pos.template_orig + pos.template_center - 1);
W = hVideoSource.Width; % Width in pixels
H = hVideoSource.Height; % Height in pixels
BorderCols = [1:pos.search_border(1)+4 W-pos.search_border(1)+4:W];
BorderRows = [1:pos.search_border(2)+4 H-pos.search_border(2)+4:H];
sz = [W, H];
TargetRowIndices = ...
  pos.template_orig(2)-1:pos.template_orig(2)+pos.template_size(2)-2;
TargetColIndices = ...
  pos.template_orig(1)-1:pos.template_orig(1)+pos.template_size(1)-2;
SearchRegion = pos.template_orig - pos.search_border - 1;
Offset = [0 0];
Target = zeros(18,22);
firstTime = true;
```

Stream Processing Loop

This is the main processing loop which uses the objects we instantiated above to stabilize the input video.

```
while hasFrame(hVideoSource)
    input = im2gray(im2double(readFrame(hVideoSource)));

    % Find location of Target in the input video frame
    if firstTime
      Idx = int32(pos.template_center_pos);
      MotionVector = [0 0];
      firstTime = false;
    else
      IdxPrev = Idx;

      ROI = [SearchRegion, pos.template_size+2*pos.search_border];
      Idx = hTM(input,Target,ROI);

      MotionVector = double(Idx-IdxPrev);
    end

    [Offset, SearchRegion] = updatesearch(sz, MotionVector, ...
        SearchRegion, Offset, pos);

    % Translate video frame to offset the camera motion
    Stabilized = imtranslate(input, Offset, "linear");

    Target = Stabilized(TargetRowIndices, TargetColIndices);

    % Add black border for display
    Stabilized(:, BorderCols) = 0;
    Stabilized(BorderRows, :) = 0;

    TargetRect = [pos.template_orig-Offset, pos.template_size];
    SearchRegionRect = [SearchRegion, pos.template_size + 2*pos.search_border];

    % Draw rectangles on input to show target and search region
    input = insertShape(input, "rectangle", [TargetRect; SearchRegionRect],...
                        "Color", "white");
    % Display the offset (displacement) values on the input image
```

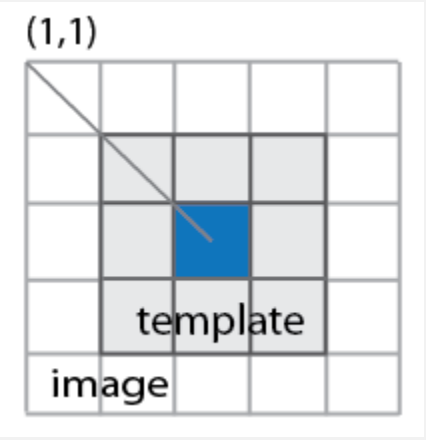
```
    txt = sprintf("(%+05.1f,%+05.1f)", Offset);
    input = insertText(input(:,:,1),[191 215],txt,"FontSize",16, ...
                    "TextColor", "white", "BoxOpacity", 0);
    % Display video
    hVideoOut([input(:,:,1) Stabilized]);
end
```

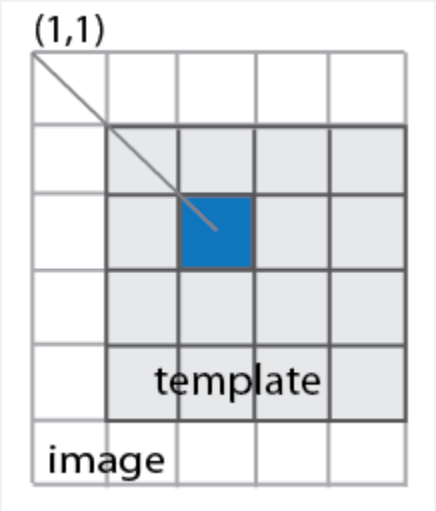
Conclusion

Using the Computer Vision Toolbox™ functionality from MATLAB® command line it is easy to implement complex systems like video stabilization.

Appendix

The following helper function is used in this example.





- updatesearch.m

Algorithms

Typical use of the template matcher involves finding a small region within a larger image. The region is specified by the template image which can be as large as the input image, but which is typically smaller than the input image.

The object outputs the best match coordinates, relative to the top-left corner of the image. The [*x* *y*] coordinates of the location correspond to the center of the template. When you use a template with

an odd number of pixels, the object uses the center of the template. When you use a template with an even number of pixels, the object uses the centered upper-left pixel for the location. The following table shows how the object outputs the location (`LOC`), of odd and even templates:

Odd number of pixels in template	Even number of pixels in template

vision.Variance

Namespace: `vision`

(Removed) Find variance values in input or sequence of inputs

Note `vision.Variance` function has been removed. Use the `var` and `movvar` functions to find variance values, instead.

Description

Find the variance values in an input or sequence of inputs.

To track a set of points:

1. Create the `vision.Variance` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
varObj = vision.Variance
varObj = vision.Variance(Name,Value)
```

Description

`varObj = vision.Variance` returns an object, `varObj`, that computes the value and index of the maximum elements in an input or a sequence of inputs.

`varObj = vision.Variance(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `varObj = vision.Variance('RunningVariance',false)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`RunningVariance` — Calculate over single input or multiple inputs

`false` (default) | `true`

Calculate over single input or multiple inputs, specified as `true` or `false`. When you set this property to `true`, the object computes the variance value over a sequence of inputs. When you set this property to `false`, the object computes the variance value over the current input.

`ResetInputPort` — Additional input to enable resetting of running variance
`false` (default) | `true`

Additional input to enable resetting of running variance, specified as `true` or `false`. When you set this property to `true`, a reset input must be specified to reset the running variance. This property applies only when you set the `RunningVariance` property to `true`.

`ResetCondition` — Condition that triggers resetting of running variance
`'Non-zero'` (default) | `'Rising edge'` | `'Falling edge'` | `'Either edge'`

Condition that triggers resetting of running variance, specified as `'Rising edge'`, `'Falling edge'`, `'Either edge'`, or `'Non-zero'`. This property applies only when you set the `ResetInputPort` property to `true`.

`Dimension` — Dimension to operate along
`'Column'` (default) | `{'All'}` | `'Row'` | `'Custom'`

Dimension to operate along, specified as `{'All'}`, `'Row'`, `'Column'`, or `'Custom'`. This property applies only when you set the `RunningVariance` property to `false`.

`CustomDimension` — Numerical dimension to calculate over
1 (default) | numerical scalar

Numerical dimension to calculate over, specified as a numerical scalar. This property only applies when you set the `Dimension` property to `'Custom'`.

`ROIProcessing` — Enable region-of-interest processing
`false` (default) | `true`

Enable region-of-interest processing, specified as `true` or `false`. This property applies when you set the `Dimension` property to `'All'` and the `RunningVariance` property to `false`.

`ROIForm` — Type of ROI
`'Rectangles'` (default) | `Lines'` | `'Label matrix''Binary mask'`

Type of ROI, specified as `'Rectangles'`, `'Lines'`, `'Label matrix'`, or `'Binary mask'`. This property applies only when you set the `ROIProcessing` property to `true`.

`ROIStatistics` — Calculate statistics for each ROI or one for all ROIs
`'Individual statistics for each ROI'` (default) | `'Single statistic for all ROIs'`

Calculate statistics for each ROI or one for all ROIs, specified as `'Individual statistics for each ROI'` or `'Single statistic for all ROIs'`. This property applies only when you set the `'ROIForm'` property to `'Rectangles'`, `'Lines'`, or `'Label matrix'`.

`ValidityOutputPort` — Flag to indicate if any part of ROI is outside input image
`false` (default) | `true`

Flag to indicate if any part of ROI is outside input image, specified as `true` or `false`.

This applies when you set the `ROIForm` property to `'Lines'` or `'Rectangles'`.

Set this property to `true` to return the validity of the specified label numbers. This applies when you set the `ROIForm` property to `'Label matrix'`.

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest''Round'` | `'Simplest''Zero'`

Rounding method for fixed-point operations, specified as `'Floor'`, `'Ceiling'`, `'Convergent'`, `'Nearest'` , `'Round'` , `'Simplest'` , or `'Zero'`.

`OverflowAction` — Action to take when integer input is out-of-range
`'Wrap'` (default) | `'Saturate'`

Action to take when integer input is out-of-range, specified as `'Wrap'` or `'Saturate'`.

`ProductDataType` — Product data type
`'Same as input'` (default) | `'Custom'`

Product data type, specified as `'Same as input'` or `'Custom'`.

`CustomProductDataType` — Product word and fraction lengths
`numerictype(true,32,30)` (default) | scaled `numerictype` object

Product word and fraction lengths, specified as a scaled `numerictype` object. This property applies only when you set the `AccumulatorDataType` property to `'Custom'`.

`AccumulatorDataType` — Data type of accumulator
`'Same as product'` (default) | `'Same as input'` | `'Custom'`

Data type of accumulator, specified as `'Same as product'`, `'Same as input'`, or `'Custom'`.

`CustomAccumulatorDataType` — Accumulator word and fraction lengths
`numerictype(true,32,30)` (default) | scaled `numerictype` object

Accumulator word and fraction lengths, specified as a scaled `numerictype` object. This property applies only when you set the `AccumulatorDataType` property to `'Custom'`.

Usage

Syntax

```
[value,index] = varObj(input)
index = varObj(input)

[___] = varObj(I,ROI)
[___,flag] = varObj(I,ROI)

[___] = varObj(I,label,labelNumbers)
[___,flag] = varObj(I,label,labelNumbers)
```

Description

`[value,index] = varObj(input)` returns the variance value and index of the input.

`index = varObj(input)` returns the one-based index of the variance value when you set the `IndexOutputPort` property to `true` and the `ValueOutputPort` property to `false`. The `RunningVariance` property must be set to `false`.

`[ ___ ] = varObj(I,ROI)` returns the variance value in the input image within the given region of interest.

`[ ___ ,flag] = varObj(I,ROI)` additionally returns a flag to indicate whether the given ROI is within the bounds of the image.

`[ ___ ] = varObj(I,label,labelNumbers)` returns the variance of the input image for a region the labels specified in the `labelNumbers` vector. The regions are defined and labeled in the `label` matrix.

`[ ___ ,flag] = varObj(I,label,labelNumbers)` additionally returns a flag to indicate whether the input label numbers are valid.

Input Arguments

`input` — Input data
vector | matrix | multidimensional array

Input data, specified as a vector, matrix, or multidimensional array.

`ROI` — Region of interest
four-element vector

Region of interest, specified as a four-element vector, [*x y width height*]. This option is available when you set the `ROIProcessing` property to `true` and the `ROIForm` property to `'Lines'`, `'Rectangles'`, or `'Binary Mask'`.

`label` — Label numbers
matrix

Label numbers, specified as a matrix. This option is available when you set the `ROIProcessing` property to `true` and the `ROIForm` property to `'Label matrix'`.

`labelNumbers` — Label numbers
vector

Label numbers, specified as a vector. This option is available when you set the `ROIProcessing` property to `true` and the `ROIForm` property to `'Label matrix'`.

Output Arguments

`value` — Variance value
same as input

Variance value, returned as the same data type as the input

`index` — Index to variance value
one-based index

Index to variance value, returned as a one-based index.

`flag` — Flag for valid data
`true` | `false`

Flag for valid data, returned as `true` or `false`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Determine Variance in Grayscale Image

1. Read a color image.

```
img = imread('peppers.png');
```

2. Convert the image to grayscale.

```
img = im2single(rgb2gray(img));
```

3. Find the variance.

```
varObj = vision.Variance;
varValue = varObj(img);
```

Version History

Introduced in R2012a

R2024b: `vision.Variance` function has been removed

Errors starting in R2024b

`vision.Variance` function has been removed. Use the `var` and `movvar` functions to find variance values, instead.

R2024a: `vision.Variance` function will be removed

Warns starting in R2024a

`vision.Variance` function will be removed in a future release. Use the `var` and `movvar` functions to find variance values, instead.

Extended Capabilities

`var` | `movvar`

vision.VideoPlayer

Namespace: `vision`

Play video or display image

Description

Play a video or display image sequences.

Note If you own the MATLAB Coder product, you can generate C or C++ code from MATLAB code in which an instance of this system object is created. When you do so, the scope system object is automatically declared as an extrinsic variable. In this manner, you are able to see the scope display in the same way that you would see a figure using the `plot` function, without directly generating code from it. For the full list of system objects supporting code generation, see Code Generation Support, Usage Notes, and Limitations.

Creation

Syntax

```
videoPlayer = vision.VideoPlayer
videoPlayer = vision.VideoPlayer( ___ ,Name,Value)
```

Description

`videoPlayer = vision.VideoPlayer` returns a video player object, `videoPlayer`, for displaying video frames.

`videoPlayer = vision.VideoPlayer( ___ ,Name,Value)` specifies properties using one or more name-value arguments in addition to the previous syntax. For example, `videoPlayer = vision.VideoPlayer('Name','Caption title')` sets the caption display on the video player window.

Properties

`Name` — Caption display on video player window

`Video` (default) | character vector

Caption display on video player window, specified as a character vector.

Tunable: Yes

`Position` — Size and position of the video player window in pixels

four-element vector

Size and position of the video player window in pixels, specified as a four-element vector, `[left bottom width height]`. The default size depends on your screen resolution. The window is positioned in the center of the screen, 400 pixels in width by 300 pixels in height.

Tunable: Yes

Usage

Syntax

```
videoPlayer(videoFrame)
```

Description

`videoPlayer(videoFrame)` displays one grayscale or truecolor RGB video frame,`videoFrame`, in the video player.

Input Arguments

`videoFrame` — Video frame

truecolor | 2-D grayscale image

Video frame, specified as a truecolor or 2-D grayscale image.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Play a Video File

Read video from a file and set up player object.

```
videoReader = VideoReader('viplanedeparture.mp4');
videoPlayer = vision.VideoPlayer;
```

Play video.

```
while hasFrame(videoReader)
   frame = readFrame(videoReader);
   videoPlayer(frame);
end
```

Close the video player.

```
release(videoPlayer);
```

fastRCNNObjectDetector

(Not recommended) Detect objects using Fast R-CNN deep learning detector

Note `fastRCNNObjectDetector` is not recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` detector. For more information, see “Version History”.

Description

The `fastRCNNObjectDetector` object detects objects from an image, using a Fast R-CNN (regions with convolution neural networks) object detector. To detect objects in an image, pass the trained detector to the `detect` function. To classify image regions, pass the detector to the `classifyRegions` function.

When using the `detect` or `classifyRegions` functions with `fastRCNNObjectDetector`, use of a CUDA enabled NVIDIA GPU is highly recommended. The GPU reduces computation time significantly. Usage of the GPU requires Parallel Computing Toolbox. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

Creation

Create a `fastRCNNObjectDetector` object by calling the `trainFastRCNNObjectDetector` function with training data (requires Deep Learning Toolbox).

```
detector = trainFastRCNNObjectDetector(trainingData,...)
```

Properties

`ModelName` — Name of classification model
character vector | string scalar

Name of the classification model, specified as a character vector or string scalar. By default, the name is set to the heading of the second column of the `trainingData` table specified in the `trainFastRCNNObjectDetector` function. You can modify this name after creating your `fastRCNNObjectDetector` object.

Example: `'stopSign'`

`Network` — Trained Fast R-CNN object detection network
DAGNetwork object

This property is read-only.

Trained Fast R-CNN detection network used within the Fast R-CNN detector, specified as a `DAGNetwork` object. This object stores the layers that define the convolutional neural network used within the Fast R-CNN detector. This network classifies region proposals produced by the `RegionProposalFcn` property.

`RegionProposalFcn` — Region proposal method
function handle

Region proposal method, specified as a function handle.

`ClassNames` — Object class names
cell array

This property is read-only.

Names of the object classes that the Fast R-CNN detector was trained to find, specified as a cell array. This property is set by the `trainingData` input argument for the `trainFastRCNNObjectDetector` function. Specify the class names as part of the `trainingData` table.

`MinObjectSize` — Minimum object size supported
[*height width*] vector

This property is read-only.

Minimum object size supported by the Fast R-CNN network, specified as a [*height width*] vector. The minimum size depends on the network architecture.

Object Functions

detect	(Not recommended) Detect objects using Fast R-CNN object detector
classifyRegions	(Not recommended) Classify objects in image regions using Fast R-CNN object detector

Examples

Detect Vehicles Using Faster R-CNN

Detect vehicles within an image by using a Faster R-CNN object detector.

Load a Faster R-CNN object detector pretrained to detect vehicles.

```
data = load('fasterRCNNVehicleTrainingData.mat', 'detector');
detector = data.detector;
```

Read in a test image.

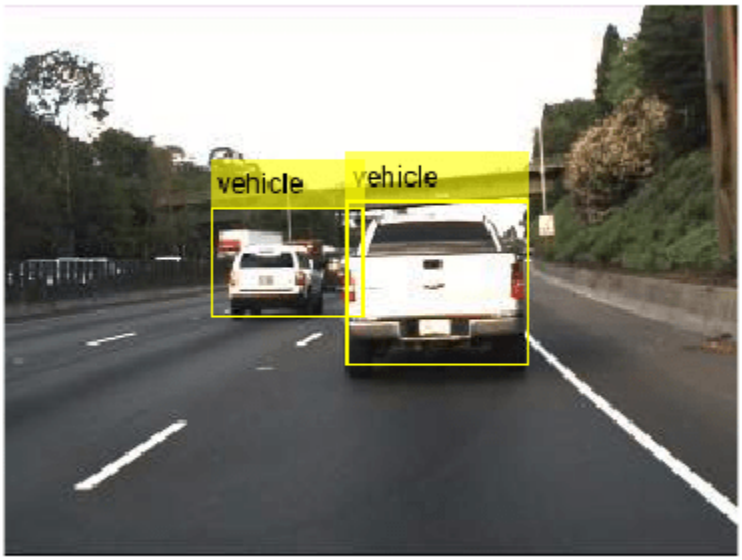
```
I = imread('highway.png');
imshow(I)
```

Run the detector on the image and inspect the results. The labels come from the `ClassNames` property of the detector.

```
[bboxes,scores,labels] = detect(detector,I)
```

```
bboxes = 2×4

   150    86    80    72
    91    89    67    48



scores = 2×1 single column vector

    1.0000
    0.9001

labels = 2×1 categorical
     vehicle
     vehicle
```

The detector has high confidence in the detections. Annotate the image with the bounding boxes for the detections and the corresponding detection scores.

```
detectedI = insertObjectAnnotation(I,'Rectangle',bboxes,cellstr(labels));
figure
imshow(detectedI)
```

Version History

Introduced in R2017a

R2024b: Not Recommended

Not recommended starting in R2024b

Starting in R2024b, R-CNN object detectors are no longer recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` object. These object detectors are faster than R-CNN object detectors. For more information, see “Choose an Object Detector”.

fasterRCNNObjectDetector

(Not recommended) Detect objects using Faster R-CNN deep learning detector

Note `fasterRCNNObjectDetector` is not recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` detector. For more information, see "Version History".

Description

The `fasterRCNNObjectDetector` object detects objects from an image, using a Faster R-CNN (regions with convolution neural networks) object detector. To detect objects in an image, pass the trained detector to the `detect` function.

When using the `detect` function, use of a CUDA enabled NVIDIA GPU is highly recommended. The GPU reduces computation time significantly. Usage of the GPU requires Parallel Computing Toolbox. For information about the supported compute capabilities, see "GPU Computing Requirements" (Parallel Computing Toolbox).

Creation

Create a `fasterRCNNObjectDetector` object by calling the `trainFasterRCNNObjectDetector` function with training data (requires Deep Learning Toolbox).

```
detector = trainFasterRCNNObjectDetector(trainingData,...)
```

Properties

`ModelName` — Name of classification model
character vector | string scalar

This property is read-only.

Name of the classification model, specified as a character vector or string scalar. By default, the name is set to the heading of the second column of the `trainingData` table specified in the `trainFasterRCNNObjectDetector` function. You can modify this name after creating your `fasterRCNNObjectDetector` object.

`Network` — Trained Fast R-CNN object detection network
`DAGNetwork` object

This property is read-only.

Trained Fast R-CNN object detection network, specified as a `DAGNetwork` object. This object stores the layers that define the convolutional neural network used within the Faster R-CNN detector.

`AnchorBoxes` — Size of anchor boxes
M-by-2 matrix

This property is read-only.

Size of anchor boxes, specified as an *M*-by-2 matrix, where each row is in the format [*height width*]. This value is set during training.

`ClassNames` — Object class names
cell array

This property is read-only.

Names of the object classes that the Faster R-CNN detector was trained to find, specified as a cell array. This property is set by the `trainingData` input argument for the `trainFasterRCNNObjectDetector` function. Specify the class names as part of the `trainingData` table.

`MinObjectSize` — Minimum object size supported
[*height width*] vector

This property is read-only.

Minimum object size supported by the Faster R-CNN network, specified as a [*height width*] vector. The minimum size depends on the network architecture.

Object Functions

detect (Not recommended) Detect objects using Faster R-CNN object detector

Examples

Object Detection Using Faster R-CNN Deep Learning

This example shows how to train a Faster R-CNN (regions with convolutional neural networks) object detector.

Deep learning is a powerful machine learning technique that you can use to train robust object detectors. Several deep learning techniques for object detection exist, including Faster R-CNN and you only look once (YOLO) v2. This example trains a Faster R-CNN vehicle detector using the `trainFasterRCNNObjectDetector` function. For more information, see “Object Detection”.

Download Pretrained Detector

Download a pretrained detector to avoid having to wait for training to complete. If you want to train the detector, set the `doTraining` variable to true.

```
doTraining = false;
if ~doTraining && ~exist("fasterRCNNResNet50EndToEndVehicleExample.mat","file")
    disp("Downloading pretrained detector (118 MB)...");
    pretrainedURL = "https://www.mathworks.com/supportfiles/vision/data/fasterRCNNResNet50EndToEn
    websave("fasterRCNNResNet50EndToEndVehicleExample.mat",pretrainedURL);
end
```

```
Downloading pretrained detector (118 MB)...
```

Load Data Set

This example uses a small labeled dataset that contains 295 images. Many of these images come from the Caltech Cars 1999 and 2001 data sets, created by Pietro Perona and used with permission. Each image contains one or two labeled instances of a vehicle. A small dataset is useful for exploring the Faster R-CNN training procedure, but in practice, more labeled images are needed to train a robust detector. Unzip the vehicle images and load the vehicle ground truth data.

```
unzip vehicleDatasetImages.zip
data = load("vehicleDatasetGroundTruth.mat");
vehicleDataset = data.vehicleDataset;
```

The vehicle data is stored in a two-column table, where the first column contains the image file paths and the second column contains the vehicle bounding boxes.

Split the dataset into training, validation, and test sets. Select 60% of the data for training, 10% for validation, and the rest for testing the trained detector.

```
rng(0)
shuffledIndices = randperm(height(vehicleDataset));
idx = floor(0.6 * height(vehicleDataset));

trainingIdx = 1:idx;
trainingDataTbl = vehicleDataset(shuffledIndices(trainingIdx),:);

validationIdx = idx+1 : idx + 1 + floor(0.1 * length(shuffledIndices) );
validationDataTbl = vehicleDataset(shuffledIndices(validationIdx),:);

testIdx = validationIdx(end)+1 : length(shuffledIndices);
testDataTbl = vehicleDataset(shuffledIndices(testIdx),:);
```

Use `imageDatastore` and `boxLabelDatastore` to create datastores for loading the image and label data during training and evaluation.

```
imdsTrain = imageDatastore(trainingDataTbl{:,"imageFilename"});
bldsTrain = boxLabelDatastore(trainingDataTbl(:,"vehicle"));

imdsValidation = imageDatastore(validationDataTbl{:,"imageFilename"});
bldsValidation = boxLabelDatastore(validationDataTbl(:,"vehicle"));

imdsTest = imageDatastore(testDataTbl{:,"imageFilename"});
bldsTest = boxLabelDatastore(testDataTbl(:,"vehicle"));
```

Combine image and box label datastores.

```
trainingData = combine(imdsTrain,bldsTrain);
validationData = combine(imdsValidation,bldsValidation);
testData = combine(imdsTest,bldsTest);
```

Display one of the training images and box labels.

```
data = read(trainingData);
I = data{1};
bbox = data{2};
annotatedImage = insertShape(I,"rectangle",bbox);
annotatedImage = imresize(annotatedImage,2);
figure
imshow(annotatedImage)
```

Create Faster R-CNN Detection Network

A Faster R-CNN object detection network is composed of a feature extraction network followed by two subnetworks. The feature extraction network is typically a pretrained CNN, such as ResNet-50 or Inception v3. The first subnetwork following the feature extraction network is a region proposal network (RPN) trained to generate object proposals - areas in the image where objects are likely to exist. The second subnetwork is trained to predict the actual class of each object proposal.

The feature extraction network is typically a pretrained CNN (for details, see “Pretrained Deep Neural Networks” (Deep Learning Toolbox)). This example uses ResNet-50 for feature extraction. You can also use other pretrained networks such as MobileNet v2 or ResNet-18, depending on your application requirements.

Use `fasterRCNNLayers` to create a Faster R-CNN network automatically given a pretrained feature extraction network. `fasterRCNNLayers` requires you to specify several inputs that parameterize a Faster R-CNN network:

- Network input size
- Anchor boxes
- Feature extraction network

First, specify the network input size. When choosing the network input size, consider the minimum size required to run the network itself, the size of the training images, and the computational cost incurred by processing data at the selected size. When feasible, choose a network input size that is

close to the size of the training image and larger than the input size required for the network. To reduce the computational cost of running the example, specify a network input size of [224 224 3], which is the minimum size required to run the network.

```
inputSize = [224 224 3];
```

Note that the training images used in this example are bigger than 224-by-224 and vary in size, so you must resize the images in a preprocessing step prior to training.

Next, use `estimateAnchorBoxes` to estimate anchor boxes based on the size of objects in the training data. To account for the resizing of the images prior to training, resize the training data for estimating anchor boxes. Use `transform` to preprocess the training data, then define the number of anchor boxes and estimate the anchor boxes.

```
preprocessedTrainingData = transform(trainingData, @(data)preprocessData(data,inputSize));
numAnchors = 3;
anchorBoxes = estimateAnchorBoxes(preprocessedTrainingData,numAnchors)
```

```
anchorBoxes = 3×2

     38     29
    150    125
     80     77
```

For more information on choosing anchor boxes, see “Estimate Anchor Boxes from Training Data” (Computer Vision Toolbox™) and “Anchor Boxes for Object Detection”.

Now, use `resnet50` to load a pretrained ResNet-50 model.

```
featureExtractionNetwork = resnet50;
```

Select `"activation_40_relu"` as the feature extraction layer. This feature extraction layer outputs feature maps that are downsampled by a factor of 16. This amount of downsampling is a good trade-off between spatial resolution and the strength of the extracted features, as features extracted further down the network encode stronger image features at the cost of spatial resolution. Choosing the optimal feature extraction layer requires empirical analysis. You can use `analyzeNetwork` to find the names of other potential feature extraction layers within a network.

```
featureLayer = "activation_40_relu";
```

Define the number of classes to detect.

```
numClasses = width(vehicleDataset)-1;
```

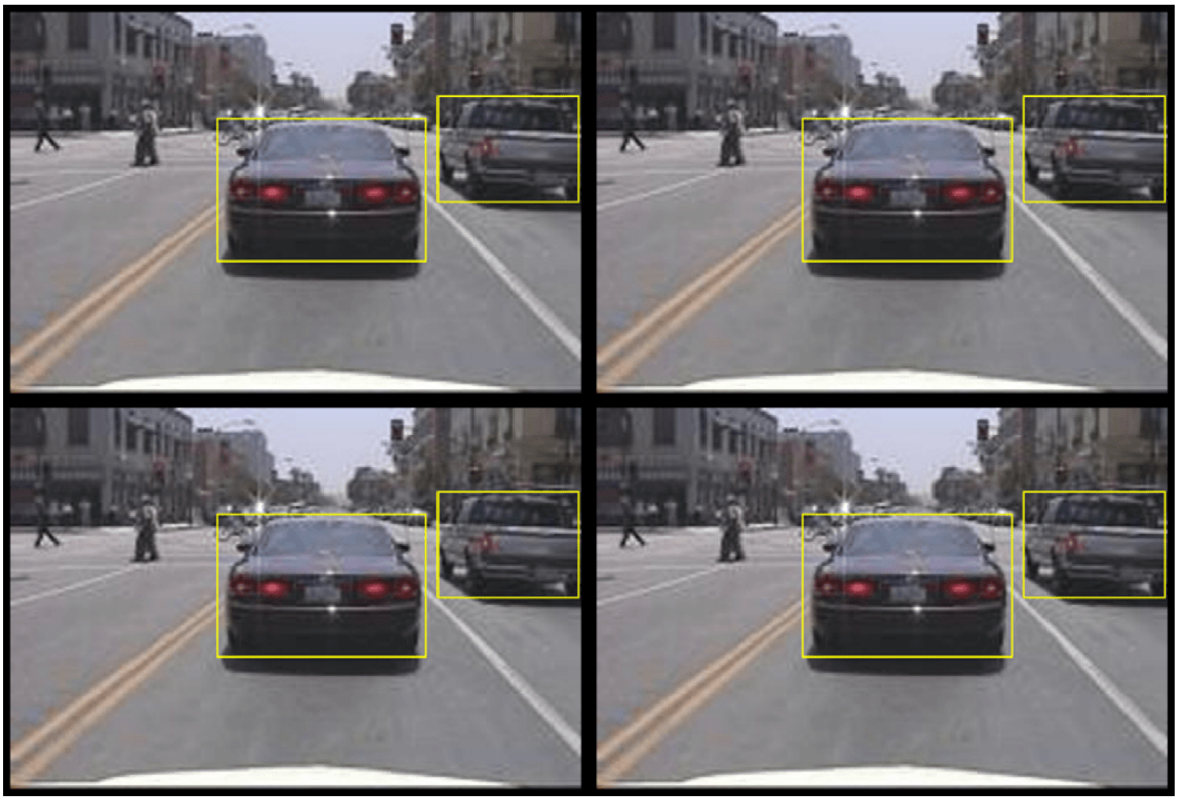
Create the Faster R-CNN object detection network.

```
lgraph = fasterRCNNLayers(inputSize,numClasses,anchorBoxes,featureExtractionNetwork,featureLayer
```

You can visualize the network using `analyzeNetwork` or Deep Network Designer from Deep Learning Toolbox™.

If more control is required over the Faster R-CNN network architecture, use Deep Network Designer to design the Faster R-CNN detection network manually. For more information, see “Getting Started with R-CNN, Fast R-CNN, and Faster R-CNN”.

Data Augmentation



Data augmentation is used to improve network accuracy by randomly transforming the original data during training. By using data augmentation, you can add more variety to the training data without actually having to increase the number of labeled training samples.

Use `transform` to augment the training data by randomly flipping the image and associated box labels horizontally. Note that data augmentation is not applied to test and validation data. Ideally, test and validation data are representative of the original data and are left unmodified for unbiased evaluation.

```
augmentedTrainingData = transform(trainingData,@augmentData);
```

Read the same image multiple times and display the augmented training data.

```
augmentedData = cell(4,1);
for k = 1:4
    data = read(augmentedTrainingData);
    augmentedData{k} = insertShape(data{1},"rectangle",data{2});
    reset(augmentedTrainingData);
end
figure
montage(augmentedData,BorderSize=10)
```

Preprocess Training Data

Preprocess the augmented training data, and the validation data to prepare for training.

```
trainingData = transform(augmentedTrainingData,@(data)preprocessData(data,inputSize));
validationData = transform(validationData,@(data)preprocessData(data,inputSize));
```

Read the preprocessed data.

```
data = read(trainingData);
```

Display the image and box bounding boxes.

```
I = data{1};
bbox = data{2};
annotatedImage = insertShape(I,"rectangle",bbox);
annotatedImage = imresize(annotatedImage,2);
figure
imshow(annotatedImage)
```

Train Faster R-CNN

Use `trainingOptions` to specify network training options. Set `"ValidationData"` to the preprocessed validation data. Set `"CheckpointPath"` to a temporary location. This enables the saving of partially trained detectors during the training process. If training is interrupted, such as by a power outage or system failure, you can resume training from the saved checkpoint.

```
options = trainingOptions("sgdm",...
    MaxEpochs=10,...
    MiniBatchSize=2,...
    InitialLearnRate=1e-3,...
    CheckpointPath=tempdir,...
    ValidationData=validationData);
```

Use `trainFasterRCNNObjectDetector` to train Faster R-CNN object detector if `doTraining` is true. Otherwise, load the pretrained network.

```
if doTraining
    % Train the Faster R-CNN detector.
    % * Adjust NegativeOverlapRange and PositiveOverlapRange to ensure
    %   that training samples tightly overlap with ground truth.
    [detector, info] = trainFasterRCNNObjectDetector(trainingData,lgraph,options, ...
        NegativeOverlapRange=[0 0.3], ...
        PositiveOverlapRange=[0.6 1]);
else
    % Load pretrained detector for the example.
    pretrained = load("fasterRCNNResNet50EndToEndVehicleExample.mat");
    detector = pretrained.detector;
end
```

This example was verified on an Nvidia(TM) Titan X GPU with 12 GB of memory. Training the network took approximately 20 minutes. The training time varies depending on the hardware you use.

As a quick check, run the detector on one test image. Make sure you resize the image to the same size as the training images.

```
I = imread(testDataTbl.imageFilename{3});
I = imresize(I,inputSize(1:2));
[bboxes,scores] = detect(detector,I);
```

Display the results.

```
I = insertObjectAnnotation(I,"rectangle",bboxes,scores);
figure
imshow(I)
```

Evaluate Detector Using Test Set

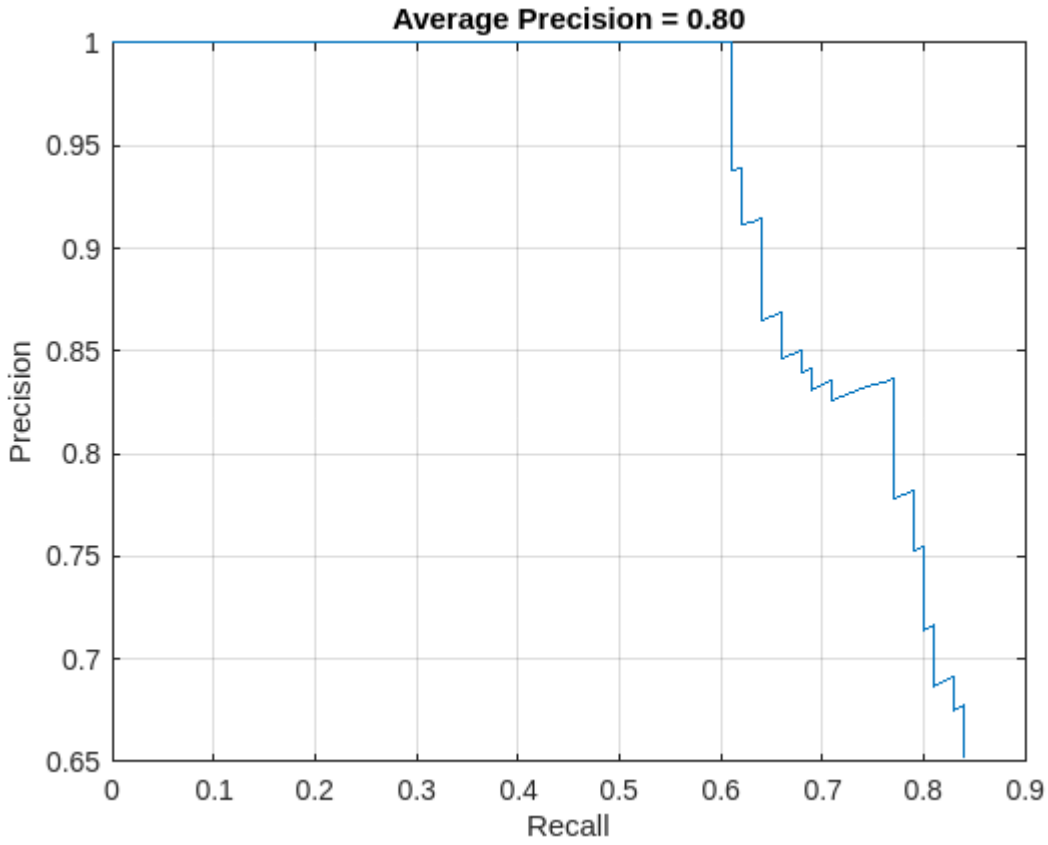
Evaluate the trained object detector on a large set of images to measure the performance. Computer Vision Toolbox™ provides an object detector evaluation function (`evaluateObjectDetection`) to measure common metrics such as average precision and log-average miss rate. For this example, use the average precision metric to evaluate performance. The average precision provides a single number that incorporates the ability of the detector to make correct classifications (precision) and the ability of the detector to find all relevant objects (recall).

Apply the same preprocessing transform to the test data as for the training data.

```
testData = transform(testData,@(data)preprocessData(data,inputSize));
```

Run the detector on all the test images. Set the detection threshold to a low value to detect as many objects as possible. This helps you evaluate the detector precision across the full range of recall values.

```
detectionResults = detect(detector,testData,...
    Threshold=0.2,...
    MiniBatchSize=4);
```



Evaluate the object detector using the average precision metric.

```
metrics = evaluateObjectDetection(detectionResults,testData);
[precision,recall] = precisionRecall(metrics,ClassName="vehicle");
AP = averagePrecision(metrics,ClassName="vehicle");
```

The precision-recall (PR) curve highlights how precise a detector is at varying levels of recall. The ideal precision is 1 at all recall levels. The use of more data can help improve the average precision but might require more training time. Plot the PR curve.

```
figure
plot(recall{:},precision{:})
xlabel("Recall")
ylabel("Precision")
```

```
grid on
title(sprintf("Average Precision = %.2f", AP))
```

Supporting Functions

```
function data = augmentData(data)
% Randomly flip images and bounding boxes horizontally.
tform = randomAffine2d("XReflection",true);
sz = size(data{1});
rout = affineOutputView(sz,tform);
data{1} = imwarp(data{1},tform,"OutputView",rout);

% Sanitize boxes, if needed. This helper function is attached as a
% supporting file. Open the example in MATLAB to open this function.
data{2} = helperSanitizeBoxes(data{2});

% Warp boxes.
data{2} = bboxwarp(data{2},tform,rout);
end

function data = preprocessData(data,targetSize)
% Resize image and bounding boxes to targetSize.
sz = size(data{1},[1 2]);
scale = targetSize(1:2)./sz;
data{1} = imresize(data{1},targetSize(1:2));
```

```
% Sanitize boxes, if needed. This helper function is attached as a
% supporting file. Open the example in MATLAB to open this function.
data{2} = helperSanitizeBoxes(data{2});

% Resize boxes.
data{2} = bboxresize(data{2},scale);
end
```

Version History

Introduced in R2017a

R2024b: Not Recommended

Not recommended starting in R2024b

Starting in R2024b, R-CNN object detectors are no longer recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` object. These object detectors are faster than R-CNN object detectors. For more information, see “Choose an Object Detector”.

maskrcnn

Detect objects using Mask R-CNN instance segmentation

Description

The `maskrcnn` object performs instance segmentation of objects in an image using a Mask R-CNN (regions with convolution neural networks) object detector. To detect objects in an image, pass the trained detector to the `segmentObjects` function.

Note This function requires the Computer Vision Toolbox Model for Mask R-CNN Instance Segmentation. You can install the Computer Vision Toolbox Model for Mask R-CNN Instance Segmentation from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons. To run this function, you will require the Deep Learning Toolbox.

Creation

Syntax

```
detector = maskrcnn("resnet50-coco")
detector = maskrcnn("resnet50-coco",classNames)
detector = maskrcnn("resnet50-coco",classNames,anchorBoxes)
detector = maskrcnn( ___ ,Name=Value)
```

Description

`detector = maskrcnn("resnet50-coco")` loads a pretrained Mask R-CNN object detector trained on the COCO data set with a ResNet-50 network as the feature extractor.

`detector = maskrcnn("resnet50-coco",classNames)` creates a pretrained Mask R-CNN object detector and configures it to perform transfer learning using a specified set of object classes. The `classNames` argument sets the `ClassNames` property. For optimal results, train the detector on new training images before performing detection.

`detector = maskrcnn("resnet50-coco",classNames,anchorBoxes)` creates a pretrained Mask R-CNN object detector and configures it to perform transfer learning using a specified set of object classes and anchor boxes. The `classNames` argument sets the `ClassNames` property. The `anchorBoxes` argument sets the `AnchorBoxes` property.

`detector = maskrcnn( ___ ,Name=Value)` uses name-value arguments to specify ROI pooling sizes or to set the `ModelName` or `InputSize` properties. Specify name-value arguments in addition to the input arguments from any of the previous syntaxes.

For example, `maskrcnn("resnet50-coco",classNames,anchorBoxes,PoolSize=[11 11])` specifies the ROI pooling size for the detection head as 11-by-11 pixels.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `maskrcnn("resnet50-coco",classNames,anchorBoxes,PoolSize=[11 11])` specifies the ROI pooling size for the detection head as 11-by-11 pixels.

`PoolSize` — ROI pooling size for detection head
`[14 14]` (default) | 1-by-2 vector

ROI pooling size for the detection head, specified as a 1-by-2 vector in the format [*height width*].

`MaskPoolSize` — ROI pooling size for mask segmentation head
`[14 14]` (default) | 1-by-2 vector

ROI pooling size for the mask segmentation head, specified as a 1-by-2 vector in the format [*height width*].

Properties

`ModelName` — Name of trained Mask R-CNN object detection network
`"maskrcnn"` | string scalar | character vector

Name of the trained Mask R-CNN object detection network, specified as a string scalar or character vector.

`AnchorBoxes` — Size of anchor boxes
M-by-2 matrix

Size of anchor boxes, specified as an *M*-by-2 matrix, where each row is in the format [*height width*]. The default value consists of 15 anchor boxes defined by the MS-COCO data set. When you specify the anchor boxes, the `maskrcnn` object reinitializes the final convolution layers in the region proposal subnetwork to the correct size based on the number of anchor boxes.

You cannot modify the value of this property after you create the object.

`ClassNames` — Object class names
cell array

Names of the object classes that the Mask R-CNN detector is trained to detect, specified as a cell array. The default value consists of the 80 object class names in the MS-COCO data set, such as "person", "bicycle", and "car". When you specify the class names, the `maskrcnn` object reinitializes the final convolution layers in the detection head and mask segmentation head to the correct size based on the number of classes.

You cannot modify the value of this property after you create the object.

`InputSize` — Image size
`[800 1200 3]` | 1-by-3 vector

Image size to use for detection, specified as a 1-by-3 vector of positive integers in the format [*height width* 3]. The detector resizes input images to this size while maintaining the aspect ratio. The default value is the network input size.

You cannot modify the value of this property after you create the object.

Object Functions

forward	Run forward pass on Mask R-CNN network
segmentObjects	Segment objects using Mask R-CNN instance segmentation

Examples

Segment Instances of Objects

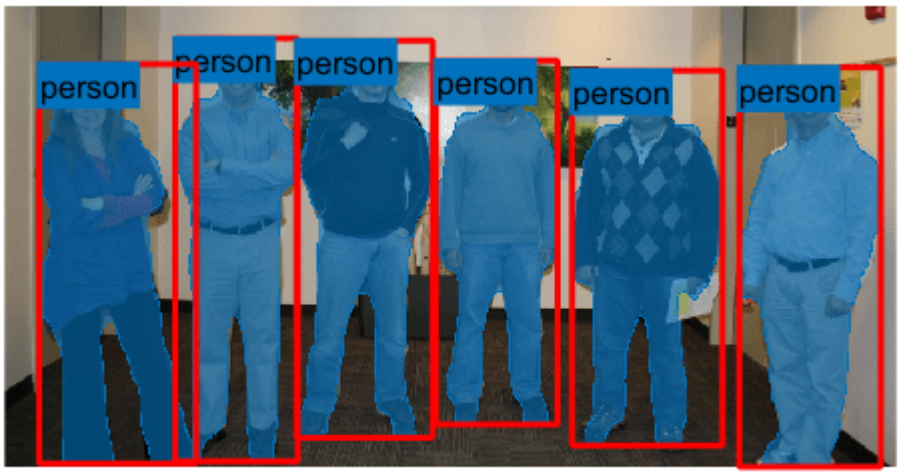
Load a pretrained Mask R-CNN object detector.

```
detector = maskrcnn("resnet50-coco")
```

```
detector =
  maskrcnn with properties:

      ModelName: 'maskrcnn'
     ClassNames: {1×80 cell}
      InputSize: [800 1200 3]
    AnchorBoxes: [15×2 double]
```

Read a test image that includes objects that the network can detect, such as people.



```
I = imread("visionteam.jpg");
```

Segment instances of objects using the Mask R-CNN object detector.

```
[masks,labels,scores,boxes] = segmentObjects(detector,I,Threshold=0.95);
```

Overlay the detected object masks in blue on the test image. Display the bounding boxes in red and the object labels.

```
overlayedImage = insertObjectMask(I,masks);
imshow(overlayedImage)
showShape("rectangle",boxes,Label=labels,LineColor=[1 0 0])
```

Version History

Introduced in R2021b

Functions

`trainMaskRCNN` | `evaluateInstanceSegmentation`

Topics

“Getting Started with Mask R-CNN for Instance Segmentation”

“Perform Instance Segmentation Using Mask R-CNN”

forward

Run forward pass on Mask R-CNN network

Syntax

```
[dlRPNScores,dlRPNReg,dlProposals,dlBoxScores,dlBoxReg,dlMasks] = forward(
detector,dlX)
[dlRPNScores,dlRPNReg,dlProposals,dlBoxScores,dlBoxReg,dlMasks,state] =
forward(detector,dlX)
```

Description

`[dlRPNScores,dlRPNReg,dlProposals,dlBoxScores,dlBoxReg,dlMasks] = forward( detector,dlX)` calculates features of the image `dlX` from the output layers of the Mask R-CNN object detector.

`[dlRPNScores,dlRPNReg,dlProposals,dlBoxScores,dlBoxReg,dlMasks,state] = forward(detector,dlX)` also returns the state information of the network. Use the state to update the network parameters.

Note This function requires the Computer Vision Toolbox Model for Mask R-CNN Instance Segmentation. You can install the Computer Vision Toolbox Model for Mask R-CNN Instance Segmentation from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons. To run this function, you will require the Deep Learning Toolbox.

Examples

Calculate Features of Color Image

Load a pretrained Mask R-CNN object detector.

```
detector = maskrcnn("resnet50-coco");
```

Read an image to use for training, and convert the image to a formatted `dlarray` object.

```
I = imread("visionteam.jpg");
dlX = dlarray(single(I),"SSCB");
```

Calculate features of the training image.

```
[dlRPNScores,dlRPNReg,dlProposals,dlBoxScores,dlBoxReg,dlMasks] = forward(detector,dlX);
```

Input Arguments

`detector` — Mask R-CNN object detector

`maskrcnn` object

Mask R-CNN object detector, specified as a `maskrcnn` object.

`dlX` — Training data
formatted `dlarray` object

Training data, specified as a formatted `dlarray` object containing real, nonsparse data. The dimension labels of the data must be `"SSCB"`.

Output Arguments

`dlRPNScores` — RPN classification output
`dlarray` object

RPN classification output after the softmax operation, returned as a `dlarray` object of size *h*-by-*w*-by-*numAnchors*-by-*B*. The feature map has spatial size *h*-by-*w*. *B* is the number of images in the batch.

`dlRPNReg` — RPN regression output
`dlarray` object

RPN regression output, returned as a `dlarray` object of size *h*-by-*w*-by-(4×*numAnchors*)-by-*B*. The feature map has spatial size *h*-by-*w*. *B* is the number of images in the batch.

`dlProposals` — Region proposals
`dlarray` object

Region proposals, returned as a `dlarray` object of size 5-by-*numProposals*-by-1-by-1. Each column of the proposals contains a box proposal in the format [*xStart, yStart, xEnd, yEnd, batchIdx*].

`dlBoxScores` — Detection network classification output
`dlarray` object

Detection network classification output after the softmax operation, returned as a `dlarray` object of size 1-by-1-by-(*numClasses*+1)-by-*numProposals*.

`dlBoxReg` — Detection network regression output
`dlarray` object

Detection network regression output, returned as a `dlarray` object of size 1-by-1-by-(4×*numClasses*)-by-*numProposals*.

`dlMasks` — Mask segmentation output
`dlarray` object

Mask segmentation output, returned as a `dlarray` object of size h_{mask}-by-w_{mask}-by-*numClasses*-by-*numProposals*. The mask segmentation output has spatial size h_{mask}-by-w_{mask}.

`state` — Updated network state
table

Updated network state, returned as a table. The network state is a table with three columns:

- `Layer` – Layer name, returned as a string scalar.
- `Parameter` – Parameter name, returned as a string scalar.

- `Value` – Value of parameter, returned as a numeric array object.

The network state contains information remembered by the network between iterations.

Version History

Introduced in R2021b

R2022a: Features returned in different format

Behavior changed in R2022a

The `forward` function now returns the feature maps for the six output layers in separate output arguments. Before, the function returned the feature maps as a 1-by-6 cell array in a single output argument.

See Also

`maskrcnn` | `segmentObjects`

segmentObjects

Segment objects using Mask R-CNN instance segmentation

Syntax

```
masks = segmentObjects(detector,I)
[masks,labels] = segmentObjects(detector,I)
[masks,labels,scores] = segmentObjects(detector,I)
[masks,labels,scores,bboxes] = segmentObjects(detector,I)

dsResults = segmentObjects(detector,imds)

[___] = segmentObjects(___,Name=Value)
```

Description

`masks = segmentObjects(detector,I)` detects object masks within a single image or an array of images, `I`, using a Mask R-CNN object detector.

`[masks,labels] = segmentObjects(detector,I)` also returns the labels assigned to the detected objects.

`[masks,labels,scores] = segmentObjects(detector,I)` also returns the detection score for each of the detected objects.

`[masks,labels,scores,bboxes] = segmentObjects(detector,I)` also returns the location of segmented object as bounding boxes, `bboxes`.

`dsResults = segmentObjects(detector,imds)` performs instance segmentation of images in a datastore using a Mask R-CNN object detector. The function returns a datastore with the instance segmentation results, including the instance masks, labels, detection scores, and bounding boxes.

`[___] = segmentObjects(___,Name=Value)` configures the segmentation using additional name-value arguments. For example, `segmentObjects(detector,I,Threshold=0.9)` specifies the detection threshold as `0.9`.

Note This function requires the Computer Vision Toolbox Model for Mask R-CNN Instance Segmentation. You can install the Computer Vision Toolbox Model for Mask R-CNN Instance Segmentation from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons. To run this function, you will require the Deep Learning Toolbox.

Examples

Segment Instances of Objects

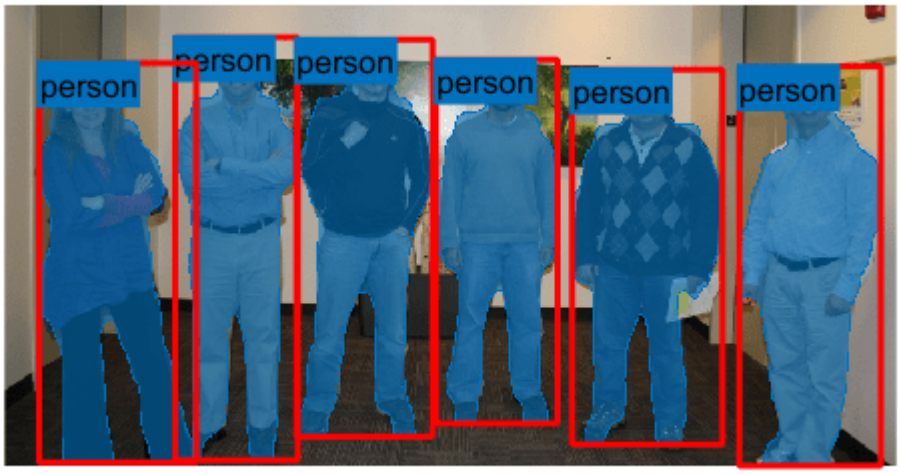
Load a pretrained Mask R-CNN object detector.

```
detector = maskrcnn("resnet50-coco")
```

```
detector =
  maskrcnn with properties:

      ModelName: 'maskrcnn'
     ClassNames: {1×80 cell}
      InputSize: [800 1200 3]
    AnchorBoxes: [15×2 double]
```

Read a test image that includes objects that the network can detect, such as people.



```
I = imread("visionteam.jpg");
```

Segment instances of objects using the Mask R-CNN object detector.

```
[masks,labels,scores,boxes] = segmentObjects(detector,I,Threshold=0.95);
```

Overlay the detected object masks in blue on the test image. Display the bounding boxes in red and the object labels.

```
overlayedImage = insertObjectMask(I,masks);
imshow(overlayedImage)
showShape("rectangle",boxes,Label=labels,LineColor=[1 0 0])
```

Segment Instances of Objects in Image Datastore

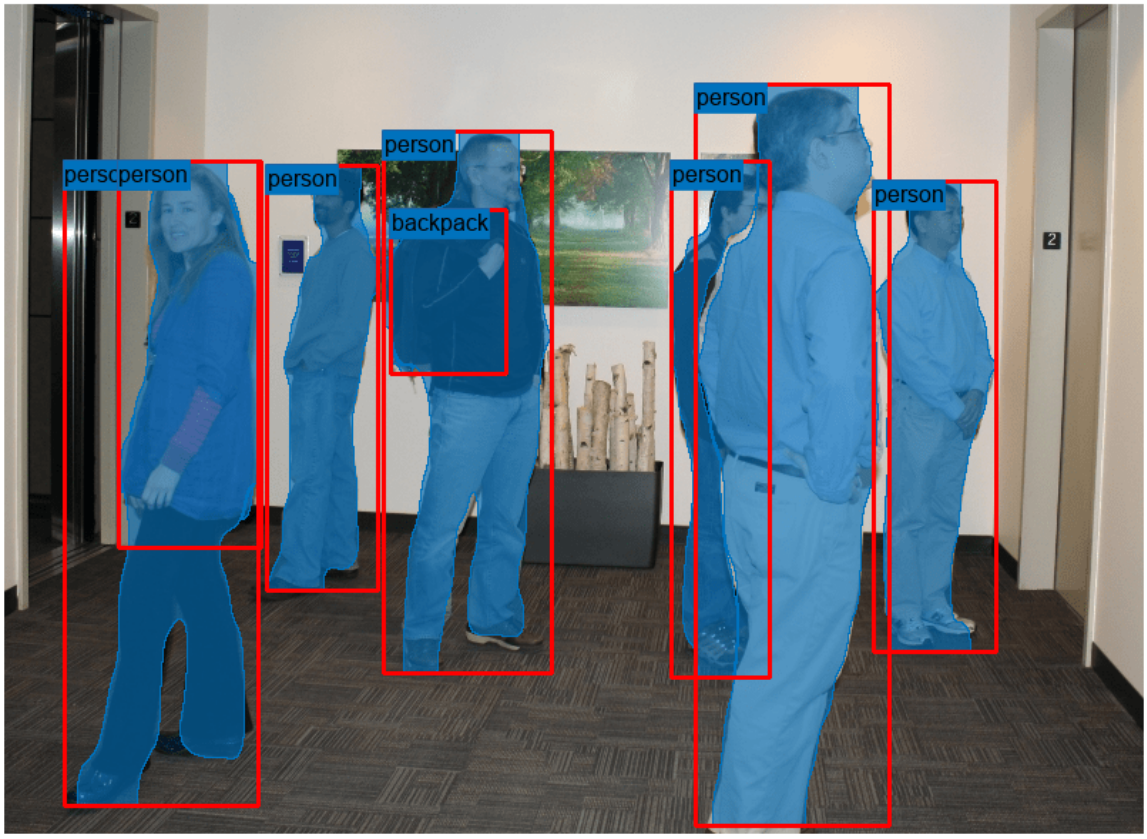
Load a pretrained Mask R-CNN object detector.

```
detector = maskrcnn("resnet50-coco");
```

Create a datastore of test images.

```
imageFiles = fullfile(toolboxdir("vision"),"visiondata","visionteam*.jpg");
dsTest = imageDatastore(imageFiles);
```

Segment instances of objects using the Mask R-CNN object detector.



```
dsResults = segmentObjects(detector,dsTest);
```

```
Running Mask R-CNN network
-------------------------
* Processed 2 images.
```

For each test image, display the instance segmentation results. Overlay the detected object masks in blue on the test image. Display the bounding boxes in red and the object labels.

```
while(hasdata(dsResults))
    testImage = read(dsTest);
    results = read(dsResults);
    overlayedImage = insertObjectMask(testImage,results{1});
    figure
    imshow(overlayedImage)
    showShape("rectangle",results{4},Label=results{2},LineColor=[1 0 0])
end
```

Input Arguments

`detector` — Mask R-CNN object detector

`maskrcnn` object

Mask R-CNN object detector, specified as a `maskrcnn` object.

`I` — Image or batch of images

numeric matrix | numeric array

Image or batch of images to segment, specified as one of these values.

Image Type	Data Format
Single grayscale image	2-D matrix of size *H*-by-*W*
Single color image	3-D array of size *H*-by-*W*-by-3.
Batch of *B* grayscale or color images	4-D array of size *H*-by-*W*-by-*C*-by-*B*. The number of color channels *C* is 1 for grayscale images and 3 for color images.

The height *H* and width *W* of each image must be greater than or equal to the input height *h* and width *w* of the network.

`imds` — Datastore of images
datastore

Datastore of images, specified as a datastore such as an `imageDatastore` or a `CombinedDatastore`. If calling the datastore with the `read` function returns a cell array, then the image data must be in the first cell.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `segmentObjects(detector,I,Threshold=0.9)` specifies the detection threshold as `0.9`.

Options for All Image Formats

`Threshold` — Detection threshold
`0.7` (default) | numeric scalar

Detection threshold, specified as a numeric scalar in the range [0, 1]. The Mask R-CNN object detector does not return detections with scores less than the threshold value. Increase this value to reduce false positives.

`NumStrongestRegions` — Maximum number of strongest region proposals
`1000` (default) | positive integer | `Inf`

Maximum number of strongest region proposals, specified as a positive integer. Reduce this value to speed up processing time at the cost of detection accuracy. To use all region proposals, specify this value as `Inf`.

`SelectStrongest` — Select strongest bounding box
`true` or `1` (default) | `false` or `0`

Select the strongest bounding box for each detected object, specified as a numeric or logical `1` (`true`) or `0` (`false`).

- `true` — Return the strongest bounding box per object. To select these boxes, the `segmentObjects` function calls the `selectStrongestBboxMulticlass` function, which uses nonmaximal suppression to eliminate overlapping bounding boxes based on their confidence scores.
- `false` — Return all detected bounding boxes. You can then create your own custom operation to eliminate overlapping bounding boxes.

`MinSize` — Minimum size of region
`[1 1]` (default) | two-element numeric vector

Minimum size of a region containing an object, in pixels, specified as a two-element numeric vector of the form [*height width*]. By default, `MinSize` is the smallest object that the trained detector can detect. Specify this argument to reduce the computation time.

`MaxSize` — Maximum size of region
two-element numeric vector

Maximum size of a region containing an object, in pixels, specified as a two-element numeric vector of the form [*height width*].

To reduce computation time, set this value to the known maximum region size for the objects being detected in the image. By default, `MaxSize` is set to the height and width of the input image, `I`.

`ExecutionEnvironment` — Hardware resource

`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource for processing images with a network, specified as `"auto"`, `"gpu"`, or `"cpu"`.

`ExecutionEnvironment`	Description
`"auto"`	Use a GPU if available. Otherwise, use the CPU. The use of GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
`"gpu"`	Use the GPU. If a suitable GPU is not available, the function returns an error message.
`"cpu"`	Use the CPU.

Options for Datastore Inputs

`MiniBatchSize` — Number of observations in each batch

positive integer

Number of observations that are returned in each batch. The default value is equal to the `ReadSize` property of datastore `imds`.

You can specify this argument only when you specify a batch of images, `I`, or datastore of images, `imds`, as an input to the `segmentObjects` function.

`WriteLocation` — Location to place writable data

string scalar | character vector

Location to place writable data, specified as a string scalar or character vector. The specified folder must have write permissions. If the folder already exists, the `segmentObjects` function creates a new folder and adds a suffix to the folder name with the next available number. The default write location is `fullfile(pwd,"SegmentObjectResults")` where `pwd` is the current working directory.

You can specify this argument only when you specify a datastore of images, `imds`.

Data Types: `char` | `string`

`NamePrefix` — Prefix added to written filenames

`"segmentObj"` (default) | string scalar | character vector

Prefix added to written filenames, specified as a string scalar or character vector. The files are named *`NamePrefix_imageName.mat`*, where *`imageName`* is the name of the input image without its extension.

If `imds` contains identical file names in different folders, the function names the output files *`NamePrefix_folder_imageName.mat`*, where *`folder`* is the folder containing the files with the same name.

If `imds` contains identical file names in folders of the same name within different directory hierarchies, the function names the output files *`NamePrefix_folder_imageName_#.mat`*, where `#` is a distinct integer.

You can specify this argument only when you specify a datastore of images, `imds`.

Data Types: `char` | `string`

`Verbose` — Enable progress display to screen
`true` or `1` (default) | `false` or `0`

Enable progress display to screen, specified as a numeric or logical `1` (`true`) or `0` (`false`).

You can specify this argument only when you specify a datastore of images, `imds`.

Output Arguments

`masks` — Object masks
H-by-*W*-by-*M* logical array | *B*-by-1 cell array

Objects masks, returned as a logical array of size *H*-by-*W*-by-*M*. *H* and *W* are the height and width of the input image `I`. *M* is the number of objects detected in the image. Each of the *M* channels contains the mask for a single detected object.

When `I` represents a batch of *B* images, `masks` is returned as a *B*-by-1 cell array. Each element in the cell array indicates the masks for the corresponding input image in the batch.

`labels` — Object labels
M-by-1 categorical vector | *B*-by-1 cell array

Objects labels, returned as an *M*-by-1 categorical vector where *M* is the number of detected objects in image `I`.

When `I` represents a batch of *B* images, then `labels` is a *B*-by-1 cell array. Each element is an *M*-by-1 categorical vector with the labels of the objects in the corresponding image.

`scores` — Detection scores
M-by-1 vector | *B*-by-1 cell array

Detection confidence scores, returned as an *M*-by-1 numeric vector, where *M* is the number of detected objects in image `I`. A higher score indicates higher confidence in the detection.

When `I` represents a batch of *B* images, then `scores` is a *B*-by-1 cell array. Each element is an *M*-by-1 numeric vector with the labels of the objects in the corresponding image.

`bboxes` — Location of detected objects
M-by-4 matrix | *B*-by-1 cell array

Location of detected objects within the input image, returned as an *M*-by-4 matrix, where *M* is the number of detected objects in image `I`. Each row of `bboxes` contains a four-element vector of the

form [*x y width height*]. This vector specifies the upper left corner and size of that corresponding bounding box in pixels.

When `I` represents a batch of *B* images, then `bboxes` is a *B*-by-1 cell array. Each element is an *M*-by-4 numeric matrix with the bounding boxes of the objects in the corresponding image.

`dsResults` — Predicted instance segmentation
`FileDatastore` object

Predicted instance segmentation results, returned as a `FileDatastore` object. The datastore is set up so that calling the datastore with the `read` and `readall` functions returns a cell array with four columns. This table describes the format of each column.

data	***boxes***	***labels***	***masks***
RGB image that serves as a network input, returned as an *H*-by-*W*-by-3 numeric array.	Bounding boxes, returned as *M*-by-4 matrices, where *M* is the number of objects within the image. Each bounding box has the format [*x y width height*], where [*x*, *y*] represent the top-left coordinates of the bounding box.	Object class names, returned as an *M*-by-1 categorical vector. All categorical data returned by the datastore must contain the same categories.	Binary masks, returned as a logical array of size *H*-by-*W*-by-*M*. Each mask is the segmentation of one instance in the image.

Version History

Introduced in R2021b

R2022b: Supports datastores

The `segmentObjects` function now supports specifying test images as a datastore. New name-value arguments enable more options to configure the segmentation of images in a datastore. When you specify test images as a datastore, the function returns all instance segmentation results as a file datastore.

posemaskrcnn

Predict object pose using Pose Mask R-CNN pose estimation

Description

The `posemaskrcnn` object performs pose estimation of objects in an image using a pretrained Pose Mask R-CNN network, a region-based convolutional neural network designed for six degrees-of-freedom (6-DoF) pose estimation.

Note This functionality requires Deep Learning Toolbox and the Computer Vision Toolbox Model for Pose Mask R-CNN 6-DoF Object Pose Estimation. You can install the Computer Vision Toolbox Model for Pose Mask R-CNN 6-DoF Object Pose Estimation from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Creation

Syntax

```
net = posemaskrcnn(pretrainedNet)
net = posemaskrcnn(pretrainedNet,classNames)
net = posemaskrcnn(pretrainedNet,classNames,anchorBoxes)
net = posemaskrcnn( ___ ,Name=Value)
```

Description

`net = posemaskrcnn(pretrainedNet)` creates a pretrained Pose Mask R-CNN pose estimation network `net` by using the specified pretrained Pose Mask R-CNN deep learning network.

`net = posemaskrcnn(pretrainedNet,classNames)` creates a pretrained Pose Mask R-CNN pose estimation network, and configures it to perform transfer learning using a set of object classes specified by the `classNames` argument. For optimal results, train the network on new training data before performing pose estimation.

`net = posemaskrcnn(pretrainedNet,classNames,anchorBoxes)` creates a pretrained Pose Mask R-CNN network, and configures it to perform transfer learning using a set of object classes and anchor boxes specified by the `classNames` and `anchorBoxes` arguments, respectively. For optimal results, train the network on new training data before performing pose estimation.

`net = posemaskrcnn( ___ ,Name=Value)` specifies options using name-value arguments to specify ROI pooling sizes in addition to any combination of input arguments from previous syntaxes. You can also use name-value arguments to set the `ModelName` and `ImageInputSize` properties.

For example, `PoolSize=[11 11]` specifies the ROI pooling size for the detection head as 11-by-11 pixels.

Input Arguments

`pretrainedNet` — Pretrained Pose Mask R-CNN deep learning network

`"resnet50-pvc-parts"` | `"resnet50-coco"`

Pretrained Pose Mask R-CNN deep learning network, specified as one of these:

- `"resnet50-pvc-parts"` — A pretrained Pose Mask R-CNN deep learning network trained on images of PVC pipe connectors in various orientations. You can use the resulting pose estimation network to perform pose estimation on a custom bin-picking data set by using the `predictPose` object function.
- `"resnet50-coco"` — A pretrained Pose Mask R-CNN deep learning network which uses weights from a Mask R-CNN deep learning network with ResNet-50 as a backbone, trained on the COCO data set for instance segmentation. To train a pose estimation network created using this pretrained deep learning network, you must use the `trainPoseMaskRCNN` function in two stages: first with a `trainingMode` argument value of `"mask"`, and then with a `trainingMode` value of `"pose-and-mask"`.

Data Types: `char` | `string`

`classNames` — Names of object classes

vector of strings | cell array of character vectors | categorical vector

Names of the object classes that the Pose Mask R-CNN network is trained to estimate pose for, specified as a vector of strings, cell array of character vectors, or categorical vector. This argument sets the `ClassNames` property of the `posemaskrcnn` object.

Data Types: `string` | `cell` | `categorical`

`anchorBoxes` — Sizes of anchor boxes

M-by-2 matrix

Sizes of the anchor boxes, specified as an *M*-by-2 matrix, where each row is of the form [*height width*], in pixels. *M* is the number of anchor boxes. You can estimate the anchor boxes using the `estimateAnchorBoxes` function. This argument sets the `AnchorBoxes` property of the `posemaskrcnn` object.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `posemaskrcnn("resnet50-pvc-parts",classNames,anchorBoxes,PoolSize=[11 11])` specifies the ROI pooling size for the detection head as 11-by-11 pixels.

`PoolSize` — ROI pooling size for detection head

`[14 14]` (default) | 2-element row vector

ROI pooling size for the detection head, specified as a 2-element row vector of the form [*height width*]. Adjust the `PoolSize` value when your data set contains extreme variation in the scale of objects or images.

`MaskPoolSize` — ROI pooling size for mask segmentation head

`[14 14]` (default) | 2-element row vector

ROI pooling size for the mask segmentation head, specified as a 2-element row vector of the form [*height width*]. Adjust the `MaskPoolSize` value when your data contains extreme variation in the scale in the objects or images.

Properties

`ModelName` — Name of pretrained Pose Mask R-CNN pose estimation network

`"posemaskrcnn"` (default) | string scalar | character vector

This property is read-only.

Name of the pretrained Pose Mask R-CNN pose estimation network, specified as a string scalar or character vector.

To set the value of this property, you must specify it at object creation.

`AnchorBoxes` — Sizes of anchor boxes

M-by-2 matrix

This property is read-only.

Sizes of the anchor boxes, specified as an *M*-by-2 matrix where each row is of the form [*height width*], in pixels. The default value of this property depends on the specified value of `pretrainedNet`:

- `"resnet50-pvc-parts"` — An 8-by-2 matrix of anchor box values.
- `"resnet50-coco"` — A 15-by-2 matrix of anchor box values.

When you specify anchor boxes, the `posemaskrcnn` object reinitializes the final convolution layers in the region proposal subnetwork to the correct size based on the number of anchor boxes *M*.

The `anchorBoxes` argument sets this property.

`ClassNames` — Object class names

vector of strings | cell array of character vectors | categorical vector

This property is read-only.

Names of the object classes that the Pose Mask R-CNN network is trained to estimate pose for, specified as a vector of strings, cell array of character vectors, or categorical vector. The default value of this property depends on the specified value of `pretrainedNet`:

- `"resnet50-pvc-parts"` — Four object class names that correspond to the four object orientations in the PVC pipe data set.
- `"resnet50-coco"` — Eighty object class names that correspond to various objects detected in the COCO data set.

When you specify class names, the `posemaskrcnn` object reinitializes the final convolution layers in the detection head and mask segmentation head to the correct size based on the number of classes.

The `classNames` argument sets this property.

`ImageInputSize` — Image size

`[720 1280 3]` (default) | 3-element row vector

This property is read-only.

Image size to use for pose estimation, specified as a 1-by-3 vector of positive integers of the form [*height width channels*]. The values of *height* and *width* specify the image dimensions, in pixels, and *channels* specifies the number of color channels. The network resizes input images to this size while maintaining the aspect ratio. The default value is the network input size.

To set the value of this property, you must specify it at object creation.

`DepthImageInputSize` — Depth image size
`[720 1280 1]` (default) | 3-element row vector

This property is read-only.

Depth image size used for pose estimation, specified as a 3-element row vector of positive integers of the form [*height width* `1`].

Object Functions

predictPose Estimate object pose using Pose Mask R-CNN deep learning network

Examples

Create Pretrained Pose Mask R-CNN Network

Create a pretrained Pose Mask R-CNN pose estimation network that was trained on images of PVC pipe connectors in various orientations.

```
net = posemaskrcnn("resnet50-pvc-parts")
```

```
net =
  posemaskrcnn with properties:

              ModelName: 'posemaskrcnn'
             ClassNames: {4×1 cell}
         ImageInputSize: [720 1280 3]
    DepthImageInputSize: [720 1280 1]
            AnchorBoxes: [8×2 double]
```

Display the names of the object classes.

```
net.ClassNames
```

```
ans = 4×1 cell array
    "'I_shape'"
    "'X_shape'"
    "'L_shape'"
    "'T_shape'"
```

predictPose

Estimate object pose using Pose Mask R-CNN deep learning network

Syntax

```
poses = predictPose(net,I,depthImage,intrinsics)
[poses,labels,scores,bboxes] = predictPose( ___ )
[poses,labels,scores,bboxes,masks] = predictPose( ___ )

[ ___ ] = predictPose( ___ ,Name=Value)
```

Description

`poses = predictPose(net,I,depthImage,intrinsics)` returns 6-degrees-of-freedom (6-DoF) pose of objects within a single image or a batch of images `I` using a trained Pose Mask R-CNN network.

`[poses,labels,scores,bboxes] = predictPose( ___ )` also returns the labels assigned to the detected objects, the detection score for each detected object, and the bounding box location of each detected object, using the input arguments from the previous syntax.

`[poses,labels,scores,bboxes,masks] = predictPose( ___ )` performs instance segmentation of the objects, and returns the binary object masks, `masks`.

`[ ___ ] = predictPose( ___ ,Name=Value)` specifies options using additional name-value arguments. For example, `Threshold=0.7` specifies the detection threshold as `0.7`.

Note This functionality requires Deep Learning Toolbox and the Computer Vision Toolbox Model for Pose Mask R-CNN 6-DoF Object Pose Estimation. You can install the Computer Vision Toolbox Model for Pose Mask R-CNN 6-DoF Object Pose Estimation from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Input Arguments

`net` — Pose Mask R-CNN pose estimation network

`posemaskrcnn` object

Pose Mask R-CNN pose estimation network, specified as a `posemaskrcnn` object.

`I` — Image or batch of images

numeric matrix | numeric array

Image to segment, specified as a numeric matrix or numeric array. The size of this argument depends on the number of images specified and whether they are color or grayscale.

Image Type and Number	Data Format
Single grayscale image	2-D matrix of size *H*-by-*W*

Image Type and Number	Data Format
Single color image	3-D array of size *H*-by-*W*-by-3.
Batch of *B* grayscale or color images	4-D array of size *H*-by-*W*-by-*C*-by-*B*. The number of color channels *C* is 1 for grayscale images and 3 for color images.

The height *H* and width *W* of each image must be greater than or equal to the input height *h* and width *w* of the network.

Tip For best network performance, use input image data of the same size that the network has been trained on.

`depthImage` — Depth map for estimating 3-D pose

numeric matrix | numeric array

Depth map for estimating the 3-D pose, specified as a numeric matrix or array. The size of this argument depends on the number of depth maps specified.

Number of Depth Maps	Data Format
Single depth map	2-D numeric matrix of size *H*-by-*W*.
Batch of *B* depth maps	4-D array of size *H*-by-*W*-by-1-by-*B*.

H and *W* must be equal to the corresponding values of `I`, and the number of depth maps must match the number of images specified.

`intrinsics` — Camera intrinsic parameters

`cameraIntrinsics` object | *B*-by-1 cell array of `cameraIntrinsics` objects

Camera intrinsic parameters, specified as a `cameraIntrinsics` object or a *B*-by-1 cell array of `cameraIntrinsics` objects. If you specify this value as a scalar, the function applies the same camera intrinsic parameters to every input image. If you specify this value as a cell array, the number of `cameraIntrinsics` objects must match the number of input images *B*.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `predictPose(net,I,depthImage,intrinsics,Threshold=0.7)` specifies the detection threshold as `0.7`.

Options for All Image Formats

`Threshold` — Object detection threshold

`0.5` (default) | numeric scalar

Object detection threshold, specified as a numeric scalar in the range [0, 1]. The Pose Mask R-CNN network does not use object detections with scores less than the threshold value for pose estimation. Increase this value to reduce false positives.

`NumStrongestRegions` — Maximum number of strongest region proposals
`1000` (default) | positive integer | `Inf`

Maximum number of strongest region proposals, specified as a positive integer or `Inf`. Reduce this value to increase processing speed at the cost of detection accuracy. To use all region proposals, specify this value as `Inf`.

`SelectStrongestMulticlassThreshold` — Strongest bounding box threshold per class
`0.5` (default) | numeric scalar

Strongest bounding box threshold per class, specified as a positive numeric scalar in the range [0, 1]. The strongest bounding boxes per class are returned when their confidence scores are higher than this value. To select these boxes, `predictPose` uses the `selectStrongestBboxMulticlass` function, which uses nonmaximal suppression to eliminate overlapping bounding boxes with the same class label based on their confidence scores.

Note `predictPose` first performs nonmaximal suppression using the `selectStrongestBboxMulticlass` function and the threshold value specified by `SelectStrongestMulticlassThreshold`. In the second step, `predictPose` performs nonmaximal suppression using the `selectStrongestBbox` function and the threshold value specified by `SelectStrongestThreshold`. You can manually determine the optimal threshold values for your application by using a validation data subset when training on a custom data set.

`SelectStrongestThreshold` — Strongest bounding box threshold per object
`0.3` (default) | numeric scalar

Strongest bounding box threshold per object, specified as a positive numeric scalar in the range [0, 1]. The strongest bounding boxes per object are returned when their confidence scores are higher than this value. To select these boxes, `predictPose` uses the `selectStrongestBbox` function, which uses nonmaximal suppression to eliminate overlapping bounding boxes based on their confidence scores across all classes.

Note `predictPose` first performs nonmaximal suppression using the `selectStrongestBboxMulticlass` function and the threshold value specified by `SelectStrongestMulticlassThreshold`. In the second step, `predictPose` performs nonmaximal suppression using the `selectStrongestBbox` function and the threshold value specified by `SelectStrongestThreshold`. You can manually determine the optimal threshold values for your application by using a validation data subset when training on a custom data set.

`MinSize` — Minimum size of object-containing region
`[1 1]` (default) | two-element numeric vector

Minimum size of an object-containing region, in pixels, specified as a two-element numeric vector of the form [*height width*]. `MinSize` is the size of the smallest object that the trained detector can detect. Specify larger values for this argument to reduce computation time.

`MaxSize` — Maximum size of object-containing region
two-element numeric vector

Maximum size of an of object-containing region, in pixels, specified as a two-element numeric vector of the form [*height width*].

To reduce computation time, set this value to the known maximum region size for the objects being detected in the image. By default, `MaxSize` uses the height and width of the input image `I`.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource for processing images with the network, specified as `"auto"`, `"gpu"`, or `"cpu"`.

`ExecutionEnvironment`	Description
`"auto"`	Use a GPU if available. Otherwise, use the CPU. The use of GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
`"gpu"`	Use the GPU. If a suitable GPU is not available, the function returns an error message.
`"cpu"`	Use the CPU.

Options for Batch Inputs

`MiniBatchSize` — Number of observations in each batch
1 (default) | positive integer

Number of observations returned in each batch, specified as a positive integer.

Output Arguments

`poses` — Object poses
M-by-1 vector of `rigidtform3d` objects | *B*-by-1 cell array

Object poses, returned as an *M*-by-1 vector of `rigidtform3d` objects or a *B*-by-1 cell array. The value of this output depends on the number of input images *B*.

Image Type	`poses` Value
Single image	*M*-by-1 vector of `rigidtform3d` objects. *M* is the number of objects detected in the image.
Batch of *B* images	*B*-by-1 cell array, where each cell contains an *M*-by-1 vector of `rigidtform3d` objects.

`labels` — Object labels
M-by-1 categorical vector | *B*-by-1 cell array

Object labels, returned as an *M*-by-1 categorical vector or a *B*-by-1 cell array. When `I` is a single image, `labels` is an *M*-by-1 categorical vector, where *M* is the number of detected objects in the image.

When `I` is a batch of *B* images, `labels` is a *B*-by-1 cell array in which each cell contains an *M*-by-1 categorical vector with the labels of the objects detected in the corresponding image.

`scores` — Detection confidence scores
M-by-1 numeric vector | *B*-by-1 cell array

Detection confidence scores, returned as an *M*-by-1 numeric vector, or a *B*-by-1 cell array. When `I` is a single image, `scores` is an *M*-by-1 numeric vector, where *M* is the number of detected objects in the image.

When `I` is a batch of *B* images, then `scores` is a *B*-by-1 cell array. Each element is an *M*-by-1 numeric vector with the scores of the objects detected in the corresponding image.

The score for each object is in the range [0, 1]. A higher score indicates higher confidence in the detection.

`bboxes` — Locations of detected objects
M-by-4 numeric matrix | *B*-by-1 cell array

Locations of detected objects within the input image, returned as an *M*-by-4 numeric matrix, or a *B*-by-1 cell array. When `I` is a single image, `bboxes` is an *M*-by-1 numeric matrix, where *M* is the number of detected objects in the image. Each row of the matrix is of the form [*x y width height*], where *x* and *y* specify the upper-left corner of the corresponding bounding box, and *width* and *height* specify its size in pixels.

When `I` is a batch of *B* images, `bboxes` is a *B*-by-1 cell array in which each cell contains an *M*-by-4 numeric matrix with the bounding boxes of the objects detected in the corresponding image.

`masks` — Object masks
H-by-*W*-by-*M* logical array | *B*-by-1 cell array

Object masks, returned as a *H*-by-*W*-by-*M* logical array or a *B*-by-1 cell array. When `I` is a single image, `masks` is an *H*-by-*W*-by-*M* logical array, where *H* and *W* are the height and width of the input image, respectively, and *M* is the number of detected objects in the image.

When `I` is a batch of *B* images, `masks` is a *B*-by-1 cell array in which each cell contains an *H*-by-*W*-by-*M* logical array with the masks for the corresponding image.

Tips

- To refine estimated object poses predicted by the network, use point cloud registration techniques to postprocess your results, especially for objects of a symmetric shape. To learn more about refining pose estimation results, see the “Perform 6-DoF Pose Estimation for Bin Picking Using Deep Learning” example.

reidentificationNetwork

Re-identification deep learning network for re-identifying and tracking objects

Description

The `reidentificationNetwork` object configures a re-identification (ReID) deep learning network to extract features and train with a new set of classes. You can use the configured ReID network to re-identify objects in a sequence of image frames.

Note This functionality requires Deep Learning Toolbox.

Creation

Syntax

```
reID = reidentificationNetwork(backbone,classNames)
reID = reidentificationNetwork( ___ ,Name=Value)
```

Description

`reID = reidentificationNetwork(backbone,classNames)` creates a ReID network and configures it to perform transfer learning using a set of object classes specified by the `classNames` argument. For optimal performance, train the network on new training data using the `trainReidentificationNetwork` function.

`reID = reidentificationNetwork( ___ ,Name=Value)` specifies options using name-value arguments in addition to the input arguments from the previous syntax. You can also use name-value arguments to set the `ModelName`, `InputSize`, `FeatureLength`, and `FeatureLayer` properties of the network.

For example, `InputSize=[460 460 3]` sets the size of image used for classification and re-identification.

Input Arguments

backbone — Backbone feature extraction network
`dlnetwork` object

Backbone feature extraction network with an image input layer, specified as a `dlnetwork` object. The network must have a layer that produces an array with only one non-singleton dimension. If you do not specify the `FeatureLayer` property `reidentificationNetwork` appends the classification head network to the last layer in the network that meets the singleton criteria.

classNames — Names of object classes
vector of strings | cell array of character vectors | categorical vector

Names of the object classes that the ReID network is trained to re-identify, specified as a vector of strings, cell array of character vectors, or categorical vector. This argument sets the `ClassNames` property of the `reidentificationNetwork` object.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `reidentificationNetwork(net,classNames,InputSize=[460 460 3])` sets the size of image used for classification and re-identification.

`ClassificationNetwork` — Classification layers

`dlnetwork` object

Classification layers in the final layers of the ReID network, specified as a `dlnetwork` object. The classification layers contain these components by default: a batch normalization layer, a ReLU layer, a dropout layer, and a custom layer that contains a fully connected layer corresponding to the total number of classes and a softmax layer. The specified network must contain a fully connected layer and be able to process features output by the feature extraction layer `FeatureLayer`. The ReID network uses the output of the `ClassificationNetwork` layers for classification training.

`NormalizationStatistics` — Normalization statistics

1-by-1 structure (default) | structure

Normalization statistics, specified as a structure with mean and standard deviation fields. The structure must contain the fields `Mean` and `StandardDeviation`, which specify the means and standard deviations per channel, respectively, as 1-by-*C* vectors. The input image layer `imageInputLayer` of the backbone network `network` specifies which normalization method to use.

When `InputSize` is different than the `imageInputLayer` of the backbone network, `NormalizationStatistics` is a structure with these fields, which contain values from the COCO data set:

Field	Description	Value
`Mean`	1-by-*C* vector of means per channel.	`[123.6750 116.2800 103.5300]`
`StandardDeviation`	1-by-*C* vector of standard deviations per channel.	`[58.3950 57.1200 57.3750]`

The number of channels *C* must match the number of channels in the image specified by `InputSize`.

Properties

`ModelName` — Name of ReID network

`"ReidentificationNetwork"` (default) | string scalar | character vector

This property is read-only.

Name of the ReID network, specified as a string scalar or character vector.

To set the value of this property, you must specify it at object creation.

`Network` — Configured ReID network

`dlnetwork` object

This property is read-only.

Configured ReID network, stored as a `dlnetwork` object.

`InputSize` — Input image size

1-by-3 vector

This property is read-only.

Input image size to use for classification and re-identification, specified as a 1-by-3 vector of positive integers [*height width channels*]. The values of *height* and *width* specify the image dimensions, in pixels, and *channels* specifies the number of color channels. The network resizes input images to this size. The default value is the network input size.

To set the value of this property, you must specify it at object creation.

`ClassNames` — Object class names

vector of strings | cell array of character vectors | categorical vector

This property is read-only.

Names of the object classes that the ReID network is trained to re-identify, specified as a cell array, categorical vector, or cell array of character vectors.

`FeatureLayer` — Feature extraction layer

character vector | string scalar

This property is read-only.

Feature extraction layer of the backbone ReID network, specified as a character vector or a string scalar. This layer returns the appearance feature vectors when you use the `extractReidentificationFeatures` function. The default feature extraction layer is a fully connected layer named `"fc_num_features"` with an output size specified by the `FeatureLength` property.

The output of the feature extraction layer must be a valid input to the specified classification layers `ClassificationNetwork`, and consist of an array with only one non-singleton dimension. If you specify a `FeatureLayer` value, `reidentificationNetwork` ignores the `FeatureLength` value.

To set the value of this property, you must specify it at object creation.

`FeatureLength` — Feature vector size

`256` (default) | positive integer

This property is read-only.

Feature vector size for ReID inference, specified as a positive integer. When you call the `extractReidentificationFeatures` object function, the output is an *M*-by-*B* matrix, where *M* is equal to `FeatureLength` and *B* is the batch size.

extractReidentificationFeatures

Extract object re-identification (ReID) features from image

Syntax

```
features = extractReidentificationFeatures(reID,I)
[features,labels] = extractReidentificationFeatures(reID,ds)

[___] = extractReidentificationFeatures(___,Name=Value)
```

Description

`features = extractReidentificationFeatures(reID,I)` extracts object re-identification features from an image or a batch of images `I`.

Note This functionality requires Deep Learning Toolbox.

`[features,labels] = extractReidentificationFeatures(reID,ds)` extracts features and their respective labels from the images returned by the `read` function of the input datastore `ds`. Specify this syntax to obtain all the feature vectors from a datastore, or to evaluate ReID network performance using the `evaluateReidentificationNetwork` function.

`[___] = extractReidentificationFeatures(___,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `MiniBatchSize=4` specifies the minimum batch size to use for inference as `4`.

Input Arguments

`reID` — Re-identification network

`reidentificationNetwork` object

Re-identification network, specified as a `reidentificationNetwork` object.

`I` — Images

numeric array

Images, specified as a size *H*-by-*W*-by-*C* or *H*-by-*W*-by-*C*-by-*B* numeric array. You must specify real and nonsparse grayscale or RGB images.

- *H* — Height of the input images.
- *W* — Width of the input images.
- *C* — Number of channels. The channel size of each image must be equal to the input channel size of the network. For example, for grayscale images, *C* must be `1`. For RGB color images, it must be `3`.
- *B* — Number of test images in the batch. The `extractReidentificationFeatures` function extracts features for each test image in the batch.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single`

`ds` — Datastore of RGB or grayscale images
`ImageDatastore` object | datastore

Datastore of RGB or grayscale images, specified as an `imageDatastore` object with a populated `Labels` property, or a datastore whose `read` function returns a 2-by-*B* cell array, where *B* is the number of images in the datastore. Each row of the cell array is of the form {*Image Class*}.

Image	Class
RGB image, stored as an *H*-by-*W*-by-3 numeric array, or grayscale image, stored as an *H*-by-*W* matrix.	String or a categorical cell vector which contains the object class name for the corresponding input image in *Image*. All categorical data returned by the datastore must have the same categories.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `MiniBatchSize=4` specifies the minimum batch size to use for inference as 4.

`MiniBatchSize` — Minimum batch size
1 (default) | positive integer

Minimum batch size, specified as a positive integer. Adjusting the `MiniBatchSize` value can help you process a large collection of images. The `extractReidentificationFeatures` function groups images into minibatches of the specified size and processes them together, which can improve computation efficiency at the cost of increased memory demand. Increase the minibatch size to decrease processing time. Decrease the minibatch size to use less memory.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the re-identification network feature extraction, specified as one of these values:

- `"auto"` — Use a GPU if Parallel Computing Toolbox is installed and a supported GPU device is available. Otherwise, use the CPU.
- `"gpu"` — Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA-enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Use the CPU.

`Acceleration` — Performance optimization
`"auto"` (default) | `"none"`

Performance optimization, specified as one of these options:

- `"auto"` — Automatically apply compatible optimizations suitable for the input network and hardware resource.
- `"none"` — Disable all acceleration.

The `Acceleration` option `"auto"` can improve performance on subsequent calls with compatible parameters, at the expense of an increased initial run time. Use performance optimization when you plan to call the function multiple times using new input data.

`Verbose` — Visible progress display
`true` or `1` (default) | `false` or `0`

Visible progress display, specified as a numeric or logical `1` (`true`) or `0` (`false`).

Output Arguments

`features` — Features extracted from re-identification network
M-by-1 vector | *M*-by-*B* matrix | *M*-by-*N* matrix

Features extracted from the re-identification network, returned as one of these options:

- *M*-by-1 vector — `I` is a single image. *M* is the feature vector size `FeatureLength`.
- *M*-by-*B* matrix — `I` is a batch of images. *B* is the number of images in the batch.
- *M*-by-*N* matrix — `I` is a datastore, `ds`. *N* is the number of images in the datastore.

`labels` — Labels
1-by-*N* vector of strings

Labels corresponding to the object ID or class name of each feature vector in `features`, returned as a 1-by-*N* vector of strings. *N* is the number of images in the input datastore, `ds`.

Version History

Introduced in R2024a

reidentificationMetrics

Re-identification (ReID) quality metrics

Description

An `reidentificationMetrics` object stores ReID quality metrics, such as the cumulative matching characteristic (CMC) curve and mean average precision (mAP), for a set of images.

Creation

Create an `reidentificationMetrics` object by using the `evaluateReidentificationNetwork` function.

Properties

`DataSetMetrics` — Metrics aggregated over the data set
table

This property is read-only.

Metrics aggregated over the data set, stored as a table with one row. The `DatasetMetrics` property has columns corresponding to these evaluation metrics. These metrics are not in output table order.

- `AP` — Average precision, stored as a numeric scalar. The average precision metric represents the accuracy of image search results for a query image.
- `mAP` — Mean average precision (mAP), stored as a numeric scalar. The mAP is an average of the average precision `AP` in the same table across all corresponding queries.
- `CMC` — Cumulative matching characteristic, stored as a numeric scalar.

`ClassMetrics` — Metrics for each class
table

This property is read-only.

Metrics for each class, stored as a table with *C* rows, where *C* is the number of object classes specified to the `labels` argument of the `evaluateReidentificationNetwork` function. The `ClassMetrics` has columns corresponding to these evaluation metrics. These metrics are not in output table order.

- `AP` — Average precision, stored as a numeric scalar. The average precision metric represents the accuracy of image search results for a query image.
- `mAP` — Mean average precision (mAP), stored as a numeric scalar. The mAP is an average of the average precision `AP` in the same table across all corresponding queries.
- `CMC` — Cumulative matching characteristic, stored as a numeric scalar.

`ClassNames` — Object class names
cell array | categorical vector | cell array of character vectors

This property is read-only.

Names of the object classes that the ReID network is trained to re-identify, stored as a cell array, categorical vector, or cell array of character vectors.

Object Functions

plot Plot re-identification (ReID) metrics

solov2

Segment objects using SOLOv2 instance segmentation network

Description

The `solov2` object performs instance segmentation of objects in an image using a Segmenting Objects by Locations version 2 (SOLOv2) instance segmentation network. To perform instance segmentation of objects in an image, pass the pretrained or trained network to the `segmentObjects` function.

Note This functionality requires Deep Learning Toolbox and the Computer Vision Toolbox Model for SOLOv2 Instance Segmentation. You can install the Computer Vision Toolbox Model for SOLOv2 Instance Segmentation from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Creation

Syntax

```
detector = solov2(detectorName)
detector = solov2(detectorName,classNames)
detector = solov2( ___ ,Property=Value)
```

Description

`detector = solov2(detectorName)` creates a pretrained SOLOv2 instance segmentation network `detectorName` by using the specified SOLOv2 deep learning network trained on the COCO data set.

`detector = solov2(detectorName,classNames)` creates a pretrained SOLOv2 instance segmentation network and configures it to perform transfer learning on a specified set of object classes. The `classNames` argument sets the `ClassNames` property. For optimal results, train the network on new training images before performing segmentation.

`detector = solov2( ___ ,Property=Value)` sets writeable properties `ModelName` and `InputSize` using name-value arguments, in addition to any combination of input arguments from previous syntaxes.

For example, `InputSize=[400 400 3]` specifies the input image size as 400-by-400 pixels with 3 channels.

Input Arguments

`detectorName` — Name of pretrained SOLOv2 deep learning network
`"resnet50-coco"` | `"light-resnet18-coco"`

Name of the pretrained SOLOv2 deep learning network, specified as one of these options:

- `"resnet50-coco"` — A pretrained SOLOv2 deep learning network that uses ResNet-50 as the base network, trained on the COCO data set.
- `"light-resnet18-coco"` — A pretrained SOLOv2 deep learning network that uses a version of ResNet-18 with a reduced number of features as a base network, trained on the COCO data set.

Data Types: `char` | `string`

`classNames` — Names of object classes
vector of strings | cell array of character vectors | categorical vector

Names of object classes for training the network, specified as a vector of strings, cell array of character vectors, or categorical vector. This argument sets the `classNames` property of the `solov2` object.

Data Types: `char` | `string` | `categorical`

Properties

`ModelName` — Name of trained SOLOv2 instance segmentation network
string scalar | character vector

Name of the trained SOLOv2 instance segmentation network, represented as string scalar or character vector. The default `ModelName` is empty unless specified by `detectorName`.

To set the value of this property, you must specify it at object creation.

`InputSize` — Image size
`[800 800 3]` (default) | 1-by-3 vector

Image size to use during training and inference, represented as a 1-by-3 vector of positive integers of the form [*height width channel*]. The network resizes input images to this size while maintaining the aspect ratio.

To set the value of this property, you must specify it at object creation.

`ClassNames` — Object class names
string array

This property is read-only.

Object class names, represented as a string array. The default value consists of the 80 object class names in the MS-COCO data set, such as `"person"`, `"bicycle"`, and `"car"`. When you specify the `ClassNames` argument, the `solov2` object reinitializes the final convolution layers in the detection head and mask segmentation head to the correct size based on the number of classes you specify.

`GridSizes` — Grid sizes
`[12 16 24 46 40]` (default) | 1-by-5 vector

This property is read-only.

Grid sizes used at the five levels of the feature pyramid network in the SOLOv2 network detection head, represented as a 1-by-5 vector. Each level of the feature pyramid corresponds to a different spatial resolution, with higher stages corresponding to lower resolution and larger receptive fields. The model uses multiple grid sizes in the detection head to predict object masks at different scales and resolutions, which helps to improve the accuracy of the segmentation results.

Object Functions

segmentObjects Segment objects using SOLOv2 instance segmentation

Examples

Segment Instances of Objects with SOLOv2

Load a pretrained SOLOv2 instance segmentation network.

```
model = solov2("resnet50-coco")
```

```
model =
  solov2 with properties:

     ModelName: "resnet50-coco"
    ClassNames: {1×80 cell}
     InputSize: [800 800 3]
     GridSizes: [12 16 24 36 40]
```

Read a test image that includes objects that the network is trained detect, such as people, into the workspace.

```
I = imread("visionteam.jpg");
```

Segment instances of objects in the image using the SOLOv2 instance segmentation model.

```
[masks,labels,scores] = segmentObjects(model,I,Threshold=0.6);
```

Overlay the detected object masks on the test image.

```
overlayedImage = insertObjectMask(I,masks);
figure
imshow(overlayedImage)
```

Version History

Introduced in R2023b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- To prepare a `solov2` object for code generation, use `coder.loadDeepLearningNetwork`.
- For code generation, the `solov2` object does not support `imageDatastore` object as input.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- To prepare a `solov2` object for code generation, use `coder.loadDeepLearningNetwork`.
- For code generation, the `solov2` object does not support `imageDatastore` object as input.

segmentObjects

Segment objects using SOLOv2 instance segmentation

Syntax

```
masks = segmentObjects(detector,I)
[masks,labels] = segmentObjects(detector,I)
[masks,labels,scores] = segmentObjects(detector,I)

dsResults = segmentObjects(detector,imds)

[___] = segmentObjects(___,Name=Value)
```

Description

`masks = segmentObjects(detector,I)` segments objects within a single image or array of images `I` using SOLOv2 instance segmentation, and returns the predicted object masks for the input image or images.

Note This functionality requires Deep Learning Toolbox and the Computer Vision Toolbox Model for SOLOv2 Instance Segmentation. You can install the Computer Vision Toolbox Model for SOLOv2 Instance Segmentation from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

`[masks,labels] = segmentObjects(detector,I)` also returns the labels assigned to the predicted object instance masks.

`[masks,labels,scores] = segmentObjects(detector,I)` also returns the prediction score for each predicted object instance mask.

`dsResults = segmentObjects(detector,imds)` segments objects within images in a datastore using SOLOv2 instance segmentation. The function returns a datastore with the instance segmentation results, including the instance masks, labels, prediction scores, and bounding boxes.

`[___] = segmentObjects(___,Name=Value)` specifies options using additional name-value arguments in addition to any combination of arguments from previous syntaxes.. For example, `Threshold=0.9` specifies the confidence threshold as `0.9`.

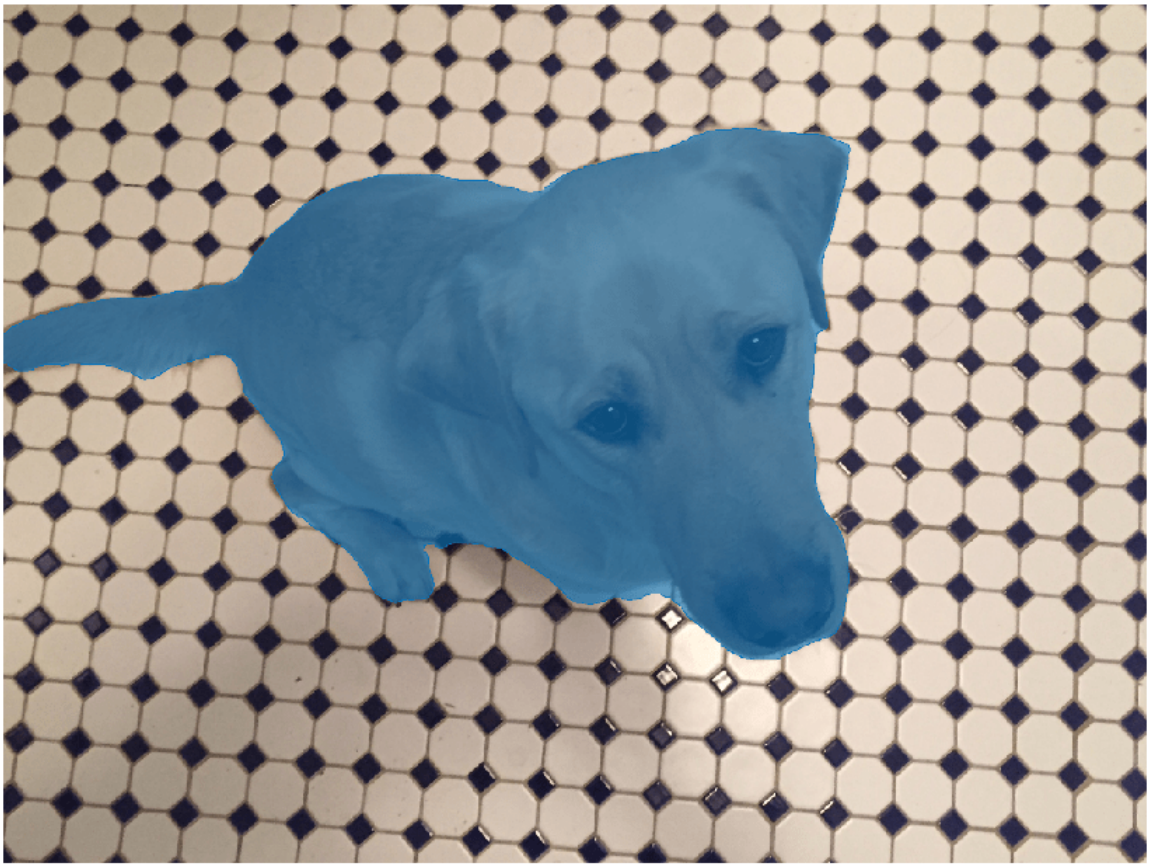
Examples

Segment Instances of Objects

Create a pretrained SOLOv2 instance segmentation network.

```
model = solov2("light-resnet18-coco");
```

Read a test image that includes objects that the network can detect, such as dogs, into the workspace.



```
I = imread("kobi.png");
```

Segment instances of objects in the image using the SOLOv2 instance segmentation model.

```
[masks,labels,scores] = segmentObjects(model,I);
```

Display the instance segmentation results. Overlay the detected object instance mask on the test image.

```
overlayedImage = insertObjectMask(I,masks);
imshow(overlayedImage)
```

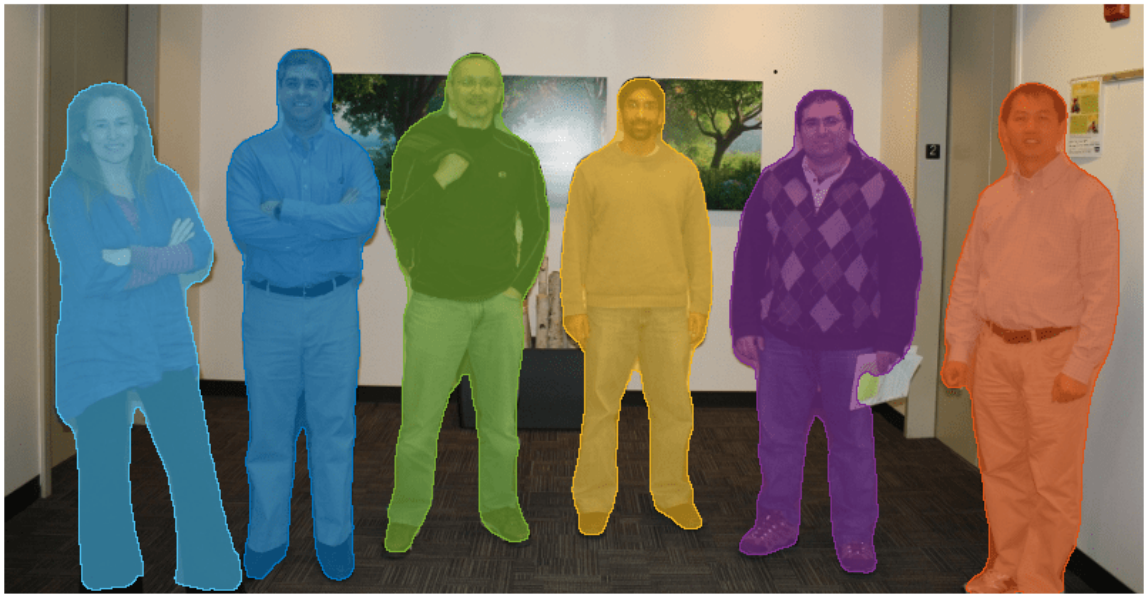
Segment Instances of Objects in Image Datastore with SOLOv2

Load a pretrained SOLOv2 instance segmentation network.

```
model = solov2("resnet50-coco");
```

Create a datastore of test images.

```
imageFiles = fullfile(toolboxdir("vision"),"visiondata","visionteam*.jpg");
dsTest = imageDatastore(imageFiles);
```



Segment instances of objects using the SOLOv2 instance segmentation model.

```
dsResults = segmentObjects(model,dsTest,Threshold=0.55);
```

```
Running SoloV2 network
-------------------------
* Processed 2 images.
```

For each test image, display the instance segmentation results. Overlay the detected object masks on the test image.

```
while(hasdata(dsResults))
    testImage = read(dsTest);
    results = read(dsResults);
    maskColors = lines(numel(results{2}));
    figure
    overlayedImage = insertObjectMask(testImage,results{1},Color=maskColors);
    imshow(overlayedImage)
end
```

Input Arguments

`detector` — SOLOv2 instance segmentation object

`solov2` object

SOLOv2 instance segmentation model, specified as a `solov2` object.

`I` — Image or batch of images

numeric matrix | numeric array

Image or batch of images on which to perform instance segmentation, specified as one of these values.

Image Type	Data Format
Single grayscale image	2-D matrix of size *H*-by-*W*
Single color image	3-D array of size *H*-by-*W*-by-3.
Batch of *B* grayscale or color images	4-D array of size *H*-by-*W*-by-*C*-by-*B*. The number of color channels *C* is 1 for grayscale images and 3 for color images.

The height *H* and width *W* of each image must be greater than or equal to the input height *h* and width *w* of the network.

`imds` — Datastore of images
datastore

Datastore of images, specified as a datastore such as an `ImageDatastore` or `CombinedDatastore` object. If calling the datastore with the `read` function returns a cell array, then the image data must be in the first cell.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `segmentObjects(detector,I,Threshold=0.9)` specifies the confidence threshold as `0.9`.

Options for All Image Formats

`Threshold` — Confidence threshold
`0.5` (default) | numeric scalar in range `[0, 1]`

Confidence threshold, specified as a numeric scalar in the range `[0, 1]`. The `segmentObjects` function filters out predictions with confidence scores less than the threshold value. Increase this value to reduce the number of false positives, at the possible expense of missing some true positives.

`MaskThreshold` — Mask probability threshold
`0.5` (default) | numeric scalar in range `[0, 1]`

Mask probability threshold, specified as a numeric scalar in the range `[0, 1]`. The mask probability threshold is the threshold value for the mask probabilities, determined by an output activation function, that separate object mask pixels from background pixels. If the threshold is too high, the function might incorrectly classify some foreground object pixels as background pixels, reducing the accuracy of the segmentation.

`SelectStrongest` — Select strongest mask prediction
`true` or `1` (default) | `false` or `0`

Select the strongest mask prediction for each segmented object instance using non-maximum suppression, specified as a numeric or logical `1` (`true`) or `0` (`false`).

- `true` — Return the strongest object mask prediction per object. The `segmentObjects` function selects these predictions by using non-maximum suppression to eliminate overlapping bounding boxes based on their confidence scores.
- `false` — Return all predictions. You can then create a custom operation to eliminate overlapping object masks.

`Acceleration` — Network acceleration type
`"auto"` (default) | `"mex"` | `"none"`

Network acceleration type to use for performance optimization, specified as one of these options:

- `"auto"` — Automatically select optimizations suitable for the input network and environment.
- `"mex"` — Compile and execute a MEX function. This option is available when using a GPU only. Using a GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If Parallel Computing Toolbox or a suitable GPU is not available, then the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"none"` — Disable all acceleration.

Use network acceleration to improve performance when using the same instance segmentation network and segmentation parameters across multiple image inputs, at the expense of additional overhead on the initial function call, and a possible increase in memory usage.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to process images with the network, specified as one of the execution environment options in this table.

`ExecutionEnvironment`	Description
`"auto"`	Use a GPU if available. Otherwise, use the CPU. The use of a GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
`"gpu"`	Use the GPU. If a suitable GPU is not available, the function returns an error message. Using a GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If Parallel Computing Toolbox or a suitable GPU is not available, then the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
`"cpu"`	Use the CPU.

`MaxNumKernels` — Maximum number of convolution kernels
`"auto"` (default) | positive integer in range `[1, 3096]`

Maximum number of convolution kernels, specified as a positive integer in the range [1, 3096]. This value sets the maximum number of convolution kernels, or filters, that the SOLOv2 network uses to perform a convolution operation for producing segmentation masks.

Specify the value of `MaxNumKernels` only when performing code generation. Otherwise, use the default value. The default value, `"auto"`, sets the maximum number of kernels depending on the content of the image, based on the number of kernels with an acceptable confidence threshold.

Tip Determine the optimal value of `MaxKernelSize` for your application by using the `evaluateInstanceSegmentation` function to evaluate the network performance at different `MaxKernelSize` values. Increase the value of `MaxKernelSize` to increase instance segmentation accuracy at the expense of slower inference speed.

Options for Datastore Inputs

`MiniBatchSize` — Number of observations returned in each batch

`1` (default) | positive integer

Number of observations returned in each batch, specified as a positive integer. If you set a higher `MiniBatchSize`, segmentation requires more memory, which can cause errors if your system does not have sufficient memory.

You can specify this argument only when you specify a batch of images, `I`, or datastore of images, `imds`, as an input to the `segmentObjects` function.

`WriteLocation` — Location to store writable data

string scalar | character vector

Location to store writable data, specified as a string scalar or character vector. The specified folder must have write permissions. If the folder already exists, the `segmentObjects` function creates a new folder and adds a suffix to the folder name with the next available number. The default write location is `fullfile(pwd,"SegmentObjectResults")`, where `pwd` is the current working directory.

You can specify this argument only when you specify a datastore of images, `imds`, as an input to the `segmentObjects` function.

Data Types: `char` | `string`

`NamePrefix` — Prefix added to written filenames

`"segmentObj"` (default) | string scalar | character vector

Prefix added to written filenames, specified as a string scalar or character vector. The function names the output files *`NamePrefix_imageName.mat`*, where *`imageName`* is the name of the input image without its file extension.

If `imds` contains identical file names in different folders, the function names the output files *`NamePrefix_folder_imageName.mat`*, where *`folder`* is the folder containing the files with the same name.

If `imds` contains identical file names in folders of the same name within different directory hierarchies, the function names the output files *`NamePrefix_folder_imageName_#.mat`*, where `#` is a distinct integer.

You can specify this argument only when you specify a datastore of images, `imds`.

Data Types: `char` | `string`

`Verbose` — Visible progress display

`true` or `1` (default) | `false` or `0`

Visible progress display, specified as a numeric or logical `1` (`true`) or `0` (`false`).

You can specify this argument only when you specify a datastore of images, `imds`.

Output Arguments

`masks` — Object masks

H-by-*W*-by-*M* logical array | *B*-by-1 cell array

Object masks, returned as an *H*-by-*W*-by-*M* logical array for a single image or a *B*-by-1 cell array for a batch of *B* images. *H* and *W* are the height and width, respectively, of the input image `I`, and *M* is the number of objects masks predicted in the image. Each of the *M* channels contains the mask for a single predicted object instance.

For a batch of *B* images, each cell of the *B*-by-1 cell array contains an *H*-by-*W*-by-*M* array of object masks the corresponding image from the batch.

`labels` — Object labels
M-by-1 categorical vector | *B*-by-1 cell array

Objects labels, returned as an *M*-by-1 categorical vector for a single image or a *B*-by-1 cell array for a batch of *B* images. *M* is the number of predicted object instances in the input image `I`.

For a batch of *B* images, each cell of the *B*-by-1 cell array contains an *M*-by-1 categorical vector with the labels of the objects in the corresponding image from the batch.

`scores` — Prediction scores
M-by-1 vector | *B*-by-1 cell array

Prediction confidence scores, returned as an *M*-by-1 numeric vector for a single image or a *B*-by-1 cell array for a batch of *B* images. *M* is the number of predicted object instances in the input image `I`. A higher score indicates higher confidence in the object instance segmentation.

For a batch of *B* images, each cell of the *B*-by-1 cell array contains an *M*-by-1 numeric vector with the confidence scores for the object segmentation predictions in the corresponding image from the batch.

`dsResults` — Predicted instance segmentation results
`FileDatastore` object

Predicted instance segmentation results, returned as a `FileDatastore` object. The function organizes the datastore so that calling the `read` and `readall` functions on it returns a cell array with three columns. This table describes the format of each cell in each column.

`masks`	`labels`	`scores`
Binary masks, returned as a logical array of size *H*-by-*W*-by-*M*, where *M* is the number of predicted object instances in the corresponding image. Each mask is the segmentation of one object instance in the image.	Object class names, returned as an *M*-by-1 categorical vector, where *M* is the number of predicted object instances in the corresponding image. All categorical data returned by the datastore contains the same categories.	Prediction scores, returned as an *M*-by-1 numeric vector, where *M* is the number of predicted object instances in the corresponding image.

Version History

Introduced in R2023b

R2024b: Specify maximum number of convolution kernels to use for code generation

For code generation, the `segmentObjects` function now requires you to specify the maximum number of convolution kernels to use for mask prediction using the new `MaxNumKernels` name-value argument.

R2024b: Support for C and GPU code generation

`segmentObjects` now supports the generation of C code (requires MATLAB Coder) and optimized CUDA code (requires GPU Coder).

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- For code generation, the `segmentObjects` function does not support `WriteLocations`, `NamePrefix`, and `Verbose` name-value arguments.
- For code generation, the `MiniBatchSize` name-value argument must be a code generation constant (`coder.const()`).
- For code generation, the `MaxNumKernels` name-value argument must be specified as a non-default value.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- For code generation, the `segmentObjects` function does not support `WriteLocations`, `NamePrefix`, and `Verbose` name-value arguments.
- For code generation, the `MiniBatchSize` name-value argument must be a code generation constant (`coder.const()`).
- For code generation, the `MaxNumKernels` name-value argument must be specified as a non-default value.

yolov2ObjectDetector

Detect objects using YOLO v2 object detector

Description

The `yolov2ObjectDetector` object creates a you only look once version 2 (YOLO v2) object detector for detecting objects in an image. Using this object, you can:

- Create a pretrained YOLO v2 object detector by using YOLO v2 deep learning networks trained on COCO data set.
- Create a custom YOLO v2 object detector by using a custom trained YOLO v2 deep learning network.

Creation

Syntax

```
detector = yolov2ObjectDetector(name)

detector = yolov2ObjectDetector(name,classes,aboxes)
detector = yolov2ObjectDetector(net,classes,aboxes)
detector = yolov2ObjectDetector(baseNet,classes,
aboxes,DetectionNetworkSource=layer)
detector = yolov2ObjectDetector( ___ ,Name=Value)
```

Description

Pretrained YOLO v2 Object Detector

`detector = yolov2ObjectDetector(name)` creates a pretrained YOLO v2 object detector by using YOLO v2 deep learning networks trained on a COCO data set.

Note To use pretrained YOLO v2 networks trained on the COCO data set, you must download and install the Computer Vision Toolbox Model for YOLO v2 Object Detection support package. You can download the Computer Vision Toolbox Model for YOLO v2 Object Detection from the Add-On Explorer. For more information, see “Get and Manage Add-Ons”.

Custom YOLO v2 Object Detector

`detector = yolov2ObjectDetector(name,classes,aboxes)` creates a pretrained YOLO v2 object detector and configures it to perform transfer learning.

For optimal results, you must train the detector on new training images before performing detection. Use the `trainYOLOv2ObjectDetector` function for training the detector.

`detector = yolov2ObjectDetector(net,classes,aboxes)` creates an object detector by using the YOLO v2 deep learning network `net`.

If `net` is a pretrained YOLO v2 deep learning network, then the function creates a pretrained YOLO v2 object detector. `classes` and `aboxes` specify the object classes and anchor boxes that were used to train the network.

If `net` is an untrained YOLO v2 deep learning network, then the function creates a YOLO v2 object detector to use for training and inference. `classes` and `aboxes` specify the object classes and the anchor boxes, respectively, for training the YOLO v2 network. You must train the detector on a training data set before performing object detection. For information about how to train a YOLO v2 object detector, see “Object Detection Using YOLO v2 Deep Learning”.

The input network can also be an imported network from ONNX™ (Open Neural Network Exchange). For more information, see “Import Pretrained ONNX YOLO v2 Object Detector”.

`detector = yolov2ObjectDetector(baseNet,classes, aboxes,DetectionNetworkSource=layer)` adds a detection head to the specified feature extraction layer `layer` in the base network, `baseNet`.

If `baseNet` is a pretrained deep learning network, the function creates a YOLO v2 object detector and configures it to perform transfer learning with the specified object classes and anchor boxes.

If `baseNet` is an untrained deep learning network, the function creates a YOLO v2 object detector and configures it for training. `classes` and `aboxes` specify the object classes and the anchor boxes, respectively, for training the YOLO v2 network.

You must train the detector on a training data set before performing object detection.

`detector = yolov2ObjectDetector( ___ ,Name=Value)` sets properties on page 2-1231 of the object detector by using name-value arguments. You can specify one or more of the `InputSize on page 2-0`, `LossFactors on page 2-0`, and `ModelName on page 2-0` properties, in addition to any combination of input arguments from previous syntaxes.

You can enable multiscale training by setting the `TrainingImageSize on page 2-0` property using a name-value argument.

When you specify the `layer` input argument, then you can improve detection accuracy for smaller objects by setting the `ReorganizeLayerSource on page 2-0` property using a name-value argument.

Example: `detector = yolov2ObjectDetector(net,classes,aboxes,InputSize=[224 224 3])` sets the size of the images used for training to `[224 224 3]`.

Input Arguments

`name` — Name of pretrained YOLO v2 deep learning network

`"darknet19-coco"` | `"tiny-yolov2-coco"`

Name of the pretrained YOLO v2 deep learning network, specified as one of these:

- `"darknet19-coco"` — A pretrained YOLO v2 deep learning network created using DarkNet-19 as the base network and trained on COCO data set.
- `"tiny-yolov2-coco"` — A pretrained YOLO v2 deep learning network created using a small base network and trained on COCO data set.

Data Types: `char` | `string`

`classes` — Names of object classes
string vector | cell array of character vectors | categorical vector

Names of object classes for training the detector, specified as a string vector, cell array of character vectors, or categorical vector. This argument sets the `ClassNames on page 2-0` property of the `yolov2ObjectDetector` object.

Data Types: `char` | `string` | `categorical`

`aboxes` — Anchor boxes
N-by-1 cell array

Anchor boxes for training the detector, specified as an *N*-by-1 cell array. *N* is the number of output layers in the YOLO v2 deep learning network. Each cell contains an *M*-by-2 matrix, where *M* is the number of anchor boxes in that layer. Each cell can contain a different number of anchor boxes. Each row in the *M*-by-2 matrix denotes the size of an anchor box in the form [*height width*].

The first element in the cell array specifies the anchor boxes to associate with the first output layer, the second element in the cell array specifies the anchor boxes to associate with the second output layer, and so on. For accurate detection results, specify large anchor boxes for the first output layer and small anchor boxes for the last output layer. That is, the anchor box sizes must decrease for each output layer in the order in which the layers appear in the YOLO v2 deep learning network.

This argument sets the `AnchorBoxes on page 2-0` property of the `yolov2ObjectDetector` object.

Data Types: `cell`

`net` — Custom trained YOLO v2 network
`dlnetwork` object

Custom trained YOLO v2 network, specified as a `dlnetwork` object. The `dlnetwork` must have an image input layer and a YOLO v2 transform layer.

`baseNet` — Base network
`dlnetwork` object

Base network for creating the YOLO v2 deep learning network, specified as a `dlnetwork` object. The network can be either an untrained or a pretrained deep learning network.

`layer` — Name of feature extraction layer
character vector | string scalar

Name of the feature extraction layer, specified as a character vector or string scalar. The features extracted from this layer are given as input to the YOLO v2 object detection subnetwork.

You can specify the feature extraction layer as any network layer except the fully connected layer. The feature extraction layer is typically one of the deeper layers in `network`. You can use the `analyzeNetwork` function to view the names of the layers in the input network.

Data Types: `char` | `string`

Properties

`Network` — YOLO v2 object detection network
`dlnetwork` object

This property is read-only.

YOLO v2 object detection network, specified as a `dlnetwork` object.

`InputSize` — Size of input image
two-element vector | three-element vector

Size of input image, specified as one of these values:

- Two-element vector of form [*H W*] - For a grayscale image of size *H*-by-*W*
- Three-element vector of form [*H W* 3] - For an RGB color image of size *H*-by-*W*

The default value is the size of the image input layer of the network.

`TrainingImageSize` — Set of image sizes used for training
M-by-2 matrix

Set of image sizes used for training, specified as an *M*-by-2 matrix, where each row is of the form [`height` `width`]. By default, `yolov2ObjectDetector` uses a single image size, equal to the height and width specified by the `InputSize on page 2-0` property.

Note

- The image sizes specified by `TrainingImageSize` must be greater than or equal to the `InputSize` property of the `imageInputLayer` within the network of the detector.
- The `height` and `width` values of `TrainingImageSize` must be divisible by the height and width of the `BlockSize` property of the `spaceToDepthLayer` object within the network of the detector.

You cannot change the value of this property after you create the object.

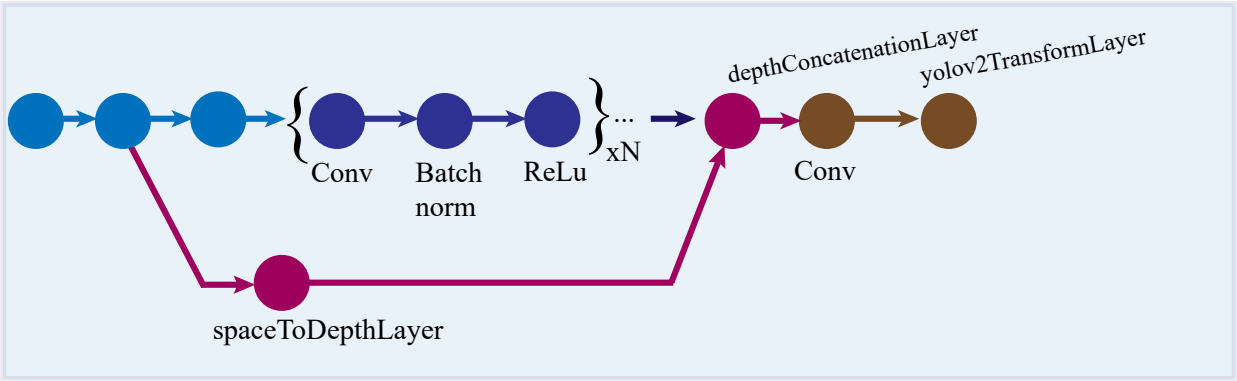
`AnchorBoxes` — Set of anchor boxes
N-by-2 matrix

This property is read-only.

Set of anchor boxes, specified as an *N*-by-2 matrix defining the width and the height of *N* anchor boxes. Each row in the *M*-by-2 matrix denotes the size of the anchor box in the form of [*height width*].

The size of each anchor box is determined based on the scale and aspect ratio of different object classes present in input training data. Also, the size of each anchor box must be smaller than or equal to the size of the input image. You can use the clustering approach for estimating anchor boxes from the training data. For more information, see “Estimate Anchor Boxes from Training Data”.

`ClassNames` — Names of object classes
cell array of character vectors



This property is read-only.

Names of object classes that the YOLO v2 object detector is trained to find, specified as a cell array of character vectors.

`ReorganizeLayerSource` — Name of layer providing input to reorganization layer
"" (default) | character vector | string scalar

Name of the layer providing input to the reorganization layer, specified as a character vector or string scalar. A reorganization layer improves detection accuracy for smaller objects by adding low-level image information. To include a reorganization layer in the network, you must also specify the `layer` argument. If you do not set the `ReorganizeLayerSource` property, then the detector does not include a reorganization layer in the network.

When you include a reorganization branch, the object adds a `spaceToDepthLayer` and `depthConcatenationLayer` to the network. The space-to-depth layer extracts low-level features from the base network. The depth concatenation layer combines the high-level features from the detection head with the low-level features. The figure shows a modified network that includes a reorganization branch.

depthConcatenationLayer
yolov2TransformLayer
Conv
Batch norm
ReLu
...
xN
Conv
spaceToDepthLayer

The input to the reorganization layer must be from any one of the network layers that lie above the feature extraction layer specified by `layer`. Typically, you attach the reorganization layer to a layer within the feature extraction network whose output feature map is larger than the feature extraction layer output. You can use the `analyzeNetwork` function to view the names of the layers in the input `network`.

`LossFactors` — Loss factors
`[5 1 1 1]` (default) | 1-by-4 numeric vector

This property is read-only.

Loss factors for each component of the YOLO v2 loss function, specified as a 1-by-4 numeric vector. For more information, see YOLO v2 Training Loss on page 3-1402.

`ModelName` — Name for object detector
character vector | string scalar

Name for object detector, specified as a character vector or string scalar. The default value of this property is set to the name of the pretrained YOLO v2 network specified at the input.

Object Functions

detect Detect objects using YOLO v2 object detector

Examples

Detect Objects Using Pretrained YOLO v2 Object Detector

To run this example, you must download and install the Computer Vision Toolbox Model™ for YOLO v2 Object Detection support package.

Specify the name of a pretrained YOLO v2 deep learning network.

```
name = "tiny-yolov2-coco";
```

Create a YOLO v2 object detector by using the pretrained YOLO v2 network.

```
detector = yolov2ObjectDetector(name);
```

Display and inspect the properties of the YOLO v2 object detector.

```
disp(detector)
```

```
  yolov2ObjectDetector with properties:

                Network: [1×1 dlnetwork]
              InputSize: [416 416 3]
      TrainingImageSize: [416 416]
            AnchorBoxes: [5×2 double]
             ClassNames: [80×1 categorical]
  ReorganizeLayerSource: ''
            LossFactors: [5 1 1 1]
              ModelName: 'tiny-yolov2-coco'
```

Detect objects in an unknown image by using the pretrained YOLO v2 object detector.

```
img = imread("highway.png");
[bboxes,scores,labels] = detect(detector,img);
```

Display the detection results.

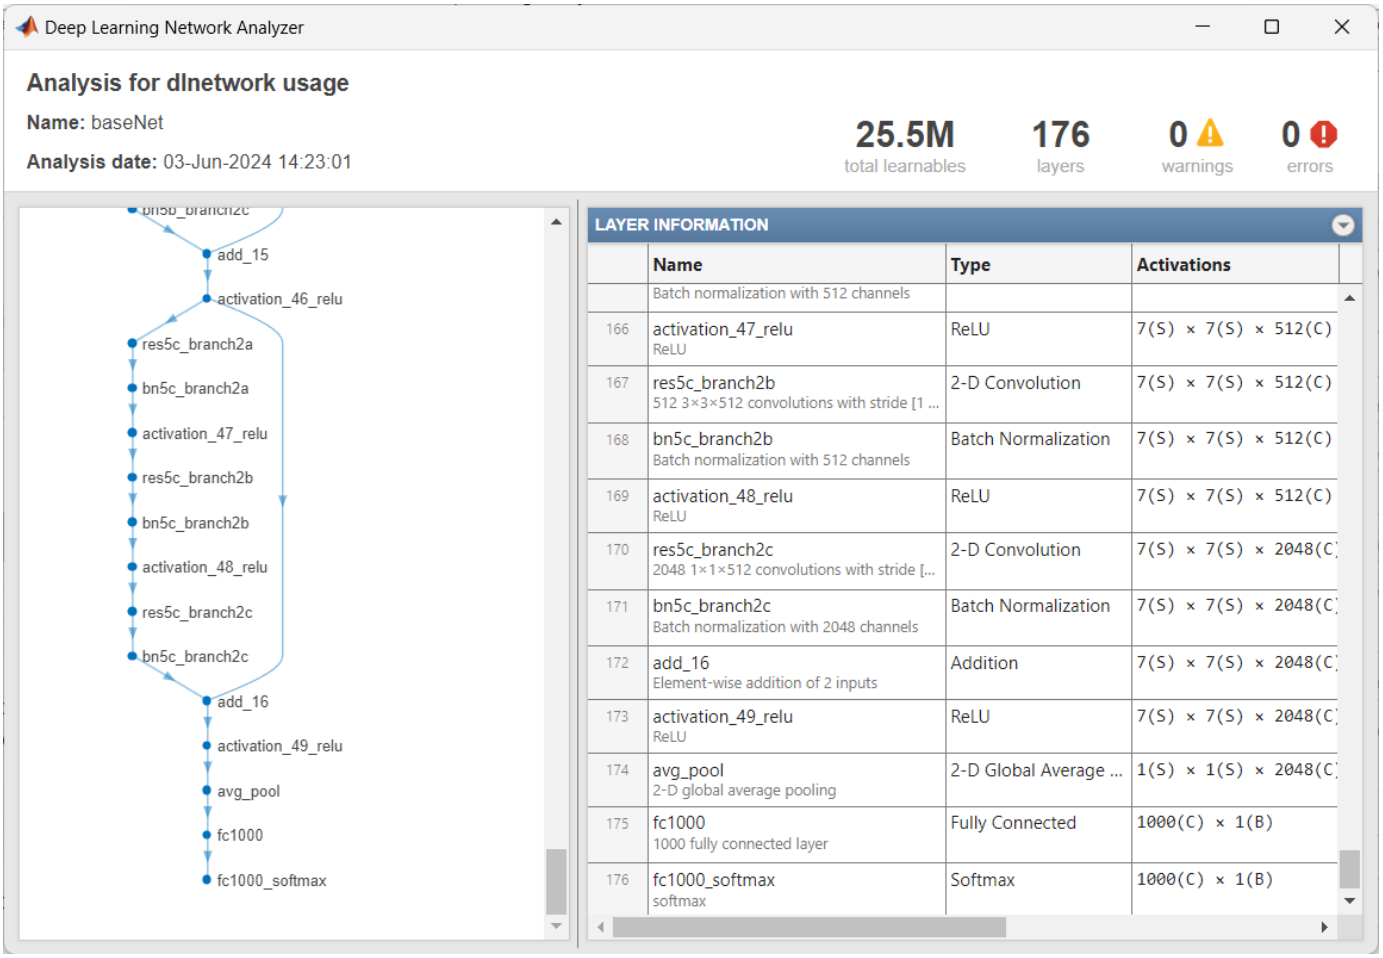
```
detectedImg = insertObjectAnnotation(img,"Rectangle",bboxes,labels);
imshow(detectedImg)
```

Create YOLO v2 Network with Reorganization Layer

Specify the class for the network to detect. The class must be one of the classes from the ImageNet database.

```
classes = "car";
```

Define anchor boxes.



```
anchorBoxes = [1 1;4 6;5 3;9 6];
```

Specify the base network as the pretrained ResNet-50 network. To use this pretrained network, you need to install the *Deep Learning Toolbox Model for ResNet-50 Network* support package.

```
baseNet = imagePretrainedNetwork("resnet50");
```

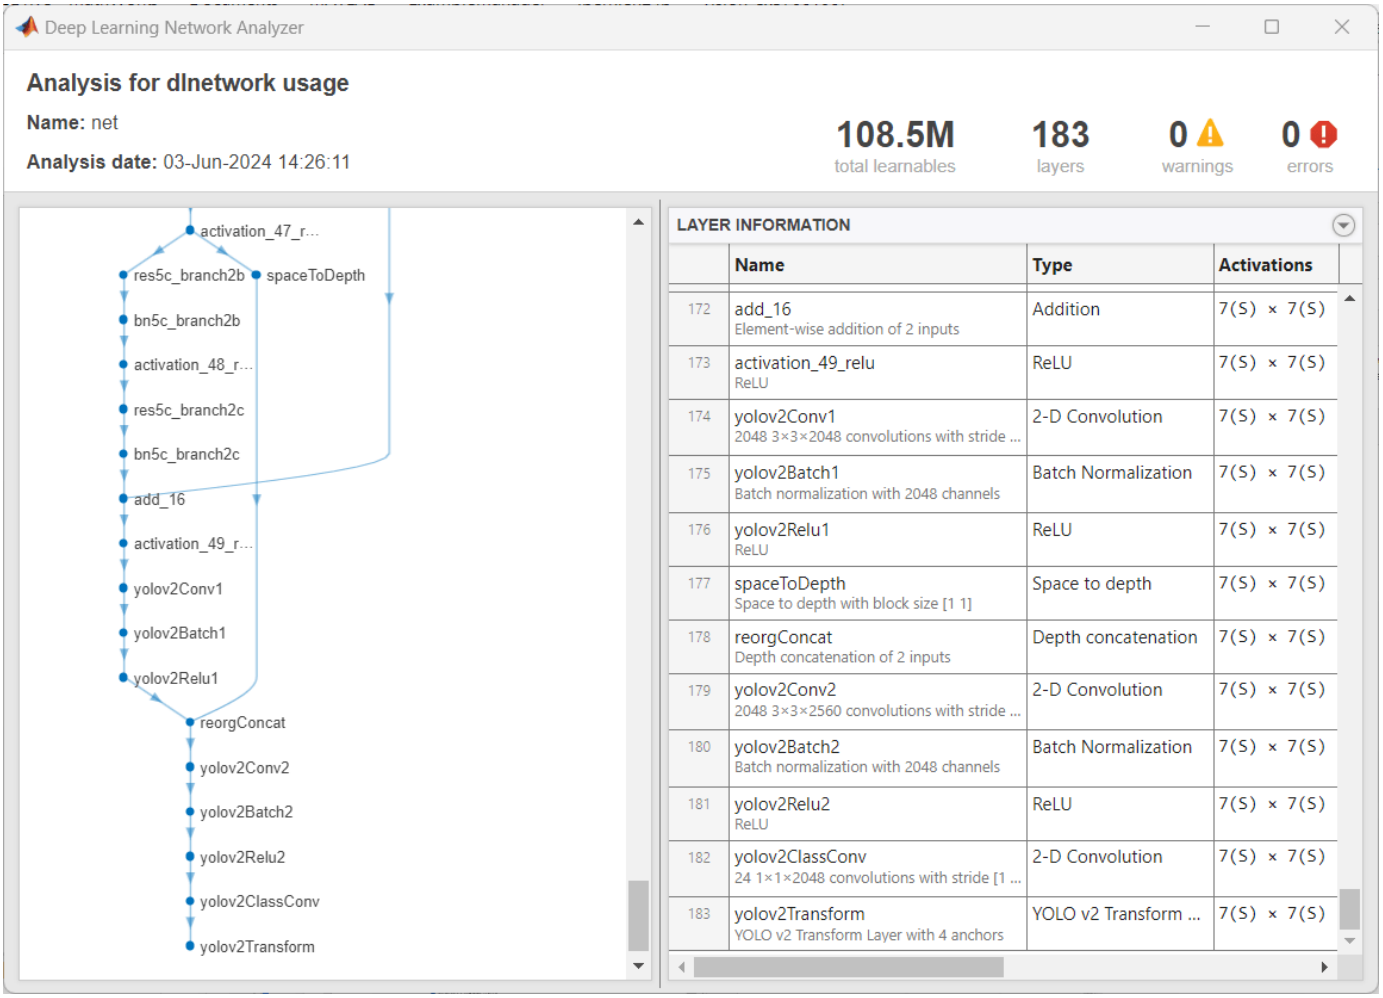
Analyze the network architecture and view all of the network layers.

```
analyzeNetwork(baseNet)
```

Specify the network layer to be used for feature extraction. You can choose any layer except the fully connected layer.

```
featureSource = "activation_49_relu";
```

Specify the network layer to be used as input to the reorganization layer.



```
reorgSource = "activation_47_relu";
```

Create the YOLO v2 object detector. The detector creates and stores the YOLO v2 network as a `dlnetwork` object.

```
detector = yolov2ObjectDetector(baseNet,classes,anchorBoxes, ...
    DetectionNetworkSource=featureSource,ReorganizeLayerSource=reorgSource);
```

Analyze the YOLO v2 network architecture. The layers after the feature extraction layer are removed. The detection subnetwork, including the YOLO v2 transform layer, follow the feature extraction layer. The reorganization layer (a space to depth layer) and the depth concatenation layer are also added to the network.

```
net = detector.Network;
```

Version History

Introduced in R2019a

R2024b: New properties

Starting in R2024b, these new properties enable training custom YOLO v2 object detectors specified as `dlnetwork` objects:

- `InputSize` on page 2-0
- `ReorganizeLayerSource` on page 2-0
- `LossFactors` on page 2-0

R2024b: `DAGNetwork` objects are not recommended

Not recommended starting in R2024b

Starting in R2024b, `DAGNetwork` objects are not recommended. If you want to use a custom pretrained YOLO v2 network, specify `net` or `baseNet` as a `dlnetwork` object instead. You must also specify the class names and anchor boxes using new input arguments.

There are no plans to remove support for `DAGNetwork` objects. However, `dlnetwork` objects have these advantages and are recommended instead:

- `dlnetwork` objects are a unified data type that supports network building, prediction, built-in training, visualization, compression, verification, and custom training loops.
- `dlnetwork` objects support a wider range of network architectures that you can create or import from external platforms.
- Training and prediction with `dlnetwork` objects is typically faster than with `DAGNetwork` objects.

You can convert a trained `DAGNetwork` object to a `dlnetwork` object by using the `dag2dlnetwork` function.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `detect` method of the `yolov2ObjectDetector` is supported for code generation.
- The `roi` argument to the `detect` method must be a code generation constant (`coder.const()`) and a 1-by-4 vector.
- Only the `Threshold`, `SelectStrongest`, `MinSize`, and `MaxSize` name-value arguments for `detect` are supported.
- To create a `yolov2ObjectDetector` object for code generation, see “Load Pretrained Networks for Code Generation” (MATLAB Coder).

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

For code generation,

- Only the `detect` method of the `yolov2ObjectDetector` is supported for code generation.
- The `roi` argument to the `detect` method must be a codegen constant (`coder.const()`) and a 1-by-4 vector.
- Only the `Threshold`, `SelectStrongest`, `MinSize`, `MaxSize`, and `MiniBatchSize` name-value arguments are supported.
- The height, width, channel, and batch size of the input image must be fixed size.
- The minimum batch size value passed to detect method must be fixed size.
- To create a `yolov2ObjectDetector` object for code generation, see “Load Pretrained Networks for Code Generation” (GPU Coder).

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

yolov3ObjectDetector

Detect objects using YOLO v3 object detector

Description

The `yolov3ObjectDetector` object creates a you only look once version 3 (YOLO v3) object detector for detecting objects in an image. Using this object, you can:

- Create a pretrained YOLO v3 object detector by using YOLO v3 deep learning networks trained on COCO dataset.
- Create a custom YOLO v3 object detector by using any pretrained or untrained YOLO v3 deep learning network.

Creation

Syntax

```
detector = yolov3ObjectDetector(name)

detector = yolov3ObjectDetector(name,classes,aboxes)
detector = yolov3ObjectDetector(net,classes,aboxes)
detector = yolov3ObjectDetector(baseNet,classes,
aboxes,DetectionNetworkSource=layer)
detector = yolov3ObjectDetector( ___ ,Name=Value)
```

Description

Pretrained YOLO v3 Object Detector

`detector = yolov3ObjectDetector(name)` creates a pretrained YOLO v3 object detector by using YOLO v3 deep learning networks trained on a COCO dataset.

Note To use the pretrained YOLO v3 deep learning networks trained on COCO dataset, you must install the Computer Vision Toolbox Model for YOLO v3 Object Detection from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons. To run this function, you will require the Deep Learning Toolbox.

Custom YOLO v3 Object Detector

`detector = yolov3ObjectDetector(name,classes,aboxes)` creates a pretrained YOLO v3 object detector and configures it to perform transfer learning using a specified set of object classes and anchor boxes. For optimal results, you must train the detector on new training images before performing detection.

`detector = yolov3ObjectDetector(net,classes,aboxes)` creates an object detector by using the deep learning network `net`.

If `net` is a pretrained YOLO v3 deep learning network, the function creates a pretrained YOLO v3 object detector. The `classes` and `aboxes` are values used for training the network.

If `net` is an untrained YOLO v3 deep learning network, the function creates a YOLO v3 object detector to use for training and inference. `classes` and `aboxes` specify the object classes and the anchor boxes, respectively, for training the YOLO v3 network.

You must train the detector on a training dataset before performing object detection. For information about how to train a YOLO v3 object detector, see **Preprocess Training Data** and **Train Model** sections in the “Object Detection Using YOLO v3 Deep Learning” example.

`detector = yolov3ObjectDetector(baseNet,classes, aboxes,DetectionNetworkSource=layer)` creates a YOLO v3 object detector by adding detection heads to a base network, `baseNet`.

The function adds detection heads to the specified feature extraction layers `layer` in the base network. To specify the names of the feature extraction layers, use the name-value argument `DetectionNetworkSource=layer`.

If `baseNet` is a pretrained deep learning network, the function creates a YOLO v3 object detector and configures it to perform transfer learning with the specified object classes and anchor boxes.

If `baseNet` is an untrained deep learning network, the function creates a YOLO v3 object detector and configures it for object detection. `classes` and `aboxes` specify the object classes and the anchor boxes, respectively, for training the YOLO v3 network.

You must train the detector on a training dataset before performing object detection.

`detector = yolov3ObjectDetector( ___ ,Name=Value)` specifies one or more options using name-value arguments in addition to any combination of input arguments from previous syntaxes. Use this syntax to:

- Modify the detection network sources in a YOLO v3 object detection network and train the network with different numbers of object classes, anchor boxes, or both. Specify the new detection network sources using the `DetectionNetworkSource=layer` name-value argument.
- Set the `InputSize on page 2-0` and `ModelName on page 2-0` properties of the object detector. For example, `InputSize=[224 224 3]` sets the size of the images used for training to `[224 224 3]`.

Input Arguments

`name` — Name of pretrained YOLO v3 deep learning network

`'darknet53-coco'` | `'tiny-yolov3-coco'`

Name of the pretrained YOLO v3 deep learning network, specified as one of these:

- `'darknet53-coco'` — A pretrained YOLO v3 deep learning network created using DarkNet-53 as the base network and trained on COCO dataset.
- `'tiny-yolov3-coco'` — A pretrained YOLO v3 deep learning network created using a small base network and trained on COCO dataset.

Data Types: `char` | `string`

`classes` — Names of object classes

string vector | cell array of character vectors | categorical vector

Names of object classes for training the detector, specified as a string vector, cell array of character vectors, or categorical vector. This argument sets the `ClassNames` property of the `yolov3ObjectDetector` object.

Data Types: `char` | `string` | `categorical`

aboxes — Anchor boxes
N-by-1 cell array

Anchor boxes for training the detector, specified as an *N*-by-1 cell array. *N* is the number of output layers in the YOLO v3 deep learning network. Each cell contains an *M*-by-2 matrix, where *M* is the number of anchor boxes in that layer. Each cell can contain a different number of anchor boxes. Each row in the *M*-by-2 matrix denotes the size of an anchor box in the form [*height width*].

The first element in the cell array specifies the anchor boxes to associate with the first output layer, the second element in the cell array specifies the anchor boxes to associate with the second output layer, and so on. For accurate detection results, specify large anchor boxes for the first output layer and small anchor boxes for the last output layer. That is, the anchor box sizes must decrease for each output layer in the order in which the layers appear in the YOLO v3 deep learning network.

This argument sets the `AnchorBoxes` property of the `yolov3ObjectDetector` object.

Data Types: `cell`

`net` — YOLO v3 deep learning network
`dlnetwork` object

YOLO v3 deep learning network, specified as a `dlnetwork` object. The input network can be either an untrained or a pretrained deep learning network.

`baseNet` — Base network
`dlnetwork` object

Base network for creating the YOLO v3 deep learning network, specified as a `dlnetwork` object. The network can be either an untrained or a pretrained deep learning network.

`layer` — Names of feature extraction layers
cell array of character vectors | string array

Names of the feature extraction layers in the base network, specified as a cell array of character vectors, or a string array. The function creates a YOLO v3 network by adding detection head layers to the output of the feature extraction layers in the base network.

In the pre-trained YOLO v3 base network, you must connect the detection head layers to feature extraction layers where the input image feature map changes spatial dimension by downsampling factors of 4, 8, 16, and 32.

- Use the `analyzeNetwork` function to display the pre-trained YOLO v3 network architecture to obtain the information about the spatial dimensions of the feature maps.
- Use this table to know about the default feature extraction layers and choose alternate feature extraction layers supported by the pre-trained YOLO v3 networks. Choose feature extraction layers using empirical evaluation based on the detection accuracy, training speed, and object size to detect.
    - For multi-scale feature extraction and to achieve higher detection accuracy, choose feature extraction layers with both higher and lower downsampling factors. Layers with lower

downsampling factor capture small objects and layers with higher downsampling factor ensure a thorough feature refinement.

- To achieve higher training and inference speeds, choose feature extraction layers with lower downsampling factor.
- The number of detection network sources specified must be equal to the number of anchor boxes specified at the input.

Backbone	Number of Detection Heads	Default Feature Extraction Layers		Examples of Alternate Feature Extraction Layers		Remarks
		Layer	Downsampling Factor	Layer	Downsampling Factor	
`tiny-yolov3-coco`	2	`leaky_relu_7` `leaky_relu_5`	32 16	`leaky_relu_6` `leaky_relu_3`	16 8	Select any two feature extraction layers with different downsampling factors preceding the `leaky_relu_7` layer to use as detection network sources. For example, specify the new detection network sources as `layer = {'leaky_relu_6','leaky_relu_3'}`

`darknet53-coco`	3	`add_23`

				`add_4`
					8	

				`add_3` `add_2`	4	

Data Types: `char` | `string` | `cell`

Properties

`Network` — YOLO v3 deep learning network

`dlnetwork` object

This property is read-only.

YOLO v3 deep learning network to use for object detection, stored as a `dlnetwork` object.

`AnchorBoxes` — Set of anchor boxes

N-by-1 cell array

This property is read-only.

Set of anchor boxes, stored as a *N*-by-1 cell array. *N* is the number of output layers in the YOLO v3 deep learning network for which the anchor boxes are defined. Each element in the cell is a *M*-by-2 matrix. *M* denotes the number of anchor boxes. Each cell can contain a different number of anchor boxes. Each row in the *M*-by-2 matrix denotes the size of the anchor box in the form of [*height width*]. The first element in the cell array specifies the anchor boxes for the first output layer, the second element in the cell array specifies the anchor boxes for the second output layer, and so on.

You can set this property by using the input argument `aboxes`.

`ClassNames` — Names of object classes

categorical vector

This property is read-only.

Names of object classes to detect, stored as a categorical vector. You can set this property by using the input argument `classes`.

`InputSize` — Image size used for training

vector

This property is read-only.

Image size used for training, stored as a vector of form [*height width*] or [*height width channels*]. To set this property, specify it at object creation.

For example, `detector = yolov3ObjectDetector(net,classes,aboxes,InputSize=[224 224 3])`.

`ModelName` — Name for object detector

`' '` (default) | character vector

Name for the object detector, stored as a character vector. To set this property, specify it at object creation.

For example, `yolov3ObjectDetector(net,classes,aboxes,'ModelName','customDetector')` sets the name for the object detector to `'customDetector'`.

`PredictedBoxType` — Bounding box format for object detector

`"axis-aligned"` (default) | `"rotated"`

This property is read-only.

Bounding box format for an object detector, stored as `"axis-aligned"` or `"rotated"`. When the `PredictedBoxType` is `"axis-aligned"`, the object detector will train and perform inference on only axis-aligned bounding boxes. If it is set to `"rotated"`, the object detector will train and perform inference on only rotated bounding boxes. Set this property when you create the object.

Object Functions

detect	Detect objects using YOLO v3 object detector
preprocess	Preprocess training and test images
forward	Compute YOLO v3 deep learning network output for training
predict	Compute YOLO v3 deep learning network outputs for inference

Examples

Create Pretrained YOLO v3 Object Detector

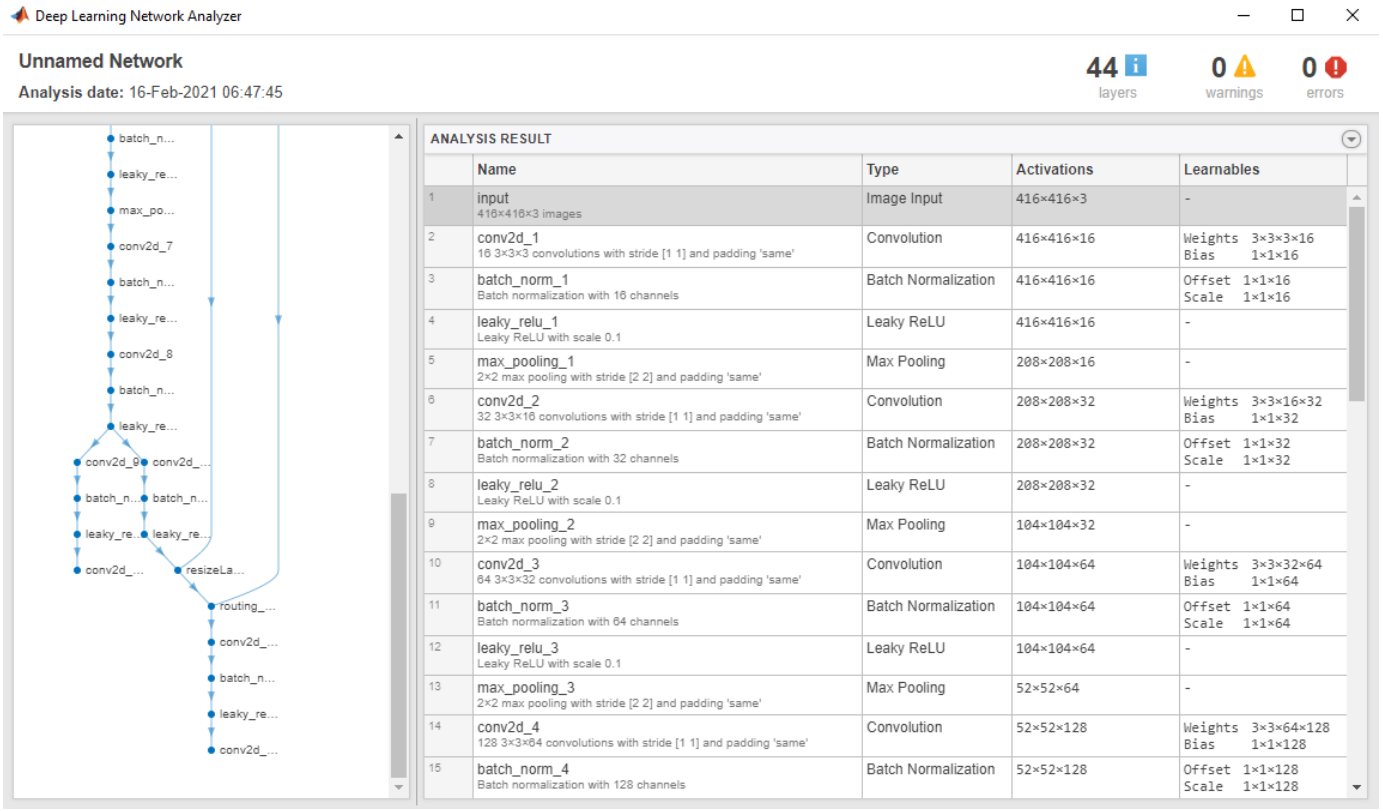
Specify the name of a pretrained YOLO v3 deep learning network.

```
name = 'tiny-yolov3-coco';
```

Create YOLO v3 object detector by using the pretrained YOLO v3 network.

```
detector = yolov3ObjectDetector(name);
```

Display and inspect the properties of the YOLO v3 object detector.



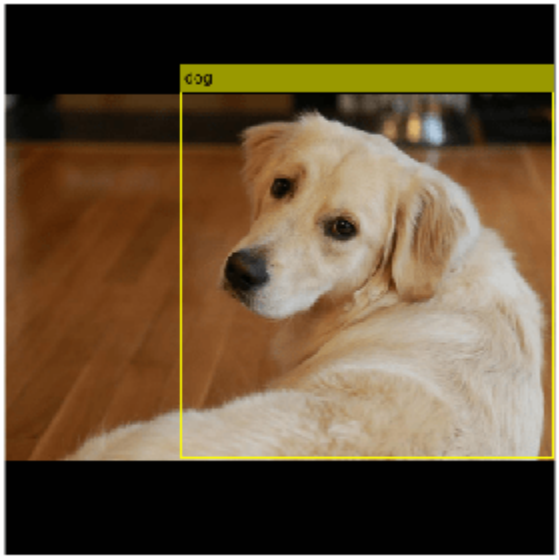
```
disp(detector)
```

```
  yolov3ObjectDetector with properties:

           Network: [1×1 dlnetwork]
       AnchorBoxes: {2×1 cell}
        ClassNames: [80×1 categorical]
         InputSize: [416 416 3]
    PredictedBoxType: 'axis-aligned'
         ModelName: 'tiny-yolov3-coco'
```

Use `analyzeNetwork` to display the YOLO v3 network architecture and get information about the network layers. The network has two detection heads attached to the feature extraction network.

```
analyzeNetwork(detector.Network)
```



Detect objects in an unknown image by using the pretrained YOLO v3 object detector.

```
img = imread('sherlock.jpg');
img = preprocess(detector,img);
img = im2single(img);
[bboxes,scores,labels] = detect(detector,img,'DetectionPreprocessing','none');
```

Display the detection results.

```
detectedImg = insertObjectAnnotation(img,'Rectangle',bboxes,labels);
figure
imshow(detectedImg)
```

Create Custom YOLO v3 Object Detector

This example shows how to create a custom YOLO v3 object detector by using a pretrained SqueezeNet as the base network.

Load a pretrained SqueezeNet network. The SqueezeNet network is a convolutional neural network that you can use as the base network for creating a YOLO v3 object detector.

```
net = imagePretrainedNetwork("squeezenet");
```

Inspect the architecture of the base network by using `analyzeNetwork` (Deep Learning Toolbox) function.

```
analyzeNetwork(net)
```

Specify the anchor boxes and the classes to use to train the YOLO v3 network.

```
aboxes = {[150,127;97,90;68,67];[38,42;41,29;31,23]};
classes = ["Car","Truck"];
```

Select two feature extraction layers in the base network to serve as the source for detection subnetwork.

```
layer = ["fire9-concat","fire8-concat"];
```

Create a custom YOLO v3 object detector by adding detection heads to the feature extraction layers of the base network. Specify the model name, classes, and the anchor boxes.

```
detector = yolov3ObjectDetector(net,classes,aboxes, ...
    ModelName="Custom YOLO v3",DetectionNetworkSource=layer);
```

Inspect the architecture of the YOLO v3 deep learning network by using `analyzeNetwork` (Deep Learning Toolbox) function.

```
analyzeNetwork(detector.Network)
```

Inspect the properties of the YOLO v3 object detector. You can now train the YOLO v3 object detector on a custom training dataset and perform object detection.

```
disp(detector)
```

```
  yolov3ObjectDetector with properties:

            Network: [1×1 dlnetwork]
        AnchorBoxes: {2×1 cell}
         ClassNames: [2×1 categorical]
          InputSize: [227 227 3]
    PredictedBoxType: 'axis-aligned'
          ModelName: 'Custom YOLO v3'
```

For information about how to train a YOLO v3 object detector, see the “Object Detection Using YOLO v3 Deep Learning” example.

Version History

Introduced in R2021a

R2024b: Code generation support for rotated rectangle bounding boxes

Starting in R2024b, YOLO v3 object detector with `PredictedBoxType` property set as `"rotated"` supports both CPU and GPU code generation.

R2024a: `DAGNetwork` objects are not recommended

Not recommended starting in R2024a

Starting in R2024a, `DAGNetwork` objects are not recommended. If you specify a base network `baseNet`, use a `dlnetwork` object instead.

There are no plans to remove support for `DAGNetwork` objects.

R2024a: Rotated rectangle bounding box support

The deep learning YOLO v3 object detector now supports rotated rectangle bounding boxes.

R2024b: Modify detection network source

Starting in R2024b, you can modify the detection network sources of a YOLO v3 object detection network when you perform transfer learning. You can specify the new detection network sources using the name-value argument `DetectionNetworkSource=layer`.

- Specify new detection network sources for the `tiny-yolov3-coco` and `darknet53-coco` pretrained YOLO v3 object detectors by using the syntax

  ```
  detector = yolov3ObjectDetector(name,classes,aboxes,DetectionNetworkSource=layer);
  ```

- Specify new detection network sources for a YOLO v3 object detection network by using the syntax

  ```
  detector = yolov3ObjectDetector(net,classes,aboxes,DetectionNetworkSource=layer);
  ```

For an example, the below code modifies the detection network sources of the pretrained `tiny-yolov3-coco` network to `leaky_relu_2` and `leaky_relu_5`.

```
name = "tiny-yolov3-coco";
layer = ["leaky_relu_2","leaky_relu_5"];
detector = yolov3ObjectDetector(name,classes,aboxes,DetectionNetworkSource=layer);
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `detect` method of the `yolov3ObjectDetector` is supported for code generation.
- The `roi` argument to the `detect` method must be a code generation constant (`coder.const()`) and a 1x4 vector.
- Only the `Threshold`, `SelectStrongest`, `MinSize`, and `MaxSize` name-value pairs for `detect` are supported.
- To create a `yolov3ObjectDetector` object for code generation, see “Load Pretrained Networks for Code Generation” (MATLAB Coder).

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- Only the `detect` method of the `yolov3ObjectDetector` is supported for code generation.
- The `roi` argument to the `detect` method must be a codegen constant (`coder.const()`) and a 1x4 vector.
- Only the `Threshold`, `SelectStrongest`, `MinSize`, and `MaxSize` name-value pairs are supported.
- The height, width, and channel of the input image must be fixed size.
- To create a `yolov3ObjectDetector` object for code generation, see “Load Pretrained Networks for Code Generation” (MATLAB Coder).

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- Only the `detect` method of the `yolov3ObjectDetector` is supported for GPU Arrays based processing.
- GPU Arrays is not supported for rotated rectangle bounding box inputs.

detect

Detect objects using YOLO v3 object detector

Syntax

```
bboxes = detect(detector,I)
[bboxes,scores] = detect(detector,I)
[bboxes,scores,labels] = detect(detector,I)
[bboxes,scores,labels,info] = detect(detector,I)

detectionResults = detect(detector,ds)

[___] = detect(___,roi)
[___] = detect(___,Name=Value)
```

Description

`bboxes = detect(detector,I)` detects objects within a single image or an array of images, `I`, using a you only look once version 3 (YOLO v3) object detector, `detector`. The input size of the image must be greater than or equal to the network input size of the pretrained detector. The locations of objects detected are returned as a set of bounding boxes.

Note To use the pretrained YOLO v3 object detection networks trained on COCO dataset, you must install the Computer Vision Toolbox Model for YOLO v3 Object Detection. You can download and install the Computer Vision Toolbox Model for YOLO v3 Object Detection from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons. To run this function, you will require the Deep Learning Toolbox.

`[bboxes,scores] = detect(detector,I)` also returns the class-specific confidence scores for each bounding box.

`[bboxes,scores,labels] = detect(detector,I)` returns a categorical array of labels assigned to the bounding boxes. The labels for object classes are defined during training.

`[bboxes,scores,labels,info] = detect(detector,I)` also returns information about the class probabilities and objectness scores for each detection.

`detectionResults = detect(detector,ds)` detects objects within all the images returned by the `read` function of the input datastore `ds`.

`[___] = detect(___,roi)` detects objects within the rectangular search region `roi`, in addition to any combination of arguments from previous syntaxes.

`[___] = detect(___,Name=Value)` specifies options using one or more name-value arguments, in addition to any combination of arguments from previous syntaxes.

Examples

Detect Objects Using YOLO v3 Object Detector

Load a pretrained YOLO v3 object detector.

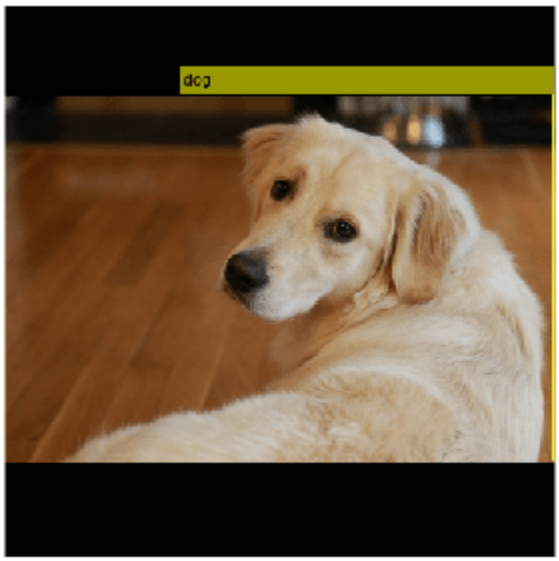
```
detector = yolov3ObjectDetector('tiny-yolov3-coco');
```

Read a test image and preprocess the test image by using the `preprocess` function.

```
img = imread('sherlock.jpg');
img = preprocess(detector,img);
```

Detect objects in the test image.

```
[bboxes,scores,labels] = detect(detector,img);
```



Display the detection results.

```
results = table(bboxes,labels,scores)
```

```
results=1×3 table
             bboxes              labels    scores
    _____________________________    ______    _______

    133     67    283    278      dog       0.51784
```

```
detectedImg = insertObjectAnnotation(img,'Rectangle',bboxes,labels);
figure
imshow(detectedImg)
```

Detect Objects from Images Stored in Image Datastore

Load a pretrained YOLOv3 object detector.

```
detector = yolov3ObjectDetector('tiny-yolov3-coco');
```

Read the test data and store as an image datastore object.

```
location = fullfile(matlabroot,'toolbox','vision','visiondata','vehicles');
imds = imageDatastore(location);
```

Detect objects in the test dataset. Set the `Threshold` parameter value to 0.3 and `MiniBatchSize` parameter value to 32.

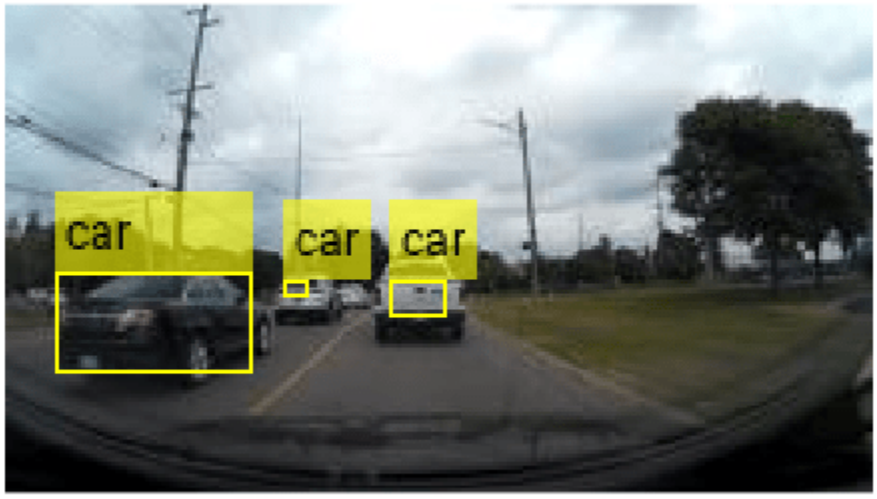
```
detectionResults = detect(detector,imds,'Threshold',0.3,'MiniBatchSize',32);
```

Read an image from the test dataset and extract the corresponding detection results.

```
num = 10;
I = readimage(imds,num);
bboxes = detectionResults.Boxes{num};
labels = detectionResults.Labels{num};
scores = detectionResults.Scores{num};
```

Perform non-maximal suppression to select strongest bounding boxes from the overlapping clusters. Set the `OverlapThreshold` parameter value to 0.2.

```
[bboxes,scores,labels] = selectStrongestBboxMulticlass(bboxes,scores,labels,'OverlapThreshold',0
```



Display the detection results.

```
results = table(bboxes,labels,scores)
```

```
results=3×3 table
             bboxes             labels    scores
    ____________________________    ______    _______

     14     71     52     27      car       0.93352
     74     73      7      5      car       0.65369
    102     73     15     10      car       0.85313
```

```
detectedImg = insertObjectAnnotation(I,'Rectangle',bboxes,labels);
figure
imshow(detectedImg)
```

Detect Objects Within ROI

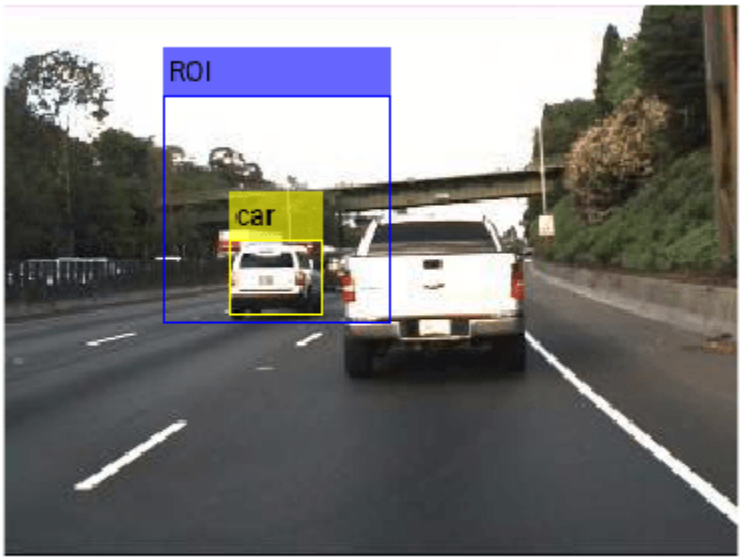
Load a pretrained YOLO v3 object detector.

```
detector = yolov3ObjectDetector('tiny-yolov3-coco');
```

Read a test image.

```
img = imread('highway.png');
```

Specify a region of interest (ROI) within the test image.



```
roiBox = [70 40 100 100];
```

Detect objects within the specified ROI.

```
[bboxes,scores,labels] = detect(detector,img,roiBox);
```

Display the ROI and the detection results.

```
img = insertObjectAnnotation(img,'Rectangle',roiBox,'ROI','AnnotationColor',"blue");
detectedImg = insertObjectAnnotation(img,'Rectangle',bboxes,labels);
figure
imshow(detectedImg)
```

Input Arguments

`detector` — YOLO v3 object detector

`yolov3ObjectDetector` object

YOLO v3 object detector, specified as a `yolov3ObjectDetector` object.

`I` — Test images

numeric array

Test images, specified as a numeric array of size *H*-by-*W*-by*C* or *H*-by-*W*-by*C*-by-*T*. Images must be real, nonsparse, grayscale or RGB image.

- *H*: Height
- *W*: Width
- *C*: The channel size in each image must be equal to the network's input channel size. For example, for grayscale images, *C* must be equal to `1`. For RGB color images, it must be equal to `3`.
- *T*: Number of test images in the array. The function computes the object detection results for each test image in the array.

The intensity range of the test image must be similar to the intensity range of the images used to train the detector. For example, if you train the detector on `uint8` images, rescale the test image to the range [0, 255] by using the `im2uint8` or `rescale` function. The size of the test image must be comparable to the sizes of the images used in training. If these sizes are very different, the detector has difficulty detecting objects because the scale of the objects in the test image differs from the scale of the objects the detector was trained to identify.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single`

`ds` — Test images
`ImageDatastore` object | `CombinedDatastore` object | `TransformedDatastore` object

Test images, specified as a `ImageDatastore` object, `CombinedDatastore` object, or `TransformedDatastore` object containing full filenames of the test images. The images in the datastore must be grayscale, or RGB images.

`roi` — Search region of interest
[*x y width height*] vector

Search region of interest, specified as an [*x y width height*] vector. The vector specifies the upper left corner and size of a region in pixels.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `detect(detector,I,Threshold=0.25)`

`Threshold` — Detection threshold
`0.5` (default) | scalar in the range [0, 1]

Detection threshold, specified as a scalar in the range [0, 1]. Detections that have scores less than this threshold value are removed. To reduce false positives, increase this value.

`SelectStrongest` — Select strongest bounding box
`true` (default) | `false`

Select the strongest bounding box for each detected object, specified as `true` or `false`.

- `true` — Returns the strongest bounding box per object. The method calls the `selectStrongestBboxMulticlass` function, which uses nonmaximal suppression to eliminate overlapping bounding boxes based on their confidence scores.

  By default, the `selectStrongestBboxMulticlass` function is called as follows

  ```
  selectStrongestBboxMulticlass(bboxes,scores,labels, ...
                                RatioType="Union", ...
                                OverlapThreshold=0.5);
  ```

- `false` — Return all the detected bounding boxes. You can then write your own custom method to eliminate overlapping bounding boxes.

`MinSize` — Minimum region size
`[1 1]` (default) | vector of the form [*height width*]

Minimum region size, specified as a vector of the form [*height width*]. Units are in pixels. The minimum region size defines the size of the smallest region containing the object.

By default, `MinSize` is 1-by-1.

`MaxSize` — Maximum region size
`size(I)` (default) | vector of the form [*height width*]

Maximum region size, specified as a vector of the form [*height width*]. Units are in pixels. The maximum region size defines the size of the largest region containing the object.

By default, `MaxSize` is the height and width of the input image, `I`. To reduce computation time, set this value to the known maximum region size for the objects that can be detected in the input test image.

`MiniBatchSize` — Minimum batch size
128 (default) | scalar

Minimum batch size, specified as a scalar value. Use the `MiniBatchSize` to process a large collection of image. Images are grouped into minibatches and processed as a batch, which can improve computational efficiency at the cost of increased memory demand. Decrease the size to use less memory.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as `"auto"`, `"gpu"`, or `"cpu"`.

- `"auto"` — Use a GPU if it is available. Otherwise, use the CPU.
- `"gpu"` — Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA-enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Use the CPU.

`Acceleration` — Performance optimization
`"auto"` (default) | `"mex"` | `"none"`

Performance optimization, specified one of the following:

- `"auto"` — Automatically apply a number of optimizations suitable for the input network and hardware resource.
- `"mex"` — Compile and execute a MEX function. This option is available when using a GPU only. Using a GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If Parallel Computing Toolbox or a suitable GPU is not available, then the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"none"` — Disable all acceleration.

The default option is `"auto"`. If `"auto"` is specified, MATLAB applies a number of compatible optimizations. If you use the `"auto"` option, MATLAB does not ever generate a MEX function.

Using the `Acceleration` options `"auto"` and `"mex"` can offer performance benefits, but at the expense of an increased initial run time. Subsequent calls with compatible parameters are faster. Use performance optimization when you plan to call the function multiple times using new input data.

The `"mex"` option generates and executes a MEX function based on the network and parameters used in the function call. You can have several MEX functions associated with a single network at one time. Clearing the network variable also clears any MEX functions associated with that network.

The `"mex"` option is only available for input data specified as a numeric array, cell array of numeric arrays, table, or image datastore. No other types of datastore support the `"mex"` option.

The `"mex"` option is only available when you are using a GPU. You must also have a C/C++ compiler installed. For setup instructions, see “Set Up Compiler” (GPU Coder).

`"mex"` acceleration does not support all layers. For a list of supported layers, see “Supported Layers” (GPU Coder).

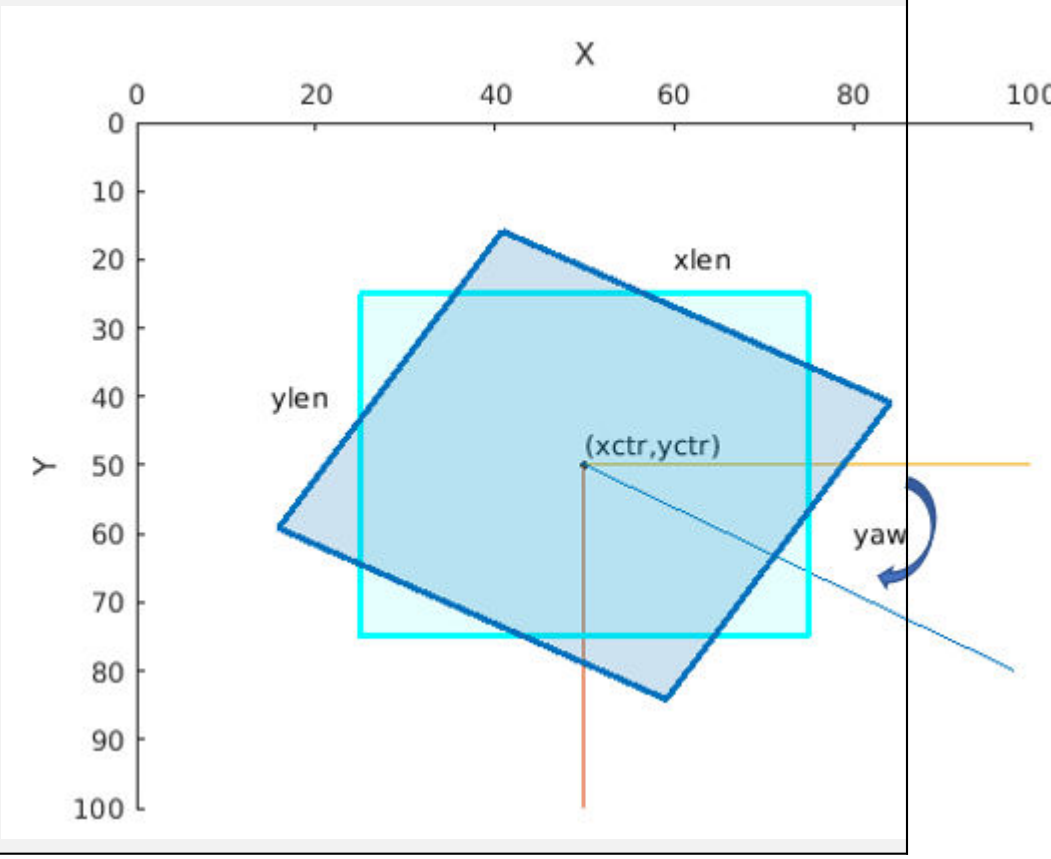
`DetectionPreprocessing` — Option to preprocess test images
`"auto"` (default) | `"none"`

Option to preprocess the test images before performing object detection, specified as one of these values:

- `"auto"` — To preprocess the test image before performing object detection. The `detect` function calls the `preprocess` function that perform these operations:
  - Rescales the intensity values of the training images to the range [0, 1].
  - Resizes the training images to one of the nearest network input sizes and updates the bounding box coordinate values for accurate training. The function preserves the original aspect ratio of the training data.
- `"none"` — To perform object detection without preprocessing the test image. If you choose this option, the datatype of the test image must be either `single` or `double`.

Data Types: `char` | `string`

Output Arguments



`bboxes` — Location of objects detected
M-by-4 matrix | *M*-by-5 matrix | *T*-by-1 cell array

Location of objects detected within the input image or images, returned as a

- *M*-by-4 matrix or an *M*-by-5 matrix if the input is a single test image.
- *T*-by-1 cell array if the input is an array of test images. *T* is the number of test images in the array. *M* is the number of bounding boxes in an image

The table describes the format of bounding boxes.

Bounding Box	Description
`rectangle`	Defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and `y` specify the upper-left corner of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis. • *h* specifies the height of the rectangle, which is its length along the *y*-axis.

Bounding Box	Description
`rotated-rectangle`	Defined in spatial coordinates as an *M*-by-5 numeric matrix with rows of the form [*xctr yctr xlen ylen yaw*], where: • *M* is the number of rotated rectangles. • *xctr* and *yctr* specify the center of the rectangle. • *xlen* specifies the width of the rectangle, which is its length along the *x*-axis before rotation. • *ylen* specifies the height of the rectangle, which is its length along the *y*-axis before rotation. • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the bounding box. 

`scores` — Detection scores

M-by-1 numeric vector | *T*-by-1 cell array

Detection confidence scores for each bounding box, returned as one of these options:

- *M*-by-1 numeric vector — The input is a single test image. *M* is the number of bounding boxes detected in the image.
- *B*-by-1 cell array — The input is a batch of test images, where *B* is the number of test images in the batch. Each cell in the array contains an *M*-element row vector, where each element indicates the detection score for a bounding box in the corresponding image.

A higher score indicates higher confidence in the detection. The confidence score for each detection is a product of the corresponding objectness score and maximum class probability. The objectness score is the probability that the object in the bounding box belongs to a class in the image. The maximum class probability is the largest probability that a detected object in the bounding box belongs to a particular class.

`labels` — Labels for bounding boxes
M-by-1 categorical vector | *T*-by-1 cell array

Labels for bounding boxes, returned as one of these options:

- *M*-by-1 categorical vector if the input is a single test image.
- *T*-by-1 cell array if the input is an array of test images. *T* is the number of test images in the array. Each cell in the array contains a *M*-by-1 categorical vector containing the names of the object classes.

M is the number of bounding boxes detected in an image.

`detectionResults` — Detection results
3-column table

Detection results, returned as a 3-column table with variable names, *Boxes*, *Scores*, and *Labels*. The *Boxes* column can contain rectangles or rotated rectangle bounding boxes of the form :

- rectangle — *M*-by-4 matrices, of *M* bounding boxes for the objects found in the image. Each row specifies a rectangle as a 4-element vector of the form [*x*,*y*,*width*,*height*], where (*x*,*y*) specifies the upper-left corner location and (*width*, *height*) specifies the size in pixels
- rotated rectangle — *M*-by-5 matrices of *M* bounding boxes for the objects found in the image. Each row specifies a rotated rectangle as a 5-element vector of the form [*xctr*,*yctr*,*width*, *height*,*yaw*], where (*xctr*,*yctr*) specifies the center, (*width*,*height*) specifies the size, and *yaw* specifies the rotated angle.

`info` — Class probabilities and objectness scores
structure array

Class probabilities and objectness scores of the detections, returned as a structure array with these fields.

- `ClassProbabilities` — Class probabilities for each of the detections, returned as a *B*-by-1 cell array. *B* is the number of images in the input batch of images, `I`. Each cell in the array contains the class probabilities as an *M*-by-*N* numeric matrix. *M* is the number of bounding boxes and *N* is the number of classes. Each class probability is a numeric scalar, indicating the probability that the detected object in the bounding box belongs to a class in the image.
- `ObjectnessScores` — Objectness scores for each of the detections, returned as a *B*-by-1 cell array. *B* is the number of images in the input batch of images, `I`. Each cell in the array contains the objectness score for each bounding box as an *M*-by-1 numeric vector. *M* is the number of bounding boxes. Each objectness score is a numeric scalar, indicating the probability that the bounding box contains an object belonging to one of the classes in the image.

Version History

Introduced in R2021a

R2024b: Code generation support for rotated rectangle bounding boxes

Starting in R2024b, `bboxes` output argument returned as rotated rectangle bounding box predictions, supports both CPU and GPU code generation.

R2024a: Rotated rectangle bounding box support

The output argument `bboxes` now support rotated rectangle bounding box predictions.

R2024a: Option to return class probabilities and objectness scores

Specify the `info` output argument to return information about the class probability and objectness score for each detection.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `roi` argument to the `detect` method must be a code generation constant (`coder.const()`) and a 1-by-4 vector.
- Only the `Threshold`, `SelectStrongest`, `MinSize`, `MiniBatchSize`, and `MaxSize` name-value arguments are supported.
- The `MiniBatchSize` name-value argument is not supported for code generation when the image input `I` is an *H*-by-*W*-by-*C*-by-*B* numeric array of images. All images will processed in one batch.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- The `roi` argument to the `detect` method must be a codegen constant (`coder.const()`) and a 1-by-4 vector.
- Only the `Threshold`, `SelectStrongest`, `MinSize`, and `MaxSize` name-value arguments are supported.
- The height, width, and channel of the input image must be fixed size.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- GPU Arrays is not supported for rotated rectangle bounding box.

preprocess

Preprocess training and test images

Syntax

```
outputData = preprocess(detector,trainingData)
outputImg = preprocess(detector,img)
[___,scaleInfo] = preprocess(___)
```

Description

`outputData = preprocess(detector,trainingData)` preprocesses the training data `trainingData` before using it to train the YOLO v3 object detector. The training images and the corresponding bounding boxes are stored in the `trainingData`. The `preprocess` function performs these operations:

- Rescales the intensity values of the training images to the range [0, 1].
- Resizes the training images to one of the nearest network input sizes and updates the bounding box coordinate values for accurate training. The function preserves the original aspect ratio of the training data.

`outputImg = preprocess(detector,img)` preprocesses the test images `img` for object detection using a YOLO v3 object detector. The `preprocess` function performs these operations:

- Rescales the intensity values of the test images to the range [0, 1].
- Resizes the test images to one of the nearest network input sizes and preserves the original aspect ratio of each test image.

`[___,scaleInfo] = preprocess(___)` returns information on the scale factor applied for image resizing, in addition to any combination of arguments from previous syntaxes.

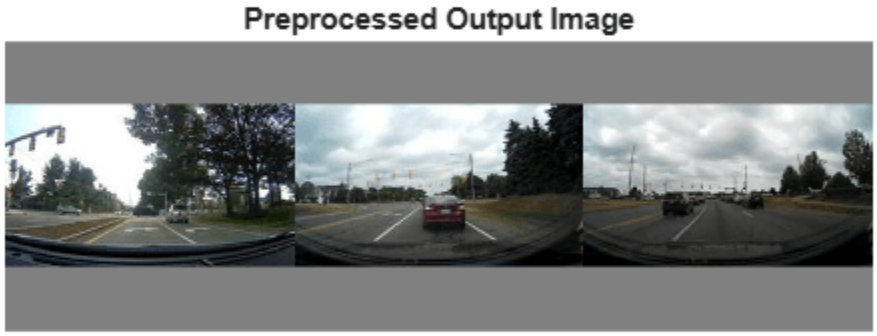
Examples

Preprocess Training Data Stored in Cell Array

Load a pretrained YOLO v3 object detector.

```
detector = yolov3ObjectDetector('tiny-yolov3-coco');
```

Load the training dataset into the workspace. The training data is a cell array that contains three training images and the corresponding bounding box values and class labels.



```
load('trainingData.mat','trainingData');
```

Resize the training images to the nearest network input size and rescale the intensity values by using the `preprocess` function.

```
[outputData,info] = preprocess(detector,trainingData);
```

Display the output images and the scale information used for resizing the images.

```
figure
montage({outputData{1,1},outputData{2,1},outputData{3,1}},Size=[1 3])
title("Preprocessed Output Image")
```

```
ScaleX = [info{1,1}.ScaleX;info{2,1}.ScaleX;info{3,1}.ScaleX];
ScaleY = [info{1,1}.ScaleY;info{2,1}.ScaleY;info{3,1}.ScaleY];
table(ScaleX,ScaleY)

```

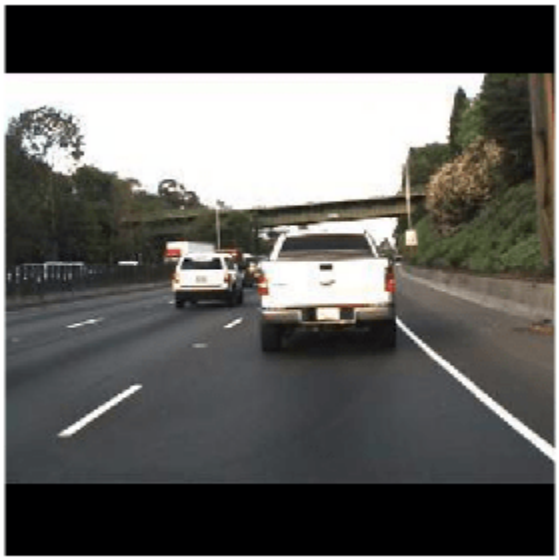
Preprocess Test Image

Load a pretrained YOLO v3 object detector.

```
detector = yolov3ObjectDetector('tiny-yolov3-coco');
```

Read a test image.



```
I = imread('highway.png');
```

Resize the test image to the network input size and rescale the intensity values by using the `preprocess` function.

```
[outputImg,scaleInfo] = preprocess(detector,I);
```

Display the output image and the scale information used for resizing the image.

```
figure
imshow(outputImg)
```

```
disp(scaleInfo)
```

```
                  ScaleX: 0.7692
                  ScaleY: 0.5769
    PreprocessedImageSize: [416 416 3]
```

Input Arguments

`detector` — YOLO v3 object detector

`yolov3ObjectDetector` object

YOLO v3 object detector, specified as a `yolov3ObjectDetector` object.

`trainingData` — Training data for YOLO v3 object detector

N-by-3 cell array

Training data for YOLO v3 object detector, specified as a *N*-by-3 cell array that contains the images, bounding boxes, and the class labels. Each row is of the form [*images bounding boxes labels*]. *N* is the number of output layers in the network. The bounding boxes must be stored as a *K*-by-4 matrix of the form [*x y width height*]. *K* is the number of object classes.

`img` — Test images

numeric array

Test images, specified as a numeric array of size *M*-by-*N*-by-*C* or *M*-by-*N*-by-*C*-by-*T*. *M* is the number of rows, *N* is the number of columns, and *C* is the number of color channels. The value of *C* is `1` for grayscale images and `3` for RGB color images. *T* is the number of test images in the array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`outputData` — Preprocessed training data

N-by-3 cell array

Preprocessed training data, returned as a *N*-by-3 cell array.

Data Types: `cell`

`outputImg` — Preprocessed test images

numeric array

Preprocessed test images, returned as a numeric array of size *P*-by-*Q*-by-*C* or *P*-by-*Q*-by-*C*-by-*T*. *P* and *Q* are the number of rows and columns, respectively, in the preprocessed image.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`scaleInfo` — Information about scale factor for image resizing

structure

Information about the scale factor for resizing the input images, returned as a structure with fields `PreprocessedImageSize`, `ScaleX`, and `ScaleY`.

- `PreprocessedImageSize` — Size of the output resized image.
- `ScaleX` — Scale factor for resizing an image in the *X*-direction (along the rows).
- `ScaleY` — Scale factor for resizing an image in the *Y*-direction (along the columns).

Data Types: `struct`

“Getting Started with YOLO v3”

predict

Compute YOLO v3 deep learning network outputs for inference

Syntax

```
output = predict(detector,dlX)
```

Description

`output = predict(detector,dlX)` computes the YOLO v3 deep learning network outputs during inference, given the detector and the test data. Use this function to get predictions from the output layers of the YOLO v3 deep learning network during inference.

Note To run this function, you will require the Deep Learning Toolbox.

Examples

Compute YOLO v3 Network Predictions

Load a pretrained YOLO v3 object detector.

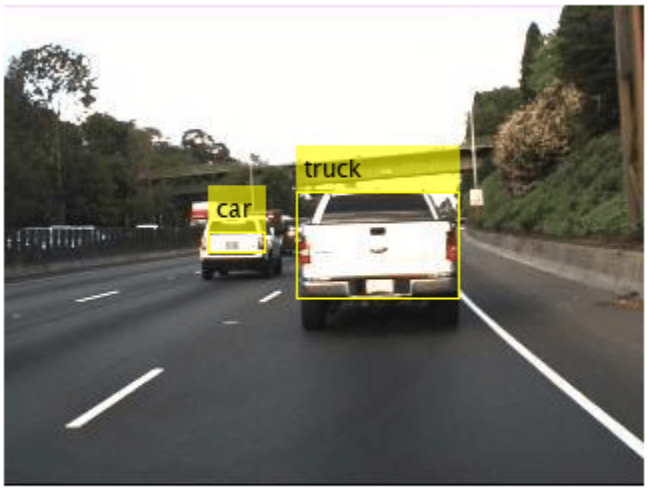
```
detector = yolov3ObjectDetector('tiny-yolov3-coco');
```

Load the test image for prediction.

```
I = imread('highway.png');
```

Preprocess the test image and convert the preprocessed image to a formatted dlarray object.

```
[Ip,info] = preprocess(detector,I);
Ip = im2single(Ip);
dlX = dlarray(Ip,'SSCB');
```



Compute predictions for the test image. The `predict` function returns the predictions for the feature maps from the output layers of the YOLO v3 deep learning network. The first column contains the confidence scores. Columns 2 to 5 contain the bounding box locations computed relative to the grid cell coordinates. The sixth column contains the class probabilities for each class used during training. The seventh and the eighth column contains the prior width and prior height of bounding boxes as computed by the network, respectively.

```
output = predict(detector,dlX)
```

```
output=2×8 cell array
    {13×13×3×1 dlarray}    {13×13×3×1 dlarray}    {13×13×3×1 dlarray}    {13×13×3×1 dlarray}    ←
    {26×26×3×1 dlarray}    {26×26×3×1 dlarray}    {26×26×3×1 dlarray}    {26×26×3×1 dlarray}    ←
```

You can then get the final detections by using the predictions for features with maximum objectness scores. The objectness score is the product of confidence score and class probability. To compute the

exact bounding box location, you must map the predicted bounding box values to box coordinates. Alternatively, you can use the `detect` function to directly get the detection results. The `detect` function internally calls the `predict` function to compute the feature maps.

Input Arguments

`detector` — YOLO v3 object detector

`yolov3ObjectDetector` object

YOLO v3 object detector, specified as a `yolov3ObjectDetector` object.

`dlX` — Test data

formatted `dlarray`

Test data, specified as a formatted `dlarray` object. The test data can contain one or more test images.

Output Arguments

`output` — Output predictions

N-by-8 cell array of formatted `dlarray`

Output predictions, returned as an *N*-by-8 cell array of formatted `dlarray` objects. *N* is the number of output layers in the YOLO v3 deep learning network. Each row in the cell array is of form [*conf* b_x b_y b_w b_h *prob* t_w t_h]. The function returns predictions as a formatted `dlarray` value..

Predictions	Description
conf	Confidence scores for each bounding box.

b_x	*X*-coordinate of the center of the predicted bounding box relative to the location of the grid cell.
b_y	*Y*-coordinate of the center of the predicted bounding box relative to the location of the grid cell.
b_w	Width of the predicted bounding box relative to the location of the grid cell.
b_h	Height of the predicted bounding boxes relative to the location of the grid cell.
prob	Class probabilities predicted for each feature in the output feature map.
t_w	Prior width of the bounding boxes as computed by the network.
t_h	Prior height of the bounding boxes as computed by the network.

Version History

Introduced in R2021a

forward

Compute YOLO v3 deep learning network output for training

Syntax

```
features = forward(detector,dlX)
[features,activations] = forward(detector,dlX)
[features,activations,state] = forward(detector,dlX)
```

Description

`features = forward(detector,dlX)` computes the output features of the network during training given the input data `dlX`.

`[features,activations] = forward(detector,dlX)` also computes the activations of the network that you can use for modeling the gradient loss.

`[features,activations,state] = forward(detector,dlX)` also returns the updated network state.

Note To run this function, you will require the Deep Learning Toolbox.

Examples

Compute YOLO v3 Network Output During Forward Pass

Load a pretrained YOLO v3 object detector.

```
detector = yolov3ObjectDetector('tiny-yolov3-coco');
```

Read an image to use for training.

```
I = imread('highway.png');
```

Preprocess the training data and convert the preprocessed training data to a formatted `dlarray` object.

```
[Ip,info] = preprocess(detector,I);
Ip = im2single(Ip);
dlX = dlarray(Ip,'SSCB');
```

Compute the network outputs obtained during training. The `forward` function returns the activations from the output layers of the YOLO v3 deep learning network. The first column contains the confidence scores. Columns 2 to 5 contain the bounding box locations computed relative to the grid cell coordinates. The sixth column contains the class probabilities for each class used during training. The seventh and the eighth column contains the prior width and prior height of bounding boxes as computed by the network, respectively. The output features computed during the forward pass are used to model the gradient losses for the network.

```
[output,activations,state] = forward(detector,dlX)

output=2×8 cell array

    "batch_norm_8"    "TrainedVariance"    {1×1×256  dlarray}
      ⋮
```

Input Arguments

`detector` — YOLO v3 object detector

`yolov3ObjectDetector` object

YOLO v3 object detector, specified as a `yolov3ObjectDetector` object.

`dlX` — Training data

formatted `dlarray`

Training data, specified as a formatted `dlarray` object.

Output Arguments

`features` — Output features in box coordinates

N-by-8 cell array

Output features in box coordinates, returned as an *N*-by-8 cell array. *N* is the number of output layers in the YOLO v3 deep learning network.

`activations` — Activations of network
N-by-8 cell array of formatted `dlarray`

Activations of the network, returned as an *N*-by-8 cell array of formatted `dlarray` objects. *N* is the number of output layers in the YOLO v3 deep learning network.

Each row in the cell array is of form [*conf* b_x b_y b_w b_h *prob* t_w t_h]. The function returns each activation as a formatted `dlarray` value.

Activations	Description
conf	Estimated confidence scores for each bounding box.
b_x	Estimated *X*-coordinate value for the center of the bounding box relative to the location of the grid cell.
b_y	Estimated *Y*-coordinate value for the center of the bounding box relative to the location of the grid cell.
b_w	Estimated width of the bounding box relative to the location of the grid cell.
b_h	Estimated height of the bounding box relative to the location of the grid cell.
prob	Class probabilities estimated for each feature in the output feature map.
t_w	Prior width of the bounding box as estimated by the network.
t_h	Prior height of the bounding box as estimated by the network.

`state` — Updated network state
table

Updated network state, returned as a table. The network state is a table with three columns:

- `Layer` – Layer name, returned as a string scalar.
- `Parameter` – Parameter name, returned as a string scalar.
- `Value` – Value of parameter, returned as a numeric array object.

The network state contains information remembered by the network between iterations.

yolov4ObjectDetector

Detect objects using YOLO v4 object detector

Description

The `yolov4ObjectDetector` object creates a you only look once version 4 (YOLO v4) one-stage object detector for detecting objects in an image. Using this object, you can:

- Create a pretrained YOLO v4 object detector by using YOLO v4 deep learning networks trained on COCO dataset.
- Create a custom YOLO v4 object detector by using any pretrained or untrained YOLO v4 deep learning network.

Creation

Syntax

```
detector = yolov4ObjectDetector(name)

detector = yolov4ObjectDetector(name,classes,aboxes)
detector = yolov4ObjectDetector(net,classes,aboxes)
detector = yolov4ObjectDetector(baseNet,classes,
aboxes,DetectionNetworkSource=layer)
detector = yolov4ObjectDetector( ___ ,Name=Value)
```

Description

Pretrained YOLO v4 Object Detector

`detector = yolov4ObjectDetector(name)` creates a pretrained YOLO v4 object detector by using YOLO v4 deep learning networks trained on a COCO dataset.

Custom YOLO v4 Object Detector

`detector = yolov4ObjectDetector(name,classes,aboxes)` creates a pretrained YOLO v4 object detector and configures it to perform transfer learning using a specified set of object classes and anchor boxes. For optimal results, you must train the detector on new training images before performing detection. Use the `trainYOLOv4ObjectDetector` function for training the detector.

`detector = yolov4ObjectDetector(net,classes,aboxes)` creates an object detector by using the deep learning network `net`.

If `net` is a pretrained YOLO v4 deep learning network, the function creates a pretrained YOLO v4 object detector. The `classes` and `aboxes` are values used for training the network.

If `net` is an untrained YOLO v4 deep learning network, the function creates a YOLO v4 object detector to use for training and inference. `classes` and `aboxes` specify the object classes and the anchor boxes, respectively, for training the YOLO v4 network.

Use the `trainYOLOv4ObjectDetector` function to train the network before performing object detection.

`detector = yolov4ObjectDetector(baseNet,classes, aboxes,DetectionNetworkSource=layer)` creates a YOLO v4 object detector by adding detection heads to a base network, `baseNet`.

The function adds detection heads to the specified feature extraction layers `layer` in the base network. To specify the names of the feature extraction layers, use the name-value argument `DetectionNetworkSource=layer`.

If `baseNet` is a pretrained deep learning network, the function creates a YOLO v4 object detector and configures it to perform transfer learning with the specified object classes and anchor boxes.

If `baseNet` is an untrained deep learning network, the function creates a YOLO v4 object detector and configures it for object detection. `classes` and `aboxes` specify the object classes and the anchor boxes, respectively, for training the YOLO v4 network.

You must train the detector on a training dataset before performing object detection. Use the `trainYOLOv4ObjectDetector` function for training the detector.

`detector = yolov4ObjectDetector( ___ ,Name=Value)` specifies one or more options using name-value arguments in addition to any combination of input arguments from previous syntaxes. Use this syntax to:

- Modify the detection network sources in a YOLO v4 object detection network and train the network with different numbers of object classes, anchor boxes, or both. Specify the new detection network sources using the `DetectionNetworkSource=layer` name-value argument.
- Set the `InputSize on page 2-0` and `ModelName on page 2-0` properties of the object detector. For example, `InputSize=[224 224 3]` sets the size of the images used for training to `[224 224 3]`.

Note To use the pretrained YOLO v4 object detection networks trained on COCO dataset, you must install the Computer Vision Toolbox Model for YOLO v4 Object Detection. You can download and install the Computer Vision Toolbox Model for YOLO v4 Object Detection from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons. To run this function, you will require the Deep Learning Toolbox.

Input Arguments

`name` — Name of pretrained YOLO v4 deep learning network

`"csp-darknet53-coco"` | `"tiny-yolov4-coco"`

Name of the pretrained YOLO v4 deep learning network, specified as one of these:

- `"csp-darknet53-coco"` — A pretrained YOLO v4 deep learning network created using CSP-DarkNet-53 as the base network and trained on COCO dataset.
- `"tiny-yolov4-coco"` — A pretrained YOLO v4 deep learning network created using a small base network and trained on COCO dataset.

Data Types: `char` | `string`

`classes` — Names of object classes
string vector | cell array of character vectors | categorical vector

Names of object classes for training the detector, specified as a string vector, cell array of character vectors, or categorical vector. This argument sets the `ClassNames` property of the `yolov4ObjectDetector` object.

Data Types: `char` | `string` | `categorical`

`aboxes` — Anchor boxes
cell array

Anchor boxes for training the detector, specified as an *N*-by-1 column vector cell array or a 1-by-*N* row vector cell array. *N* is the number of output layers in the YOLO v4 deep learning network. Each cell contains an *M*-by-2 matrix, where *M* is the number of anchor boxes in that layer. Each cell can contain a different number of anchor boxes. Each row in the *M*-by-2 matrix denotes the size of an anchor box in the form [*height width*].

The first element in the cell array specifies the anchor boxes to associate with the first output layer, the second element in the cell array specifies the anchor boxes to associate with the second output layer, and so on. For accurate detection results, specify large anchor boxes for the first output layer and small anchor boxes for the last output layer. That is, the anchor box sizes must decrease for each output layer in the order in which the layers appear in the YOLO v4 deep learning network.

This argument sets the `AnchorBoxes` property of the `yolov4ObjectDetector` object.

Data Types: `cell`

`net` — YOLO v4 deep learning network
`dlnetwork` object

YOLO v4 deep learning network, specified as a `dlnetwork` object. The input network can be either an untrained or a pretrained deep learning network. The input network must have an image input layer.

`baseNet` — Base network
`dlnetwork` object

Base network for creating the YOLO v4 deep learning network, specified as a `dlnetwork` object. The network can be either an untrained or a pretrained deep learning network. The input network must have an image input layer.

`layer` — Names of feature extraction layers
cell array of character vectors | string array

Names of the feature extraction layers in the base network, specified as a cell array of character vectors, or a string array. The function creates a YOLO v4 network by adding detection head layers to the output of the feature extraction layers in the base network.

In the pre-trained yolo v4 base network, you must connect the detection head layers to feature extraction layers where the input image feature map changes spatial dimension by downsampling factors of 4, 8, 16, and 32.

- Use the `analyzeNetwork` function to display the pre-trained YOLO v4 network architecture to obtain the information about the spatial dimensions of the feature maps.

- Use this table to know about the default feature extraction layers and choose alternate feature extraction layers supported by the pre-trained YOLO v4 networks. Choose feature extraction layers using empirical evaluation based on the detection accuracy, training speed, and object size to detect.
  - To achieve higher detection accuracy, choose feature extraction layers with both higher and lower downsampling factors. Layers with lower downsampling factor capture small objects and layers with higher downsampling factor ensure a thorough feature refinement.
  - To achieve higher training and inference speeds, choose feature extraction layers with lower downsampling factor.
  - The number of detection network sources specified must be equal to the number of anchor boxes specified at the input.

Backbone	**Number of Detection Heads**	**Default Feature Extraction Layers**		**Examples of Alternate Feature Extraction Layers**		**Remarks**
		Layer	**Downsampling Factor**	**Layer**	**Downsampling Factor**	
`tiny-yolov4-coco`	2	`leaky_28` `leaky_25`	32 16	`leaky_17` `leaky_9`	8 4	Select any two feature extraction layers with different downsampling factors preceding the `leaky_28` layer to use as detection network sources. For example, specify the new detection network sources as `layer = {'leaky_17','leaky_9'}`

`csp-darknet53-coco`	3	`mish_106`
		`mish_87`
		`mish_56`
			32
			16
			8
				`mish_88`
				`mish_102`
					32	Select any three feature extraction layers with different

				`mish_68` `mish_57`	16	

				`mish_37` `mish_26`	8	downsampling factors preceding the `mish_106` layer to use as detection network sources. For example, specify the new detection network sources as `layer = {'mish_57','mish_26','mish_13'}`

				`mish_25`
				`mish_18`
				`mish_13`
					4	

Data Types: `char` | `string` | `cell`

Properties

`Network` — YOLO v4 deep learning network

`dlnetwork` object

YOLO v4 deep learning network to use for object detection, stored as a `dlnetwork` object.

`ClassNames` — Names of object classes

categorical vector

Names of object classes to detect, stored as a categorical vector. You can set this property by using the input argument `classes`.

`AnchorBoxes` — Set of anchor boxes

N-by-1 cell array

This property is read-only.

Set of anchor boxes, stored as a *N*-by-1 cell array. *N* is the number of output layers in the YOLO v4 deep learning network for which the anchor boxes are defined. Each element in the cell is a *M*-by-2 matrix. *M* denotes the number of anchor boxes. Each cell can contain a different number of anchor boxes. Each row in the *M*-by-2 matrix denotes the size of the anchor box in the form of [*height width*]. The first element in the cell array specifies the anchor boxes for the first output layer, the second element in the cell array specifies the anchor boxes for the second output layer, and so on.

You can set this property by using the input argument `aboxes`.

`InputSize` — Image size used for training

vector

This property is read-only.

Image size used for training, stored as a vector of form [*height width*] or [*height width channels*]. To set this property, specify it at object creation. The size of the training images must be a multiple of 32.

For example, `detector = yolov4ObjectDetector(net,classes,aboxes,InputSize=[224 224 3])`.

`ModelName` — Name for object detector
`' '` (default) | character vector | string scalar

Name for the object detector, stored as a character vector or string scalar. To set this property, specify it at object creation.

For example, `yolov4ObjectDetector(net,classes,aboxes,ModelName="customDetector")` sets the name for the object detector to `"customDetector"`.

`PredictedBoxType` — Bounding box format for object detector
`"axis-aligned"` (default) | `"rotated"`

This property is read-only.

Bounding box format for an object detector, stored as `"axis-aligned"` or `"rotated"`. When the `PredictedBoxType` is `"axis-aligned"`, the object detector will train and perform inference on only axis-aligned bounding boxes. If it is set to `"rotated"`, the object detector will train and perform inference on only rotated bounding boxes. Set this property when you create the object.

Object Functions

detect Detect objects using YOLO v4 object detector

Examples

Create Pretrained YOLO v4 Object Detector

Specify the name of a pretrained YOLO v4 deep learning network.

```
name = "tiny-yolov4-coco";
```

Create YOLO v4 object detector by using the pretrained YOLO v4 network.

```
detector = yolov4ObjectDetector(name);
```

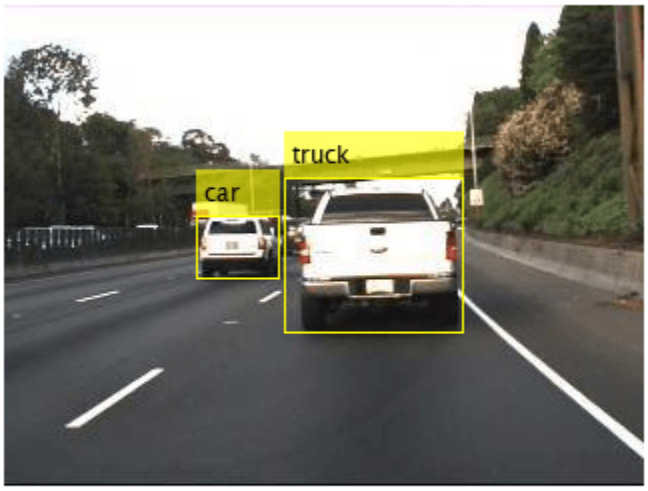
Display and inspect the properties of the YOLO v4 object detector.

```
disp(detector)
```

```
  yolov4ObjectDetector with properties:

       Network: [1×1 dlnetwork]
    AnchorBoxes: {2×1 cell}
     ClassNames: {80×1 cell}
      InputSize: [416 416 3]
      ModelName: 'tiny-yolov4-coco'
```

Use `analyzeNetwork` to display the YOLO v4 network architecture and get information about the network layers.



```
analyzeNetwork(detector.Network)
```

Detect objects in an unknown image by using the pretrained YOLO v4 object detector.

```
img = imread("highway.png");
[bboxes,scores,labels] = detect(detector,img);
```

Display the detection results.

```
detectedImg = insertObjectAnnotation(img,"Rectangle",bboxes,labels);
figure
imshow(detectedImg)
```

Create Custom YOLO v4 Object Detector

This example shows how to create a YOLO v4 object detection network based on a pretrained ResNet-50 convolutional neural network.

Load a pretrained deep learning network to use as the base network. This example uses ResNet-50 pretrained network as the base network. For information about other available pretrained networks, see “Pretrained Deep Neural Networks” (Deep Learning Toolbox).

```
basenet = imagePretrainedNetwork("resnet50");
```

Use `analyzeNetwork` to display the architecture of the base network.

```
analyzeNetwork(basenet)
```

The first layer in the base network is the image input layer. Inspect the property of the image input layer in the base network.

```
basenet.Layers(1)
```

```
ans =
  ImageInputLayer with properties:

                      Name: 'input_1'
                 InputSize: [224 224 3]
        SplitComplexInputs: 0

   Hyperparameters
          DataAugmentation: 'none'
             Normalization: 'zerocenter'
    NormalizationDimension: 'auto'
                      Mean: [224×224×3 single]
```

To create a YOLO v4 deep learning network you must set the `Normalization` property of the `ImageInputLayer` in the base network to "`none`". Define an image input layer with the `Normalization` property set as "`none`" and other property values the same as those of the base network.

```
imageSize = basenet.Layers(1).InputSize;
layerName = basenet.Layers(1).Name;
newInputLayer = imageInputLayer(imageSize,Normalization="none",Name=layerName);
```

Replace the image input layer in the base network with the new input layer.

```
dlnet = replaceLayer(basenet,layerName,newInputLayer);
```

Specify the names of the feature extraction layers in the base network to use as the detection heads.

```
featureExtractionLayers = ["activation_22_relu","activation_40_relu"];
```

Specify the class names and anchor boxes to use for training the YOLO v4 deep learning network created using ResNet-50 as the base network.

```
classes = ["car","person"];
anchorBoxes = {[122,177;223,84;80,94];...
               [111,38;33,47;37,18]};
```

Create a YOLO v4 object detector by using the specified base network and the detection heads.

```
detector = yolov4ObjectDetector(dlnet,classes,anchorBoxes, ...
    DetectionNetworkSource=featureExtractionLayers);
```

Display and inspect the properties of the YOLO v4 object detector.

```
disp(detector)
```

```
  yolov4ObjectDetector with properties:

            Network: [1×1 dlnetwork]
        AnchorBoxes: {2×1 cell}
         ClassNames: {2×1 cell}
          InputSize: [224 224 3]
```

```
    PredictedBoxType: 'axis-aligned'
           ModelName: ''
```

Use `analyzeNetwork` to display the YOLO v4 network architecture and get information about the network layers.

```
analyzeNetwork(detector.Network)
```

Detect People Using YOLO v4 Object Detector

This example shows how to detect people using a pretrained YOLO v4 object detector.

Load the pretrained YOLO v4 detector that can detect 80 common object classes.

```
detector = yolov4ObjectDetector();
```

Read image to process.

```
I = imread("visionteam.jpg");
```

Run object detector.

```
[bboxes, scores, labels] = detect(detector, I, Threshold=0.4);
```

Select detections for the person class.

```
personBoxes = bboxes(labels=="person", :);
```

Display results.

```
detectedImg = insertObjectAnnotation(I, "Rectangle", personBoxes, "person");
figure
imshow(detectedImg)
```

Version History

Introduced in R2022a

R2024b: Modify detection network source

Starting in R2024b, you can modify the detection network sources of a YOLO v4 object detection network when you perform transfer learning. You can specify the new detection network sources using the name-value argument `DetectionNetworkSource=layer`.

- Specify new detection network sources for the `tiny-yolov4-coco` and `csp-darknet53-coco` pretrained YOLO v4 object detectors by using the syntax

  ```
  detector = yolov4ObjectDetector(name,classes,aboxes,DetectionNetworkSource=layer);
  ```

- Specify new detection network sources for a YOLO v4 object detection network by using the syntax

  ```
  detector = yolov4ObjectDetector(net,classes,aboxes,DetectionNetworkSource=layer);
  ```

For an example, the below code modifies the detection network sources of the pretrained `tiny-yolov4-coco` network to `leaky_23` and `leaky_15`.

```
name = "tiny-yolov4-coco";
layer = ["leaky_23","leaky_15"];
detector = yolov4ObjectDetector(name,classes,aboxes,DetectionNetworkSource=layer);
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

- The `roi` argument to the `detect` method must be a code generation constant (`coder.const()`) and a 1x4 vector.
- Only the `Threshold`, `SelectStrongest`, `MinSize`, `MaxSize`, and `MiniBatchSize` name-value pairs for `detect` are supported.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

- The `roi` argument to the `detect` method must be a code generation constant (`coder.const()`) and a 1x4 vector.
- Only the `Threshold`, `SelectStrongest`, `MinSize`, `MaxSize`, and `MiniBatchSize` name-value pairs for `detect` are supported.

For information about how to create a `yolov4ObjectDetector` object for code generation, see "Load Pretrained Networks for Code Generation" (MATLAB Coder).

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- GPU Arrays is not supported for rotated rectangle bounding box inputs.

detect

Detect objects using YOLO v4 object detector

Syntax

```
bboxes = detect(detector,I)
[bboxes,scores] = detect(detector,I)
[bboxes,scores,labels] = detect(detector,I)
[bboxes,scores,labels,info] = detect(detector,I)

detectionResults = detect(detector,ds)

[___] = detect(___,roi)
[___] = detect(___,Name=Value)
```

Description

`bboxes = detect(detector,I)` detects objects within a single image or an array of images, `I`, using a you only look once version 4 (YOLO v4) object detector, `detector`. The `detect` function automatically resizes and rescales the input image to match that of the images used for training the detector. The locations of objects detected in the input image are returned as a set of bounding boxes.

Note To use the pretrained YOLO v4 object detection networks trained on COCO dataset, you must install the Computer Vision Toolbox Model for YOLO v4 Object Detection. You can download and install the Computer Vision Toolbox Model for YOLO v4 Object Detection from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons. To run this function, you will require the Deep Learning Toolbox.

`[bboxes,scores] = detect(detector,I)` also returns the class-specific confidence scores for each bounding box.

`[bboxes,scores,labels] = detect(detector,I)` returns a categorical array of labels assigned to the bounding boxes. The labels for object classes are defined during training.

`[bboxes,scores,labels,info] = detect(detector,I)` also returns information about the class probabilities and objectness scores for each detection.

`detectionResults = detect(detector,ds)` detects objects within all the images returned by the `read` function of the input datastore `ds`.

`[___] = detect(___,roi)` detects objects within the rectangular search region `roi`, in addition to any combination of arguments from previous syntaxes.

`[___] = detect(___,Name=Value)` specifies options using one or more name-value arguments, in addition to any combination of arguments from previous syntaxes..

Examples

Detect Objects Using Pretrained YOLO v4 Object Detector

Specify the name of a pretrained YOLO v4 deep learning network.

```
name = 'tiny-yolov4-coco';
```

Create YOLO v4 object detector by using the pretrained YOLO v4 network.

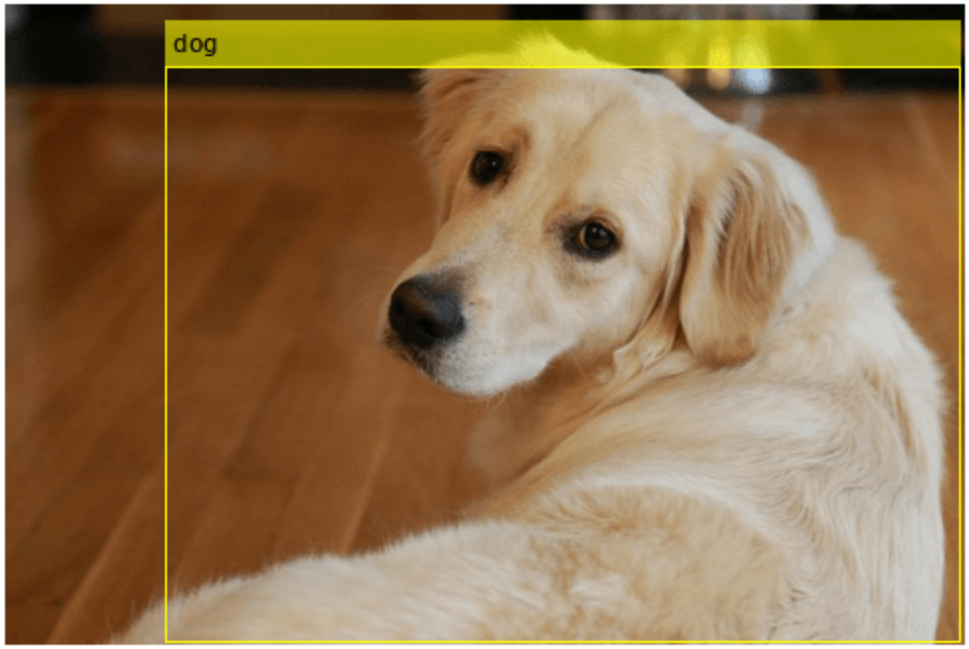
```
detector = yolov4ObjectDetector(name);
```

Detect objects in an unknown image by using the pretrained YOLO v4 object detector.

```
img = imread('sherlock.jpg');
img = im2single(imresize(img,0.5));
[bboxes,scores,labels] = detect(detector,img,Threshold=0.4)
```

```
bboxes = 1×4 single row vector

    80.9433    31.6083    398.4628    288.3917



scores = single

0.4281

labels = categorical
     dog
```

Display the detection results.

```
detectedImg = insertObjectAnnotation(img,'Rectangle',bboxes,labels);
figure
imshow(detectedImg)
```

Detect Objects in Image Datastore by Using YOLO v4 Detector

Load a pretrained YOLO v4 object detector.

```
detector = yolov4ObjectDetector("csp-darknet53-coco");
```

Read the test data and store as an image datastore object.

```
location = fullfile(matlabroot,'toolbox','vision','visiondata','vehicles');
imds = imageDatastore(location);
```

Detect objects in the test dataset. Set the `Threshold` parameter value to 0.4 and `MiniBatchSize` parameter value to 32.

```
detectionResults = detect(detector,imds,Threshold=0.4,MiniBatchSize=32);
```

Read an image from the test dataset and extract the corresponding detection results.

```
num = 20;
I = readimage(imds,num);
bboxes = detectionResults.Boxes{num};
labels = detectionResults.Labels{num};
scores = detectionResults.Scores{num};
```

Perform non-maximal suppression to select strongest bounding boxes from the overlapping clusters. Set the `OverlapThreshold` parameter value to 0.5.

```
[bboxes,scores,labels] = selectStrongestBboxMulticlass(bboxes,...
                                scores,labels,OverlapThreshold=0.5);
```

Display the detection results.

```
results = table(bboxes,labels,scores)
```

```
results=2×3 table
    17.8178,69.9661,23.4595,11.3807    car    0.9027
    75.2063,66.0107,26.1342,23.5411    car    0.5830
```

```
detectedImg = insertObjectAnnotation(I,"Rectangle",bboxes,labels);
figure
imshow(detectedImg)
```

Detect Objects Within ROI by Using YOLO v4 Detector

Load a pretrained YOLO v4 object detector.

```
detector = yolov4ObjectDetector("csp-darknet53-coco");
```

Read a test image.

```
img = imread("stopsign.jpg");
```

Specify a region of interest (ROI) within the test image.

```
roiBox = [250 60 500 300];
```

Detect objects within the specified ROI.

```
[bboxes,scores,labels] = detect(detector,img,roiBox);
```

Display the ROI and the detection results.

```
img = insertObjectAnnotation(img,"Rectangle",roiBox,"ROI",AnnotationColor="blue");
detectedImg = insertObjectAnnotation(img,"Rectangle",bboxes,labels);
figure
imshow(detectedImg)
```

Input Arguments

`detector` — YOLO v4 object detector

`yolov4ObjectDetector` object

YOLO v4 object detector, specified as a `yolov4ObjectDetector` object.

`I` — Test images

numeric array

Test images, specified as a numeric array of size *H*-by-*W*-by*C* or *H*-by-*W*-by*C*-by-*T*. Images must be real, nonsparse, grayscale or RGB image.

- *H*: Height
- *W*: Width
- *C*: The channel size in each image must be equal to the network's input channel size. For example, for grayscale images, *C* must be equal to 1. For RGB color images, it must be equal to 3.
- *T*: Number of test images in the array. The function computes the object detection results for each test image in the array.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single`

`ds` — Test images
`ImageDatastore` object | `CombinedDatastore` object | `TransformedDatastore` object

Test images, specified as a `ImageDatastore` object, `CombinedDatastore` object, or `TransformedDatastore` object containing full filenames of the test images. The images in the datastore must be grayscale, or RGB images.

`roi` — Search region of interest
[*x y width height*] vector

Search region of interest, specified as an [*x y width height*] vector. The vector specifies the upper left corner and size of a region in pixels.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `detect(detector,I,Threshold=0.25)`

`Threshold` — Detection threshold
`0.5` (default) | scalar in the range [0, 1]

Detection threshold, specified as a scalar in the range [0, 1]. Detections that have scores less than this threshold value are removed. To reduce false positives, increase this value.

`SelectStrongest` — Select strongest bounding box
`true` (default) | `false`

Select the strongest bounding box for each detected object, specified as `true` or `false`.

- `true` — Returns the strongest bounding box per object. The method calls the `selectStrongestBboxMulticlass` function, which uses nonmaximal suppression to eliminate overlapping bounding boxes based on their confidence scores.

  By default, the `selectStrongestBboxMulticlass` function is called as follows

  ```
  selectStrongestBboxMulticlass(bboxes,scores,labels, ...
                                RatioType="Union", ...
                                OverlapThreshold=0.5);
  ```

- `false` — Return all the detected bounding boxes. You can then write your own custom method to eliminate overlapping bounding boxes.

`MinSize` — Minimum region size
`[1 1]` (default) | vector of the form [*height width*]

Minimum region size, specified as a vector of the form [*height width*]. Units are in pixels. The minimum region size defines the size of the smallest region containing the object.

By default, `MinSize` is 1-by-1.

`MaxSize` — Maximum region size
`size(I)` (default) | vector of the form [*height width*]

Maximum region size, specified as a vector of the form [*height width*]. Units are in pixels. The maximum region size defines the size of the largest region containing the object.

By default, `MaxSize` is set to the height and width of the input image, `I`. To reduce computation time, set this value to the known maximum region size for the objects that can be detected in the input test image.

`MiniBatchSize` — Minimum batch size
128 (default) | scalar

Minimum batch size, specified as a scalar value. Use the `MiniBatchSize` to process a large collection of image. Images are grouped into minibatches and processed as a batch, which can improve computational efficiency at the cost of increased memory demand. Decrease the size to use less memory.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as `"auto"`, `"gpu"`, or `"cpu"`.

- `"auto"` — Use a GPU if it is available. Otherwise, use the CPU.
- `"gpu"` — Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA-enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Use the CPU.

`Acceleration` — Performance optimization
`"auto"` (default) | `"mex"` | `"none"`

Performance optimization, specified one of the following:

- `"auto"` — Automatically apply a number of optimizations suitable for the input network and hardware resource.
- `"mex"` — Compile and execute a MEX function. This option is available when using a GPU only. Using a GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If Parallel Computing Toolbox or a suitable GPU is not available, then the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"none"` — Disable all acceleration.

The default option is `"auto"`. If `"auto"` is specified, MATLAB applies a number of compatible optimizations. If you use the `"auto"` option, MATLAB does not ever generate a MEX function.

Using the `Acceleration` options `"auto"` and `"mex"` can offer performance benefits, but at the expense of an increased initial run time. Subsequent calls with compatible parameters are faster. Use performance optimization when you plan to call the function multiple times using new input data.

The `"mex"` option generates and executes a MEX function based on the network and parameters used in the function call. You can have several MEX functions associated with a single network at one time. Clearing the network variable also clears any MEX functions associated with that network.

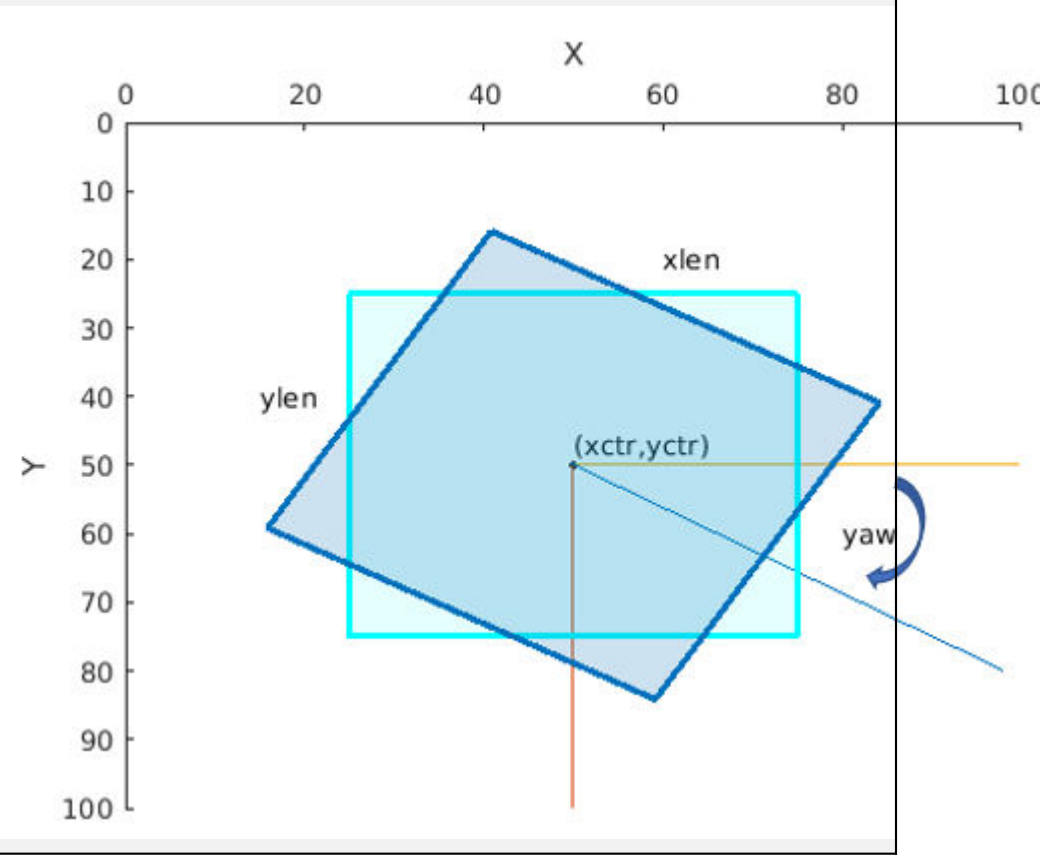
The `"mex"` option is only available for input data specified as a numeric array, cell array of numeric arrays, table, or image datastore. No other types of datastore support the `"mex"` option.

The `"mex"` option is only available when you are using a GPU. You must also have a C/C++ compiler installed. For setup instructions, see “Set Up Compiler” (GPU Coder).

`"mex"` acceleration does not support all layers. For a list of supported layers, see “Supported Layers” (GPU Coder).

Output Arguments

bboxes — Location of objects detected



M-by-4 matrix | *M*-by-5 matrix | *T*-by-1 cell array

Location of objects detected within the input image or images, returned as a

- *M*-by-4 matrix or an *M*-by-5 matrix if the input is a single test image.
- *T*-by-1 cell array if the input is an array of test images. *T* is the number of test images in the array. *M* is the number of bounding boxes in an image

The table describes the format of bounding boxes.

Bounding Box	Description
`rectangle`	Defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and `y` specify the upper-left corner of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis. • *h* specifies the height of the rectangle, which is its length along the *y*-axis.

Bounding Box	Description
`rotated-rectangle`	Defined in spatial coordinates as an *M*-by-5 numeric matrix with rows of the form [*xctr yctr xlen ylen yaw*], where: • *M* is the number of rotated rectangles. • *xctr* and *yctr* specify the center of the rectangle. • *xlen* specifies the width of the rectangle, which is its length along the *x*-axis before rotation. • *ylen* specifies the height of the rectangle, which is its length along the *y*-axis before rotation. • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the bounding box. 

`scores` — Detection scores

M-by-1 numeric vector | *T*-by-1 cell array

Detection confidence scores for each bounding box, returned as one of these options:

- *M*-by-1 numeric vector — The input is a single test image. *M* is the number of bounding boxes detected in the image.
- *B*-by-1 cell array — The input is a batch of test images, where *B* is the number of test images in the batch. Each cell in the array contains an *M*-element row vector, where each element indicates the detection score for a bounding box in the corresponding image.

A higher score indicates higher confidence in the detection. The confidence score for each detection is a product of the corresponding objectness score and maximum class probability. The objectness score is the probability that the object in the bounding box belongs to a class in the image. The maximum class probability is the largest probability that a detected object in the bounding box belongs to a particular class.

`labels` — Labels for bounding boxes
M-by-1 categorical vector | *T*-by-1 cell array

Labels for bounding boxes, returned as one of these options:

- *M*-by-1 categorical vector if the input is a single test image.
- *T*-by-1 cell array if the input is an array of test images. *T* is the number of test images in the array. Each cell in the array contains a *M*-by-1 categorical vector containing the names of the object classes.

M is the number of bounding boxes detected in an image.

`detectionResults` — Detection results
3-column table

Detection results, returned as a 3-column table with variable names, *Boxes*, *Scores*, and *Labels*. The *Boxes* column can contain rectangles or rotated rectangle bounding boxes of the form :

- rectangle — *M*-by-4 matrices, of *M* bounding boxes for the objects found in the image. Each row specifies a rectangle as a 4-element vector of the form [*x*,*y*,*width*,*height*], where (*x*,*y*) specifies the upper-left corner location and (*width*, *height*) specifies the size in pixels
- rotated rectangle — *M*-by-5 matrices of *M* bounding boxes for the objects found in the image. Each row specifies a rotated rectangle as a 5-element vector of the form [*xctr*,*yctr*,*width*, *height*,*yaw*], where (*xctr*,*yctr*) specifies the center, (*width*,*height*) specifies the size, and *yaw* specifies the rotated angle.

`info` — Class probabilities and objectness scores
structure array

Class probabilities and objectness scores of the detections, returned as a structure array with these fields.

- `ClassProbabilities` — Class probabilities for each of the detections, returned as a *B*-by-1 cell array. *B* is the number of images in the input batch of images, `I`. Each cell in the array contains the class probabilities as an *M*-by-*N* numeric matrix. *M* is the number of bounding boxes and *N* is the number of classes. Each class probability is a numeric scalar, indicating the probability that the detected object in the bounding box belongs to a class in the image.
- `ObjectnessScores` — Objectness scores for each of the detections, returned as a *B*-by-1 cell array. *B* is the number of images in the input batch of images, `I`. Each cell in the array contains the objectness score for each bounding box as an *M*-by-1 numeric vector. *M* is the number of bounding boxes. Each objectness score is a numeric scalar, indicating the probability that the bounding box contains an object belonging to one of the classes in the image.

Version History

Introduced in R2022a

R2024a: Option to return class probabilities and objectness scores

Specify the `info` output argument to return information about the class probability and objectness score for each detection.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

- The `roi` argument to the `detect` method must be a code generation constant (`coder.const()`) and a 1-by-4 vector.
- Only the `Threshold`, `SelectStrongest`, `MinSize`, `MaxSize`, and `MiniBatchSize` name-value arguments are supported.
- The `MiniBatchSize` name-value argument is not supported for code generation when the image input `I` is an *H*-by-*W*-by-*C*-by-*B* numeric array of images. All images will processed in one batch.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

- The `roi` argument to the `detect` method must be a code generation constant (`coder.const()`) and a 1-by-4 vector.
- Only the `Threshold`, `SelectStrongest`, `MinSize`, `MaxSize`, and `MiniBatchSize` name-value arguments for are supported.

For information about how to create a `yolov4ObjectDetector` object for code generation, see "Load Pretrained Networks for Code Generation" (MATLAB Coder).

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- GPU Arrays is not supported for rotated rectangle bounding box inputs.

yoloxObjectDetector

Detect objects using YOLOX object detector

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

The `yoloxObjectDetector` object creates a You Only Look Once X (YOLOX) object detector for detecting objects in an image of arbitrary size. YOLOX is a type of YOLO detector that offers one-stage architecture and real-time performance without the need for predefined anchor boxes. Using this object, you can:

- Create a pretrained YOLOX object detector by using YOLOX deep learning networks trained on the COCO data set.
- Create a custom YOLOX object detector by using a pretrained or untrained YOLOX deep learning network.

Note This functionality requires Deep Learning Toolbox.

Creation

Syntax

```
detector = yoloxObjectDetector
detector = yoloxObjectDetector(name)
detector = yoloxObjectDetector(name,classes)
detector = yoloxObjectDetector( ___ ,Name=Value)
```

Description

`detector = yoloxObjectDetector` creates a YOLOX object detector trained to detect 80 object classes from the COCO data set using a CSP-Darknet-53 network.

`detector = yoloxObjectDetector(name)` creates a pretrained YOLOX object detector by using YOLOX deep learning networks trained on the COCO data set.

`detector = yoloxObjectDetector(name,classes)` creates a pretrained YOLOX object detector and configures it to perform transfer learning using a specified set of object classes. For optimal results, you must train the detector on new training images before performing detection.

Use the `trainYOLOXObjectDetector` function to train the detector before performing object detection.

`detector = yoloxObjectDetector( ___ ,Name=Value)` sets the `ModelName` and `InputSize` properties of the object, and specifies the `NormalizationStatistics` of the detector, using name-value arguments in addition to any combination of input arguments from previous syntaxes. For

example, `ModelName="customDetector"` sets the name of the object detector to `"customDetector"`.

Input Arguments

name — Name of pretrained YOLOX deep learning network

`"nano-coco"` | `"tiny-coco"` | `"small-coco"` | `"medium-coco"` | `"large-coco"`

Name of the pretrained YOLOX deep learning network, created using a CSP-DarkNet-53 as the base network and trained on the COCO data set [1], specified as one of these values.

- `"nano-coco"` — Pretrained YOLOX-nano deep learning network with fewest filters and fewest convolutional layers. Use YOLOX-nano when you have few available computational resources and require the fastest performance speed and real-time inference.
- `"tiny-coco"` — Pretrained YOLOX-tiny deep learning network. Use YOLOX-tiny for slightly less constrained real-time applications with an improvement in accuracy from YOLOX-nano.
- `"small-coco"` — Pretrained YOLOX-small deep learning network. Use YOLOX-small for a higher level of accuracy than YOLOX-tiny when moderate computational resources are available.
- `"medium-coco"` — Pretrained YOLOX-medium deep learning. Use YOLOX-medium for a higher level of accuracy than YOLOX-small when some computational resources (e.g. GPU hardware) are available.
- `"large-coco"` — Pretrained YOLOX-large deep learning network with the largest number of filters and convolutional layers. Use the YOLOX-large network for the highest level accuracy of object detection at the expense of computational cost and speed.

Tip To improve accuracy and performance of complex detection tasks, increase the pretrained model size at the expense of decreased inference speed, larger computation time, and greater memory requirements. Use YOLOX-nano for real-time inference at the expense of detection accuracy. Use YOLOX-tiny and YOLOX-small for near-real time applications due to fast inference. Use YOLOX-medium and YOLOX-large when sufficient computational resources are available for the largest accuracy, at the expense of lower computation speeds.

Data Types: `char` | `string`

classes — Names of object classes

vector of strings | cell array of character vectors | categorical vector

Names of object classes for training the detector, specified as a vector of strings, cell array of character vectors, or categorical vector. This argument sets the `ClassNames` property of the `yoloxObjectDetector` object.

Data Types: `char` | `string` | `categorical`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `yoloxObjectDetector(detector,classes,ModelName="customDetector")` sets the name for the object detector to `"customDetector"`.

`ModelName` — Name for object detector

"" (default) | character vector | string scalar

Name for the object detector, specified as a character vector or string scalar.

`InputSize` — Image size used for training

row vector

Image size used for training the object detector, specified as a row vector `[H W C]`, where *H*, *W*, and *C* correspond to the height, width, and number of channels, respectively. The default is the network input size.

`NormalizationStatistics` — *Z*-score normalization statistics

1-by-1 structure (default) | structure

Z-score normalization statistics, specified as a structure with these fields, which contain the values from the COCO data set:

Field	Description	Default Value
`Mean`	1-by-*C* vector of means per channel.	`[123.6750 116.2800 103.5300]`
`StandardDeviation`	1-by-*C* vector of standard deviations per channel.	`[58.3950 57.1200 57.3750]`

The number of channels *C* must match the number of channels in the image specified by `InputSize`.

Properties

`ModelName` — Name for object detector

"" (default) | character vector | string scalar

This property is read-only.

Name for the object detector, stored as a character vector or string scalar. To set this property, specify it at object creation.

`ClassNames` — Names of object classes

categorical vector

This property is read-only.

Names of object classes to detect, stored as a categorical vector. To set this property, use the `classes` argument at object creation.

`InputSize` — Image size used for training

row vector of integers

This property is read-only.

Image size used for training and inference, stored as a row vector of integers, of the form [*height width channels*]. To set this property, specify it at object creation.

Object Functions

detect Detect objects using YOLOX object detector

Examples

Create Pretrained YOLOX Object Detector

Specify the name of a pretrained YOLOX deep learning network.

```
networkName = "small-coco"
```

```
networkName =
"small-coco"
```

Create a YOLOX object detector by using the pretrained YOLOX network.

```
detector = yoloxObjectDetector(networkName);
```

Display and inspect the properties of the YOLOX object detector.

```
disp(detector)
```

```
  yoloxObjectDetector with properties:

                ClassNames: {80×1 cell}
                 InputSize: [640 640 3]
    NormalizationStatistics: [1×1 struct]
                 ModelName: 'small-coco'
```

Detect objects in a chosen image.

```
I = imread("carsonroad.png");
[bboxes,scores,labels] = detect(detector,I);
```

Display the detection results.

```
detectedImg = insertObjectAnnotation(I,"Rectangle",bboxes,labels);
figure
imshow(detectedImg)
```

Version History

Introduced in R2023b

R2024b: Use `coder.loadDeepLearningNetwork` for code generation

Starting in R2024b, you can use the `coder.loadDeepLearningNetwork` function to load a `yoloxObjectDetector` object for CPU and GPU code generation.

R2024b: Specify base network as pretrained YOLOX-nano, YOLOX-medium, or YOLOX-large

The `yoloxObjectDetector` object enables you to specify a YOLOX-nano, YOLOX-medium, or YOLOX-large deep learning network as the base network of the pretrained detector using the `name` input argument.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- To prepare a `yoloxObjectDetector` object for CPU code generation, you can use either`vision.loadYOLOXObjectDetector` or `coder.loadDeepLearningNetwork` function. The recommended approach is to use `coder.loadDeepLearningNetwork`. For information on how to load the detector for code generation, see “Load Pretrained Networks for Code Generation” (MATLAB Coder).
- The `roi` argument to the `detect` method must be a code generation constant (`coder.const()`) and a 1x4 vector.
- The `AutoResize` argument to the `detect` method must be a code generation constant (`coder.const()`).
- Only the `Threshold`, `SelectStrongest`, `MinSize`, `MaxSize`, `MiniBatchSize`, and `AutoResize` name-value pairs for `detect` are supported.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- To prepare a `yoloxObjectDetector` object for GPU code generation, you can use either`vision.loadYOLOXObjectDetector` or `coder.loadDeepLearningNetwork` function. The recommended approach is to use `coder.loadDeepLearningNetwork`. For information on how to load the detector for code generation, see “Load Pretrained Networks for Code Generation” (GPU Coder).
- The `roi` argument to the `detect` method must be a code generation constant (`coder.const()`) and a 1x4 vector.
- The `AutoResize` argument to the `detect` method must be a code generation constant (`coder.const()`).
- Only the `Threshold`, `SelectStrongest`, `MinSize`, `MaxSize`, and `MiniBatchSize`, and `AutoResize` name-value pairs for `detect` are supported.

hrnetObjectKeypointDetector

Create object keypoint detector using HRNet deep learning network

Description

The `hrnetObjectKeypointDetector` object creates a high resolution deep learning network (HRNet) object keypoint detector for detecting object keypoints in an image. Using this object, you can:

- Create a pretrained HRNet object keypoint detector by using HRNet deep learning networks trained on the COCO keypoint detection data set.
- Create a custom HRNet object keypoint detector by using a pretrained HRNet deep learning network.

Creation

Syntax

```
detector = hrnetObjectKeypointDetector
detector = hrnetObjectKeypointDetector(name)

detector = hrnetObjectKeypointDetector(name,keypointClassNames)
```

Description

Pretrained HRNet Object Keypoint Detector

`detector = hrnetObjectKeypointDetector` creates a default pretrained HRNet object keypoint detector. To create the default HRNet object keypoint detector, MATLAB uses an HRNet deep learning network, HRNet-W32, trained on the COCO keypoint detection data set. In an HRNet-W32 network, the last three stages of the high-resolution subnetworks have 32 convolved feature maps. For more information about HRNet architecture, see “Getting Started with HRNet”.

`detector = hrnetObjectKeypointDetector(name)` creates a pretrained HRNet object keypoint detector by using the specified HRNet deep learning network, which has been trained on the COCO keypoint detection data set.

Custom HRNet Object Keypoint Detector

`detector = hrnetObjectKeypointDetector(name,keypointClassNames)` creates a pretrained HRNet object detector, and configures it to perform transfer learning using a specified set of keypoint classes. For optimal results, you must train the detector on new training images before performing detection.

`detector = hrnetObjectKeypointDetector(name,keypointClassNames,Name=Value)` sets the “ModelName” on page 2-0 , “InputSize” on page 2-0 , “KeypointConnections” on page 2-0 and “Threshold” on page 2-0 properties of the object keypoint detector using one or more name-value arguments.

Example:
`hrnetObjectKeypointDetector(name,keypointClassNames,ModelName="customDetector")` sets the name for the object detector to `"customDetector"`.

Note This functionality requires Deep Learning Toolbox and the Computer Vision Toolbox Model for Object Keypoint Detection. You can download and install the Computer Vision Toolbox Model for Object Keypoint Detection from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Input Arguments

`name` — Name of pretrained HRNet deep learning network
`"human-full-body-w32"` | `"human-full-body-w48"`

Name of the pretrained HRNet deep learning network, specified as one of these options:

- `"human-full-body-w32"` — A pretrained HRNet deep learning network created using HRNet-W32 as the base network, and trained on the COCO keypoint detection data set.
- `"human-full-body-w48"` — A pretrained HRNet deep learning network created using HRNet-W48 as the base network, and trained on the COCO keypoint detection data set.

In HRNet-W32 and HRNet-W48 networks, the last three stages of the high-resolution subnetworks have 32 and 48 convolved feature maps, respectively.

Data Types: `char` | `string`

`keypointClassNames` — Names of object keypoint classes
vector of strings | cell array of character vectors | categorical vector

Names of object keypoint classes for training the detector, specified as a vector of strings, cell array of character vectors, or categorical vector. This argument sets the `KeyPointClasses` property of the `hrnetObjectKeypointDetector` object.

Data Types: `cell` | `string` | `categorical`

Properties

`Network` — HRNet deep learning network
`dlnetwork` object

This property is read-only.

HRNet deep learning network to use for object keypoint detection, stored as a `dlnetwork` object.

`ModelName` — Name of object keypoint detector
`'human-full-body-w32'` (default) | character vector | string scalar

This property is read-only.

Name for the object keypoint detector, specified as a character vector or string scalar. To set this property, specify it at object creation. You can set this property only when you also specify the `keypointClassNames` input argument.

Example: `hrnetObjectKeypointDetector(name,keypointClassNames,ModelName="customDetector")` sets the name for the object detector to `"customDetector"`.

`InputSize` — Image size used for training
row vector of integers

This property is read-only.

Image size used for training the object detector, specified as a row vector of integers of the form `[H W C]`, where *H*, *W*, and *C* are the height, width, and number of channels of the image, respectively. The default value is the network input size. To set this property, specify it at object creation. You can set this property only when also specify the `keypointClassNames` input argument.

Example: `detector = hrnetObjectKeypointDetector(name,keypointClassNames,InputSize=[384 288 3])` specifies the image size of the training images as 384-by-288 pixels across 3 channels.

`KeyPointClasses` — Names of object keypoint classes
categorical vector

This property is read-only.

Names of object keypoint classes to detect, specified as a categorical vector.

You can set this property only when you specify the `keypointClassNames` input argument. Otherwise, the object uses the default classes for the specified HRNet deep learning network.

`KeypointConnections` — Keypoint class indices of keypoint connections
L-by-2 matrix

This property is read-only.

Keypoint class indices of the keypoint connections, specified as an *L*-by-2 matrix. Each row denotes the keypoint class indices that connect two keypoints, where *L* is the number of keypoint connections. To set this property, specify it at object creation. You can set this property only when you specify the `keypointClassNames` input argument.

Example: `hrnetObjectKeypointDetector(name,keypointClassNames,KeypointConnections=[2 4; 3 5])` establishes two connections: one between a set of keypoints with keypoint class indices `2` and `4`, and the other between a set of keypoints with the keypoint classes indices `3` and `5`.

`Threshold` — Threshold value for valid keypoints
`0.2` (default) | scalar in the range [0, 1]

Threshold value for valid keypoints, specified as a scalar in the range `[0, 1]`. For a threshold value of 0.4, the object treats keypoints with a confidence score greater than or equal to 0.4 as valid keypoints. To set this property, specify it at object creation. You can set this property only when you specify the `keypointClassNames` input argument.

You can also specify a different threshold when calling the `detect` object function. This lets you adjust threshold for individual detection calls without creating a new `hrnetObjectKeypointDetector` object.

Object Functions

detect	Detect object keypoints using HRNet object keypoint detector
visibleKeypoints	Extract visible keypoints from keypoints detected by HRNet object keypoint detector

Examples

Create Pretrained HRNet Object Keypoint Detector

Specify the name of a pretrained HRNet object keypoint detector.

```
name = "human-full-body-w32";
```

Create an HRNet object keypoint detector by using the pretrained HRNet deep learning network.

```
keypointDetector = hrnetObjectKeypointDetector(name);
```

Display and inspect the properties of the HRNet object keypoint detector.

```
disp(keypointDetector)
```

```
  hrnetObjectKeypointDetector with properties:

             ModelName: 'human-full-body-w32'
               Network: [1×1 dlnetwork]
       KeyPointClasses: [17×1 categorical]
             InputSize: [384 288 3]
   KeypointConnections: [17×2 double]
             Threshold: 0.2000
```

```
analyzeNetwork(keypointDetector.Network)
```

Read a test image into the workspace.

```
I = imread("visionteam.jpg");
```

Use a YOLOv4 object detector to detect bounding boxes around humans in the image.

```
detector = yolov4ObjectDetector("csp-darknet53-coco");
[bboxes,scores,labels] = detect(detector,I,Threshold=0.4);
```

Select the bounding box detections for the `person` class.

```
personIndices = labels == "person";
personBoxes = bboxes(personIndices,:);
```

Detect the object keypoints of the people in the test image by using the pretrained HRNet object keypoint detector.

```
[keypoints,keypointScores,valid] = detect(keypointDetector,I,personBoxes);
```

Insert the detected keypoints into the test image and display the results.

```
detectedKeypoints = insertObjectKeypoints(I,keypoints,KeypointColor="yellow",KeypointSize=2);
imshow(detectedKeypoints)
```

Version History

Introduced in R2023b

R2025a: Adjust number of bounding boxes during code generation

Starting from R2025a, you can vary the number of bounding boxes specified as input to the `detect` function during code generation. This means that the limitations on bounding boxes from previous releases have been removed. You can now assign bounding boxes dynamically during runtime.

R2024b: Adjust bounding box values during code generation

Prior to R2024b, the `bboxes` argument to the `detect` function must be a code generation constant (`coder.const()`) and a `M`-by-4 matrix. The number of bounding boxes `M` and the values of the bounding boxes must be fixed for code generation.

Starting from R2024b, you can dynamically adjust the bounding box values during runtime. However, the number of bounding boxes `M` must be a code generation constant.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

- The `detect` function does not support `ImageDatastore` objects as input for code generation.
- Code generation does not support the `MiniBatchSize`, `ExecutionEnvironment`, and `Acceleration` name-value arguments for `detect`.

- To prepare an `hrnetObjectKeypointDetector` object for code generation, use `loadHRNETObjectKeypointDetector`.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

- The `detect` function does not support `ImageDatastore` object as input for code generation.
- Code generation does not support the `MiniBatchSize`, `ExecutionEnvironment`, and `Acceleration` name-value arguments for `detect`.
- To prepare an `hrnetObjectKeypointDetector` object for code generation, use `loadHRNETObjectKeypointDetector`.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

detect

Detect object keypoints using HRNet object keypoint detector

Syntax

```
keypoints = detect(detector,I,bboxes)
[keypoints,scores] = detect(detector,I,bboxes)
[keypoints,scores,valid] = detect(detector,I,bboxes)

[keypoints,scores,valid] = detect(detector,ds)

detectionResults = detect( ___ ,Name=Value)
```

Description

`keypoints = detect(detector,I,bboxes)` detects object keypoints within an RGB image, `I`, using an HRNet object keypoint detector, `detector`. The `detect` function automatically resizes and rescales the input to match the size of the images used to train the detector. The function returns the locations of keypoints detected in each input image as a set of object keypoints.

`[keypoints,scores] = detect(detector,I,bboxes)` returns the detection confidence score for each keypoint. The confidence score determines the location accuracy of the detected keypoint. The value of keypoint confidence score is in the range of [0, 1]. A higher score indicates greater confidence in the detection.

`[keypoints,scores,valid] = detect(detector,I,bboxes)` returns the validity for each detected object keypoint.

`[keypoints,scores,valid] = detect(detector,ds)` detects object keypoints within all images returned by the `read` function of the input datastore `ds` and returns the detection results as a table.

`detectionResults = detect( ___ ,Name=Value)` specifies options using one or more name-value arguments.

Examples

Detect Objects Keypoints Using Pretrained HRNet

Read a sample image into the workspace.

```
I = imread("visionteam.jpg");
```

Crop and display one person from the image.

```
personBox = [262.5 19.51 127.98 376.98];
[personImg] = imcrop(I,personBox);
figure
imshow(personImg)
```

Specify a bounding box for the person in the image. You can use the bounding box region as input to the object keypoint detector to detect the person.

```
bbox = [3.87,21.845,118.97,345.91];
```

Load a pretrained HRNet object keypoint detector.

```
keypointDetector = hrnetObjectKeypointDetector("human-full-body-w32");
```

Detect the keypoints of the person in the image by using the pretrained HRNet object keypoint detector.

```
[keypoints,keypointScores,valid] = detect(keypointDetector,personImg,bbox)
```

```
keypoints = 17×2 single matrix

Input Arguments

`detector` — HRNet object keypoint detector

`hrnetObjectKeypointDetector` object

HRNet object keypoint detector, specified as an `hrnetObjectKeypointDetector` object.

`I` — Test images

numeric array

Test images, specified as a numeric array of size *H*-by-*W*-by-*C*-by-*T*. Images must be real, nonsparse, and RGB.

- *H*— Height of the image, in pixels.
- *W*— Width of the image, in pixels.
- *C*— The channel size in each image must be equal to the input channel size. Because this function requires RGB images, the channel size must be `3`.
- *T*— Number of test images in the array. The function computes the object keypoint detection results for each test image in the array.

The intensity range of the test image must be similar to the intensity range of the images used to train the detector. For example, if you train the detector on `uint8` images, rescale the test image to the range [0, 255] by using the `im2uint8` or `rescale` function. The size of the test image must be comparable to the sizes of the images used in training. If these sizes are very different, the detector has difficulty detecting object keypoints because the scale of the objects in the test image differs from the scale of the objects the detector is trained to identify.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single`

bboxes — Locations of objects detected in the image
M-by-4 matrix | *T*-by-1 cell array

Locations of the objects detected in the input image or images, specified as one of these options:

- *M*-by-4 matrix— The input is a single test image. *M* is the number of object bounding boxes in the image.
- *T*-by-1 cell array— The input is an array of test images. *T* is the number of test images in the array. Each cell contains an *M*-by-4 matrix of object bounding boxes for the corresponding image, where *M* is the number of bounding boxes in the image.

The table describes the possible formats of bounding boxes.

Bounding Box	Description
`rectangle`	Defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and `y` specify the upper-left corner of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis. • *h* specifies the height of the rectangle, which is its length along the *y*-axis.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single`

ds — Test images
`ImageDatastore` object | `CombinedDatastore` object | `TransformedDatastore` object

Test images, specified as an `ImageDatastore`, `CombinedDatastore`, or `TransformedDatastore` object containing the full filenames of the test images. The images in the datastore must be RGB images.

When using the read function the datastore `ds` must return a table or a cell array with these columns:

`image data`	`bboxes`	`box labels`
T-by-1 cell array, in which each cell contains an input image. The images in the datastore must be RGB images.	*T*-by-1 cell array, in which each cell contains an *M*-by-4 matrix of 2-D bounding boxes specifying object locations within the corresponding input image. Each row of the matrix specifies the location of a bounding box in the format [*x y w h*].	*T*-by-1 cell array, in which each cell contains an *M*-by-1 categorical vector of object class names. All the categorical data returned by the datastore must use the same categories.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `detect(detector,I,MiniBatchSize=16)` detects object keypoints in each image using 16-element batches of bounding boxes.

`MiniBatchSize` — Minimum batch size
32 (default) | positive integer

Minimum batch size, specified as a positive integer. Use the `MiniBatchSize` argument when processing an image with a large number of objects. When you specify this argument, the function groups the bounding boxes surrounding the objects into batches of the specified size and processes them together to improve computational efficiency. Increase the minimum batch size to decrease processing time. Decrease the size to use less memory.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as `"auto"`, `"gpu"`, or `"cpu"`.

- `"auto"` — Use a GPU if it is available. Otherwise, use the CPU.
- `"gpu"` — Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA-enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"cpu"` — Use the CPU.

`Acceleration` — Performance optimization
`"auto"` (default) | `"mex"` | `"none"`

Performance optimization, specified as one of these options:

- `"auto"` — Automatically apply a number of optimizations suitable for the input network and hardware resource.
- `"mex"` — Compile and execute a MEX function. This option is available only when using a GPU. Using a GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If Parallel Computing Toolbox or a suitable GPU is not available, then the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
- `"none"` — Disable all acceleration.

The default option is `"auto"`. If you specify `"auto"`, MATLAB applies a number of compatible optimizations. The `"auto"` option, MATLAB never generates a MEX function.

Using the `Acceleration` options `"auto"` and `"mex"` can offer performance benefits, but at the expense of an increased initial run time. Subsequent calls with compatible parameters are faster. Use performance optimization when you plan to call the function multiple times using new input data.

The `"mex"` option generates and executes a MEX function based on the network and parameters used in the function call. You can have several MEX functions associated with a single network at one time. Clearing the network variable also clears any MEX functions associated with that network.

The `"mex"` option is available only for input data specified as a numeric array, cell array of numeric arrays, table, or image datastore. No other type of datastore supports the `"mex"` option.

The `"mex"` option is available only when you use a GPU. You must also have a C/C++ compiler installed. For setup instructions, see “Set Up Compiler” (GPU Coder).

`"mex"` acceleration does not support all layers. For a list of supported layers, see “Supported Layers” (GPU Coder).

`Threshold` — Threshold for valid keypoints
`0.2` (default) | scalar in the range [0, 1]

Threshold for valid keypoints, specified as a scalar in the range `[0, 1]`. For a threshold value of 0.4, the detector treats keypoints with a confidence score greater than or equal to 0.4 as valid.

When specified as a name-value argument, the threshold applies only to the current function call. It overrides the value stored in the `hrnetObjectKeypointDetector` object, but does not modify the object's persistent `Threshold` property.

A low threshold treats more detected keypoints as valid, including those with lower confidence scores. This increases sensitivity and helps retain keypoints in challenging conditions such as small objects, occlusion, or low-quality images. However, it may also admit more false positives and noisier detections.

A high threshold restricts validity to only the most confident keypoints, improving robustness and reducing false positives. While this results in cleaner detections, it may discard true keypoints that have lower confidence due to image quality, scale, or pose complexity.

Output Arguments

`keypoints` — Locations of object keypoints detected in input image
17-by-2-by-*M* array | *T*-by-1 cell array

Locations of object keypoints detected in the input image or images, returned as one of these options:

- 17-by-2-by-*M* array — The input is a single test image. Each row in the array is of the form [*x* *y*] where *x* and *y* specify the location of a detected keypoint in an object. *M* is the number of objects in the image.
- *T*-by-1 cell array — The input is an array of test images. *T* is the number of test images in the array. Each cell in the cell array contains a 17-by-2-by-*M* array specifying the keypoint detections for the *M* objects in the image.

Each object has 17 detected keypoints.

Data Types: `double`

`scores` — Detection confidence scores for object keypoints
17-by-*M* matrix | *T*-by-1 cell array

Detection confidence scores for object keypoints, returned as one of these options:

- 17-by-*M* matrix — The input is a single test image. *M* is the number of objects in the image.
- *T*-by-1 cell array — The input is an array of test images. *T* is the number of test images in the array. Each cell in the array contains a 17-by-*M* matrix indicating the detection scores for the keypoints of each of the *M* objects in an image.

Each object in an image has 17 has keypoint confidence scores. A higher score indicates higher confidence in the detection.

Data Types: `double`

`valid` — Validity of detected object keypoints
17-by-*M* matrix | *T*-by-1 cell array

Validity of the detected object keypoints, returned as one of these options:

- 17-by-*M* logical matrix — The input is a single test image. *M* is the number of objects in the image.
- *T*-by-1 cell array — The input is an array of test images. *T* is the number of test images in the array. Each cell in the array contains a 17-by-*M* logical matrix indicating the keypoint validity values for the keypoints of each of the *M* objects in the corresponding image.

Each object in an image has 17 keypoint validity values. A value of `1` (`true`) indicates a valid keypoint and `0` (`false`) indicates an invalid keypoint.

The value is set to `1`, when the confidence score of a keypoint is greater than the value specified by the `Threshold` name-value argument. Otherwise, the value is set to 0.

Data Types: `logical`

`detectionResults` — Detection results
two-column table

Detection results, returned as a two-column table with variable names `Keypoints` and `Scores`. Each element of the `Keypoints` column contains a 17-by-2-by-*M* array, for *M* objects in the image. Each row of the array contains a keypoint location for the corresponding object in the format [*x y*]. Each element of the `Scores` column contains 17-by-1-by-*M* array, where *M* is the number of objects in the image. Each row of the array contains the keypoint detection confidence score for one of the 17 keypoints in the corresponding object in that image.

Version History

Introduced in R2023b

R2026a: Specify keypoint detection threshold per call using Name-value argument.

Starting from R2026a, you can specify threshold for detecting keypoints directly in the `detect` function by using the `Threshold` name-value argument. This argument overrides the `Threshold` property of the `hrnetObjectKeypointDetector` object for the current call. It does not modify the stored property.

R2025a: Adjust number of bounding boxes during code generation

Starting from R2025a, you can vary the number of bounding boxes specified as input to the `detect` function during code generation. This means that the limitations on bounding boxes from previous releases have been removed. You can now assign bounding boxes dynamically during runtime.

R2024b: Adjust bounding box values during code generation

Prior to R2024b, the `bboxes` argument to the `detect` function must be a code generation constant (`coder.const()`) and a `M`-by-4 matrix. The number of bounding boxes `M` and the values of the bounding boxes must be fixed for code generation.

Starting from R2024b, you can dynamically adjust the bounding box values during runtime. However, the number of bounding boxes `M` must be a code generation constant.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

- The `detect` function does not support `ImageDatastore` object as input for code generation.
- Code generation does not support the `MiniBatchSize`, `ExecutionEnvironment`, and `Acceleration` name-value arguments for `detect`.
- To prepare an `hrnetObjectKeypointDetector` object for code generation, use `loadHRNETObjectKeypointDetector`.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

- The `detect` function does not support `ImageDatastore` object as input for code generation.
- Code generation does not support the `MiniBatchSize`, `ExecutionEnvironment`, and `Acceleration` name-value arguments for `detect`.
- To prepare an `hrnetObjectKeypointDetector` object for code generation, use `loadHRNETObjectKeypointDetector`.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Topics

“Getting Started with HRNet”

visibleKeypoints

Extract visible keypoints from keypoints detected by HRNet object keypoint detector

Syntax

```
visiblePoints = visibleKeypoints(detector,keypoints,scores,valid)
[visiblePoints,visibleScores,visibleLabels] = visibleKeypoints(detector,
keypoints,scores,valid)
```

Description

`visiblePoints = visibleKeypoints(detector,keypoints,scores,valid)` extracts visible object keypoint locations from the object keypoint locations `keypoints` detected by the HRNet object keypoint detector `detector`. The function obtains the locations of visible object keypoints by using the keypoint validity values `valid`, which are based on the keypoint detection confidence scores `scores`.

`[visiblePoints,visibleScores,visibleLabels] = visibleKeypoints(detector, keypoints,scores,valid)` returns the detection confidence scores for the visible keypoints `visibleScores`, and the labels assigned to the visible keypoints `visibleLabels`.

Examples

Detect Visible Keypoints in Objects

Read a sample image into the workspace.

```
I = imread("visionteam.jpg");
```

Crop and display one person from the image.

```
personBox = [18.51 42.51 137.21 370.98];
[personImg] = imcrop(I,personBox);
figure
imshow(personImg)
```

Specify a bounding box for the person in the image. You can use the bounding box region as input to the object keypoint detector to detect the person.

```
bbox = [3.87 21.845 118.97 345.91];
```

Create an HRNet object keypoint detector by using a pretrained HRNet deep learning network.

```
keypointDetector = hrnetObjectKeypointDetector("human-full-body-w32");
```

Detect the object keypoints of the person in the test image by using the pretrained HRNet object keypoint detector.

```
[keypoints,keypointScores,valid] = detect(keypointDetector,personImg,bbox);
```

Detect keypoints with keypoints confidence scores greater than `0.9`.

```
isValid = keypointScores > 0.9;
```

Extract visible keypoints from keypoints detected by HRNet object keypoint detector.

```
[visiblePoints,visibleScores,visibleLabels] = visibleKeypoints(keypointDetector,keypoints,keypoi
```

Insert and display visible keypoints.

```
detectedKeypoints = insertObjectKeypoints(personImg,visiblePoints{1},KeypointColor="yellow",Keypo
figure
imshow(detectedKeypoints);
```

Display all the visible keypoint levels.

```
visibleLabels{1}
```

```
ans = 10×1 categorical array
     "Nose"
     "Left-eye"
     "Right-eye"
     "Left-ear"
     "Right-ear"
     "Left-shoulder"
     "Right-shoulder"
     "Left-elbow"
     "Right-elbow"
     "Left-wrist"
```

Input Arguments

`detector` — HRNet object keypoint detector

`hrnetObjectKeypointDetector` object

HRNet object keypoint detector, specified as an `hrnetObjectKeypointDetector` object.

`keypoints` — Locations of object keypoints detected in input image

17-by-2-by-*M* array | *T*-by-1 cell array

Locations of object keypoints detected in the input image or images, returned as one of these options:

- 17-by-2-by-*M* array — The keypoints come from a single test image. Each row in the array is of the form [*x* *y*] where *x* and *y* specify the location of a detected keypoint in an object. *M* is the number of objects in the image.
- *T*-by-1 cell array — The keypoints come from an array of test images. *T* is the number of test images in the array. Each cell in the cell array contains a 17-by-2-by-*M* array specifying the keypoint detections for the *M* objects in the image.

Each object has 17 detected keypoints.

Data Types: `double`

`scores` — Detection confidence scores for object keypoints

17-by-*M* matrix | *T*-by-1 cell array

Detection confidence scores for object keypoints, returned as one of these options:

- 17-by-*M* matrix — The keypoint scores come from a single test image. *M* is the number of objects in the image.
- *T*-by-1 cell array — The keypoint scores come from an array of test images. *T* is the number of test images in the array. Each cell in the array contains a 17-by-*M* matrix indicating the detection scores for the keypoints of each of the *M* objects in an image.

Each object in an image has 17 has keypoint confidence scores. A higher score indicates higher confidence in the detection.

Data Types: `double`

`valid` — Validity of detected object keypoints

17-by-*M* matrix | *T*-by-1 cell array

Validity of the detected object keypoints, returned as one of these options:

- 17-by-*M* logical matrix — The keypoint validity values come from a single test image. *M* is the number of objects in the image.
- *T*-by-1 cell array — The keypoint validity values come from an array of test images. *T* is the number of test images in the array. Each cell in the array contains a 17-by-*M* logical matrix indicating the keypoint validity values for the keypoints of each of the *M* objects in the corresponding image.

Each object in an image has 17 keypoint validity values. A value of `1` (`true`) indicates a valid keypoint and `0` (`false`) indicates an invalid keypoint.

Data Types: `logical`

Output Arguments

`visiblePoints` — Locations of visible keypoints

17-by-2-by-*M* array | *T*-by-1 cell array

Location of visible keypoints detected in the input image or images, returned as one of these options:

- 17-by-2-by-*M* array — The visible keypoints come from a single test image. Each row in the array is of the form [*x* *y*] where *x* and *y* specify the location of a detected visible keypoint in an object. *M* is the number of objects in the image.
- *T*-by-1 cell array — The visible keypoints come from an array of test images. *T* is the number of test images in the array. Each cell in the cell array has an *N*-by-2 matrix specifying the valid keypoint locations of the form [*x*, *y*]. *N* is the number of visible keypoints for each object in the image, as determined by the `scores` input argument. *N* is less than or equal to 17. *M* is the number of objects in the image.

`visibleScores` — Detection confidence scores of visible keypoints
17-by-*M* matrix | *T*-by-1 cell array

Detection confidence scores of visible keypoints, returned as one of these options:

- 17-by-2-by-*M* array — The detection scores of visible keypoints come from a single test image. *M* is the number of objects in the image.
- *T*-by-1 cell array — The detection scores of visible keypoints come from an array of test images. *T* is the number of test images in the array. Each cell in the cell array has an *N*-by-1 matrix specifying the visible keypoint scores. *N* is the number of visible keypoints for each object in the image, as determined by the `scores` input argument. *N* is less than or equal to 17. *M* is the number of objects in the image.

`visibleLabels` — Validity labels of visible keypoints
17-by-*M* matrix | *T*-by-1 cell array

Validity labels of visible keypoints, returned as one of these options:

- 17-by-1-by-*M* array — The validity labels of visible keypoints come from a single test image. *M* is the number of objects in the image.
- *T*-by-1 cell array — The validity labels of visible keypoints come from an array of test images. *T* is the number of test images in the array. Each cell in the cell array has an *N*-by-1 matrix specifying the valid keypoint labels. *N* is the number of visible keypoints for each object in the image, as determined by the `scores` input argument. *N* is less than or equal to 17. *M* is the number of objects in the image.

vision.ChromaResampler

Namespace: `vision`

Downsample or upsample chrominance components of images

Description

To downsample or upsample chrominance components of images:

1. Create the `vision.ChromaResampler` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
resampler = vision.ChromaResampler
gammaCorr = vision.ChromaResampler(Name,Value)
```

Description

`resampler = vision.ChromaResampler` returns a chroma resampling object, `Cresampler`, that downsamples or upsamples chroma components of a YCbCr signal to reduce the bandwidth and storage requirements.

`gammaCorr = vision.ChromaResampler(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `resampler = vision.ChromaResampler('InterpolationFilter','Linear')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Resampling` — Resampling format

`'4:4:4 to 4:2:2'` (default) | resample format

Resampling format, specified as one of the following:

```
'4:4:4 to 4:2:2'
'4:4:4 to 4:2:0 (MPEG1)'
```

```
'4:4:4 to 4:2:0 (MPEG2)'
'4:4:4 to 4:1:1'
'4:2:2 to 4:2:0 (MPEG1)'
'4:2:2 to 4:2:0 (MPEG2)'
```

To upsample the chrominance components of images, set this property to one of the following:

```
'4:2:2 to 4:4:4'
'4:2:0 (MPEG1) to 4:4:4'
'4:2:0 (MPEG2) to 4:4:4'
'4:1:1 to 4:4:4'
'4:2:0 (MPEG1) to 4:2:2'
'4:2:0 (MPEG2) to 4:2:2'
```

`InterpolationFilter` — Method used to approximate missing values
`Pixel replication` (default) | `Linear`

Method used to approximate missing values, specified as `Pixel replication` or `Linear`. The default is `Linear`. When you set this property to `Linear`, the object uses linear interpolation to calculate the missing values. When you set this property to `Pixel replication`, the object replicates the chrominance values of the neighboring pixels to create the upsampled image. This property applies when you upsample the chrominance values.

`AntialiasingFilterSource` — Lowpass filter used to prevent aliasing
`Auto` (default) | `Property` | `None`

Lowpass filter used to prevent aliasing, specified as `Auto`, `Property` , or `None`. When you set this property to `Auto`, the object uses a built-in lowpass filter. When you set this property to `Property`, the coefficients of the filters are specified by the `HorizontalFilterCoefficients` and `VerticalFilterCoefficients` properties. When you set this property to `None`, the object does not filter the input signal. This property applies when you downsample the chrominance values.

`HorizontalFilterCoefficients` — Horizontal filter coefficients
`[0.2 0.6 0.2]` (default) | three-element vector

Horizontal filter coefficients, specified as a three-element vector. This property applies when you set the `Resampling` property to one of `[4:4:4 to 4:2:2]` | `[4:4:4 to 4:2:0 (MPEG1)]` | `[4:4:4 to 4:2:0 (MPEG2)]` | `[4:4:4 to 4:1:1]` and the `AntialiasingFilterSource` property to `Property`.

`VerticalFilterCoefficients` — Specify the filter coefficients to apply to the input signal
`[0.5 0.5]` (default) | two-element vector

Specify the filter coefficients to apply to the input signal, specified as a two-element vector. This property applies when you set the `Resampling` property to one of `[4:4:4 to 4:2:0 (MPEG1)]` | `[4:4:4 to 4:2:0 (MPEG2)]` | `[4:2:2 to 4:2:0 (MPEG1)]` | `[4:2:2 to 4:2:0 (MPEG2)]` and the `AntialiasingFilterSource` property to `Property`.

`TransposedInput` — Input is row-major format
`false` (default) | `true`

Input is row-major format , specified as `true` or `false`. Set this property to `true` when the input contains data elements from the first row first, then data elements from the second row second, and so on through the last row. Otherwise, the object assumes that the input data is stored in column-major format.

Usage

Syntax

```
[Cb1,Cr1] = resampler(Cb,Cr)
```

Description

`[Cb1,Cr1] = resampler(Cb,Cr)` resamples the input chrominance components Cb and Cr and returns Cb1 and Cr1, as the resampled outputs.

Input Arguments

`Cb1` — Chrominance component
matrix

Chrominance component of an image, specified as a matrix.

`Cr2` — Chrominance component
matrix

Chrominance component of an image, specified as a matrix.

Output Arguments

`Cb1` — Resampled chrominance component
same as input (default)

Chrominance component of an image, returned as a matrix.

`Cr1` — Resampled chrominance component
same as input (default)

Chrominance component of an image, returned as a matrix.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Resample Chrominance Components of Image

Create a resampler object.

```
resampler = vision.ChromaResampler;
```

Read an RGB image and convert it to YCbCr.

```
imageRGB = imread('peppers.png');
imageYCbCr = rgb2ycbcr(imageRGB);
```

Resample the Cb and Cr chrominance components.

```
[Cb,Cr] = resampler(imageYCbCr(:,:,2), imageYCbCr(:,:,3));
```

Version History

Introduced in R2012a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

`rgb2ycbcr`

groundTruthDataSource

Object for storing ground truth data sources

Description

The `groundTruthDataSource` object defines the source of ground truth data. Use this object to specify a data source for the `groundTruth` object. To label the data source, load the `groundTruthDataSource` object into a labeling app.

- The Image Labeler supports data sources for collections of images.
- The Video Labeler supports data sources for videos and image sequences. This app also supports custom data sources.

Creation

Syntax

```
gtSource = groundTruthDataSource(imds)

gtSource = groundTruthDataSource(imageFiles)

gtSource = groundTruthDataSource(videoName)

gtSource = groundTruthDataSource(imageSeqFolder)
gtSource = groundTruthDataSource(imageSeqFolder,timestamps)

gtSource = groundTruthDataSource(sourceName,readerFcn,timestamps)
```

Description

Image Datastore Source

`gtSource = groundTruthDataSource(imds)` returns a ground truth data source object for an `imageDatastore` specified by `imds`.

Collection of Images Source

`gtSource = groundTruthDataSource(imageFiles)` returns a ground truth data source object for a collection of images specified by `imageFiles`. Images must be in a file format readable by `imread`.

Video File Source

`gtSource = groundTruthDataSource(videoName)` returns a ground truth data source object for a video file specified by `videoName`. Videos must be in a file format readable by `VideoReader`.

Video as a Sequence of Images Source

`gtSource = groundTruthDataSource(imageSeqFolder)` returns a ground truth data source object for an image sequence located in the folder specified by `imageSeqFolder`.

`gtSource = groundTruthDataSource(imageSeqFolder,timestamps)` returns a ground truth data source object for an image sequence with a corresponding timestamp for each image contained in the specified folder. `timestamps` sets the `TimeStamps` property.

Custom Data Source

`gtSource = groundTruthDataSource(sourceName,readerFcn,timestamps)` returns a ground truth data source object by using the custom reader function handle, `readerFcn`. `sourceName` sets the `Source` property and `timestamps` set the `TimeStamps` property. The custom reader function loads an image from `sourceName` that corresponds to the current timestamp specified in the `duration` vector `timestamps`.

Input Arguments

`imds` — Image datastore

`imagedatastore` object

Image datastore, specified as an `imageDatastore` object.

`imageFiles` — Image file names

string array | cell array of character vectors

Image file names, specified as a string array or a cell array of character vectors. Images must be in a file format readable by `imread`. For a list of the supported image file formats, see `imformats`.

`videoName` — Name of video file

string scalar | character vector

Name of video file, specified as a string scalar or character vector. Videos must be in a file format readable by `VideoReader`. For a list of the supported video file formats, see `VideoReader.getFileFormats`. If your video format is not supported, specify a custom reader function, `readerFcn`.

`imageSeqFolder` — Image sequence folder

string scalar | character vector

Image sequence folder, specified as a string scalar or a character vector. The image files name extensions must be supported by `imformats`. If your video format is not supported, specify a custom reader function, `readerFcn`.

The images are loaded in the order returned by the `dir` command.

`readerFcn` — Custom reader function

function handle

Custom reader function, specified as a function handle. The custom reader function must load an image from a source at a specified timestamp by using this syntax:

```
outputImage = readerFcn(sourceName,currentTimestamp)
```

- `readerFcn` is the name of your custom reader function.
- `sourceName` is the name of the data source.
- `currentTimestamp` is the current timestamp, as specified by the input vector `timestamp`.

The `outputImage` returned by the custom function must be a grayscale or RGB image in any format supported by `imshow`. For more information, see “Use Custom Image Source Reader for Labeling”.

Properties

`TimeStamps` — Timestamps of video or image sequence

`duration` vector

This property is read-only.

Timestamps of video or image sequence, specified as a `duration` vector.

- For a video file, `Timestamps` is automatically populated with the timestamps that are present for the video frames.
- For an image sequence or custom reader, `Timestamps` is populated with the values in the input `duration` vector `timestamps`.
- For an image collection, the `TimeStamps` property remains empty.

.

`Source` — Source of ground truth data

character vector | cell array of character vectors

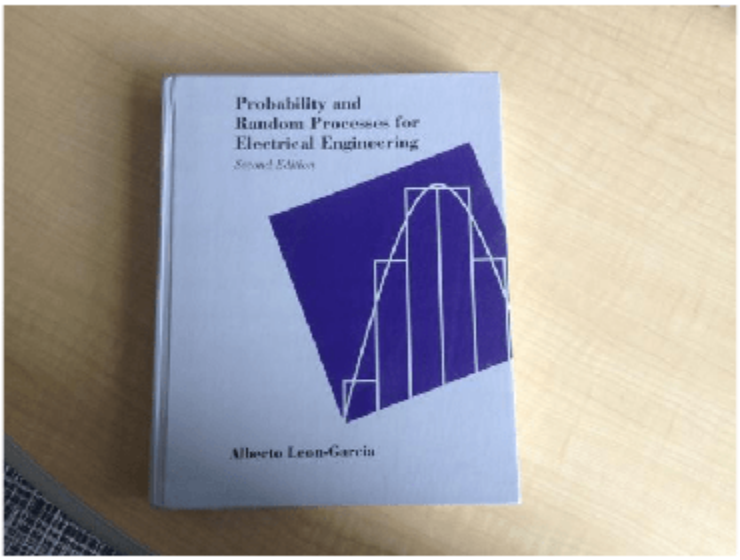
This property is read-only.

Source of ground truth data, specified as a character vector or cell array of character vectors. The source name can refer to image file names, a video file name, image sequence file names, or custom data source names.

Examples

Create Data Source from Image Datastore

Load image collection file names.



```
imageDir = fullfile(matlabroot,'toolbox','vision','visiondata','bookCovers');
imds = imageDatastore(imageDir);
```

Create a data source from an image datastore.

```
dataSource = groundTruthDataSource(imds);
```

Read and display an image from the datastore.

```
I = read(dataSource.Source);
figure,imshow(I)
```

Create a Ground Truth Data Source from a Video File

Use the `groundTruthDataSource` object to create a data source.

Read a video file and create a data source.

```
videoName = 'vipunmarkedroad.avi';
dataSource = groundTruthDataSource(videoName)
```

```
dataSource =
groundTruthDataSource for a video file with properties

        Source: ...tlab\toolbox\vision\visiondata\vipunmarkedroad.avi
    TimeStamps: [84×1 duration]
```

Create a VideoReader to read the video frames.

```
reader = VideoReader(videoName);
```

Read the 5th frame in the video and display

```
timeStamp = seconds(dataSource.TimeStamps(5));
reader.CurrentTime = timeStamp;
I = readFrame(reader);

figure
imshow(I)
```

Create Data Source from Image Sequence

Create a ground truth data source from an image sequence stored in a specified folder.

Specify the folder containing a sequence of images.

```
imageDir = fullfile(matlabroot,'toolbox','vision',...
        'visiondata','building');
```

Create a data source for the images that are in the `imageDir` folder.

```
    dataSource = groundTruthDataSource(imageDir)
```

```
dataSource =
groundTruthDataSource for a video as an image sequence with properties

                     Source: {
                             'B:\runnable\matlab\toolbox\vision\visiondata\building\building1.JP
                             'B:\runnable\matlab\toolbox\vision\visiondata\building\building2.JP
                             'B:\runnable\matlab\toolbox\vision\visiondata\building\building3.JP
                              ... and 2 more
                             }
                 TimeStamps: [5×1 duration]
```

Read the 5th frame in the sequence.

```
    I = imread(dataSource.Source{5});
    figure
    imshow(I)
```

Create Data Source Using Custom Reader

Create a ground truth data source by using a custom reader function.

Specify an image folder containing a sequence of road images.

```
imgFolder = fullfile(matlabroot,'toolbox','vision','visiondata','building');
```

Use an image datastore as the custom data source.

```
imgDataStore = imageDatastore(imgFolder);
```

Write a reader function, `readerFcn`, to read images from the datastore. The first input argument, `sourceName`, is not used. The second input argument, `currentTimestamp`, is the current timestamp. The function converts `currentTimestamp` from a `duration` scalar to a 1-based index suitable for reading images from the datastore.

```
readerFcn = @(~,idx)readimage(imgDataStore,seconds(idx));
```

Create a data source for the images in the image folder by using the custom reader function.

```
dataSource = groundTruthDataSource(imgFolder,readerFcn,1:5)
```

```
dataSource =
groundTruthDataSource for a custom data source with properties

        Source: B:\runnable\matlab\toolbox\vision\visiondata\building
    TimeStamps: [5×1 duration]
```

Read the fifth frame in the sequence.

```
I = readerFcn(imgFolder,seconds(5));
figure
imshow(I)
```

Tips

- `groundTruth` objects for video-based `groundTruthDataSource` objects rely on the video reading capabilities of your operating system. A `groundTruth` object created using a video data source remains consistent only for the same platform that was used to create it. To create a platform-specific `groundTruth` object, convert the video into a sequence of images.

Version History

Introduced in R2017a

groundTruth

Ground truth label data

Description

The `groundTruth` object contains information about the data source, label definitions, and marked label annotations for a set of ground truth labels. You can export or import a `groundTruth` object from the Image Labeler and Video Labeler apps. For a summary about the data stored in the `groundTruth` object, see “Elements of Ground Truth Objects”.

- To create training data for an object detector from arrays of `groundTruth` objects, use the `objectDetectorTrainingData` function.
- To create training data for a semantic segmentation network from arrays of `groundTruth` objects, use the `pixelLabelTrainingData` function.

Creation

To export a `groundTruth` object from a labeling app, on the app toolstrip, select **Export Labels** > **To Workspace**. The app exports the object to the MATLAB workspace. To create a `groundTruth` object programmatically, use the `groundTruth` function (described here).

Syntax

```
gTruth = groundTruth(dataSource,labelDefs,labelData)
```

Description

`gTruth = groundTruth(dataSource,labelDefs,labelData)` returns an object containing ground truth labels that can be imported into the Image Labeler and Video Labeler apps.

- `dataSource` specifies the source of the ground truth data and sets the `DataSource` property.
- `labelDefs` specifies the label, sublabel, and attribute definitions of the ground truth data and sets the `LabelDefinitions` property.
- `labelData` specifies the identifying information, position, and timestamps for marked labels and sets the `LabelData` property.

Properties

`DataSource` — Source of ground truth data

`groundTruthDataSource` object

Source of ground truth data, specified as a `groundTruthDataSource` object. The object contains information that describes the video, image sequence, or custom data source from which ground truth data was labeled.

To access images from the original data source, use `VideoReader` or `imageDatastore`. You can also use a custom read function. For more details, see “Use Custom Image Source Reader for Labeling”.

`LabelDefinitions` — Label definitions

table

This property is read-only.

Label definitions, specified as a table. To create this table, use one of these options.

- In one of the labeling apps, create label definitions, and then export them as part of a `groundTruth` object.
- Use a `labelDefinitionCreator` object to generate a label definitions table. If you save this table to a MAT-file, you can then load the label definitions into a labeling app session by selecting **Load** > **Label Definitions** from the app toolstrip.
- Create the label definitions table at the MATLAB command line.

This table describes the required and optional columns of the table specified in the `LabelDefinitions` property.

Column	Description	Required or Optional
`Name`	Strings or character vectors specifying the name of each label definition.	Required
`Type`	`labelType` enumerations that specify the type of each label definition, such as `Rectangle` or `Scene`.	Required

Column	Description	Required or Optional
`LabelColor`	1-by-3 row vectors of RGB triplets that specify the colors of the label definitions. Values are in the range [0, 1]. The color yellow (RGB triplet [1 1 0]) is reserved for the color of selected labels in the labeling apps.	Optional When you define labels in a labeling app, you must specify a color. Therefore, an exported label definitions table always includes this column. When you create label definitions using the `labelDefinitionCreator` object without specifying colors, the returned label definitions table includes this column, but all column values are empty.

Column	Description	Required or Optional
`PixelLabelID`	Scalars, column vectors, or *M*-by-3 matrices of integer-valued label IDs. `PixelLabelID` specifies the pixel label values used to represent a label definition. Pixel label ID values must be between 0 and 255.	Optional When you define pixel labels in a labeling app or the `labelDefinitionCreator` object, the generated label definitions table includes this column. When creating a label definitions table at the MATLAB command line, if you set `Type` to `labelType.PixelLabel` for any label, then this column is required.

Column	Description	Required or Optional
`Group`	Strings or character vectors specifying the group to which each label definition belongs.	Optional If you create the label definitions table at the MATLAB command line, you do not need to include a `Group` column. If you export label definitions from a labeling app or create them using a `labelDefinitionCreator` object, the label definitions table includes this column, even if you did not specify groups. The app assigns each label definition a `Group` value of `'None'`.

Column	Description	Required or Optional
`Description`	Strings or character vectors that describe each label definition.	Optional If you create the label definitions table at the MATLAB command line, you do not need to include a `Description` column. If you export label definitions from a labeling app or create them using a `labelDefinitionCreator` object, the label definitions table includes this column, even if you did not specify descriptions. The `Description` for these label definitions is an empty character vector.
`Hierarchy`	Structures containing sublabel and attribute data for each label definition. For an example of the `Hierarchy` format, see “Get Started with the Image Labeler” or “Get Started with the Video Labeler”.	Optional In labeling apps, when you define sublabels or attributes, the exported `groundTruth` object includes this column.

For example, consider a table with label definitions named `Sky`, `Vegetation`, `Lanes`, `StopSign`, and `Vehicle`, and that was exported from the Video Labeler app.

```
>> gTruth.LabelDefinitions

ans =

  5×6 table

       Name          Type            LabelColor     PixelLabelID    Group      Description
    ____________    _____________    ____________    ____________    _______    ____________

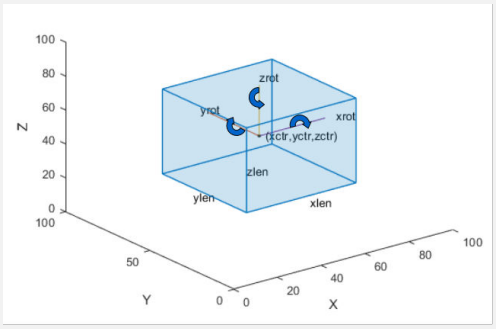
    {'Sky'       }    PixelLabel       {1×3 double}    {[       1]}    {'None'}    {0×0 char}
    {'Vegetation'}    PixelLabel       {1×3 double}    {[       2]}    {'None'}    {0×0 char}
    {'Lanes'     }    Line             {1×3 double}    {0×0 double}    {'None'}    {0×0 char}
    {'StopSign'  }    Rectangle        {1×3 double}    {0×0 double}    {'None'}    {0×0 char}
    {'Vehicle'   }    ProjectedCuboid  {1×3 double}    {0×0 double}    {'None'}    {0×0 char}
```

- The label definitions include pixel labels, so the table includes a `PixelLabelID` column.
- Two of the labels contain attributes, so the app created a `Hierarchy` column that applies across all label definitions.
- The label definitions do not have assigned groups, so the `Group` column is `'None'` for all label definitions.

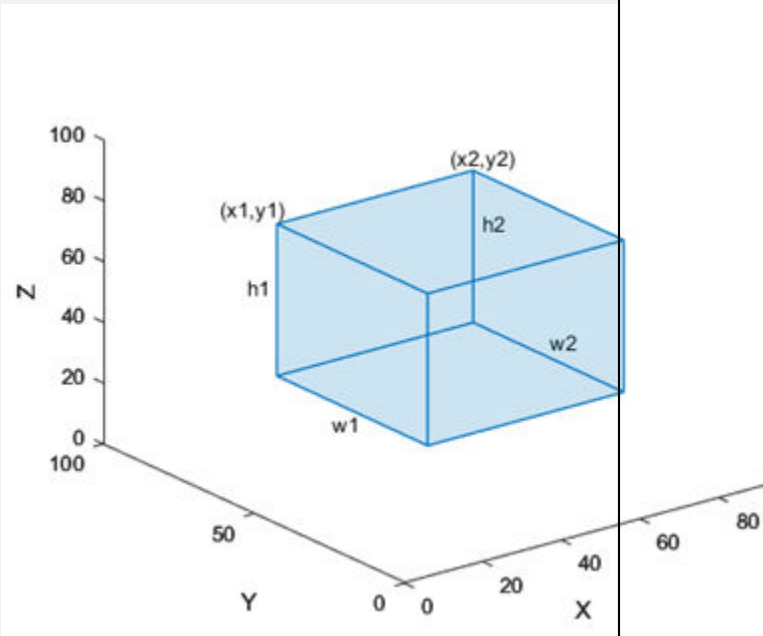
Note Labeler apps can only load pixel data that have pixel IDs between 1 and 255.

`LabelData` — Label data for each ROI and scene label

table | timetable

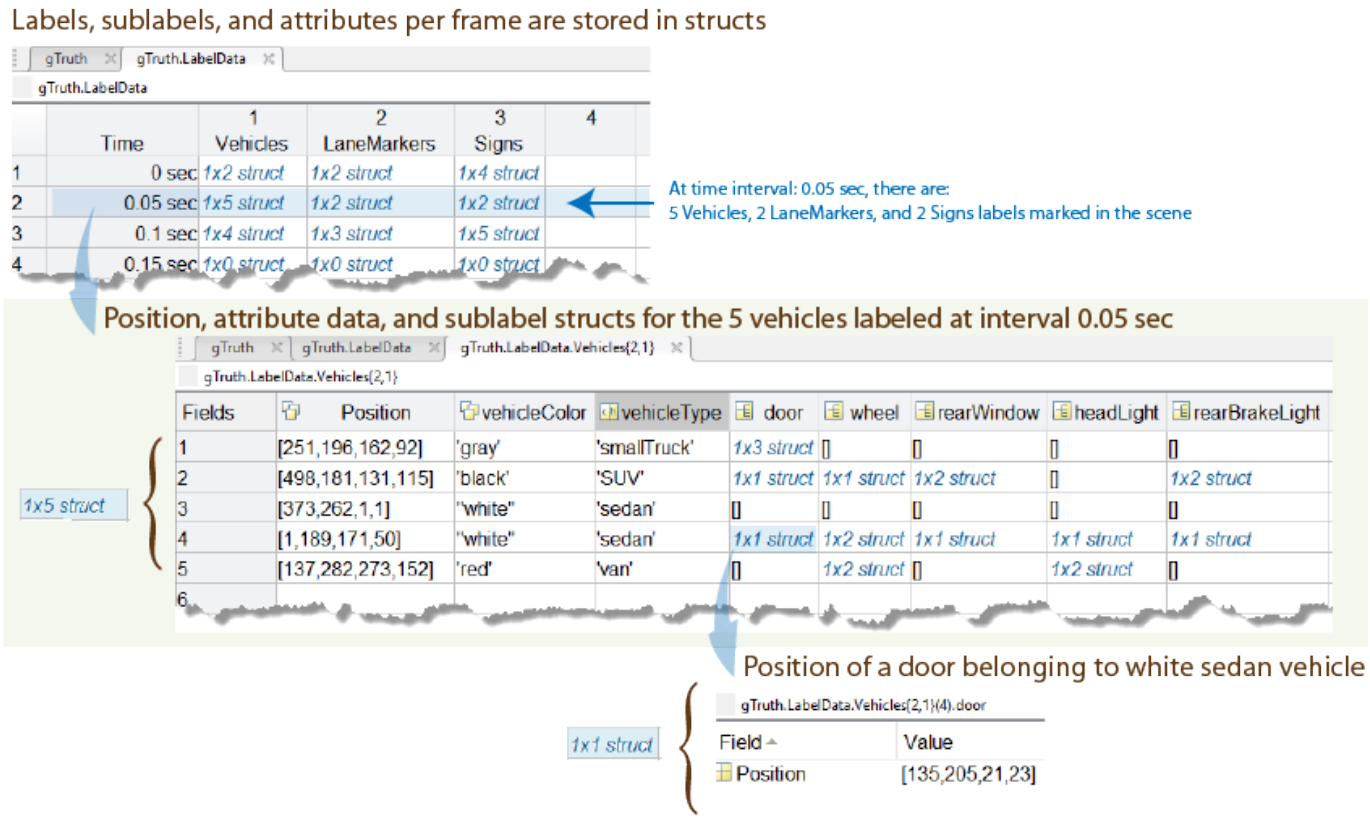


This property is read-only.



Label data for each ROI and scene label, specified as a `table` for image collections or a `timetable` for videos or image sequences. Each column of `LabelData` holds labels for a single label definition and corresponds to the `Name` value for each row in `LabelDefinitions`. These `LabelData` describes the elements of the table. The label categories are specified as `labelType` enumerations.

Alternatively, for ROI label data that is grouped by label type, a single column labeled `ROILabelData`, can be used and specified as a structure containing at least one label type, `RectangleData`, `PolygonData`, `LineData`, or `ProjCuboidData`.



The storage format for each label type is described in the table.

Label Type	Storage Format for Labels at Each Timestamp
`labelType.Rectangle`	`M`-by-4 numeric matrix of the form `[x, y, w, h]`, where: • `M` is the number of labels in the frame. • `x` and `y` specify the upper-left corner of the rectangle. • `w` specifies the width of the rectangle, which is its length along the *x*-axis. • `h` specifies the height of the rectangle, which is its length along the *y*-axis.
`labelType.RotatedRectangle`	For one or more rotated rectangles, specify in spatial coordinates as an *M*-by-5 numeric matrix, where each row specifies a rotated rectangle of the form [*xctr yctr w h yaw*]. • *M* is the number of rotated rectangles. • *xctr* and *yctr* specify the center of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis before rotation. • *h* specifies the height of the rectangle, which is its length along the *y*-axis before rotation. • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the rectangle.

Label Type	Storage Format for Labels at Each Timestamp
`labelType.Cuboid`	M-by-9 numeric matrix with rows of the form `[xctr, yctr, zctr, xlen, ylen, zlen, xrot, yrot, zrot]`, where: • `M` is the number of labels in the frame. • `xctr`, `yctr`, and `zctr` specify the center of the cuboid. • `xlen`, `ylen`, and `zlen` specify the length of the cuboid along the *x*-axis, *y*-axis, and *z*-axis, respectively, before rotation has been applied. • `xrot`, `yrot`, and `zrot` specify the rotation angles for the cuboid along the *x*-axis, *y*-axis, and *z*-axis, respectively. These angles are clockwise-positive when looking in the forward direction of their corresponding axes. The figure shows how these values determine the position of a cuboid. 

Label Type	Storage Format for Labels at Each Timestamp
`labelType.ProjectedCuboid`	`M`-by-8 vector of the form `[x1, y1, w1, h1, x2, y2, w2, h2]`, where: • `M` is the number of labels in the frame. • `x1, y1` specifies the *x*,*y* coordinates for the upper-left location of the front-face of the projected cuboid • `w1` specifies the width for the front-face of the projected cuboid. • `h1` specifies the height for the front-face of the projected cuboid. • `x2, y2` specifies the *x*,*y* coordinates for the upper-left location of the back-face of the projected cuboid. • `w2` specifies the width for the back-face of the projected cuboid. • `h2` specifies the height for the back-face of the projected cuboid. The figure shows how these values determine the position of a cuboid. 
`labelType.Line`	`M`-by-1 vector of cell arrays, where `M` is the number of labels in the frame. Each cell array contains an `N`-by-2 numeric matrix of the form `[x1 y1; x2 y2; ... ; xN yN]` for `N` points in the polyline.

Label Type	Storage Format for Labels at Each Timestamp
`labelType.PixelLabel`	Label data for all pixel label definitions is stored in a single *M*-by-1 `PixelLabelData` column for *M* images or frames. Each element contains a filename for a pixel label image. A pixel label image describes the label or labels contained in the corresponding image. The labels can be described as a 1- or 3- channel label matrix. To use `PixelLabelData` with any of the labeler apps, you must use a single-channel label matrix, where the values are of type `uint8`. You can convert a 3-channel pixel label data matrix to a single-channel label matrix programmatically to use with the labeler apps.
`labelType.Polygon`	`M`-by-1 vector of cell arrays, where `M` is the number of labels. Each cell array contains an `N`-by-2 numeric matrix of the form `[x1 y1; x2 y2; ... ; xN yN]` for `N` points in the polygon.
`labelType.Custom`	Labels are stored exactly as they are specified in the timetable. If you import a `groundTruthMultisignal` object containing custom label data into the Ground Truth Labeler app, this data is not imported into the app. Use custom data when gathering label data for training and combining it with data labeled in the app.
`labelType.Scene`	Stored as a `logical`.

To add ground truth data that is not in one of the native supported ROIs or a `Scene` label category to a `groundTruth` object, you must provide a label definition with a `labelType` that is `Custom`. The custom data is not visible when you load it into the labeling app.

Object Functions

selectLabelsByGroup	Select ground truth labels by label group
selectLabelsByType	Select ground truth labels by label type
selectLabelsByName	Select ground truth labels by label name
changeFilePaths	Change file paths in ground truth data
gatherLabelData	Gather label data from ground truth
writeFrames	Write ground truth video frames to disk
merge	Merge two or more ground truth objects

Examples

Create Ground Truth for Stop Signs and Cars

Create a data source from a collection of images.

```
data = load('stopSignsAndCars.mat');
imageFilenames = data.stopSignsAndCars.imageFilename(1:2)
```

```
imageFilenames = 2×1 cell
    {'stopSignImages/image001.jpg'}
```

```
    {'stopSignImages/image002.jpg'}
```

```
imageFilenames = fullfile(toolboxdir('vision'),'visiondata',imageFilenames);
dataSource = groundTruthDataSource(imageFilenames);
```

Define labels used to specify the ground truth. Use `labelDefinitionCreator` to create the label definitions table.

```
ldc = labelDefinitionCreator();
addLabel(ldc,'stopSign',labelType.Rectangle);
addLabel(ldc,'carRear',labelType.Rectangle);
labelDefs = create(ldc)
```

```
labelDefs=2×5 table
        Name          Type       LabelColor     Group      Description
    ____________    _________    __________    ________    ___________

    {'stopSign'}    Rectangle    {0×0 char}    {'None'}       {' '}
    {'carRear' }    Rectangle    {0×0 char}    {'None'}       {' '}
```

Initialize label data for rectangle ROIs.

```
stopSignTruth = {[856   318    39    41];[445   523    52    54]};
carRearTruth = {[398   378   315   210];[332   633   691   287]};
```

Construct a table of label data.

```
labelNames = {'stopSign';'carRear'};
labelData = table(stopSignTruth,carRearTruth,'VariableNames',labelNames)
```

```
labelData=2×2 table
        stopSign              carRear
    __________________    ____________________

    {[856 318 39 41]}    {[398 378 315 210]}
    {[445 523 52 54]}    {[332 633 691 287]}
```

Create a ground truth object.

```
gTruth = groundTruth(dataSource,labelDefs,labelData)
```

```
gTruth =
  groundTruth with properties:

          DataSource: [1×1 groundTruthDataSource]
    LabelDefinitions: [2×5 table]
           LabelData: [2×2 table]
```

Create Ground Truth Data of Road Lanes

Create a `groundTruth` object to store data representing marked road lanes.

Create a data source from an image.

```
dataSource = groundTruthDataSource({'stopSignTest.jpg'});
```

Define labels used to specify ground truth. Use `labelDefinitionCreator` to create label definitions table.

```
ldc = labelDefinitionCreator();
addLabel(ldc,'Lane',labelType.Line);
labelDefs = create(ldc);
```

Assign two lane markers in the image.

```
laneMarkerTruth = {[257 254;311 180] [327 183;338 205;374 250]};
```

Construct a table of label data.

```
labelNames = {'Lane'};
labelData = table(laneMarkerTruth,'VariableNames',labelNames)
```

```
labelData=table
                Lane
    ________________________________

    {2×2 double}    {3×2 double}
```

Create a groundTruth object.

```
gTruth = groundTruth(dataSource,labelDefs,labelData)
```

```
gTruth =
  groundTruth with properties:

          DataSource: [1×1 groundTruthDataSource]
    LabelDefinitions: [1×5 table]
           LabelData: [1×1 table]
```

Create Ground Truth Data for Pixel Labels

Create a `groundTruth` object to store data representing parts of a scene.

Create a data source.

```
dataSource = groundTruthDataSource({'visionteam.jpg'});
```

Use `labelDefinitionCreator` to create the label definitions table. Define labels, `'Person'` and `'Background'`. Assign their corresponding label type as `PixelLabel`.

```
ldc =labelDefinitionCreator();
addLabel(ldc,'Person',labelType.PixelLabel);
addLabel(ldc,'Background',labelType.PixelLabel);
labelDefs = create(ldc)
```

```
labelDefs=2×6 table
         Name            Type       LabelColor    PixelLabelID     Group      Description
    _____________    ___________    __________    _____________    ________    ___________
```

```
    {'Person'    }    PixelLabel    {0×0 char}       {[1]}        {'None'}       {' '}
    {'Background'}    PixelLabel    {0×0 char}       {[2]}        {'None'}       {' '}
```

Specify the location of the pixel label data for the image.

```
dataFile = {'visionteamPixelLabels.png'}
```

```
dataFile = 1×1 cell array
    {'visionteamPixelLabels.png'}
```

Construct a table of label data for the pixel label data.

```
labelData = table(dataFile,'VariableNames',{'PixelLabelData'})
```

```
labelData=table
           PixelLabelData
    ______________________________

    {'visionteamPixelLabels.png'}
```

Create a `groundTruth` object.

```
gTruth = groundTruth(dataSource,labelDefs,labelData)
```

```
gTruth =
  groundTruth with properties:

          DataSource: [1×1 groundTruthDataSource]
    LabelDefinitions: [2×6 table]
           LabelData: [1×1 table]
```

Tips

- `groundTruth` objects for video-based data sources rely on the video reading capabilities of your operating system. A `groundTruth` object created using a video data source remains consistent only for the same platform that was used to create it. To create a platform-independent `groundTruth` object, convert the video into a sequence of images and include the associated timestamps with the image sequence.

Version History

Introduced in R2017a

writeFrames

Write ground truth video frames to disk

Syntax

```
files = writeFrames(gTruth,location)
files = writeFrames(gTruth,location,timestamps)
files = writeFrames( ___ ,Name=Value)
```

Description

`files = writeFrames(gTruth,location)` writes all video frames from one or more ground truth objects `gTruth` to the folder specified by `location`. The function returns the paths to the output video frames `files`.

`files = writeFrames(gTruth,location,timestamps)` writes video frames with the specified timestamps to disk.

`files = writeFrames( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of input arguments from previous syntaxes. For example, `ImageFormat="jpg"` sets the returned video frames to the JPEG format.

Examples

Write Video Frames from Ground Truth Object

Load a ground truth object that contains rectangle labels for a video into the workspace.

```
data = load("peopleWalkingGroundtruth.mat");
gTruth = data.peopleWalking;
```

Gather rectangle labels from the video.

```
labelTypes = labelType.Rectangle;
[labelData,timestamps] = gatherLabelData(gTruth,labelTypes);
```

Write the image frames associated with the gathered label data to a temporary folder location. Use the timestamps returned by the `gatherLabelData` function to indicate which video frames to write.

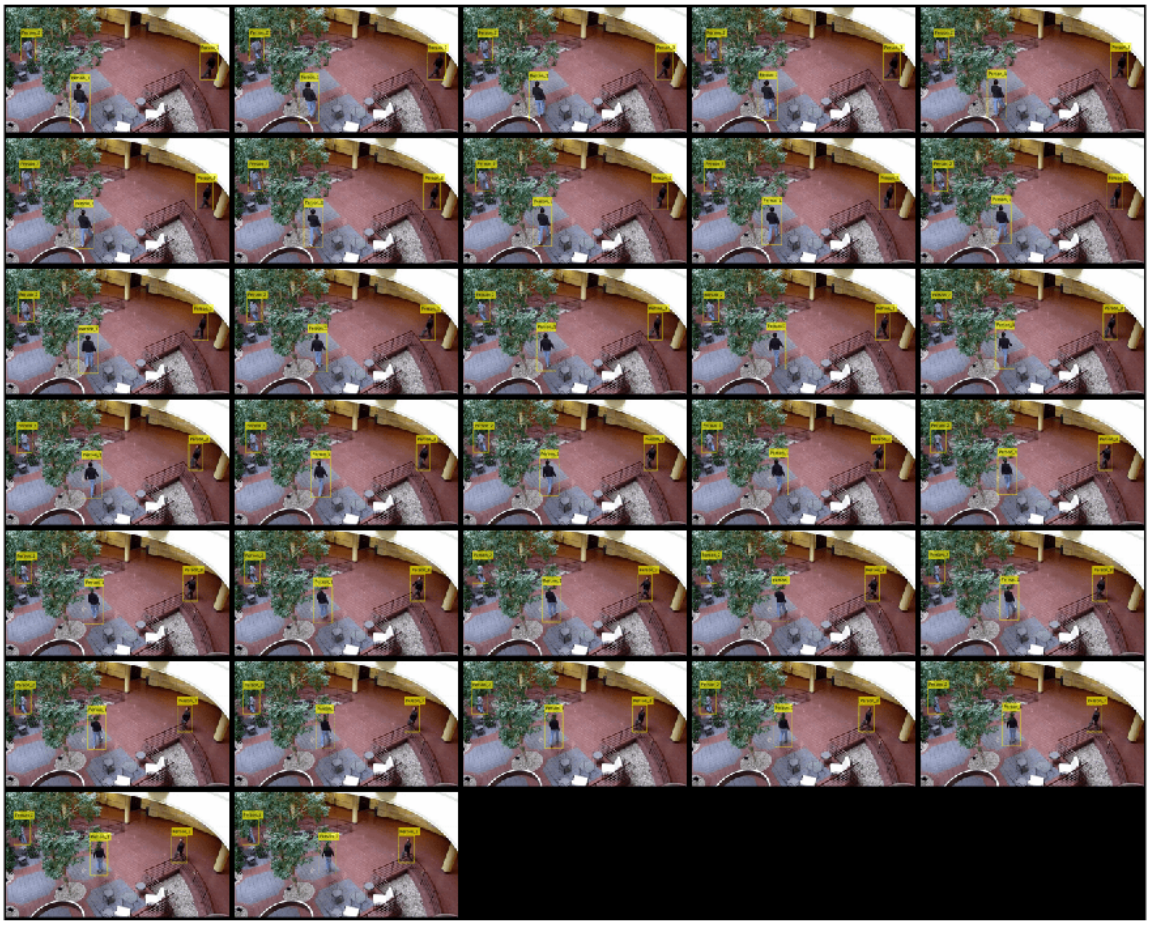
```
outputFolder = fullfile(tempdir,"videoFrames");
fileNames = writeFrames(gTruth,outputFolder,timestamps);
```

```
Write images extracted for training to folder:
    C:\Users\ncorriel\AppData\Local\Temp\videoFrames

Writing 600 images extracted from atrium.mp4...Completed.
```

Create an image datastore of the written video image frames, and a box label datastore of the corresponding rectangle label data.

```
imds = imageDatastore(fileNames{1});
blds = boxLabelDatastore(labelData{1});
```



Combine the datastores using the `combine` function.

```
ds = combine(imds,blds);
```

Visualize the written video image frames using the `montage` function.

```
frameData = {};
while hasdata(ds)
    data = read(ds);
    % Only visualize frames with box data.
    if ~isempty(data{2})
        frameData{end + 1} = insertObjectAnnotation(data{1},"Rectangle",data{2},data{3});
    end
end

figure
montage(frameData,BorderSize=3)
```

Input Arguments

`gTruth` — Ground truth labels
`groundTruth` object | array of `groundTruth` objects

Ground truth labels, specified as a `groundTruth` object or as an array of `groundTruth` objects.

`location` — Destination folder
string scalar | character vector

Destination folder to which to write the video frames, specified as a string scalar or character vector.

`timestamps` — Timestamps
cell array of `duration` vectors

Timestamps, specified as an *M*-by-1 cell array of `duration` vectors, where *M* is the number of `groundTruth` objects in `gTruth`. To use this argument, you must specify an input ground truth object that contains duration-based data. If the input ground truth object does not have duration-based data, the function ignores the timestamps argument and writes all image data from the ground truth object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `writeFrames(gTruth,location,ImageFormat="jpg")` sets the returned video frames to the JPEG format.

`ImageFormat` — Image format
character vector | string scalar

Image format, specified as a character vector or string scalar. This value specifies the image format for the returned video frames `files`. You must specify a file format supported by `imwrite`.

`NamePrefix` — Prefix for output filenames
string scalar | character vector

Prefix for output filenames, specified as a string scalar or character vector. The output image files use this naming convention::

`NamePrefix`*_source_number_image_number*`.ImageFormat`, where,

- `NamePrefix` is the filename prefix, specified by the `NamePrefix` name-value argument.
- *source_number* corresponds to the ground truth object. For example, if the input `gTruth` is an array of three ground truth objects, the function outputs files with three different *source_number* values, `1`, `2`, and `3`, corresponding to the index of each ground truth object in the array.
- *image_number* is the image or video frame number.

The default value `NamePrefix` depends on the source of the data.

- Video or custom data source — `NamePrefix` uses the name of the data source, `sourceName`.

- Image datastore — `NamePrefix` uses the value `"datastore"`.

The function ignores this argument when:

- The input `groundTruth` object was created from an image sequence data source.
- The array of input `groundTruth` objects all contain image datastores using the same custom `read` function.
- Any of the input `groundTruth` objects contain datastores and use the default `read` functions.

`UseParallel` — Run parallel computations
`false` or `0` (default) | `true` or `1`

Run parallel computations , specified as a numeric or logical `1` (`true`) or `0` (`false`).

To run in parallel, set `UseParallel` to `true`, or enable parallel computation by default using the Computer Vision Toolbox preferences.

For more information, see “Parallel Computing Toolbox Support”.

`Verbose` — Flag to display training progress
`true` or `1` (default) | `false` or `0`

Flag to display training progress at the MATLAB command line, specified as a numeric or logical `1` (`true`) or `0` (`false`). This argument applies only for `groundTruth` objects created using a video file or a custom data source.

Output Arguments

`files` — File paths of written frames
M-by-1 cell array

File paths of written frames, returned as an *M*-by-1 cell array. *M* is the number of ground truth objects. Each cell contains an *N*-element vector of strings, where *N* is the number of image frames written to the specified folder. Each string specifies the full path of an output file. The output files use this naming convention:

`NamePrefix`*_source_number_image_number*.`ImageFormat`, where,

- `NamePrefix` is the filename prefix, specified by the `NamePrefix` name-value argument.
- *source_number* corresponds to the ground truth object. For example, if the input `gTruth` is an array of three ground truth objects, the function outputs files with three different *source_number* values, `1`, `2`, and `3`, corresponding to the index of each ground truth object in the array.
- *image_number* is the image or video frame number.

Functions
`groundTruth` | `gatherLabelData` | `objectDetectorTrainingData` | `pixelLabelTrainingData`

Topics
“Reidentify People Throughout a Video Sequence Using ReID Network”
“Convert Ground Truth Labeling Data for Object Re-Identification”

merge

Merge two or more ground truth objects

Syntax

```
gTruth = merge(gTruth1,gTruth2, ... gTruthN)
gTruth = merge( ___ ,OutputFolder=name)
```

Description

`gTruth = merge(gTruth1,gTruth2, ... gTruthN)` merges two or more ground truth objects into a new ground truth object `gTruth`. The resulting merged ground truth object contains all the data sources, label definitions, and label data from the input ground truth objects.

`gTruth = merge( ___ ,OutputFolder=name)` specifies the folder into which to save merged pixel label data in addition to the input arguments from the previous syntax. `name` must be the absolute or relative path to the save folder, specified as a character vector or string scalar. By default, the function writes merged pixel label data to a folder named `"mergedPixelLabelData"` within the current working directory. If this folder does not exist, the function creates it. If the folder already exists, the function adds a unique numeric suffix to the default name, for example `"mergedPixelLabelData_1"`, and creates a new folder.

Examples

Merge Two Ground Truth Objects

Load two separate ground truth objects into the workspace from a previously saved MAT file.

```
load("groundTruthData.mat","gTruth1","gTruth2");
```

Merge the two objects into one ground truth object. Use the logical output hasModifiedLabels, to specify any modified label data.

```
[gTruth] = merge(gTruth1,gTruth2);
```

Review merged ground truth in the Image Labeler app.

```
imageLabeler(gTruth)
```

Input Arguments

`gTruth1,gTruth2, ... gTruthN` — Ground truth data
`groundTruth` objects

Ground truth data, specified as two or more `groundTruth` objects. If any of the ground truth objects specifies a `groundTruthDataSource` or an `imageDatastore` with a custom `read` function, then all of the input ground truth objects must use the same custom `read` function.

Output Arguments

gTruth — Merged ground truth object
groundTruth object | array of groundTruth objects

Merged ground truth data, returned as a groundTruth object or an array of groundTruth objects. The function returns an array of groundTruth objects when you merge groundTruth objects that correspond to multiple video or image sequence sources. The object merges the label definitions, so that the output groundTruth contains the same label.

The merged labels obtain their description and color values from the first (of the input order) ground truth object that defines a non-empty value. The function automatically selects a new color value when required.

The method that the function uses to merge label data depends on the label type:

- Region-of-interest (ROI) — Merged by using concatenation. ROI labels include labelType.Rectangle, labelType.RotatedRectangle, labelType.Line, labelType.Point, labelType.ProjectedCuboid, labelType.Cuboid, and labelType.Polygon.

  The function merges ROIs that do not have attributes or sublabels, and contain the same position value, into one ROI. The function does not preserve the stacking order of ROI labels when merging ROI label data from ground truth objects that reference the same image.
- Scene — Merged by using majority consensus. In the case of a tie, the output uses the scene label data from the first input ground truth object.
- Pixel — Merged by using a per-pixel majority consensus. In the case of a tie, the output uses the pixel label value from the first input ground truth. This merge ignores unlabeled pixels. The function saves the merged pixel label data as PNG-format files, by using the naming convention:

  "Label_<*sourceIndex*>_<*sourceName*>.png", where <*sourceIndex*> is an index into the output ground truth object DataSource property, and <*sourceName*> is the filename of the data source.

  The object merges pixel label data to separate subfolders when the input groundTruth objects reference:

  - More than one unique video or image sequence source.
  - Image file sources and video or image sequence sources.

  The subfolders are named gTruth_<idx> and contains pixel label data that correspond to the gTruth(idx) output. These subfolders are located in the folder specified by OutputFolder.
- Custom — The merge function does not support custom labels.

vision.labeler.AutomationAlgorithm Class

Namespace: `vision.labeler`

Interface for algorithm automation in ground truth labeling

Description

The `vision.labeler.AutomationAlgorithm` class specifies the interface for defining custom automation algorithms to run in the Image Labeler, Video Labeler, and Ground Truth Labeler apps. Classes that inherit from the `AutomationAlgorithm` interface can be used with the automation workflow of the labeling apps to generate ground truth labels.

You can also use a custom function that creates an automation algorithm. The function, which you can specify in the labeling apps, enables you to adjust the automation parameters. For more details, see Create Automation Algorithm Function for Labeling.

The `vision.labeler.AutomationAlgorithm` class is a `handle` class.

Class Attributes

`Abstract`	`true`

For information on class attributes, see “Class Attributes”.

Properties

The `AutomationAlgorithm` class predefines this set of properties.

`GroundTruth` — Ground truth data

`groundTruth` object | `groundTruthMultisignal` object

Ground truth data, specified as a `groundTruth` or `groundTruthMultisignal` object. This property holds all the labels in the labeling app prior to automation.

- For automation algorithms used in the Image Labeler or Video Labeler app, this property must be a `groundTruth` object.
- For automation algorithms used in the Ground Truth Labeler app, this property must be a `groundTruthMultisignal` object.

Attributes:

`GetAccess`	`public`
`SetAccess`	`private`

`SelectedLabelDefinitions` — Selected label definitions

structure

Label definitions selected for automation in the labeling app, specified as a structure. The labeling apps support selection of only one labeling definition per automation session. In the labeling apps, the selected label definition is highlighted in yellow in either the **ROI Labels** or **Scene Labels** pane on the left.

The structure contains these fields.

Field	Description
`Type`	`labelType` enumeration that contains the type of label definition. Valid label types are: • `labelType.Rectangle` • `labelType.Polygon` • `labelType.Cuboid` (for point clouds) • `labelType.ProjectedCuboid` (for image and video data) • `labelType.Line` • `labelType.PixelLabel` • `labelType.Scene` `labelType.Custom` is not supported.
`Name`	Character vector that contains the name of the label definition.
`Attributes` (optional)	Structure array that contains one structure for each attribute in the label definition. If the label definition does not contain attributes, then this property does not include the `Attributes` field. The first field of each attribute structure in this structure array contains the attribute name. The second field contains a structure of values that are associated with that name. If you are defining a `List` attribute, you must also define the list of values for that attribute. Values for `Numeric Value`, `String`, or `Logical` attributes are optional. Descriptions for the attributes are optional for all cases.
`PixelLabelID` (optional)	Positive integer that contains the pixel label ID for the label definition. This `PixelLabelID` field applies only for label definitions of type `PixelLabel`.

To view a sample `SelectedLabelDefinitions` structure that contains an attribute, enter this code at the MATLAB command prompt.

```
selectedLabelDefs.Type = labelType.Rectangle;
selectedLabelDefs.Name = 'Car';
selectedLabelDefs.Attributes = struct('distance', ...
    struct('DefaultValue',0,'Description','Sensor distance'))
```

To view a sample `SelectedLabelDefinitions` structure that contains pixel label definitions, enter this code at the MATLAB command prompt.

```
selectedLabelDefs.Type = labelType.PixelLabel;
selectedLabelDefs.Name = 'Car';
selectedLabelDefs.Attributes = struct('distance', ...
    struct('DefaultValue',0,'Description','Sensor distance'))
```

Attributes:

```
GetAccess                                       public
SetAccess                                       private
```

`ValidLabelDefinitions` — Valid label definitions
structure array

Valid label definitions that the algorithm can automate, specified as a structure array. Each structure in the array corresponds to a valid label definition. To determine which label definitions are valid, the app uses the `checkLabelDefinition` method. This table describes the fields for each valid label definition structure.

Field	Description
`Type`	`labelType` enumeration that contains the type of label definition. Valid label types are: • `labelType.Rectangle` • `labelType.Polygon` • `labelType.Cuboid` (for point clouds) • `labelType.ProjectedCuboid` (for image and video data) • `labelType.Line` • `labelType.PixelLabel` • `labelType.Scene` `labelType.Custom` is not supported.
`Name`	Character vector that contains the name of the label definition.
`Attributes` (optional)	Structure array that contains one structure for each attribute in the label definition. If the label definition does not contain attributes, then this property does not include the `Attributes` field. The first field of each attribute structure in this structure array contains the attribute name. The second field contains a structure of values that are associated with that name. If you are defining a `List` attribute, you must also define the list of values for that attribute. Values for `Numeric Value`, `String`, or `Logical` attributes are optional. Descriptions for the attributes are optional for all cases.
`PixelLabelID` (optional)	Positive integer that contains the pixel label ID for the label definition. This `PixelLabelID` field applies only for label definitions of type `PixelLabel`.

To view a sample `ValidLabelDefinitions` structure that contains an attribute, enter this code at the MATLAB command prompt.

```
validLabelDefs(1).Type = labelType.Rectangle;
validLabelDefs(1).Name = 'Car';
validLabelDefs(2).Type = labelType.Line;
validLabelDefs(2).Name = 'LaneMarker';
validLabelDefs(3).Type = labelType.Scene
validLabelDefs(3).Name = 'Sunny';
```

To view a sample `ValidLabelDefinitions` structure that contains pixel label definitions, enter this code at the MATLAB command prompt.

```
validLabelDefs(1).Type = labelType.PixelLabel;
validLabelDefs(1).Name = 'Road';
validLabelDefs(1).PixelLabelID  = 1;
validLabelDefs(2).Type = labelType.PixelLabel;
validLabelDefs(2).Name = 'Sky';
validLabelDefs(2).PixelLabelID = 2
```

Attributes:

`GetAccess`	`public`
`SetAccess`	`private`

`CurrentIndex` — Index of current frame

integer

Index of current frame, specified as an integer. The object updates `CurrentIndex` while the algorithm runs. Use this index value to access the current frame ground truth data from the `GroundTruth` property.

Clients of the `AutomationAlgorithm` class are required to define this set of properties. These properties set up the name, description, and user instructions for your automated algorithm.

`Name` — Automation algorithm name

character vector

Automation algorithm name, specified as a character vector.

Attributes:

`GetAccess`	`public`
`Abstract`	`true`
`Constant`	`true`
`NonCopyable`	`true`

`Description` — Automation algorithm description

character vector

Algorithm description, specified as a character vector.

Attributes:

`GetAccess`	`public`
`Abstract`	`true`
`Constant`	`true`
`NonCopyable`	`true`

`UserDirections` — Algorithm directions displayed in app

cell array

Algorithm directions displayed in app, specified as a cell array. `UserDirections` are specified as a `cellstr`, with each string representing a separate direction. Use the `checkSetup` method to verify that the directions have been adhered to.

Attributes:

`GetAccess`	`public`
`Abstract`	`true`
`Constant`	`true`
`NonCopyable`	`true`

Methods

Public Methods

Clients of an `AutomationAlgorithm` implement these user-defined functions to define execution of the algorithm. For more information on creating your own automation algorithm, see “Create Custom Automation Algorithm for Labeling”.

checkLabelDefinition	Validate label definition
checkSignalType	Validate signal type
supportsMultisignalAutomation	Set multisignal algorithm automation flag
checkSetup	Set up validation (optional)
initialize	Initialize state for algorithm execution (optional)
run	Run label automation on every frame in interval
terminate	Terminate automated algorithm (optional)
settingsDialog	Display algorithm settings (optional)

“Automate Attributes of Labeled Objects” (Automated Driving Toolbox)

checkLabelDefinition

Class: `vision.labeler.AutomationAlgorithm`
Namespace: `vision.labeler`

Validate label definition

Syntax

```
isValid = checkLabelDefinition(algObj,labelDef)
```

Description

In the labeling apps, the `checkLabelDefinition` method checks whether each label defined in the **ROI Labels** and **Scene Labels** panes is valid. The method restricts an automation algorithm to use only relevant labels. For example, a label definition of type `Rectangle` cannot be used to mark a lane boundary.

Clients of `AutomationAlgorithm` must implement this method.

`isValid = checkLabelDefinition(algObj,labelDef)` returns `true` for valid label definitions and `false` for invalid definitions for the automation algorithm provided by `algObj`. `labelDef` is a structure containing all the label definitions in the **ROI Labels** and **Scene Labels** panes. Definitions that return `false` are disabled during automation.

Examples

Restrict Automation to Rectangular ROI Labels

This implementation of the `checkLabelDefinition` method designates `Rectangle` labels as valid and all other labels as invalid.

```
function isValid = checkLabelDefinition(algObj,labelDef)
    isValid = (labelDef.Type == labelType.Rectangle);
end
```

Restrict Automation to ROI Labels of Any Type

This implementation of the `checkLabelDefinition` method designates ROI labels such as `Rectangle` and `Line` as valid and all other labels as invalid.

```
function isValid = checkLabelDefinition(algObj,labelDef)
    isValid = isROI(labelDef.Type);
end
```

Input Arguments

`algObj` — Automation algorithm

`vision.labeler.AutomationAlgorithm` object

Automation algorithm, specified as a `vision.labeler.AutomationAlgorithm` object.

`labelDef` — Label definition
structure

Label definition, specified as a structure containing `Type` and `Name` fields.

Field	Description
`Type`	`labelType` enumeration that contains the type of label definition. Valid label types are: • `labelType.Rectangle` • `labelType.Cuboid` (for point clouds) • `labelType.ProjectedCuboid` (for image and video data) • `labelType.Line` • `labelType.PixelLabel` • `labelType.Scene` `labelType.Custom` is not supported.
`Name`	Character vector that contains the name of the label definition.

To view a sample `labelDef` structure that contains a rectangle label definition, enter this code at the MATLAB command prompt.

```
labelDef(1).Type = labelType.Rectangle;
labelDef(1).Name = 'Car';
```

Output Arguments

`isValid` — True of false result of label definition validity check
`1` | `0`

True or false result of the label definition validity check, returned as a `1` or `0` of data type `logical`.

Tips

- To access the selected label definitions, use the SelectedLabelDefinitions property of the automation algorithm. In the labeling apps, the selected label definitions are highlighted in yellow in the **ROI Labels** and **Scene Labels** panes on the left.

Version History

Introduced in R2017a

See Also

`labelType` | `vision.labeler.AutomationAlgorithm` | `checkSignalType` | `checkSetup`

checkSetup

Class: `vision.labeler.AutomationAlgorithm`
Namespace: `vision.labeler`

Set up validation (optional)

Syntax

```
isReady = checkSetup(algObj)
isReady = checkSetup(algObj,labelsToAutomate)
```

Description

In the labeling apps, the `checkSetup` method checks the validity of the setup when you click **Run** in an automation session. If `checkSetup` returns `true`, then the setup is valid and the app proceeds to run the automation algorithm by using the `initialize`, `run`, and `terminate` methods.

Clients of `AutomationAlgorithm` can optionally implement this method.

`isReady = checkSetup(algObj)` returns `true` if you completed set up correctly and the automation algorithm `algObj` can begin execution. Otherwise, `checkSetup` returns `false`.

`isReady = checkSetup(algObj,labelsToAutomate)` additionally provides a table, `labelsToAutomate`, that contains labels selected for the automation algorithm to use for labeling. This syntax does not support pixel label automation. In addition, this syntax is available only for time-dependent (temporal) automation algorithms. The Ground Truth Labeler and Video Labeler apps support temporal algorithms but the Image Labeler does not. For more information on these types of algorithms, see “Temporal Automation Algorithms”.

Examples

Check Setup for ROI Labels

This implementation of the `checkSetup` method checks the setup for a temporal automation algorithm. This method determines that an automation algorithm is ready to run if at least one ROI label exists.

```
function isReady = checkSetup(algObj,labelsToAutomate)

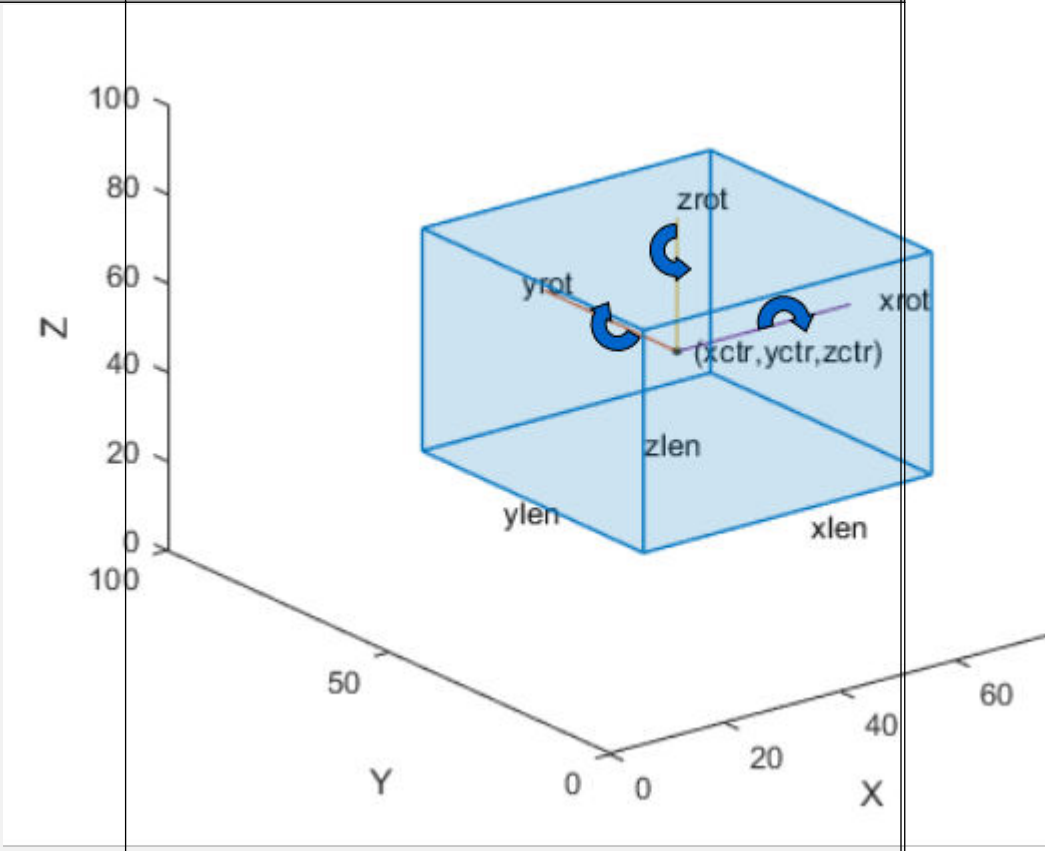
    notEmpty = ~isempty(labelsToAutomate);
    hasROILabels = any(labelsToAutomate.Type == labelType.Rectangle);
    isReady = (notEmpty && hasROILabels)

end
```

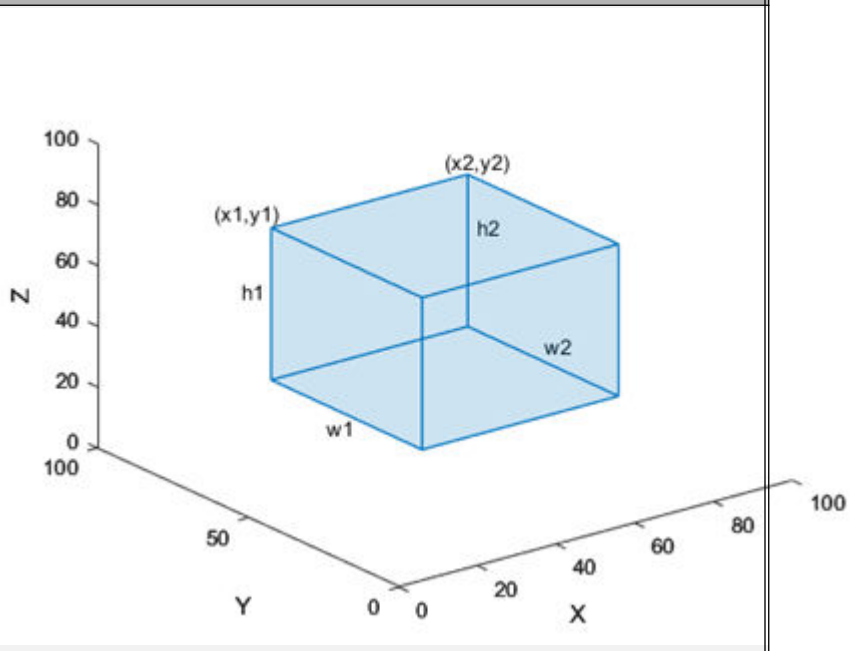
Input Arguments

`algObj` — Automation algorithm

`vision.labeler.AutomationAlgorithm` object



Automation algorithm, specified as a `vision.labeler.AutomationAlgorithm` object.



`labelsToAutomate` — Labels selected for automation
table

Labels selected for automation, specified as a table with these columns.

Column Name	Description
`Type`	`labelType` enumeration that contains the type of the label. Valid label types are: • `labelType.Rectangle` • `labelType.Cuboid` (Ground Truth Labeler app only) • `labelType.ProjectedCuboid` • `labelType.Line` • `labelType.Scene` `labelType.PixelLabel` and `labelType.Custom` are not supported.
`Name`	Character vector that contains the name of the label.
`Time`	Scalar of type `double` that specifies the time, in seconds, when the label was marked.

<table>
<tr><th>Column Name</th><th>Description</th></tr>
<tr><td>Position</td><td>Location of the label in the frame. The format of this vector depends on the label type.
<table>
<tr><th>Label Type</th><th>Position Format</th></tr>
<tr><td>Rectangle — Rectangular region of interest (ROI) labels</td><td>M-by-4 numeric vector of the form [x, y, w, h], where:
M is the number of labels in the frame.
x and y specify the upper-left corner of the rectangle.
w specifies the width of the rectangle, which is the length of the rectangle along the x-axis.
h specifies the height of the rectangle, which is the length of the rectangle along the y-axis.</td></tr>
<tr><td>Cuboid — Cuboid ROI labels</td><td>M-by-9 numeric vector of the form [xctr, yctr, zctr, xlen, ylen, zlen, xrot, yrot, zrot], where:
M is the number of labels in the frame.
xctr, yctr, and zctr specify the center of the cuboid.
xlen, ylen, and zlen specify the length of the cuboid along the x-axis, y-axis, and z-axis, respectively.
xrot, yrot, and zrot specify the rotation angles for the cuboid along the x-axis, y-axis, and z-axis, respectively. These angles are clockwise-positive when looking in the forward direction of their corresponding axes.
This figure shows how these values specify the position of a cuboid.</td></tr>
</table>
</td></tr>
</table>

Column Name	Description	
	Label Type	**Position Format**
		
	`ProjectedCuboid` — Cuboid ROI labels	`M`-by-8 vector of the form `[x1, y1, w1, h1, x2, y2, w2, h2]`, where: • `M` is the number of labels in the frame. • `x1, y1` specifies the *x*,*y* coordinates for the upper-left location of the front-face of the projected cuboid • `w1` specifies the width for the front-face of the projected cuboid. • `h1` specifies the height for the front-face of the projected cuboid. • `x2, y2` specifies the *x*,*y* coordinates for the upper-left location of the back-face of the projected cuboid. • `w2` specifies the width for the back-face of the projected cuboid. • `h2` specifies the height for the back-face of the projected cuboid. The figure shows how these values determine the position of a cuboid.

Column Name	Description	
	Label Type	**Position Format**
		
	`Line` — Polyline ROI labels	`M`-by-1 vector of cell arrays, where `M` is the number of labels in the frame. Each cell array contains an `N`-by-2 numeric matrix of the form `[x1 y1; x2 y2; ... ; xN yN]` for `N` points in the polyline.
	`Scene` — Scene labels	Logical value of `1` if the label is present in the frame and `0` otherwise.

Each row of the table corresponds to a label selected for automation. This `labelsToAutomate` table contains a rectangle label, a line label with five points, and a cuboid label.

```
    Type          Name           Time        Position
_________    _____________    _________    _____________

Rectangle    'Car'            0.033333     [1x4 double]
Line         'LaneMarker'     0.066667     [5x2 double]
Cuboid       'Truck'          0.099999     [1x9 double]
```

Output Arguments

`isReady` — True or false result of setup check

`1 | 0`

True or false result of the setup check, returned as a `1` or `0` of data type `logical`.

Version History

Introduced in R2017a

`labelType` | `vision.labeler.AutomationAlgorithm` | `checkLabelDefinition` | `checkSignalType`

checkSignalType

Class: `vision.labeler.AutomationAlgorithm`
Namespace: `vision.labeler`

Validate signal type

Syntax

```
isValid = checkSignalType(signalType)
```

Description

In the labeling apps, the `checkSignalType` method validates whether each signal selected for automation supports the signal type relevant to the automation algorithm.

- Algorithms that automate the labeling of image collections, videos, or image sequences support signals of type `Image` only.
- Algorithms that automate the labeling of lidar point clouds support signals of type `PointCloud` only.

The implementation of this method depends on which labeling app the automation algorithm is being used with.

Labeling App of Automation Algorithm	`checkSignalType` Implementation
Image Labeler Video Labeler	You do not need to implement this method. By default, this method validates that the signal being automated is of type `Image`, which is the only signal type that these apps support.
Ground Truth Labeler	Update this method to validate whether the automation algorithm supports `Image` signals, `PointCloud` signals, or both types of signals.
Lidar Labeler	You do not need to implement this method. If you do implement this method, update it to validate that the signal is of type `PointCloud`, which is the only signal type that this app supports.

`isValid = checkSignalType(signalType)` returns logical `1` (true) when the specified signal type is valid. In the Ground Truth Labeling app, if you select an automation algorithm, select signals that are of an invalid type, and then click **Automate**, the app displays an error.

Examples

Restrict Automation to Image Signals

Implement the `checkSignalType` method to designate `Image` signals as valid and all other signals as invalid.

```
function isValid = checkSignalType(signalType)
    isValid = (signalType == vision.labeler.loading.SignalType.Image);
end
```

Restrict Automation to Point Cloud Signals

Implement the `checkSignalType` method to designate `PointCloud` signals as valid and all other signals as invalid.

```
function isValid = checkSignalType(signalType)
    isValid = (signalType == vision.labeler.loading.SignalType.PointCloud);
end
```

Enable Automation for Image and Point Cloud Signals

Implement the `checkSignalType` method to designate `Image` and `PointCloud` signals as valid.

```
function isValid = checkSignalType(signalType)
    isValid = any(signalType == vision.labeler.loading.SignalType.Image) && ...
    any(signalType == vision.labeler.loading.SignalType.PointCloud);
end
```

Input Arguments

`signalType` — Signal type

`vision.labeler.loading.SignalType` enumeration

Signal type, specified as a `vision.labeler.loading.SignalType` enumeration.

Example: `vision.labeler.loading.SignalType.Image`

Example: `vision.labeler.loading.SignalType.PointCloud`

Output Arguments

`isValid` — Result of signal type validity check

`1 | 0`

Result of the signal type validity check, returned as logical `1` (true) or logical `0` (false).

Attributes

`Static`	`true`

To learn about attributes of methods, see Method Attributes.

initialize

Class: `vision.labeler.AutomationAlgorithm`
Namespace: `vision.labeler`

Initialize state for algorithm execution (optional)

Syntax

```
initialize(algObj,frame)
initialize(algObj,frame,labelsToAutomate)
```

Description

The `initialize` method initializes the state of the automation algorithm before the automation algorithm runs.

Clients of `AutomationAlgorithm` can optionally implement this method.

`initialize(algObj,frame)` initializes the state of the `algObj` automation algorithm using the first frame in the time range of the data being labeled.

Clients of `AutomationAlgorithm` must implement this user-defined method.

`initialize(algObj,frame,labelsToAutomate)` additionally provides a table, `labelsToAutomate`, that contains labels selected for the automation algorithm to use for labeling. This syntax does not support pixel label automation. In addition, this syntax is available only for time-dependent (temporal) automation algorithms. The Ground Truth Labeler (requires Automated Driving Toolbox™) and Video Labeler apps support temporal algorithms but the Image Labeler does not. For more information on these types of algorithms, see “Temporal Automation Algorithms”.

Input Arguments

`algObj` — Automation algorithm

`vision.labeler.AutomationAlgorithm` object

Automation algorithm, specified as a `vision.labeler.AutomationAlgorithm` object.

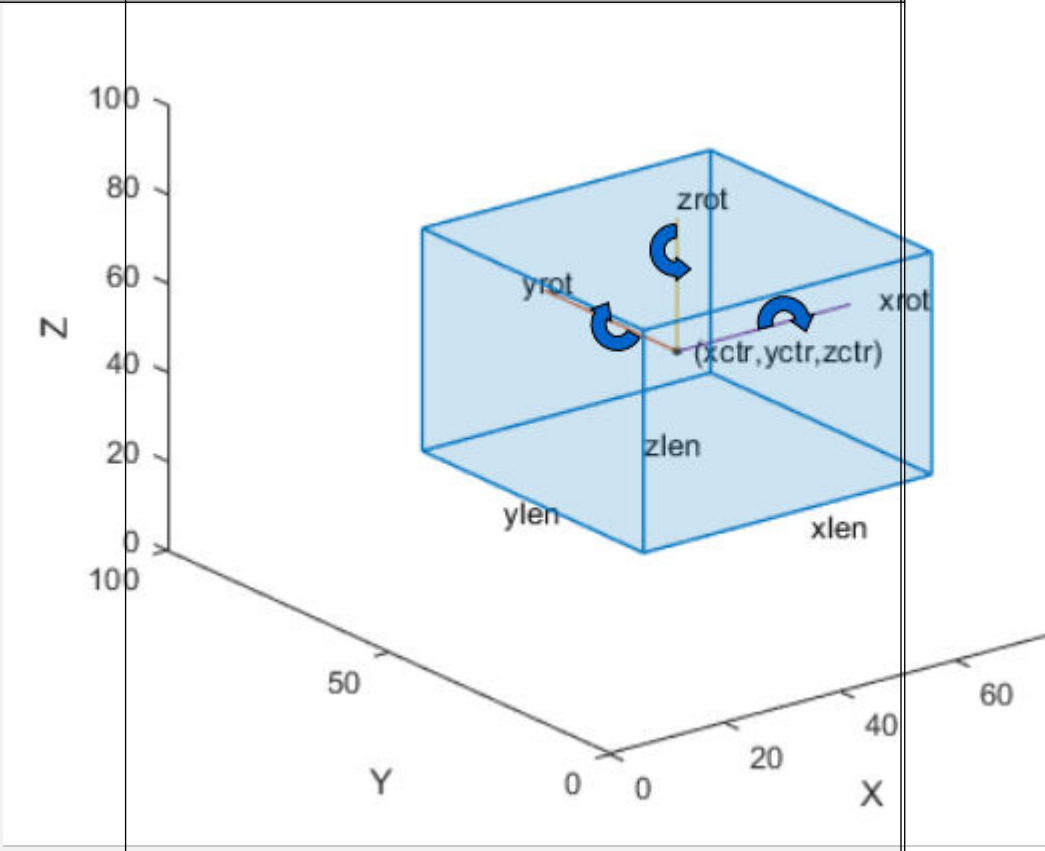
`frame` — Frame corresponding to start of time range

numeric matrix | `pointCloud` object

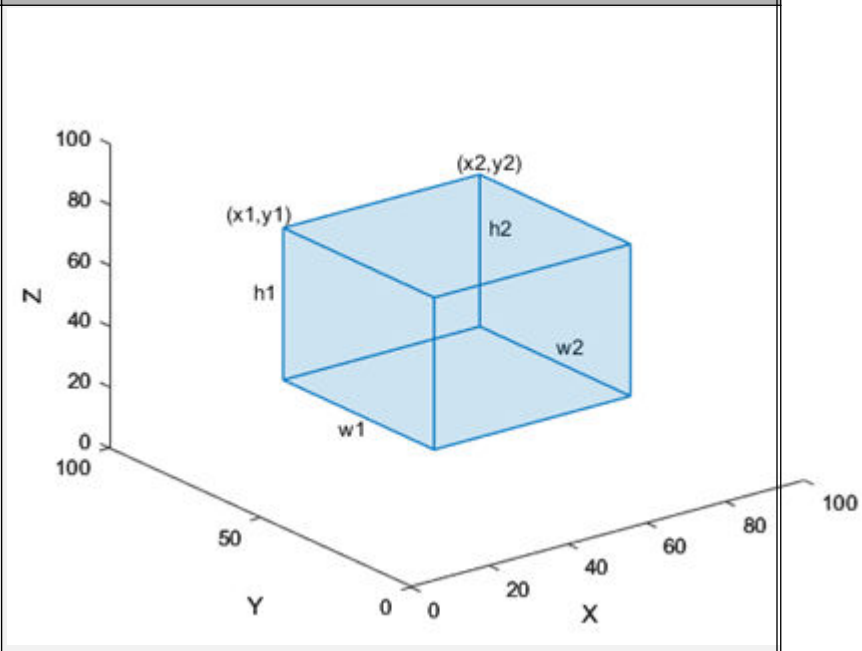
Frame corresponding to the start of time range, specified as a numeric matrix for `Image` signals or a `pointCloud` object for `PointCloud` signals.

`labelsToAutomate` — Labels selected for automation

table



Labels selected for automation, specified as a table with these columns.



Column Name	Description
`Type`	`labelType` enumeration that contains the type of the label. Valid label types are: • `labelType.Rectangle` • `labelType.Cuboid` (Ground Truth Labeler app only) • `labelType.ProjectedCuboid` • `labelType.Line` • `labelType.Scene` `labelType.PixelLabel` and `labelType.Custom` are not supported.
`Name`	Character vector that contains the name of the label.
`Time`	Scalar of type `double` that specifies the time, in seconds, when the label was marked.

`checkSetup` | `run` | `terminate` | `labelType` | `vision.labeler.AutomationAlgorithm`

run

Class: `vision.labeler.AutomationAlgorithm`
Namespace: `vision.labeler`

Run label automation on every frame in interval

Syntax

```
autoLabels = run(algObj,frame)
```

Description

The `run` method computes the automated labels for a single frame by executing the automation algorithm. During automation, the labeling apps run this method in a loop to compute the automated labels for each frame in the selection being automated. A single frame can contain multiple signals such as images and point clouds.

Clients of `AutomationAlgorithm` must implement this method.

`autoLabels = run(algObj,frame)` processes a single frame, `frame`, using the `algObj` automation algorithm, and returns the automated labels, `autoLabels`.

Input Arguments

`algObj` — Automation algorithm

`vision.labeler.AutomationAlgorithm` object

Automation algorithm, specified as a `vision.labeler.AutomationAlgorithm` object.

`frame` — Frame

numeric matrix | `pointCloud` object | *M* X *1* cell array

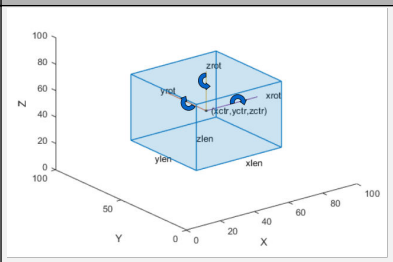
Frame whose labels are being computed, specified as a numeric image matrix, a `pointCloud` object or an *M* X *1* cell array of multiple image matrices and `pointCloud` objects. To specify a cell array of multiple signals, `algObj` must support multisignal automation.

Output Arguments

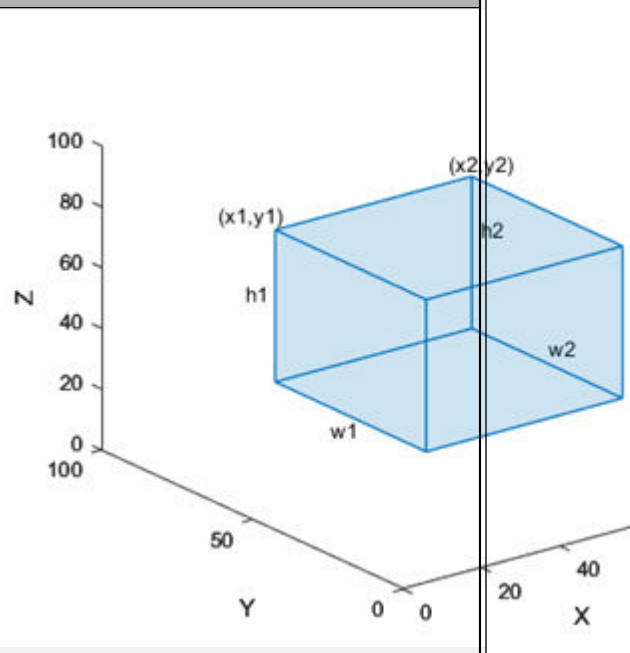
`autoLabels` — Labels produced by automation

categorical matrix | structure array | table

Labels produced by the automation algorithm, returned as a categorical matrix, structure array, or table.



For algorithms that automate pixel labeling, implement the `run` method to return `autoLabels` as a `categorical` label matrix, where each category represents a pixel label. For more information, see “How Labeler Apps Store Exported Pixel Labels”.



For algorithms that automate nonpixel labels, implement the `run` method to return a structure array. Each structure in the array contains the labels of a specific name and type. The method combines labels of the same name and type into a single structure in the array.

This table describes the columns of the `autoLabels` table or fields of each `autoLabels` structure.

Field Name	Description
`Type`	`labelType` enumeration that contains the type of the label. Valid label types are: • `labelType.Rectangle` • `labelType.Cuboid` (Ground Truth Labeler app only) • `labelType.ProjectedCuboid` • `labelType.Polygon` • `labelType.Line` • `labelType.Scene`
`Name`	Character vector, string scalar, or categorical scalar containing the name of the label.

<table>
<tr><th>Field Name</th><th>Description</th></tr>
<tr><td><code>Position</code></td><td>Position of labels of the specified <code>Name</code> and <code>Type</code>. The format of <code>Position</code> depends on the label type.
<table>
<tr><th>Label Type</th><th>Position Format</th></tr>
<tr><td><code>Rectangle</code> — Rectangular region of interest (ROI) labels</td><td><code>M</code>-by-4 numeric matrix of the form <code>[x, y, w, h]</code>, where:
<code>M</code> is the number of labels in the frame.
<code>x</code> and <code>y</code> specify the upper-left corner of the rectangle.
<code>w</code> specifies the width of the rectangle, which is its length along the x-axis.
<code>h</code> specifies the height of the rectangle, which is its length along the y-axis.</td></tr>
<tr><td><code>Cuboid</code> — Cuboid ROI labels</td><td><code>M</code>-by-9 numeric matrix with rows of the form <code>[xctr, yctr, zctr, xlen, ylen, zlen, xrot, yrot, zrot]</code>, where:
<code>M</code> is the number of labels in the frame.
<code>xctr</code>, <code>yctr</code>, and <code>zctr</code> specify the center of the cuboid.
<code>xlen</code>, <code>ylen</code>, and <code>zlen</code> specify the length of the cuboid along the x-axis, y-axis, and z-axis, respectively, before rotation has been applied.
<code>xrot</code>, <code>yrot</code>, and <code>zrot</code> specify the rotation angles for the cuboid along the x-axis, y-axis, and z-axis, respectively. These angles are clockwise-positive when looking in the forward direction of their corresponding axes.
The figure shows how these values determine the position of a cuboid.</td></tr>
</table>
</td></tr>
</table>

Field Name	Description	
	Label Type	**Position Format**
		
	`ProjectedCuboid` — Cuboid ROI labels	`M`-by-8 vector of the form `[x1, y1, w1, h1, x2, y2, w2, h2]`, where: • `M` is the number of labels in the frame. • `x1, y1` specifies the *x*,*y* coordinates for the upper-left location of the front-face of the projected cuboid • `w1` specifies the width for the front-face of the projected cuboid. • `h1` specifies the height for the front-face of the projected cuboid. • `x2, y2` specifies the *x*,*y* coordinates for the upper-left location of the back-face of the projected cuboid. • `w2` specifies the width for the back-face of the projected cuboid. • `h2` specifies the height for the back-face of the projected cuboid. The figure shows how these values determine the position of a cuboid.

<table>
<tr><th>Field Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Label Type</th><th>Position Format</th></tr>
<tr><td></td><td>
</td></tr>
<tr><td><code>Line</code> — Polyline ROI labels</td><td><code>M</code>-by-1 vector of cell arrays, where <code>M</code> is the number of labels in the frame. Each cell array contains an <code>N</code>-by-2 numeric matrix of the form <code>[x1 y1; x2 y2; ... ; xN yN]</code> for <code>N</code> points in the polyline.</td></tr>
<tr><td><code>Polygon</code></td><td><code>M</code>-by-1 vector of cell arrays, where <code>M</code> is the number of labels. Each cell array contains an <code>N</code>-by-2 numeric matrix of the form <code>[x1 y1; x2 y2; ... ; xN yN]</code> for <code>N</code> points in the polygon.</td></tr>
<tr><td><code>Scene</code> — Scene labels</td><td>Logical value of <code>1</code> if the algorithm determines that the label is present in the frame and <code>0</code> otherwise.</td></tr>
</table>
</td></tr>
<tr><td><code>Attributes</code> (optional)</td><td>Structure array that contains one structure for each attribute in the label. If the label definition does not contain attributes, then the <code>autoLabels</code> output does not include this field.

For each structure in the <code>Attributes</code> structure array, the name of that structure is the name of the corresponding attribute. The value of the structure is the value of the corresponding attribute.</td></tr>
</table>

To view a sample `autoLabels` structure array, enter this code at the MATLAB command prompt.

```
autoLabels(1).Name      = "Car";
autoLabels(1).Type      = labelType.Rectangle;
autoLabels(1).Position  = [20 20 50 50];
```

```
autoLabels(2).Name      = "Truck";
autoLabels(2).Type      = labelType.Rectangle;
autoLabels(2).Position  = [70 70 50 50; 100 100 25 25];
```

Alternatively, for nonpixel labels, you can use the `run` method to return `autoLabels` as a table. The table rows are equivalent to the structures in a structure array. The table columns are equivalent to the structure fields. This table is equivalent to the sample `autoLabels` structure array previously specified.

```
      Name          Type         Position
    ____________    _________    ____________

    "Car"           Rectangle    [1x4 double]
    "Truck"         Rectangle    [2x4 double]
```

If you want to return no labels for all label definitions, specify an empty `autoLabels` structure. If you do not want to return any labels for a specific label definition, specify an empty `Position` field for the corresponding label definition in the `autoLabels` structure.

Objects

`labelType` | `vision.labeler.AutomationAlgorithm`

Functions

`checkSetup` | `initialize` | `terminate`

settingsDialog

Class: `vision.labeler.AutomationAlgorithm`
Namespace: `vision.labeler`

Display algorithm settings (optional)

Syntax

```
settingsDialog(algObj)
```

Description

The `settingsDialog` method runs when the user clicks Settings in the labeling app. Use this method to provide a dialog figure with controls for user settings required for the algorithm. Use a modal dialog, created using functions like `dialog`, `inputdlg` or `listdlg`.

Clients of `AutomationAlgorithm` can optionally implement this method.

`settingsDialog(algObj)` displays automated algorithm settings in a dialog.

Input Arguments

`algObj` — Automation algorithm
`vision.labeler.AutomationAlgorithm` object

Automation algorithm, specified as a `vision.labeler.AutomationAlgorithm` object.

Version History

Introduced in R2017a

supportsMultisignalAutomation

Namespace: `vision.labeler`

Set multisignal algorithm automation flag

Syntax

```
success = supportsMultisignalAutomation(algObj)
```

Description

`success = supportsMultisignalAutomation(algObj)` indicates whether the automation algorithm `algObj` supports the automation of multiple signals in a single automation session. Implement this method in automation algorithms developed for the Ground Truth Labeler app, which supports the labeling and automation of multiple signals. If the algorithm supports multisignal automation, then this method returns `success` as `true`.

In automation algorithms developed for the Image Labeler, Video Labeler, and Lidar Labeler apps, which support the labeling and automation of only one signal at a time, you can either delete this method or leave it unchanged. The default implementation of this method indicates that the automation algorithm does not support multisignal automation (`success = false`).

Examples

Indicate Algorithm Supports Multisignal Automation

Implement the `supportsMultisignalAutomation` method to indicate that the automation algorithm supports multisignal automation. This method is static and does not use the input automation algorithm, `algObj`. Therefore, you can specify the input argument as unused by using the tilde (~) operator.

```
function success = supportsMultisignalAutomation(~)
      success = true;
end
```

Input Arguments

`algObj` — Automation algorithm

`vision.labeler.AutomationAlgorithm` object

Automation algorithm, specified as a `vision.labeler.AutomationAlgorithm` object.

Version History

Introduced in R2021a

terminate

Class: `vision.labeler.AutomationAlgorithm`
Namespace: `vision.labeler`

Terminate automated algorithm (optional)

Syntax

```
terminate(algObj)
```

Description

The `terminate` method cleans up the state of the automation algorithm after `run` processes the last frame in the specified interval or when you stop the automation algorithm.

Clients of `AutomationAlgorithm` can optionally implement this method.

`terminate(algObj)` cleans up the state of the automation algorithm.

Input Arguments

`algObj` — Automation algorithm
`vision.labeler.AutomationAlgorithm` object

Automation algorithm, specified as a `vision.labeler.AutomationAlgorithm` object.

`checkSetup` | `initialize` | `run` | `vision.labeler.AutomationAlgorithm`

vision.labeler.mixin.Temporal Class

Namespace: `vision.labeler.mixin`

Mixin interface for adding temporal context to automation algorithms

Description

The `vision.labeler.mixin.Temporal` class provides an interface for attaching temporal properties to an automation algorithm. You can add this class only to automation algorithms used by the Ground Truth Labeler or Video Labeler app.

The `vision.labeler.mixin.Temporal` class is a `handle` class.

Class Attributes

`Abstract`	`true`

For information on class attributes, see “Class Attributes”.

Properties

`StartTime` — Timestamp of first frame

scalar

Timestamp of the first frame of the algorithm interval, specified as a scalar.

Attributes:

`GetAccess`	`public`
`SetAccess`	`private`
`Dependent`	`true`
`NonCopyable`	`true`

`CurrentTime` — Timestamp of current executing frame

scalar

Timestamp of the current executing frame, specified as a scalar. This value updates during the execution of the algorithm.

Attributes:

`GetAccess`	`public`
`SetAccess`	`private`

`EndTime` — Timestamp of last frame

scalar

Timestamp of the last frame of the algorithm interval, specified as a scalar.

Attributes:

GetAccess	public
SetAccess	private
Dependent	true
NonCopyable	true

`StartFrameIndex` — Index of first frame

integer

Index of the first frame of the algorithm interval, specified as an integer.

Attributes:

GetAccess	public
SetAccess	private
Dependent	true
NonCopyable	true

`EndFrameIndex` — Index of last frame

integer

Index of the last frame of the algorithm interval, specified as an integer.

Attributes:

GetAccess	public
SetAccess	private
Dependent	true
NonCopyable	true

`AutomationDirection` — Direction in which to run automated algorithm

`'Forward'` | `'Reverse'`

Direction in which to run the automated algorithm, specified as `'Forward'` or `'Reverse'`.

Attributes:

GetAccess	public
SetAccess	private

supportsReverseAutomation

Set reverse algorithm automation flag

Syntax

```
flag = supportsReverseAutomation(algObj)
```

Description

`flag = supportsReverseAutomation(algObj)` indicates whether the temporal automation algorithm, `algObj`, supports automation in the reverse direction. A `true` value enables the Ground Truth Labeler or Video Labeler to open the algorithm in reverse mode.

Examples

Set Algorithm Automation Direction Flag

```
function flag = supportsReverseAutomation(algObj)
      flag = true;
end
```

Input Arguments

`algObj` — Temporal automation algorithm

object

Temporal automation algorithm, specified as a `vision.labeler.mixin.Temporal` object.

Output Arguments

`flag` — Reverse automation indicator

`true` | `false`

Reverse automation indicator, returned as `true` or `false`.

vision.labeler.mixin.BlockedImageAutomation

Mixin interface for performing blocked image automation

Description

The `BlockedImageAutomation` mixin class provides an interface for attaching blocked image properties to an automation algorithm. You can add this class only to automation algorithms used by the Image Labeler app.

Creation

Description

To use the `vision.labeler.mixin.BlockedImageAutomation` object, open the Image Labeler app, load a blocked image, and create at least one label. Then, click **Select Algorithm** in the **Automate Labeling** section of the app toolstrip. Select **Add Blocked Image Algorithm** and then choose **Create New Blocked Image Algorithm**. A class template opens in the editor that inherits from both the `vision.labeler.AutomationAlgorithm` class and the `vision.labeler.mixin.BlockedImageAutomation` mixin class. Edit this template to create your blocked image automation algorithm.

Properties

The `BlockedImageAutomation` mixin class predefines this set of properties.

`BatchSize` — Number of blocks supplied to the `apply` function at a time
numeric scalar

Number of blocks supplied to the `apply` function at a time, specified as an integer valued vector of length equal to the `NumDimensions` property of the blocked image.

`BorderSize` — Size of additional border elements
1-by-*D* numeric vector

Size of additional border elements to add around a block in each dimension, specified as a 1-by-*D* numeric vector, where *D* is equal to the `NumDimensions` property of the first `blockedImage` object.

`InclusionThreshold` — Ratio that determines whether a block should be considered for processing
double

Ratio that determines whether a block should be considered for processing, specified as a value in the range [0 1]. The value specifies the minimum percentage of nonzero pixels in the block. A value of 0 means that only one pixel in the block must be true/nonzero for it to be included in processing. A value of 1 requires that all pixels in the block be true/nonzero for it to be included in processing.

`PadMethod` — Method used to obtain padding pixels
scalar `string` | `char` vector

Method used to obtain padding pixels to honor the `BorderSize` or the `PadPartialBlocks` parameters, specified as scalar `string` or `char` vector

`PadPartialBlocks` — Pad partial blocks that might exist on the edges
`true` | `false`

Pad partial blocks that might exist on the edges, specified as a logical scalar, `true` or `false`.

`Resume` — Continue processing from where a previous run stopped
`true` | `false`

Continue processing from where a previous run stopped, specified as a logical scalar, `true` or `false`.

blockedImageAutomationAlgorithm

Implements the blocked image automation algorithm

Syntax

```
res = blockedImageAutomationAlgorithm(algObj,bstruct)
```

Description

`res = blockedImageAutomationAlgorithm(algObj,bstruct)` computes labels based on the algorithm you specify in this method. The Image Labeler app invokes this method on each image you choose for blocked image automation in the app. `algObj` is a `vision.labeler.AutomationAlgorithm` object. `bstruct` is a structure. The format of the output, `res`, depends on the type of automation algorithm specified.

Examples

Sample Blocked Image Algorithm Automation Function

- Here is an example of a blocked image algorithm automation function.

```
function res = blockedImageAutomationAlgorithm(algObj,bstruct)
   % Detect people using aggregate channel features
   detector = peopleDetectorACF('inria-100x41');
   [bboxes, scores] = detect(detector, bstruct.Data,...
            'SelectStrongest', false);

   % Apply non-maximum suppression to select the strongest bounding boxes.
   [selectedBboxes, selectedScores] = selectStrongestBbox(bboxes, scores,...
            'RatioType', 'Min',...
            'OverlapThreshold', 0.65);

   % Consider only detections that meet specified score threshold
   selectedBboxes = selectedBboxes(selectedScores > 0, :);
   selectedBboxes(:,1) = selectedBboxes(:,1)+bstruct.Start(2);
   selectedBboxes(:,2) = selectedBboxes(:,2)+bstruct.Start(1);

   if algObj.SelectedLabelDefinitions.Type == "Rectangle"
      % Add the selected label at the bounding box position(s)
      res = struct(...
          'Type', labelType.Rectangle,...
          'Name', algObj.SelectedLabelDefinitions.Name,...
          'Position', selectedBboxes);
   end
end
```

Input Arguments

`algObj` — Automation algorithm

`vision.labeler.AutomationAlgorithm` object

Automation algorithm, specified as a `vision.labeler.AutomationAlgorithm` object.

`bstruct` — Structure of data passed to function
scalar `struct`

Structure of data passed to the blocked image `apply` object function, specified as a scalar `struct` with these fields.

Field	Description
`Data`	A block of array data from the blocked image.
`Start`	Array subscripts of the first element in the block. If `BorderSize` is specified, this subscript can be out-of-bounds for edge blocks.
`End`	Array subscripts of the last element in the block. If `BorderSize` is specified, this subscript can be out-of-bounds for edge blocks.
`Blocksub`	The block subscripts of the current block
`BorderSize`	The value of the `BorderSize` parameter
`BlockSize`	The value of the `BlockSize` parameter. Note: size(data) can be less than this value for border blocks `PadPartialValue` is false.
`BatchSize`	The value of the `BatchSize` parameter

Output Arguments

`res` — Result of processing
scalar `struct`

Result of processing, returned as a scalar `struct`. The format of the structure depends on the type of automation algorithm.

For automation algorithms without pixel labels, the `struct` has fields described in this table.

Field	Description
`Type`	A `labelType` enumeration that defines the type of label. Type can have values: `Rectangle`, `Line`, `Projected cuboid`, `Cuboid`, or `Scene`.
`Name`	A character vector specifying a label name that returns `true` for `checkLabelDefinition`. Only existing label names previously defined in the Image Labeler app can be used.

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td><code>Position</code></td><td>Positions of the labels. The type of label determines the format of the position data.

<table><tr><th>Label Type</th><th>Description</th></tr><tr><td>Rectangle</td><td>P-by-1 cell array specifying P Rectangles, each containing a 1-by-4 vector specifying position of the bounding box locations as <code>[x y w h]</code> or multiple Rectangle ROIs specified as an M-by-4 matrix.</td></tr><tr><td>Line</td><td>P-by-1 cell array specifying P polylines each containing N-by-2 vector specifying N points along each polyline as: <code>[x1,y1; x2,y2;...xN,yN]</code></td></tr><tr><td>Polygons</td><td>P-by-1 cell array specifying P polygons each containing N-by-2 vector specifying N points along each polygon as: <code>[x1,y1; x2,y2;...xN,yN]</code></td></tr><tr><td>Projected Cuboid</td><td>P-by-1 cell array specifying P projected cuboids each containing 1-by-8 vector specifying position of primary and secondary faces as: <code>[x1 y1 w1 h1 x2 y2 w2 h2]</code> or multiple projected cuboid ROIs can be specified as an M-by-8 matrix.</td></tr></table></td></tr>
<tr><td><code>Attributes</code></td><td>An array of <code>structs</code> representing the attributes contained by the automated labels. Each attribute is specified as a field of the <code>struct</code> with the name of the field representing the name of the attribute and the value of the field representing the value of the attribute. This is an optional field, only present if the labels defined have attributes.</td></tr>
</table>

For automation algorithms with pixel labels, `res` is a `categorical` label matrix, where each category represents a pixel label.

Tips

- For automation algorithms without pixel labels, the `Position` field in `res` must be in a world coordinate system. This can be achieved by adding the *X* and *Y* indices in the `bstruct.Start` field to the output of the automation algorithm. To get the correct *X* coordinate, add `bstruct.Start(2)` to get the position of the automation output in world coordinates. To get the correct *Y* coordinate, add `bstruct.Start(1)` to get the position of the automation output in world coordinates.

labelType

Label type enumerations for labeling

Description

The `labelType` enumerations enable you to specify the types of labels used in these labeling apps: Image Labeler, Video Labeler, Lidar Labeler, and Ground Truth Labeler. When creating label definitions by using a `labelDefinitionCreator` or `labelDefinitionCreatorMultisignal` object, use these enumerations to create label definitions of specific types. When selecting labels from a `groundTruth` or `groundTruthMultisignal` or `groundTruthLidar` (Lidar Toolbox) object, use these enumerations to select labels of a specific type.

Creation

Syntax

```
labelType("Rectangle")
labelType("RotatedRectangle")
labelType("Line")
labelType("PixelLabel")
labelType("Polygon")
labelType("Cuboid")
labelType("ProjectedCuboid")
labelType("Scene")
labelType('Custom')
```

Description

`labelType("Rectangle")` creates an axis-aligned rectangular region of interest (ROI) label type for labeling image and video data. You can also use the programmatic format, `labelType.Rectangle`.

`labelType("RotatedRectangle")` creates a rotated rectangular region of interest (ROI) label type for labeling image and video data. You can also use the programmatic format, `labelType.RotatedRectangle`.

`labelType("Line")` creates a polyline ROI label type for labeling image and video data. You can also use the programmatic format, `labelType.Line`.

`labelType("PixelLabel")` creates a pixel ROI label type for labeling image and video data. You can also use the programmatic format, `labelType.PixelLabel`.

`labelType("Polygon")` creates a polygon ROI label type for labeling image and video data. You can also use the programmatic format, `labelType.Polygon`.

`labelType("Cuboid")` creates a cuboid ROI label type for labeling lidar point cloud data. You can also use the programmatic format, `labelType.Cuboid`.

`labelType("ProjectedCuboid")` creates a projected cuboid ROI label type for labeling image and video data. You can also use the programmatic format, `labelType.ProjectedCuboid`.

`labelType("Scene")` creates a scene label type for labeling data across a specified time range. You can also use the programmatic format, `labelType.Scene`.

`labelType('Custom')` creates a custom label type. Labeler apps do not display labels of type `Custom`. You can also use the programmatic format, `labelType.Custom`.

Object Functions

isCustom	Determine if label types are Custom labels
isROI	Determine if label types are ROI labels
isScene	Determine if label types are Scene labels

Examples

Specify Label Type in Label Definition Creator Object

Create a label definition creator object. Add a label named "Road" with the label type specified as a rectangle.

```
ldc = labelDefinitionCreator();
addLabel(ldc,'Road',labelType.Rectangle);
```

Add a label named "Sky" with the label type specified as a scene.

```
addLabel(ldc,'Sky',labelType.Scene);
```

Add a sublabel named "Lanes" to the label "Road". Specify the label type for the sublabel as a line.

```
addSublabel(ldc,'Road','Lanes',labelType.Line);
```

Display the details of the definitions stored in the label definition creator object.

```
ldc
```

```
ldc =
labelDefinitionCreator contains the following labels:

    Road with 1 sublabels and 0 attributes and belongs to None group.    (info)
    Sky with 0 sublabels and 0 attributes and belongs to None group.    (info)

For more details about attributes and sublabels, use the info method.
```

Display information about the label "Road" as a structure by using the `info` function. The `Type` field in the structure `labelStruct` indicates the type of label.

```
labelStruct = info(ldc,'Road')
```

```
labelStruct = struct with fields:
           Name: "Road"
           Type: Rectangle
     LabelColor: {''}
          Group: "None"
     Attributes: []
```

```
    Sublabels: "Lanes"
  Description: ' '
```

isCustom

Determine if label types are `Custom` labels

Syntax

```
tf = isCustom(labelTypes)
```

Description

`tf = isCustom(labelTypes)` returns a logical array that indicates which elements in `labelTypes` are `Custom` label types. `isCustom` returns logical `1` (true) for `Custom` labels and otherwise returns logical `0` (false).

Input Arguments

`labelTypes` — Type of labels

enumeration

Types of labels, specified as a `labelType` or `lidarLabelType` enumeration.

Version History

Introduced in R2017a

See Also

`isROI` | `isScene`

isROI

Determine if label types are ROI labels

Syntax

```
tf = isROI(labelTypes)
```

Description

`tf = isROI(labelTypes)` returns a logical array that indicates which elements in `labelTypes` are `ROI` label types. `isROI` returns logical `1` (true) for `ROI` labels and otherwise returns logical `0` (false). Valid `ROI` label types are `Rectangle`, `Cuboid`,`ProjectedCuboid`, `Line`, `Voxel` and `PixelLabel`.

Input Arguments

`labelTypes` — Type of labels

enumeration

Types of labels, specified as a `labelType` or `lidarLabelType` enumeration.

Version History

Introduced in R2017a

See Also

`isCustom` | `isScene`

isScene

Determine if label types are `Scene` labels

Syntax

```
tf = isScene(labelTypes)
```

Description

`tf = isScene(labelTypes)` returns a logical array that indicates which elements in `labelTypes` are `Scene` label types. `isScene` returns logical `1` (true) for `Scene` labels and otherwise returns logical `0` (false).

Input Arguments

`labelTypes` — Type of labels

enumeration

Types of labels, specified as a `labelType` or `lidarLabelType` enumeration.

Version History

Introduced in R2017a

`isCustom` | `isROI`

attributeType

Attribute type enumerations for labeling

Description

The `attributeType` enumerations enable you to specify the types of attributes used in these labeling apps: Image Labeler, Video Labeler, Lidar Labeler, and Ground Truth Labeler (requires Automated Driving Toolbox). When creating label definitions by using a `labelDefinitionCreator` or `labelDefinitionCreatorMultisignal` object, use these enumerations to create attributes of specific types.

Creation

Syntax

```
attributeType('Numeric')
attributeType('String')
attributeType('Logical')
attributeType('List')
attributeType('None')
```

Description

`attributeType('Numeric')` creates a numeric attribute type enumeration. Attributes of this type are numeric scalar values. You can also use the programmatic format, `attributeType.Numeric`.

`attributeType('String')` creates a string attribute type enumeration. Attributes of this type are string scalars. You can also use the programmatic format, `attributeType.String`.

`attributeType('Logical')` creates a logical attribute type enumeration. Attributes of this type are `true` (logical `1`), `false` (logical `0`), or an empty logical value. You can also use the programmatic format, `attributeType.Logical`.

`attributeType('List')` creates a list attribute type enumeration. Attributes of this type are lists of predefined strings. You can also use the programmatic format, `attributeType.List`.

`attributeType('None')` creates an enumeration whose type is not defined. You can also use the programmatic format, `attributeType.None`.

Object Functions

hasValue Determine if the attribute type is numeric or logical

Examples

Specify Attribute Type in Label Definition Creator Object

Create a label definition creator object and add a label named "Vehicle". Specify the type of label as a rectangle.

```
ldc = labelDefinitionCreator;
addLabel(ldc,'Vehicle',labelType.Rectangle);
```

Add an attribute named "Color" to the label "Vehicle". Specify the attribute type as a list.

```
addAttribute(ldc,'Vehicle','Color',attributeType.List,{'White','Green','Blue'})
```

Display information about the attribute "Color" as a structure by using the `info` function. The `Type` field in the output structure `colorStruct` indicates the type of attribute.

```
colorStruct = info(ldc,'Vehicle/Color')
```

```
colorStruct = struct with fields:
           Name: "Color"
           Type: List
      ListItems: {'White'  'Green'  'Blue'}
    Description: ' '
```

Version History

Introduced in R2018b

See Also

Apps

Image Labeler | Ground Truth Labeler | Video Labeler

Objects

`labelType` | `labelDefinitionCreator` | `labelDefinitionCreatorMultisignal`

hasValue

Determine if the attribute type is numeric or logical

Syntax

```
tf = hasValue(typeOfAttribute)
```

Description

`tf = hasValue(typeOfAttribute)` returns a logical value that indicates if the enumerator in `typeOfAttribute` is either `Numeric` or `Logical`. `hasValue` returns logical `1 (true)` for `Numeric` and `Logical` attributes. Otherwise returns logical `0 (false)`.

Examples

Determine the Type of Attribute

Create an `attributeType` enumeration array.

```
Type = attributeType({'Numeric'; 'String'; 'Logical'; 'List'});
```

Check if any of the enumerator defined in the `attributeType` enumeration array is Numeric or Logical.

```
tf = zeros(0,length(Type));
for i = 1:length(Type)
    tf(i) = hasValue(Type(i));
end
```

Display the output. The value 1 is returned when an enumerator in the `attributeType` enumeration array is either Numeric or Logical. Otherwise, the value 0 is returned.

```
tf
```

```
tf = 1×4

     1     0     1     0
```

Input Arguments

`typeOfAttribute` — Type of attribute

`attributeType` enumeration

Type of attribute, specified as an `attributeType` enumeration. The enumerator in the `attributeType` enumeration can be `Numeric`, `String`, `Logical`, `List`, or `None`.

Version History

Introduced in R2018b

cameraParameters

Object for storing camera parameters

Description

The `cameraParameters` object stores the intrinsic, extrinsic, and lens distortion parameters of a camera.

Creation

You can create a `cameraParameters` object using the `cameraParameters` function described here. You can also create a `cameraParameters` object by using the `estimateCameraParameters` with an *M*-by-2-by-*numImages* array of input image points. *M* is the number of keypoint coordinates in each pattern.

Syntax

```
cameraParams = cameraParameters
cameraParams = cameraParameters(Name=Value)
cameraParams = cameraParameters(paramStruct)
```

Description

`cameraParams = cameraParameters` creates a `cameraParameters` object that contains the intrinsic, extrinsic, and lens distortion parameters of a camera.

`cameraParams = cameraParameters(Name=Value)` sets properties on page 2-1411 of the `cameraParameters` object by using one or more name-value arguments. Unspecified properties use default values. For example, `WorldUnits='m'` sets the world units to `'m'`.

For example, `cameraParams = cameraParameters("RadialDistortion",[0 10])` sets the radial lens distortion property, `RadialDistortion`, as the vector `[0 10]`.

`cameraParams = cameraParameters(paramStruct)` creates an identical `cameraParameters` object from an existing `cameraParameters` object with parameters stored in `paramStruct`.

Input Arguments

`paramStruct` — Camera parameters
structure

Camera parameters, specified as a camera parameters structure. To get a `paramStruct` from an existing `cameraParameters` object, use the `toStruct` function.

Properties

Intrinsic Camera Parameters:

K — Camera intrinsic matrix

3-by-3 matrix

Camera intrinsic matrix, specified as a 3-by-3 matrix. The matrix has this format:

$$\begin{bmatrix} f_x & s & c_x \\ 0 & f_y & c_y \\ 0 & 0 & 1 \end{bmatrix}$$

The coordinates $[c_x\ c_y]$ represent the optical center (the principal point), in pixels. When the x- and y-axes are exactly perpendicular, the skew parameter s equals `0`.

$f_x = F*s_x$
$f_y = F*s_y$

- F is the focal length in world units, typically expressed in millimeters.
- s_x and s_y are the number of pixels per world unit in the x- and y-direction respectively.
- f_x and f_y are expressed in pixels.

`Intrinsics` — Camera intrinsics object

`cameraIntrinsics` object

This property is read-only.

Camera intrinsics object, stated as a `cameraIntrinsics` object. The object contains information about camera intrinsic calibration parameters, including lens distortion.

Dependency

You must provide an image size (using the `ImageSize` property) for the `Intrinsics` property to be non-empty. The intrinsics for the camera parameters depends on the image size.

`ImageSize` — Image size

two-element vector

Image size, specified as a two-element vector [*mrows ncols*].

Camera Lens Distortion:

`RadialDistortion` — Radial distortion coefficients

`[0 0]` (default) | 2-element vector | 3-element vector | 6-element vector

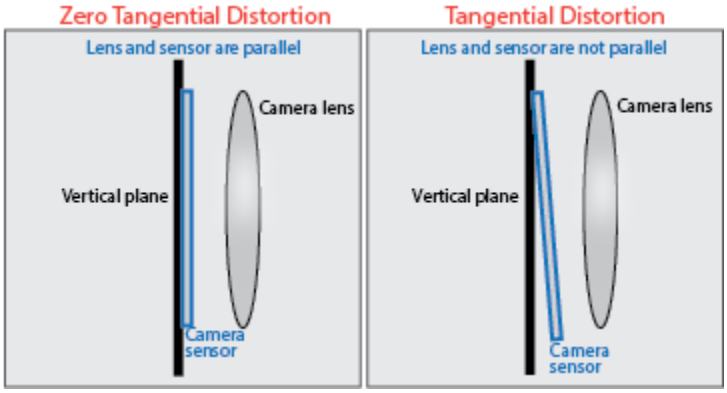
Radial lens distortion coefficients, specified as a 2-, 3-, or 6-element vector.

- 2-element vector — [*k1 k2*].
- 3-element vector — [*k1 k2 k3*].
- 6-element vector — [*k1 k2 k3 k4 k5 k6*].

The camera parameters object calculates the radial-distorted location of a point, denoted as ($x_{distorted}$, $y_{distorted}$):

$$x_{distorted} = x\left(\frac{1 + k_1 * r^2 + k_2 * r^4 + k_3 * r^6}{1 + k_4 * r^2 + k_5 * r^4 + k_6 * r^6}\right)$$

$$y_{distorted} = y\left(\frac{1 + k_1 * r^2 + k_2 * r^4 + k_3 * r^6}{1 + k_4 * r^2 + k_5 * r^4 + k_6 * r^6}\right)$$



x, y is a undistorted image point in normalized image coordinates in world units, with the origin at the optical center.
$r^2 = x^2 + y^2$
k_1, k_2, ..., k_6 are radial distortion coefficients of the lens. Typically, two coefficients are sufficient and k_3, ..., k_6 are only needed for wide-angle lenses.

`TangentialDistortion` — Tangential distortion coefficients

`[0 0]'` (default) | 2-element vector

Tangential distortion coefficients, specified as a two-element vector. Tangential distortion occurs when the lens and the image plane are not parallel. The camera parameters object calculates the tangential distorted location of a point. You can denote the distorted points as ($x_{distorted}$, $y_{distorted}$). The undistorted pixel locations appear in normalized image coordinates, with the origin at the optical center. The coordinates are expressed in world units.

Tangential distortion occurs when the lens and the image plane are not parallel. The tangential distortion coefficients model this type of distortion.

The distorted points are denoted as ($x_{distorted}$, $y_{distorted}$):

$x_{distorted} = x + [2 * p_1 * x * y + p_2 * (r^2 + 2 * x^2)]$

$y_{distorted} = y + [p_1 * (r^2 + 2 * y^2) + 2 * p_2 * x * y]$

- x, y — Undistorted pixel locations. x and y are in normalized image coordinates. Normalized image coordinates are calculated from pixel coordinates by translating to the optical center and dividing by the focal length in pixels. Thus, x and y are dimensionless.
- p_1 and p_2 — Tangential distortion coefficients of the lens.
- $r^2 = x^2 + y^2$

Extrinsic Camera Parameters:

`PatternExtrinsics` — Calibration pattern extrinsics

`[]` (default) | *N*-element vector of `rigidtform3d` objects | *N*-by-*P* matrix of `rigidtform3d` objects

This property is read-only.

Calibration pattern extrinsics, specified as an *N*-element vector or an *N*-by-*P* array of *N* number of `rigidtform3d` objects. Each `rigidtform3d` object represents the pose of the camera's image plane relative to the corresponding calibration pattern.

- The `R` property of each `rigidtform3d` object describes the 3-D rotation of the camera image plane relative to the corresponding calibration pattern.
- The `Translation` property of each `rigidtform3d` object describes the translation *t* of the camera relative to the corresponding calibration pattern, expressed in world units.

For single-pattern calibration, specify `PatternExtrinsics` as an *N*-element vector. For multiple patterns, use an *N*-by-*P* matrix.

This equation provides the transformation that relates a world coordinate in the checkerboard frame [*X Y Z*] and the corresponding image point [*x y*]:

$$w\begin{bmatrix} x \\ y \\ 1 \end{bmatrix} = K[R\ t]\begin{bmatrix} X \\ Y \\ Z \\ 1 \end{bmatrix}$$

- *w*: arbitrary scale factor
- *K*: camera intrinsic matrix
- *R*: matrix representing the 3-D rotation of the camera
- *t*: translation of the camera relative to the world coordinate system

The rigid geometric transformations do not take distortion into consideration. Use the `undistortImage` function to remove distortion.

`RotationVectors` — 3-D camera rotation vectors

`[ ]` (default) | *R*-by-3 matrix | *R*-by-3-by-*P* array

This property is read-only.

3-D camera rotation vectors, specified as an *R*-by-3 matrix or an *R*-by-3-by-*P* array, containing *R* rotation vectors, where *P* is the number of calibration patterns. Each vector describes the 3-D rotation of the camera's image plane relative to the corresponding calibration pattern.

Each vector specifies the axis of rotation in 3-D space, with its magnitude indicating the rotation angle in radians. The corresponding 3-D rotation matrices are specified by the `PatternExtrinsics` property, specifically in the form of `tform.R`, where `tform` is a `rigidtform3d` object. The `PatternExtrinsics` property specifies geometric transformation objects with the corresponding 3-D rotation matrices.

For single-pattern calibration, specify `RotationVectors` as an *R*-by-3 matrix. For multiple patterns, use an *R*-by-3-by-*P* array.

Estimated Camera Parameter Accuracy:

`MeanReprojectionError` — Average Euclidean distance

numeric value

This property is read-only.

Average Euclidean distance between reprojected and detected points, specified as a numeric value in pixels.

`ReprojectionErrors` — Estimated camera parameters accuracy

[ ] (default) | *K*-by-2-by-*V* array | *K*-by-2-by-*V*-by-*P* array

Estimated camera parameters accuracy, specified as a *K*-by-2-by-*V* or *K*-by-2-by-*V*-by-*P* array, of [*x y*] pairs. The pairs represent the translation in *x* and *y* between the reprojected pattern keypoints *K*, and the detected pattern keypoints. The values of this property represent the accuracy of the estimated camera parameters. *V* is the number of pattern views used to estimate camera parameters and *P* is the number of calibration patterns. *K* is the number of keypoints in each image.

For single-pattern calibration, specify `ReprojectionErrors` as an*K*-by-2-by-*V* array. For multiple patterns, use an*K*-by-2-by-*V*-by-*P* array.

`ReprojectedPoints` — World points reprojected onto calibration images

K-by-2-by-*V* array | *K*-by-2-by-*V*-by-*P* array

This property is read-only.

World points reprojected onto calibration images, specified as a *K*-by-2-by-*V* or *K*-by-2-by-*V*-by-*P* array of [*x y*] coordinates. The coordinates represent world points reprojected onto calibration images. The number of keypoints in each image is represented by *K*. The number of pattern views is denoted by *V*, and *P* represents the number of calibration patterns. Missing points in the detected keypoints of the pattern are denoted as `[NaN,NaN]`.

For single-pattern calibration, specify `ReprojectedPoints` as a *K*-by-2-by-*V* array. For multiple patterns, use an*K*-by-2-by-*V*-by-*P* array.

`DetectedKeypoints` — Detected keypoints in the calibration pattern

[ ] (default) | *K*-by-*V* array | *K*-by-*V*-by-*P* array

Detected keypoints in the calibration pattern, specified as a logical *K*-by-*V* or *K*-by-*V*-by-*P* array. The number of keypoints in each image is represented by *K*. The number of pattern views is denoted by *V*, and *P* represents the number of calibration patterns.

For single-pattern calibration, specify `DetectedKeypoints` as a *K*-by-*V* array. For multiple patterns, use an*K*-by-*V*-by-*P* array.

Settings for Camera Parameter Estimation:

`PatternCount` — Number of patterns to estimate camera extrinsics

scalar integer

This property is read-only.

Number of patterns to estimate camera extrinsics, specified as an scalar integer.

`NumViews` — Number of pattern views used to estimate camera extrinsics

scalar integer

This property is read-only.

Number of pattern views used to estimate camera extrinsics, specified as an scalar integer. A view is the perspective from which a camera captures a scene.

`WorldPoints` — World coordinates
M-by-2 array | `[]`

World coordinates of key points on calibration pattern, specified as an *M*-by-2 array. *M* represents the number of key points in the pattern.

`WorldUnits` — World points units
`"mm"` (default) | character vector | string scalar

World points units, specified as a character vector or string scalar. The value describes the units of measure.

`EstimateSkew` — Estimate skew flag
`false` (default) | `true`

Estimate skew flag, specified as a logical scalar. When you set the logical to `true`, the object estimates the image axes skew. When you set the logical to `false`, the image axes are exactly perpendicular.

`NumRadialDistortionCoefficients` — Number of radial distortion coefficients
2 (default) | 3 | 6

Number of radial distortion coefficients, specified as the number 2, 3, or 6.

`EstimateTangentialDistortion` — Estimate tangential distortion flag
`false` (default) | `true`

Estimate tangential distortion flag, specified as the logical scalar `true` or `false`. When you set the logical to `true`, the object estimates the tangential distortion. When you set the logical to `false`, the tangential distortion is negligible.

Examples

Remove Distortion from an Image Using Camera Parameters Object

Use the camera calibration functions to remove distortion from an image. This example creates a `cameraParameters` object manually, but in practice, you would use the `estimateCameraParameters` or the **Camera Calibrator** app to derive the object.

Create a `cameraParameters` object manually.

```
k = [715.2699 0 565.6995; 0 711.5281 355.3466; 0 0 1];
radialDistortion = [-0.3361 0.0921];
cameraParams = cameraParameters("K",k,"RadialDistortion",radialDistortion)
```

```
cameraParams =
  cameraParameters with properties:

   Camera Intrinsics
                        Intrinsics: [0×0 cameraIntrinsics]

   Camera Extrinsics
                PatternExtrinsics: [0×0 rigidtform3d]
```

```
   Accuracy of Estimation
              MeanReprojectionError: NaN
                 ReprojectionErrors: [0×2 double]
                  ReprojectedPoints: [0×2×0×0 double]

   Calibration Settings
                            NumViews: 0
                         PatternCount: 0
                   DetectedKeypoints: [0×2 double]
                         WorldPoints: [0×2 double]
                          WorldUnits: 'mm'
                        EstimateSkew: 0
    NumRadialDistortionCoefficients: 2
       EstimateTangentialDistortion: 0
```

Remove distortion from the images.

```
I = imread(fullfile(matlabroot,"toolbox","vision","visiondata","calibration","mono","image01.jpg
J = undistortImage(I,cameraParams);
```

Display the original and the undistorted images.

```
montage({I,J})
title("Original Image (left) vs. Corrected Image (right)")
```

Version History

Introduced in R2014a

R2026a: Properties enhanced for multi-camera calibration

New properties for calibration pattern count, `PatternCount`, and the number of views, `NumViews`. These other properties were enhanced to support the pattern count:

- `RotationVectors`
- `PatternExtrinsics`
- `ReprojectionErrors`
- `ReprojectionPoints`
- `DetectedKeyPoints`

R2026a: Removed `NumPatterns` property

The `NumPatterns` property is removed. Use the new `PatternCount` and `NumViews` properties instead.

R2022b: Supports premultiply matrix convention
Behavior changed in R2022b

Starting in R2022b, many Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, some properties of the `cameraParameters` object have changed to support the premultiply convention.

- The new `K` property replaces the old `IntrinsicMatrix` property. The value of `K` is the transpose of `IntrinsicMatrix`.
- The new `PatternExtrinsics` property replaces the old `RotationMatrices` and `TranslationVectors` properties. You can access the rotation matrices and translation vectors by querying the `R` and `Translation` properties of the `rigidtform3d` objects stored in the `PatternExtrinsics` property. The `R` property stores a rotation matrix as the transpose of the rotation matrix represented by `RotationMatrices`.

For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

R2024b: Import OpenCV pinhole camera model with six radial distortion coefficients

The `cameraParameters` has been updated to support OpenCV pinhole camera model with 6 radial distortion coefficients.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use the `toStruct` function to pass a `cameraParameters` object into generated code. See the "Code Generation for Depth Estimation from Stereo Video" example.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

fisheyeCalibrationErrors

Object for storing standard errors of estimated fisheye camera parameters

Description

`fisheyeCalibrationErrors` contains the standard errors of estimated camera parameters. You can access the standard errors of the intrinsics and extrinsics by using the object properties. To display the standard errors, use the `displayErrors` function.

Creation

Create a `fisheyeCalibrationErrors` object by calling the `estimateFisheyeParameters`,

Properties

`IntrinsicsErrors` — Standard errors of estimated intrinsics
`fisheyeIntrinsicsEstimationErrors` object

Standard errors of the estimated intrinsics for a fisheye camera, specified as a `fisheyeIntrinsicsEstimationErrors` object.

`ExtrinsicsErrors` — Standard errors of estimated rotations and translations
`extrinsicsEstimationErrors` object

Standard errors of the estimated rotations and translations for a fisheye camera relative to the calibration pattern, specified as a `extrinsicsEstimationErrors` object.

Object Functions

displayErrors Display standard errors of camera parameter estimates

Examples

Display Fisheye Camera Calibration Errors

Gather a set of checkerboard calibration images.

```
images = imageDatastore(fullfile(toolboxdir('vision'),'visiondata',...
 'calibration','gopro'));
```

Detect the calibration pattern from the images.

```
[imagePoints,patternDims] = detectCheckerboardPoints(images.Files);
```

Generate world coordinates for the corners of the checkerboard squares.

```
squareSize = 29; % millimeters
worldPoints = patternWorldPoints('checkerboard',patternDims,squareSize);
```

Estimate the fisheye parameters using image and world points. Use the first image to get the image size. Also, store the errors from the calibration.

```
I = readimage(images,1);
imageSize = [size(I,1) size(I,2)];
[params,~,errors] = estimateFisheyeParameters(imagePoints, ...
                                worldPoints,imageSize);
```

Display the standard errors of the estimated camera parameters.

```
displayErrors(errors,params);
```

```

fisheyeIntrinsics

Object for storing intrinsic fisheye camera parameters

Description

The `fisheyeIntrinsics` object stores the camera intrinsics for a fisheye camera. See `fisheyeParameters` for details on other fisheye parameters.

Creation

Syntax

```
intrinsics = fisheyeIntrinsics(mappingCoeffs,imageSize,distortionCenter)
intrinsics = fisheyeIntrinsics( ___ ,stretchMatrix)
```

Description

`intrinsics = fisheyeIntrinsics(mappingCoeffs,imageSize,distortionCenter)` returns a `fisheyeIntrinsics` object with the specified `[a0 a2 a3 a4]` polynomial coefficients, image size, and center of distortion. These input arguments are assigned directly to the corresponding properties of the object. See `fisheyeParameters` for more details.

`intrinsics = fisheyeIntrinsics( ___ ,stretchMatrix)` additionally specifies a 2-by-2 transformation matrix that describes the alignment between the sensor plane and the image plane. The default value is an identity matrix.

Properties

`MappingCoefficients` — Polynomial coefficients for projection function
`[a0 a2 a3 a4]` vector

This property is read-only.

Polynomial coefficients for the projection function described by Scaramuzza's Taylor model, specified as an `[a0 a2 a3 a4]` vector.

`DistortionCenter` — Center of distortion in pixels
`[cx cy]` vector

This property is read-only.

Center of distortion in pixels, specified as a `[cx cy]` vector.

`StretchMatrix` — Transformation from sensor plane to pixel in camera image plane
2-by-2 transformation matrix

This property is read-only.

Transformation from the sensor plane to a pixel in the camera image plane, specified as a 2-by-2 transformation matrix. This misalignment is caused by the lens not being parallel to the sensor and by the digitization process.

`ImageSize` — Image size
`[mrows ncols]` vector

This property is read-only.

Image size, specified as an `[mrows ncols]` vector.

Examples

Create Fisheye Intrinsics

Specify the mapping coefficients, image size, and distortion center parameters of a `fisheyeIntrinsics` object. Ignore optical axis misalignment.

```
mappingCoeffs = [880 -3e-4 0 0];    % mapping polynomial coefficients
imageSize = [1500 2000];            % in [mrows ncols]
distortionCenter = [1000 750];      % in pixels

intrinsics = fisheyeIntrinsics(mappingCoeffs,imageSize,distortionCenter);
```

fisheyeIntrinsicsEstimationErrors

Object for storing standard errors of estimated fisheye camera intrinsics

Description

`fisheyeIntrinsicsEstimationErrors` contains the standard errors of estimated fisheye camera intrinsics.

Creation

The `estimateFisheyeParameters` function returns the `fisheyeCalibrationErrors` object, which contains `fisheyeIntrinsicsEstimationErrors` and `extrinsicsEstimationErrors` as properties.

Properties

`MappingCoefficientsError` — Standard error of mapping coefficient estimates
4-element vector

Standard error of mapping coefficient estimates, specified as a 4-element vector.

`DistortionCenterError` — Standard error of distortion center estimates
2-element vector

Standard error of distortion center estimates, specified as a two-element vector.

`StretchMatrixError` — Standard error of stretch matrix estimate
3-element vector

Standard error of stretch matrix estimate, specified as a 3-element vector.

fisheyeParameters

Object for storing fisheye camera parameters

Description

The `fisheyeParameters` object is used to store fisheye camera parameters. Use `estimateFisheyeParameters` to estimate parameters using calibration images.

Creation

Syntax

```
fisheyeParams = fisheyeParameters(intrinsics)
fisheyeParams = fisheyeParameters(intrinsics,Name=Value)
```

Description

`fisheyeParams = fisheyeParameters(intrinsics)` returns an object that contains intrinsic and extrinsic parameters of a fisheye camera. `intrinsics` must be a `fisheyeIntrinsics` object. This syntax sets the `Intrinsics` property of the object.

`fisheyeParams = fisheyeParameters(intrinsics,Name=Value)` sets properties on page 2-1411 of the `cameraParameters` object by using one or more name-value arguments. Unspecified properties use default values. For example, `WorldUnits='m'` sets the world units to `'m'`.

Properties

Intrinsic Camera Parameters

`Intrinsics` — Fisheye intrinsic camera parameters
`fisheyeIntrinsics` object

Fisheye intrinsic camera parameters, specified as a `fisheyeIntrinsics` object.

Extrinsic Camera Parameters

`RotationVectors` — 3-D Camera rotations
`[ ]` (default) | *M*-by-3 matrix | *R*-by-3-by-*P* array

3-D camera rotation vectors, specified as an *R*-by-3 matrix or an *R*-by-3-by-*P* array, containing *R* rotation vectors, where *P* is the number of calibration patterns. Each vector describes the 3-D rotation of the camera's image plane relative to the corresponding calibration pattern.

Each vector specifies the axis of rotation in 3-D space, with its magnitude indicating the rotation angle in radians. The corresponding 3-D rotation matrices are specified by the `PatternExtrinsics` property, specifically in the form of `tform.R`, where `tform` is a `rigidtform3d` object. The `PatternExtrinsics` property specifies geometric transformation objects with the corresponding 3-D rotation matrices.

For single-pattern calibration, specify `RotationVectors` as an *R*-by-3 matrix. For multiple patterns, use an *R*-by-3-by-*P* array.

To ensure that the number of rotation vectors equals the number of translation vectors, you must set the `RotationVectors` and `TranslationVectors` properties together when creating the object. Setting only one property results in an error.

`TranslationVectors` — Camera translations

[ ] (default) | *M*-by-3 matrix

Camera translations, specified as an *M*-by-3 matrix. This matrix contains translation vectors for *M* images. The vectors contain the calibration pattern that estimates the calibration parameters. Each row of the matrix contains a vector that describes the translation of the camera relative to the corresponding pattern, expressed in world units.

To ensure that the number of rotation vectors equals the number of translation vectors, you must set the `RotationVectors` and `TranslationVectors` properties together when creating the object. Setting only one property results in an error.

Accuracy of Estimated Camera Parameters

`ReprojectionErrors` — Estimated camera parameters accuracy

[ ] (default) | *K*-by-2-by-*V* array | *K*-by-2-by-*V*-by-*P* array

Estimated camera parameters accuracy, specified as a *K*-by-2-by-*V* or *K*-by-2-by-*V*-by-*P* array, of [*x y*] pairs. The pairs represent the translation in *x* and *y* between the reprojected pattern keypoints *K*, and the detected pattern keypoints. The values of this property represent the accuracy of the estimated camera parameters. *V* is the number of pattern views used to estimate camera parameters and *P* is the number of calibration patterns. *K* is the number of keypoints in each image.

For single-pattern calibration, specify `ReprojectionErrors` as an*K*-by-2-by-*V* array. For multiple patterns, use an*K*-by-2-by-*V*-by-*P* array.

`ReprojectedPoints` — World points reprojected onto calibration images

K-by-2-by-*V* array | *K*-by-2-by-*V*-by-*P* array

This property is read-only.

World points reprojected onto calibration images, specified as a *K*-by-2-by-*V* or *K*-by-2-by-*V*-by-*P* array of [*x y*] coordinates. The coordinates represent world points reprojected onto calibration images. The number of keypoints in each image is represented by *K*. The number of pattern views is denoted by *V*, and *P* represents the number of calibration patterns. Missing points in the detected keypoints of the pattern are denoted as `[NaN,NaN]`.

For single-pattern calibration, specify `ReprojectedPoints` as a *K*-by-2-by-*V* array. For multiple patterns, use an*K*-by-2-by-*V*-by-*P* array.

`DetectedKeypoints` — Detected keypoints in the calibration pattern

[ ] (default) | *K*-by-*V* array | *K*-by-*V*-by-*P* array

Detected keypoints in the calibration pattern, specified as a logical *K*-by-*V* or *K*-by-*V*-by-*P* array. The number of keypoints in each image is represented by *K*. The number of pattern views is denoted by *V*, and *P* represents the number of calibration patterns.

For single-pattern calibration, specify `DetectedKeypoints` as a *K*-by-*V* array. For multiple patterns, use an*K*-by-*V*-by-*P* array.

Settings Used to Estimate Camera Parameters

`PatternCount` — Number of patterns to estimate camera extrinsics
scalar integer

This property is read-only.

Number of patterns to estimate camera extrinsics, specified as an scalar integer.

`NumViews` — Number of pattern views used to estimate camera extrinsics
scalar integer

This property is read-only.

Number of pattern views used to estimate camera extrinsics, specified as an scalar integer. A view is the perspective from which a camera captures a scene.

`WorldPoints` — World coordinates
`[ ]` (default) | *M*-by-2 matrix

World coordinates of key points on the calibration pattern, specified as an *M*-by-2 matrix. *M* represents the number of key points in the pattern.

`WorldUnits` — World point units
`'mm'` (default) | character vector | string scalar

World point units, specified as the comma-separated pair consisting of `'WorldUnits'` and a character vector or string scalar. This argument is used simply to store the unit type and does not affect any calculations.

`EstimateAlignment` — Estimate axes alignment
`false` (default) | `true`

Estimate axes alignment, specified as `false` or `true`. Set to `true` if the optical axis of the fisheye lens is not perpendicular to the image plane.

Examples

Create Fisheye Parameters Object Manually

Create a fisheye parameters object by specifying the properties manually. Alternatively, you can create this object using the `estimateFisheyeParameters` function.

Specify fisheye intrinsics.

```
mappingCoefficients = rand(1,4);
distortionCenter = [320 240];
imageSize = [480 640];
intrinsics = fisheyeIntrinsics(mappingCoefficients,imageSize,distortionCenter);
```

Create a `fisheyeParameters` object using the specified intrinsics.

```
params = fisheyeParameters(intrinsics);
```

Version History

Introduced in R2017b

R2026a: New `PatternCount` and `NumViews` properties

Adding the `PatternCount` and `NumViews` properties.

R2026a: Removed `NumPatterns` property

The `NumPatterns` property is removed. Use the new `PatternCount` and `NumViews` properties instead.

velodyneFileReader

Read point cloud data from Velodyne PCAP file

Description

The `velodyneFileReader` object reads point cloud data from a Velodyne® packet capture (PCAP) file.

Creation

Syntax

```
veloReader = velodyneFileReader(FileName,DeviceModel)
veloReader = velodyneFileReader(FileName,DeviceModel,Name=Value)
```

Description

`veloReader = velodyneFileReader(FileName,DeviceModel)` creates a Velodyne file reader that reads in point cloud data. Specify the PCAP file and the device model that generated the file. The inputs set the `FileName` and `DeviceModel` properties directly. The reader supports the VLP-16, Puck LITE, Puck Hi-Res, VLP-32C, HDL-32E, HDL-64E, VLS-128, and Velarray H800 device models.

`veloReader = velodyneFileReader(FileName,DeviceModel,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, (`OrganizePoints=true`) returns an organized point cloud.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: (`OrganizePoints=true`) returns an organized point cloud.

`CalibrationFile` — Calibration XML file
`''` (default) | string

Calibration XML file, specified as a string. If you do not specify a calibration file, the reader selects a default calibration file containing data from the Velodyne device manual.

Note If using the `"VelarrayH800"` device model, you must specify the calibration file.

`OrganizePoints` — Logical to set the structure for the output point cloud
`true` (default) | `false`

Logical to set the structure for the output point cloud, specified as a numeric or logical `1` (`true`) or `0` (`false`) scalar.

To return an organized point cloud structure, set `OrganizePoints` to `true`. For an organized point cloud, every row represents a separate laser scan, and the number of columns is based on the horizontal angle resolution of the sensor.

To return an unorganized point cloud structure, set `OrganizePoints` to `false`.

Properties

`FileName` — Velodyne PCAP file name

character vector | string scalar

This property is read-only.

Name of Velodyne PCAP file to read lidar data from, specified as a character vector or string scalar.

`DeviceModel` — Velodyne device model name

`"VLP16"` | `"PuckLITE"` | `"PuckHiRes"` | `"VLP32C"` | `"HDL32E"` | `"HDL64E"` | `"VLS128"` | `"VelarrayH800"`

This property is read-only.

Velodyne device model name, specified as `"VLP16"`, `"PuckLITE"`, `"PuckHiRes"`, `"VLP32C"`, `"HDL32E"`, `"HDL64E"`, `"VLS128"`, or `"VelarrayH800"`.

Note Specifying the incorrect device model returns an improperly calibrated point cloud.

`CalibrationFile` — Name of Velodyne calibration XML file

character vector | string scalar

This property is read-only.

Name of the Velodyne calibration XML file, specified as a character vector or string scalar. This calibration file is included with every sensor.

`NumberOfFrames` — Total number of point clouds

positive integer

This property is read-only.

Total number of point clouds in the file, specified as a positive integer.

`Duration` — Total duration of file in seconds

`duration` scalar

This property is read-only.

Total duration of the file in seconds, specified as a `duration` scalar.

`StartTime` — Time of first point cloud reading

`duration` scalar

This property is read-only.

Time of the first point cloud, specified as a `duration` scalar in seconds.

Start and end times are specified relative to the previous whole hour. For instance, if the file is recorded for 7 minutes from 1:58 p.m. to 2:05 p.m., then:

- `StartTime` = 58 min × 60 s = 3480 s
- `EndTime` = `StartTime` + 7 min × 60 s = 3900 s

`EndTime` — Time of last point cloud reading

`duration` scalar

This property is read-only.

Time of the last point cloud reading, specified as a `duration` scalar.

Start and end times are specified relative to the previous whole hour. For instance, if the file is recorded for 7 minutes from 1:58 PM to 2:05 PM, then:

- `StartTime` = 58 min × 60 s = 3480 s
- `EndTime` = `StartTime` + 7 min × 60 s = 3900 s

`CurrentTime` — Time of current point cloud reading

`duration` scalar

Time for the current point cloud reading in seconds, specified as a `duration` scalar. As you read point clouds using `readFrame`, this property is updated with the most recent point cloud reading time. You can use `reset` to reset the value of this property to the default value. The default value matches the `StartTime` property.

`Timestamps` — Start time for each point cloud frame

`duration` vector

This property is read-only.

Start time for each point cloud frame in seconds, specified as a `duration` vector. The length of the vector is equal to the value of `NumberOfFrames` property. The value of first element in the vector is same as that of the `StartTime` property. You can use this property to read point cloud frames captured at different times.

For example, read start time of a point cloud frame from the `Timestamps` property. Pass the start time as an input to the `readFrame` function and read the corresponding point cloud frame.

```
veloReader = velodyneFileReader("lidarData_ConstructionRoad.pcap","HDL32E")
frameTime  = veloReader.Timestamps(10);
ptCloud    = readFrame(veloReader,frameTime);
```

`OrganizePoints` — Logical to set the structure for the output point cloud

`true` | `false`

This property is read-only.

Logical to set the structure for the output point cloud, specified as a numeric or logical `1` (`true`) or `0` (`false`). This read-only property is set using the `OrganizePoints on page 2-0` name-value argument.

HasPositionData — Logical to indicate existence of position data
`true` | `false`

This property is read-only.

Logical to indicate existence of position data in the PCAP file, specified as a logical scalar `1` (`true`) or `0` (`false`).

Object Functions

hasFrame	Determine if another Velodyne point cloud is available
readFrame	Read Velodyne point cloud from file
reset	Reset the CurrentTime property of velodyneFileReader object to the default value

Examples

Display Point Clouds from Velodyne PCAP File

Use the `velodyneFileReader` to read a packet capture (PCAP) file from a Velodyne® sensor. View point clouds using `pcplayer`.

Read in point clouds by using a Velodyne® file reader. Specify the PCAP file to read and the Velodyne® device model.

```
veloReader = velodyneFileReader('lidarData_ConstructionRoad.pcap','HDL32E');
```

Define *x-, y-,* and *z-*axes limits for `pcplayer` in meters. Label the axes.

```
xlimits = [-60 60];
ylimits = [-60 60];
zlimits = [-20 20];
```

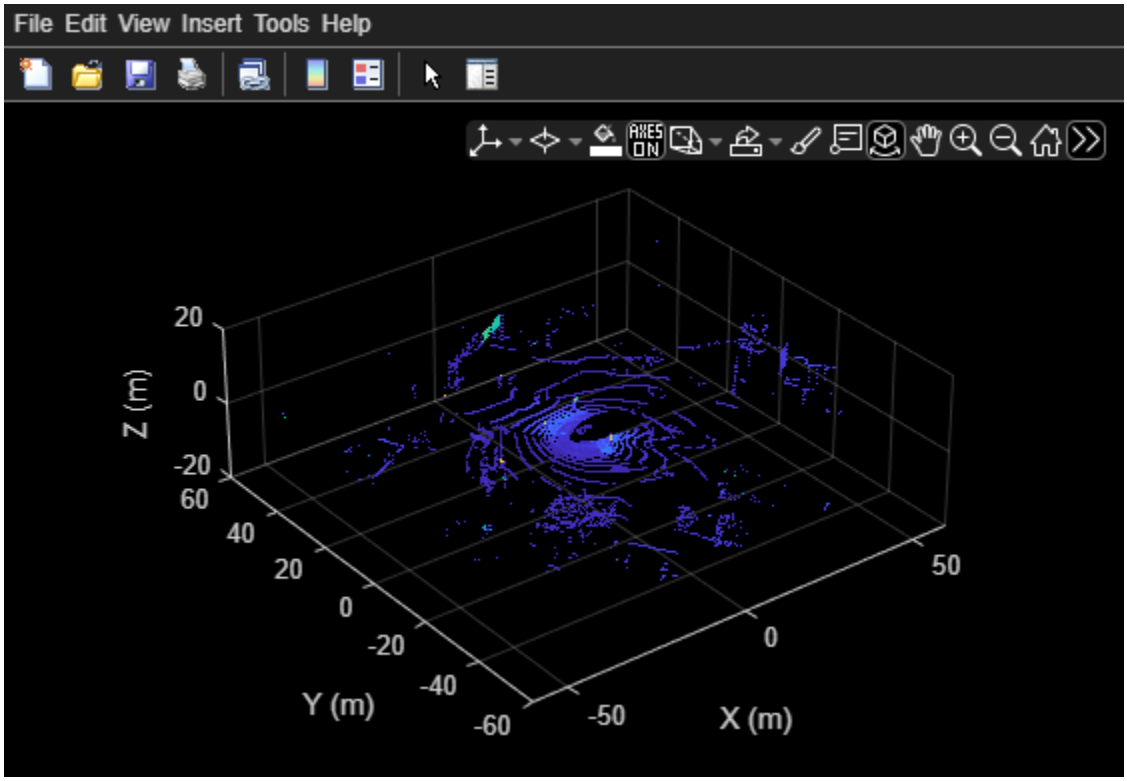
Create the point cloud player.

```
player = pcplayer(xlimits,ylimits,zlimits);
```

Label the axes.

```
xlabel(player.Axes,'X (m)');
ylabel(player.Axes,'Y (m)');
zlabel(player.Axes,'Z (m)');
```

The first point cloud of interest is captured at 0.3 second into the file. Set the `CurrentTime` property to that time to being reading point clouds from there.



```
veloReader.CurrentTime = veloReader.StartTime + seconds(0.3);
```

Display the point cloud stream for 10 seconds. Remove the last `while` condition to display the full stream.

Use `hasFrame` to check if a new frame is available. Iterate through the file by calling `readFrame` to read in point clouds. Display them using the point cloud player. Remove the last `while` condition to display the full stream.

```
while(hasFrame(veloReader) && player.isOpen() && (veloReader.CurrentTime < veloReader.StartTime +
    ptCloudObj = readFrame(veloReader);
```

```
    view(player,ptCloudObj.Location,ptCloudObj.Intensity);
    pause(0.1);
end
```

Version History

Introduced in R2018a

R2022b: Supports reading from Velarray H800 device model

The `velodyneFileReader` object additionally supports reading point cloud data from the Velarray H800 Velodyne device model.

hasFrame

Determine if another Velodyne point cloud is available

Syntax

```
isAvailable = hasFrame(veloReader)
```

Description

`isAvailable = hasFrame(veloReader)` determines if another point cloud is available in the packet capture (PCAP) file of the input Velodyne file reader. As you read point clouds using `readFrame`, the point clouds are read sequentially until this function returns `false`.

Examples

Check for Next Point Cloud in Velodyne PCAP File

Create a `velodyneFileReader` object to read a Velodyne® packet capture (PCAP) file and check for available frames using `hasFrame`.

Read in a point cloud by using a Velodyne® file reader. Specify the PCAP file to be read and Velodyne® device model.

```
veloReader = velodyneFileReader('lidarData_ConstructionRoad.pcap','HDL32E');
```

Check if the file reader has a point cloud to read.

```
disp(hasFrame(veloReader));
```

```
   1
```

Read the last frame of the file.

```
ptCloudObj = readFrame(veloReader,veloReader.NumberOfFrames);
```

Check again if the file reader has another point cloud available.

```
disp(hasFrame(veloReader));
```

```
   0
```

Input Arguments

`veloReader` — Velodyne file reader

`velodyneFileReader` object

Velodyne file reader, specified as a `velodyneFileReader` object.

Output Arguments

`isAvailable` — Indicator if frame is available
`true` | `false`

Indicator if frame is available, returned as `true` or `false`.

Version History

Introduced in R2018a

readFrame

Read Velodyne point cloud from file

Syntax

```
ptCloud = readFrame(veloReader)
ptCloud = readFrame(veloReader,frameNumber)
ptCloud = readFrame(veloReader,frameTime)
[ptCloud,pointTimestamps] = readFrame( ___ )
[ptCloud,pointTimestamps,positionData] = readFrame( ___ )
```

Description

`ptCloud = readFrame(veloReader)` reads the next point cloud in sequence from the Velodyne PCAP file and returns a `pointCloud` object.

`ptCloud = readFrame(veloReader,frameNumber)` reads the point cloud with the specific frame number from the file.

`ptCloud = readFrame(veloReader,frameTime)` reads the first point cloud recorded at or after the given `frameTime`.

`[ptCloud,pointTimestamps] = readFrame( ___ )` returns the timestamps for all points in the point cloud using any combination of input arguments from previous syntaxes.

`[ptCloud,pointTimestamps,positionData] = readFrame( ___ )` returns the positional information for each point cloud frame.

Examples

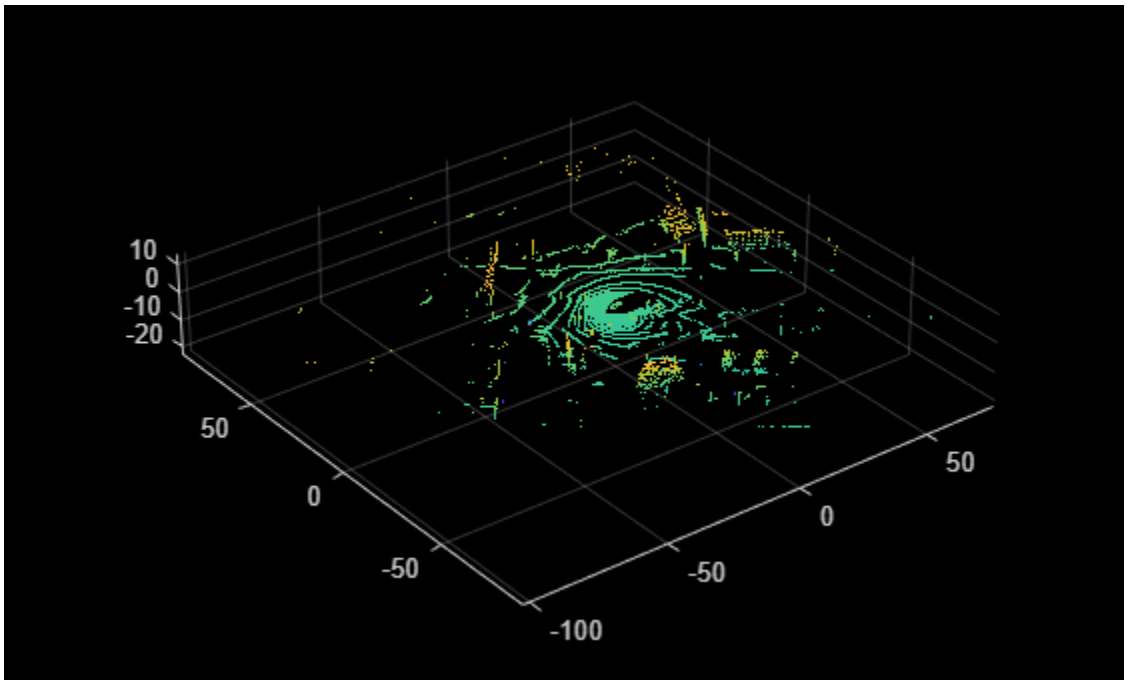
Read Point Cloud from File Using Time Duration

Create a `velodyneFileReader` object to read a Velodyne® packet capture (PCAP) file and select specific point clouds using a `duration` scalar.

Read in point clouds by using a Velodyne® file reader. Specify the PCAP file to read and the Velodyne® device model.

```
veloReader = velodyneFileReader('lidarData_ConstructionRoad.pcap','HDL32E');
```

Create a `duration` scalar that represents one second after the first point cloud reading.



```
timeDuration = veloReader.StartTime + duration(0,0,1,Format='s');
```

Read the first point cloud recorded at or after the given time duration.

```
ptCloudObj = readFrame(veloReader,timeDuration);
```

Display the point cloud using `pcshow`.

```
figure
pcshow(ptCloudObj)
```

Input Arguments

`veloReader` — Velodyne file reader
`velodyneFileReader` object

Velodyne file reader, specified as a `velodyneFileReader` object.

`frameNumber` — Frame number of desired point cloud in the file
positive integer

Frame number of the desired point cloud in file, specified as a positive integer. Frame numbers are sequential.

`frameTime` — Frame time of desired point cloud in file
`duration` scalar

Frame time of the desired point cloud in the file, specified as a `duration` scalar in seconds. The first frame available at or after `frameTime` is given.

Output Arguments

`ptCloud` — Point cloud
`pointCloud` object

Point cloud, returned as a `pointCloud` object.

`pointTimestamps` — Timestamps for all points in point cloud
`duration` vector | `duration` matrix

Timestamps for all points in the point cloud, returned as a `duration` vector or a matrix.

The function returns timestamps as:

- An *M*-element vector for unorganized point clouds. *M* is the total number of points in the point cloud.
- An *M*-by-*N* matrix for organized point clouds. *M* and *N* are the number of rows and columns in the organized point cloud, respectively.

Timestamps are between the values of `StartTime` and `EndTime`, which are properties of the `velodyneFileReader` object. Points in an organized point cloud with a `NaN` value is returned with a time stamp set to `NaN`.

`positionData` — Position data
structure

Position data, returned as a structure with five fields:

Field	Description
`GPSReadings`	GPS reading data, returned as an *M*-by-4 matrix of data type `double`. The number of rows *M* is the number of position readings within a given frame. Each row is of the form `[Latitude Longitude Heading Altitude]`, where : • `Latitude` — Latitude in decimal degrees obtained by the external GPS where north is positive. • `Longitude` — Longitude in decimal degrees obtained by the external GPS where east is positive. • `Heading` — Horizontal direction of motion in degrees from True North, obtained by the external GPS. Data in this column will be `NaN` when an external GPS is connected and a $GPGGA NMEA message is sent. • `Altitude` — Altitude in meters above sea level. Data in this column will be `NaN` when an external GPS is connected and a $GPRMC NMEA message is sent. If the GPS hardware is not connected, then the function returns `GPSReadings` as an empty array, `[]`.

Field	Description
`GyroscopeReadings`	Raw gyroscopic rotation readings in radians per second, collected from the three internal gyroscopes in GPS hardware, returned as an *M*-by-3 matrix of data type `single`. The matrix has these columns: • `Gyro1` — Gyroscopic rotation with respect to the *y*-axis where the positive direction is clockwise around the *y*-axis when viewed from the origin. • `Gyro2` — Gyroscopic rotation with respect to the *x*-axis where the positive direction is counter-clockwise around the *x*-axis when viewed from the origin. • `Gyro3` — Gyroscopic rotation with respect to the *z*-axis where the positive direction is clockwise around the *z*-axis when viewed from the origin. If the Velodyne device model is not HDL-32E, then the function returns `GyroscopeReadings` as an empty array, `[]`.
`AccelerometerReadings`	Raw accelerometer readings, in m/s^2, collected from the three internal accelerometers in GPS hardware, returned as an *M*-by-6 matrix of data type `single`. The columns of the matrix correspond to the *x*-, *y*-, and *z*-axis-axes of the sensor body for both the primary and backup accelerometer readings, as defined in the HDL-32E user manual [1 on page 2-1443]: • `AccelYPrimary` — Increases in the positive *y*-axis direction. • `AccelXPrimary` — Increases in the positive *x*-axis direction. • `AccelZPrimary` — Decreases in the positive *z*-axis direction. • `AccelYBackup` — Increases in the positive *y*-axis direction. • `AccelXBackup` — Increases in the negative *x*-axis direction. • `AccelZBackup` — Decreases in the positive *z*-axis direction. If the Velodyne device model is not HDL-32E, then the function returns `AccelerometerReadings` as an empty array, `[]`.
`PositionTimestamps`	Timestamp for each position reading, returned as an *M*-by-1 `duration` vector.
`GPSTimes`	Time of the GPS in UTC, returned as an *M*-by-1 `duration` vector, used to synchronize the timestamps of the GPS coordinates with their respective point clouds.

`positionData` returns `[]` when there is no position data in the PCAP file.

Version History

Introduced in R2018a

R2023a: Returns positional information for each point cloud frame

The `readFrame` function can return the raw position readings of point cloud data for each frame as a structure with fields for the GPS locations, gyroscope readings, accelerometer readings, position reading timestamps, and GPS reading timestamps.

R2022b: Returns timestamps for all points in point cloud

The `readFrame` function additionally returns the timestamps for all the points in the point cloud as a `duration` vector or matrix.

reset

Reset the `CurrentTime` property of `velodyneFileReader` object to the default value

Syntax

```
reset(veloReader)
```

Description

`reset(veloReader)` resets the `CurrentTime` property of `velodyneFileReader` to the default value. The default value is the `StartTime` property of `velodyneFileReader`.

Examples

Reset the velodyneFileReader Object

Construct `velodyneFileReader` object.

```
veloReader = velodyneFileReader('lidarData_ConstructionRoad.pcap','PuckLITE');
```

Inspect the properties of the `velodyneFileReader` object to know the `CurrentTime`. The default value of `CurrentTime` is the value of `StartTime`.

```
veloReader
```

```
veloReader =
  velodyneFileReader with properties:

           FileName: 'B:\runnable\matlab\toolbox\vision\visiondata\lidarData_ConstructionRoad.pca
        DeviceModel: 'PuckLITE'
    CalibrationFile: 'B:\runnable\matlab\toolbox\shared\pointclouds\utilities\velodyneFileReader
     OrganizePoints: 1
     NumberOfFrames: 40
           Duration: 1.9982 sec
          StartTime: 1145.1 sec
            EndTime: 1147.1 sec
         Timestamps: [1145.1 sec    1145.1 sec    1145.2 sec    1145.2 sec    1145.3 sec    1145
    HasPositionData: 1
        CurrentTime: 1145.1 sec
```

Use `readFrame` to read a point cloud frame from the `velodyneFileReader` object.

```
frameNumber = 30;
ptCloud = readFrame(veloReader,frameNumber);
```

Inspect the `CurrentTime` property of `velodyneFileReader` object.

```
veloReader.CurrentTime
```

```
ans = duration
   1146.6 sec
```

Reset the `CurrentTime` property of `velodyneFileReader` object.

```
reset(veloReader)
```

Inspect the `CurrentTime` property and verify that its value is reset to the default value.

```
veloReader.CurrentTime
```

```
ans = duration
   1145.1 sec
```

Input Arguments

`veloReader` — Velodyne file reader

`velodyneFileReader` object

Velodyne file reader, specified as a `velodyneFileReader` object.

Version History

Introduced in R2018a

See Also

`velodyneFileReader` | `readFrame` | `hasFrame`

changeFilePaths

Change file paths in ground truth data

Syntax

```
unresolvedPaths = changeFilePaths(gTruth,alternativePaths)
[unresolvedPaths,unresolvedFolderPaths] = changeFilePaths(gTruth,
alternativePaths)
```

Description

`unresolvedPaths = changeFilePaths(gTruth,alternativePaths)` changes the file paths stored in a `groundTruth` object, `gTruth`, based on pairs of current paths and alternative paths, `alternativePaths`. If `gTruth` is a vector of `groundTruth` objects, the function changes the file paths across all objects. The function returns the unresolved paths in `unresolvedPaths`. An unresolved path is any current path in `alternativePaths` not found in `gTruth` or any alternative path in `alternativePaths` not found at the specified path location. In both cases, `unresolvedPaths` returns only the current paths.

Use this function to update the file paths of ground truth data that changes folder locations. You can change file paths for the ground truth data source and pixel label data.

`[unresolvedPaths,unresolvedFolderPaths] = changeFilePaths(gTruth, alternativePaths)` additionally returns unresolved folder paths `unresolvedFolderPaths`, which lists the folder locations corresponding to the unresolved current paths returned in `unresolvedPaths`. Use `unresolvedFolderPaths` to identify unresolved paths at the folder level when `unresolvedPaths` contains many files from the same folder.

Examples

Change File Paths in Ground Truth Data

Change the file paths to the data source and pixel label data in a `groundTruth` object.

Load a `groundTruth` object containing ground truth data into the workspace. The data source and pixel label data of the object contains file paths corresponding to an image sequence showing a building. MATLAB® displays a warning that the path to the data source cannot be found.

```
load('gTruthSeq.mat');
```

```
Warning: The data source points to a directory that cannot be found.
'C:\CFP\building'
Update the DataSource using <a href="matlab:doc('changeFilePaths')">changeFilePaths</a> method.
```

Display the current path to the data source.

```
gTruth.DataSource
```

```
ans =
'C:\CFP\building'
```

Specify the current path to the data source and an alternative path and store these paths in a cell array. Use the `changeFilePaths` function to update the data source path based on the paths in the cell array. Because the function does not find the pixel label data at the specified new path, it returns the current unresolved paths.

```
currentPathDataSource = "C:\CFP\building";
newPathDataSource = fullfile(matlabroot,"toolbox\vision\visiondata\building");
alternativePaths = {[currentPathDataSource newPathDataSource]};
unresolvedPaths = changeFilePaths(gTruth,alternativePaths)
```

```
unresolvedPaths = 5×1 string array
    "C:\CFP\building\PixelLabelData\Label_1.png"
    "C:\CFP\building\PixelLabelData\Label_2.png"
    "C:\CFP\building\PixelLabelData\Label_3.png"
    "C:\CFP\building\PixelLabelData\Label_4.png"
    "C:\CFP\building\PixelLabelData\Label_5.png"
```

Verify that the paths in the `groundTruth` object match the unresolved paths returned by the `changeFilePaths` function. The unresolved paths are stored in the `LabelData` property of the `groundTruth` object, in the `PixelLabelData` column.

```
gTruth.LabelData.PixelLabelData
```

```
ans = 5×1 cell array
    "'C:\CFP\building\PixelLabelData\Label_1.png'"
    "'C:\CFP\building\PixelLabelData\Label_2.png'"
    "'C:\CFP\building\PixelLabelData\Label_3.png'"
    "'C:\CFP\building\PixelLabelData\Label_4.png'"
    "'C:\CFP\building\PixelLabelData\Label_5.png'"
```

Specify the current path and an alternative path for the pixel label files and change the file paths. The function updates the paths for all pixel labels. Because the function resolves all paths, it returns an empty array of unresolved paths.

```
currentPathPixels = "C:\CFP\building\PixelLabelData";
newPathPixels = fullfile(matlabroot,"toolbox\vision\visiondata\buildingPixellabels");
alternativePaths = {[currentPathPixels newPathPixels]};
unresolvedPaths = changeFilePaths(gTruth,alternativePaths)
```

```
unresolvedPaths =

  0×0 empty string array
```

To view the new data source path, use the `gTruth.DataSource` command. To view the new pixel label data paths, use the `gTruth.LabelData.PixelLabelData` command.

Input Arguments

`gTruth` — Ground truth data

`groundTruth` object | array of `groundTruth` objects

Ground truth data, specified as a `groundTruth` object or array of `groundTruth` objects. You can export these objects from the Ground Truth Labeler app or create them programmatically.

`alternativePaths` — Alternative file paths

1-by-2 string vector | cell array of 1-by-2 string vectors

Alternative file paths, specified as a 1-by-2 string vector or cell array of 1-by-2 string vectors of the form [p_{current} p_{new}].

- p_{current} is a current file path in `gTruth`. This file path can be from the data source or pixel label data of `gTruth`. Specify p_{current} using backslashes as the path separators.
- p_{new} is the new path to which you want to change p_{current}. Specify p_{new} using either forward slashes or backslashes as the path separators.

You can specify alternatives paths to these files:

- Data source — This path is stored in the `DataSource` property of `gTruth`. If you use `changeFilePaths` to update the `DataSource` property of a `groundTruth` object, the new path must already exist; otherwise, the path won't update and the old value remains. Only after the file exists at the new location will the `DataSource` property update to reflect the new path and data type.
- Pixel label data — These paths are stored in the `PixelLabelData` column of the `LabelData` property of `gTruth`.

If `gTruth` is a vector of `groundTruth` objects, the function changes the file paths across all objects.

Example: `["C:\Pixels\PixelLabelData_1" "C:\Pixels\PixelLabelData_2]` changes the path to the pixel label data folder. The function updates the path in all pixel label files stored in that folder.

Example: `{["C:\Pixels\PixelLabelData_1" "C:\Pixels\PixelLabelData_2]; ["B:\Sources\video.mp4" "C:\Sources\video.mp4"]}` changes the path to the pixel label data folder and the drive letter in the path to the data source.

Output Arguments

`unresolvedPaths` — Unresolved file paths

string array

Unresolved file paths, returned as a string array. If the function cannot find either the current path or new path in the string vectors specified by `alternativePaths`, then it returns the unresolved current paths in `unresolvedPaths`.

If the function finds and resolves all file paths, then it returns `unresolvedPaths` as an empty string array.

`unresolvedFolderPaths` — Unresolved folder paths

string array

Unresolved folder paths, returned as a string array. This value lists the folder locations for the unresolved current paths returned in `unresolvedPaths`, providing a shorter list when many unresolved files come from the same folder.

If the function finds and resolves all file paths, then it returns `unresolvedFolderPaths` as an empty string array.

Version History

Introduced in R2018b

R2026a: Additional output argument `unresolvedFolderPaths`

The function can now also return an `unresolvedFolderPaths` output, which lists the folder locations for the unresolved file paths.

`groundTruth` | `groundTruthDataSource`

Topics

“Share and Store Labeled Ground Truth Data”
“How Labeler Apps Store Exported Pixel Labels”

labelDefinitionCreator

Object for storing, modifying and creating label definitions table

Description

The `labelDefinitionCreator` object stores definitions of labels, sublabels, and attributes for labeling ground truth data. Use "Object Functions" on page 2-1451 to add, remove, modify, or display label definitions. Using the `create` object function, you can create label definitions table from the `labelDefinitionCreator` object. You can use this label definitions table with the Image Labeler, and Video Labeler apps. To create a label definitions table for use with the Ground Truth Labeler app, use a `labelDefinitionCreatorMultisignal` object instead.

Creation

Syntax

```
ldc = labelDefinitionCreator
ldc = labelDefinitionCreator(labelDefs)
```

Description

`ldc = labelDefinitionCreator` creates an empty label definition creator object, `ldc`. Add label definitions by using "Object Functions" on page 2-1451. The details of the stored labels, sublabels, and attributes can be inspected using the `info` object function.

`ldc = labelDefinitionCreator(labelDefs)` creates a label definition creator object `ldc` and stores definitions from the label definitions table `labelDefs`. Use "Object Functions" on page 2-1451 to add new label definitions or modify the existing label definitions. The details of the stored labels, sublabels, and attributes can be inspected using the `info` object function.

Input Arguments

`labelDefs` — Label definitions
table

Label definitions, specified as a table with up to seven columns. The possible columns are *Name*, *Type*, *LabelColor*, *PixelLabelID*, *Group*, *Description*, and *Hierarchy*. This table specifies the definitions of labels, sublabels, and attributes for labeling ground truth data. For more details, see "LabelDefinitions" on page 2-0 .

Output Arguments

`ldc` — Label definition creator
`labelDefinitionCreator` object

Label definition creator, returned as a `labelDefinitionCreator` object that contains information about label definitions associated with ground truth data.

Object Functions

addLabel Add label to label definition creator object
addSublabel Add sublabel to label in label definition creator object
addAttribute Add attributes to label or sublabel in label definition creator object
removeLabel Remove label from label definition creator object
removeSublabel Remove sublabel from label in label definition creator object
removeAttribute Remove attribute from label or sublabel in label definition creator object
editLabelGroup Modify a label group name
editGroupName Change group name
editLabelDescription Modify description of label or sublabel in label definition creator object
editAttributeDescription Modify description of attribute in label definition creator object
create Create label definitions table from the label definition creator object
info Display information about a label, sublabel, or attribute stored in label definition creator object

Examples

Create Label Definition Creator Object and Add Label Definitions

Create an empty label definition creator object.

```
ldc = labelDefinitionCreator
```

```
ldc =

labelDefinitionCreator with 0 labels. Use the addLabel method to add a label.
```

Add a label with the name "Vehicle" and specify the type of label as a rectangle.

```
addLabel(ldc,'Vehicle',labelType.Rectangle)
```

Add a sublabel with the name "Wheel" and an attribute with the name "Color" to the label "Vehicle" stored in `ldc`. Specify the type of sublabel as a rectangle and the attribute type as a string with value `'Red'`.

```
addSublabel(ldc,'Vehicle','Wheel',labelType.Rectangle)
addAttribute(ldc,'Vehicle','Color',attributeType.String,'Red')
```

Display the details of the label definition creator object.

```
ldc
```

```
ldc =

labelDefinitionCreator contains the following labels:

    Vehicle with 1 sublabels and 1 attributes.    (info)

For more details about attributes and sublabels, use the info method.
```

Create Label Definition Creator Object from Existing Label Definitions Table

Load an existing label definitions table into the workspace.

```
labelDefFile = fullfile(toolboxdir('vision'), 'visiondata', 'labelDefsWithAttributes.mat');
ld = load(labelDefFile)
```

```
ld =

  struct with fields:

    labelDefs: [4×4 table]
```

Create a label definition creator object from the label definitions table. Display the details of the label definition creator object.

```
ldc = labelDefinitionCreator(ld.labelDefs)
```

```
ldc =

labelDefinitionCreator contains the following labels:

    Vehicle with 0 sublabels and 3 attributes.    (info)
    Pedestrian with 0 sublabels and 0 attributes.    (info)
    LaneMarker with 0 sublabels and 2 attributes.    (info)
    TrafficLight with 1 sublabels and 0 attributes.    (info)

For more details about attributes and sublabels, use the info method.
```

Version History

Introduced in R2018b

addLabel

Add label to label definition creator object

Syntax

```
addLabel(ldc,labelName,typeOfLabel)
addLabel( ___ ,Name,Value)
```

Description

`addLabel(ldc,labelName,typeOfLabel)` adds a label with the specified name and type to the label definition creator object `ldc`.

`addLabel( ___ ,Name,Value)` specifies options using one or more name-value arguments in addition to the input arguments in the previous syntax.

Examples

Add Label Using Label Definition Creator

Create a labelDefinitionCreator.

```
ldc = labelDefinitionCreator;
```

Add a label named 'Car'.

```
addLabel(ldc,'Car',labelType.Rectangle);
```

Inspect the label.

```
ldc
```

```
ldc =
labelDefinitionCreator contains the following labels:

    Car with 0 sublabels and 0 attributes and belongs to None group.    (info)

For more details about attributes and sublabels, use the info method.
```

Add another label named 'StopSign' in a group named 'TrafficSign'. Add a description.

```
addLabel(ldc,'StopSign','Rectangle','Group','TrafficSign','Description','Bounding boxes for stop
```

Inspect the labels.

```
ldc
```

```
ldc =
labelDefinitionCreator contains the following labels:

    Car with 0 sublabels and 0 attributes and belongs to None group.    (info)
    StopSign with 0 sublabels and 0 attributes and belongs to TrafficSign group.    (info)
```

```
For more details about attributes and sublabels, use the info method.
```

Add Labels Related to Driving Scene to Label Definition Creator Object

Create an empty label definition creator object.

```
ldc = labelDefinitionCreator
```

```
ldc =
labelDefinitionCreator
```

Add label "Vehicle" to the label definition creator object. Specify the type of label as a rectangle.

```
addLabel(ldc,'Vehicle',labelType.Rectangle)
```

Add label "StopSign" to the label definition creator object. Specify the type of label as a rectangle and add a description to the label.

```
addLabel(ldc,'StopSign',labelType.Rectangle,'Description','Bounding boxes for stop signs')
```

Display the details of the label definition creator object.

```
ldc
```

```
ldc =
labelDefinitionCreator contains the following labels:

    Vehicle with 0 sublabels and 0 attributes and belongs to None group.    (info)
    StopSign with 0 sublabels and 0 attributes and belongs to None group.    (info)

For more details about attributes and sublabels, use the info method.
```

Display information about the label "Vehicle" using the object function `info`.

```
info(ldc,'Vehicle')
```

```
           Name: "Vehicle"
           Type: Rectangle
     LabelColor: {''}
          Group: "None"
     Attributes: []
      Sublabels: []
    Description: ' '
```

Display information about the label "StopSign" using the object function `info`.

```
info(ldc,'StopSign')
```

```
           Name: "StopSign"
           Type: Rectangle
     LabelColor: {''}
          Group: "None"
     Attributes: []
      Sublabels: []
    Description: 'Bounding boxes for stop signs'
```

Input Arguments

`ldc` — Label definition creator
`labelDefinitionCreator` object

Label definition creator, specified as a `labelDefinitionCreator` object.

`labelName` — Label name
character vector | string scalar

Label name, specified as a character vector or string scalar that uniquely identifies the label to be added.

`typeOfLabel` — Type of label
`labelType` enumeration | character vector | string scalar

Type of label, specified as one of these values:

- `labelType` enumeration — You can use any of these `labelType` enumerators to specify the type of label: `Rectangle`, `Line`, `PixelLabel`, `Scene`, or `Custom`.

Example: `addLabel(ldc,'Car',labelType.Rectangle);`

- Character vector or string scalar — This value must partially or fully match one of the `labelType` enumerators.

Example: `addLabel(ldc,'Car','Rec');`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `addLabel(ldc,'Car',labelType.Rectangle,'Description','Type of Vehicle');`

`Group` — Group name
`'None'` (default) | character vector | string scalar

Group name, specified as a comma-separated pair consisting of `'Group'` and a character vector or string scalar. Use this name-value pair to specify a name for a group of labels.

`Description` — Label description
`''` (default) | character vector | string scalar

Label description, specified as a comma-separated pair consisting of `'Description'` and a character vector or string scalar. Use this name-value pair to describe the label.

Version History

Introduced in R2018b

addSublabel

Add sublabel to label in label definition creator object

Syntax

```
addSublabel(ldc,labelName,sublabelName,typeOfSublabel)
addSublabel( ___ ,Name,Value)
```

Description

`addSublabel(ldc,labelName,sublabelName,typeOfSublabel)` adds a sublabel with the specified name and type to the indicated label. The sublabel is added under the hierarchy for the specified label in the label definition creator object `ldc`.

`addSublabel( ___ ,Name,Value)` specifies options using one or more name-value arguments in addition to the input arguments in the previous syntax.

Examples

Add Sublabels to Labels in Label Definition Creator Object

Load an existing label definitions table into the workspace.

```
load('labelDefsTable.mat')
```

Create a label definition creator object from the label definitions table.

```
ldc = labelDefinitionCreator(labelDefs)
```

```
ldc =
labelDefinitionCreator contains the following labels:

    Car with 0 sublabels and 0 attributes and belongs to None group.    (info)
    TrafficLight with 0 sublabels and 0 attributes and belongs to None group.    (info)

For more details about attributes and sublabels, use the info method.
```

Add sublabel "Wheel" to the label "Car". Specify the label type for sublabel as a rectangle and add description to the sublabel.

```
addSublabel(ldc,'Car','Wheel',labelType.Rectangle,'Description','Bounding box for the wheel')
```

Add sublabels "RedLight" and "GreenLight" to the label "TrafficLight". Specify the label type for the sublabels as rectangle.

```
addSublabel(ldc,'TrafficLight','RedLight',labelType.Rectangle)
addSublabel(ldc,'TrafficLight','GreenLight',labelType.Rectangle)
```

Display the details of the label definition creator object.

```
ldc
```

```
ldc =
labelDefinitionCreator contains the following labels:

    Car with 1 sublabels and 0 attributes and belongs to None group.    (info)
    TrafficLight with 2 sublabels and 0 attributes and belongs to None group.    (info)

For more details about attributes and sublabels, use the info method.
```

Display information about the sublabels under the label "Car" using the `info` object function.

```
info(ldc,'Car')
```

```
           Name: "Car"
           Type: Rectangle
     LabelColor: {''}
          Group: "None"
     Attributes: []
      Sublabels: "Wheel"
    Description: 'Bounding box for car'
```

Display information about the sublabels under the label "TrafficLight" using the `info` object function.

```
info(ldc,'TrafficLight')
```

```
           Name: "TrafficLight"
           Type: Rectangle
     LabelColor: {''}
          Group: "None"
     Attributes: []
      Sublabels: ["RedLight"    "GreenLight"]
    Description: 'Bounding boxes for traffic light'
```

Input Arguments

`ldc` — Label definition creator

`labelDefinitionCreator` object

Label definition creator, specified as a `labelDefinitionCreator` object.

`labelName` — Label name

character vector | string scalar

Label name, specified as a character vector or string scalar that uniquely identifies the label to which the sublabel is associated.

`sublabelName` — Sublabel name

character vector | string scalar

Sublabel name, specified as a character vector or string scalar that identifies the sublabel to be added.

`typeOfSublabel` — Type of sublabel

`labelType` enumeration | character vector | string scalar

Type of sublabel, specified as one of these values:

- `labelType` enumeration — The type of sublabel must be one of these `labelType` enumerators: `Rectangle` or `Line`.

Example: `addSublabel(ldc,'Car','Wheel',labelType.Rectangle)`

- Character vector or string scalar — This value must partially or fully match one of these `labelType` enumerators: `Rectangle` or `Line`.

Example: `addSublabel(ldc,'Car','Wheel','Rec')`

Note The `labelType` enumerators `PixelLabel`, `Scene`, and `Custom` are not supported as values for the type of sublabel in labeling apps.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `addSublabel(ldc,'Car','Wheel','Rect','Description','Bounding box for Wheel');`

`Description` — Sublabel description
`' '` (default) | character vector | string scalar

Sublabel description, specified as a comma-separated pair consisting of `'Description'` and a character vector or string scalar. Use this name-value pair to describe the sublabel.

addAttribute

Add attributes to label or sublabel in label definition creator object

Syntax

```
addAttribute(ldc,labelName,attributeName,typeOfAttribute,attributeDefault)
addAttribute( ___ ,Name,Value)
```

Description

`addAttribute(ldc,labelName,attributeName,typeOfAttribute,attributeDefault)` adds an attribute with specified name and type to the indicated label or sublabel. The attribute is added under the hierarchy for the specified label or sublabel in the label definition creator object `ldc`.

`addAttribute( ___ ,Name,Value)` specifies options using one or more name-value arguments in addition to the input arguments in the previous syntax.

Examples

Add Attributes to Label and Sublabel in Label Definition Creator Object

Load an existing label definitions table into the workspace.

```
load('sublabelDefsTable.mat')
```

Create a label definition creator object from the label definitions table.

```
ldc = labelDefinitionCreator(labelDefs)
```

```
ldc =
labelDefinitionCreator contains the following labels:

    Car with 1 sublabels and 0 attributes and belongs to None group.    (info)
    TrafficLight with 2 sublabels and 0 attributes and belongs to None group.    (info)

For more details about attributes and sublabels, use the info method.
```

Add attribute "Color" to the label "Car". Specify the attribute type as a string with value `'Red'`.

```
addAttribute(ldc,'Car','Color',attributeType.String,'Red')
```

Display information about the sublabels under the label "TrafficLight".

```
info(ldc,'TrafficLight')
```

```
           Name: "TrafficLight"
           Type: Rectangle
     LabelColor: {''}
          Group: "None"
     Attributes: []
```

```
      Sublabels: ["RedLight"    "GreenLight"]
    Description: 'Bounding boxes for traffic light'
```

Add attribute "IsOn" to the label "TrafficLight/RedLight". Specify the attribute type as logical with value `true`.

```
addAttribute(ldc,'TrafficLight/RedLight','IsOn','logical',true)
```

Display the details of the label definition creator object.

```
ldc
```

```
ldc =
labelDefinitionCreator contains the following labels:

    Car with 1 sublabels and 1 attributes and belongs to None group.    (info)
    TrafficLight with 2 sublabels and 0 attributes and belongs to None group.    (info)

For more details about attributes and sublabels, use the info method.
```

Display information about the attributes under the label "Car" using the `info` object function.

```
info(ldc,'Car')
```

```
           Name: "Car"
           Type: Rectangle
     LabelColor: {''}
          Group: "None"
     Attributes: "Color"
      Sublabels: "Light"
    Description: 'Bounding box for vehicle'
```

Display information about the attributes for sublabel "RedLight" under the label "TrafficLight" using the `info` object function.

```
info(ldc,'TrafficLight/RedLight')
```

```
           Name: "RedLight"
           Type: Rectangle
     Attributes: "IsOn"
      Sublabels: []
    Description: ' '
```

Input Arguments

`ldc` — Label definition creator

`labelDefinitionCreator` object

Label definition creator, specified as a `labelDefinitionCreator` object.

`labelName` — Label or sublabel name

character vector | string scalar

Label or sublabel name, specified as a character vector or string scalar that uniquely identifies the label or sublabel to which the attribute is to be added.

- To specify a label, use the form '*labelName*'.
- To specify a sublabel, use the form '*labelName/sublabelName*'. In this case, the attribute associates to the sublabel.

`attributeName` — Attribute name
character vector | string scalar

Attribute name, specified as a character vector or string scalar that identifies the attribute to be added to the label or sublabel.

`typeOfAttribute` — Type of attribute
`attributeType` enumeration | character vector | string scalar

Type of attribute, specified as one of these values:

- `attributeType` enumeration — The type of attribute must be one of these enumerators in `attributeType` enumeration: `Numeric`, `Logical`, `String`, or `List`.

Example: `addAttribute(ldc,'Car','Color',attributeType.String,'Red');`

- Character vector or string scalar — This value must partially or fully match one of the enumerators in `attributeType` enumeration.

Example: `addAttribute(ldc,'Car','Color','Str','Red');`

`attributeDefault` — Default value of attribute
numeric scalar | logical scalar | character vector | string scalar | cell array of character vectors | cell array of string scalars

Default value of the attribute, specified as one of these values:

- Numeric scalar — Specify this value when `typeOfAttribute` is `Numeric`.
- Logical scalar — Specify this value when `typeOfAttribute` is `Logical`.
- Character vector or string scalar — Specify this value when `typeOfAttribute` is `String`.
- Cell array of character vectors or cell array of string scalars — Specify this value when `typeOfAttribute` is `List`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `addAttribute(ldc,'Car/Wheel','Outsidediameter',attributeType.Numeric,740,'Description','Outside diameter in mm');`

`Description` — Attribute description
`''` (default) | character vector | string scalar

Attribute description, specified as a comma-separated pair consisting of `'Description'` and a character vector or string scalar. Use this name-value pair to describe the attribute.

removeLabel

Remove label from label definition creator object

Syntax

```
removeLabel(ldc,labelName)
```

Description

`removeLabel(ldc,labelName)` removes the specified label from the label definition creator object `ldc`.

Note Removing a label also removes any attributes or sublabels associated with that label.

Examples

Remove Label from Label Definition Creator Object

Load an existing label definitions table into the workspace.

```
labelDefFile = fullfile(toolboxdir('vision'),'visiondata','labelDefsWithAttributes.mat');
ld = load(labelDefFile)
```

```
ld = struct with fields:
    labelDefs: [4×4 table]
```

Create a label definition creator object from the label definitions table.

```
ldc = labelDefinitionCreator(ld.labelDefs)
```

```
ldc =
labelDefinitionCreator contains the following labels:

    Vehicle with 0 sublabels and 3 attributes and belongs to None group.    (info)
    Pedestrian with 0 sublabels and 0 attributes and belongs to None group.    (info)
    LaneMarker with 0 sublabels and 2 attributes and belongs to None group.    (info)
    TrafficLight with 1 sublabels and 0 attributes and belongs to None group.    (info)

For more details about attributes and sublabels, use the info method.
```

Remove the label "Vehicle" from the label definition creator object.

```
removeLabel(ldc,'Vehicle')
```

Display the details of the label definition creator object to confirm that "Vehicle" is removed from the label definitions.

```
ldc
```

```
ldc =
labelDefinitionCreator contains the following labels:

    Pedestrian with 0 sublabels and 0 attributes and belongs to None group.    (info)
    LaneMarker with 0 sublabels and 2 attributes and belongs to None group.    (info)
    TrafficLight with 1 sublabels and 0 attributes and belongs to None group.    (info)

For more details about attributes and sublabels, use the info method.
```

Input Arguments

`ldc` — Label definition creator
`labelDefinitionCreator` object

Label definition creator, specified as a `labelDefinitionCreator` object.

`labelName` — Label name
character vector | string scalar

Label name, specified as a character vector or string scalar that uniquely identifies the label to be removed from the label definition creator object.

removeSublabel

Remove sublabel from label in label definition creator object

Syntax

```
removeSublabel(ldc,labelName,sublabelName)
```

Description

`removeSublabel(ldc,labelName,sublabelName)` removes the specified sublabel from the indicated label. This label must be in the label definition creator object `ldc`.

Note Removing a sublabel also removes any attributes associated with that sublabel.

Examples

Remove Sublabel from Label in Label Definition Creator Object

Load an existing label definitions table into the workspace.

```
labelDefFile = fullfile(toolboxdir('vision'), 'visiondata', 'labelDefsWithAttributes.mat');
ld = load(labelDefFile)
```

```
ld = struct with fields:
    labelDefs: [4×4 table]
```

Create a label definition creator object from the label definitions table.

```
ldc = labelDefinitionCreator(ld.labelDefs)
```

```
ldc =
labelDefinitionCreator contains the following labels:

    Vehicle with 0 sublabels and 3 attributes and belongs to None group.    (info)
    Pedestrian with 0 sublabels and 0 attributes and belongs to None group.    (info)
    LaneMarker with 0 sublabels and 2 attributes and belongs to None group.    (info)
    TrafficLight with 1 sublabels and 0 attributes and belongs to None group.    (info)

For more details about attributes and sublabels, use the info method.
```

Display information about the label "TrafficLight" defined in the label definition creator object.

```
info(ldc,'TrafficLight')
```

```
           Name: "TrafficLight"
           Type: Rectangle
     LabelColor: {''}
          Group: "None"
     Attributes: []
```

```
      Sublabels: "Light"
    Description: 'Mark a tight bounding box around the traffic light. Use the sublabels to mark e
```

Remove the sublabel "Light" from the label "TrafficLight".

```
removeSublabel(ldc,'TrafficLight','Light')
```

Display the details of the label definition creator object to confirm that a sublabel is removed from the label "TrafficLight".

```
ldc
```

```
ldc =
labelDefinitionCreator contains the following labels:

    Vehicle with 0 sublabels and 3 attributes and belongs to None group.    (info)
    Pedestrian with 0 sublabels and 0 attributes and belongs to None group.    (info)
    LaneMarker with 0 sublabels and 2 attributes and belongs to None group.    (info)
    TrafficLight with 0 sublabels and 0 attributes and belongs to None group.    (info)

For more details about attributes and sublabels, use the info method.
```

Display information about the label "TrafficLight". Confirm that the sublabel "Light" is removed.

```
info(ldc,'TrafficLight')
```

```
           Name: "TrafficLight"
           Type: Rectangle
     LabelColor: {''}
          Group: "None"
     Attributes: []
      Sublabels: []
    Description: 'Mark a tight bounding box around the traffic light. Use the sublabels to mark e
```

Input Arguments

`ldc` — Label definition creator

`labelDefinitionCreator` object

Label definition creator, specified as a `labelDefinitionCreator` object.

`labelName` — Label name

character vector | string scalar

Label name, specified as a character vector or string scalar that uniquely identifies the label to which the sublabel is associated.

`sublabelName` — Sublabel name

character vector | string scalar

Sublabel name, specified as a character vector or string scalar that identifies the sublabel to be removed from the indicated label `labelName`.

removeAttribute

Remove attribute from label or sublabel in label definition creator object

Syntax

```
removeAttribute(ldc,labelName,attributeName)
```

Description

`removeAttribute(ldc,labelName,attributeName)` removes the specified attribute from the indicated label or sublabel in the label definition creator object `ldc`.

Examples

Remove Attributes from Label and Sublabel in Label Definition Creator Object

Load an existing label definitions table into the workspace.

```
labelDefFile = fullfile(toolboxdir('vision'),'visiondata','labelDefsWithAttributes.mat');
ld = load(labelDefFile)
```

```
ld = struct with fields:
    labelDefs: [4×4 table]
```

Create a label definition creator object from the label definitions table.

```
ldc = labelDefinitionCreator(ld.labelDefs)
```

```
ldc =
labelDefinitionCreator contains the following labels:

    Vehicle with 0 sublabels and 3 attributes and belongs to None group.    (info)
    Pedestrian with 0 sublabels and 0 attributes and belongs to None group.    (info)
    LaneMarker with 0 sublabels and 2 attributes and belongs to None group.    (info)
    TrafficLight with 1 sublabels and 0 attributes and belongs to None group.    (info)

For more details about attributes and sublabels, use the info method.
```

Remove an Attribute from a Label

Display information about the label "Vehicle" defined in the label definition creator object.

```
info(ldc,'Vehicle')
```

```
           Name: "Vehicle"
           Type: Rectangle
     LabelColor: {''}
          Group: "None"
     Attributes: ["Class"    "Color"    "View"]
      Sublabels: []
    Description: 'Draw a tight bounding box around the vehicle. Use this label for cars, buses ar
```

Remove the attribute "Color" from the label "Vehicle".

```
removeAttribute(ldc,'Vehicle','Color')
```

Display information about the label "Vehicle". Confirm that the attribute "Color" is removed.

```
info(ldc,'Vehicle')
```

```
           Name: "Vehicle"
           Type: Rectangle
     LabelColor: {''}
          Group: "None"
     Attributes: ["Class"    "View"]
      Sublabels: []
    Description: 'Draw a tight bounding box around the vehicle. Use this label for cars, buses ar
```

Remove an Attribute from a Sublabel

Display information about the label "TrafficLight" defined in the label definition creator object.

```
info(ldc,'TrafficLight')
```

```
           Name: "TrafficLight"
           Type: Rectangle
     LabelColor: {''}
          Group: "None"
     Attributes: []
      Sublabels: "Light"
    Description: 'Mark a tight bounding box around the traffic light. Use the sublabels to mark e
```

Display information about the sublabel "Light" under the label "TrafficLight".

```
info(ldc,'TrafficLight/Light')
```

```
           Name: "Light"
           Type: Rectangle
     Attributes: ["Active"    "Color"]
      Sublabels: []
    Description: 'Mark a tight bounding box around each light.'
```

Remove the attribute "Active" from the sublabel "TrafficLight/Light".

```
removeAttribute(ldc,'TrafficLight/Light','Active')
```

Display information about the sublabel "TrafficLight/Light". Confirm that the attribute "Active" is removed.

```
info(ldc,'TrafficLight/Light')
```

```
           Name: "Light"
           Type: Rectangle
     Attributes: "Color"
      Sublabels: []
    Description: 'Mark a tight bounding box around each light.'
```

Input Arguments

`ldc` — Label definition creator
`labelDefinitionCreator` object

Label definition creator, specified as a `labelDefinitionCreator` object.

`labelName` — Label or sublabel name
character vector | string scalar

Label or sublabel name, specified as a character vector or string scalar that uniquely identifies the label or sublabel from which the attribute is to be removed.

- To specify a label, use the form '*labelName*'.
- To specify a sublabel, use the form '*labelName/sublabelName*'. In this case, the attribute associates to the sublabel.

`attributeName` — Attribute name
character vector | string scalar

Attribute name, specified as a character vector or string scalar that identifies the attribute to be removed from the indicated label or sublabel `labelName`.

Version History

Introduced in R2018b

editLabelDescription

Modify description of label or sublabel in label definition creator object

Syntax

```
editLabelDescription(ldc,labelName,description)
```

Description

`editLabelDescription(ldc,labelName,description)` modifies the description of a label or sublabel identified by `labelName`. The label or sublabel must be in the label definition creator object `ldc`.

Examples

Modify Description of Label and Sublabel in Label Definition Creator Object

Load an existing label definitions table into the workspace.

```
load('editlabelDefs.mat')
```

Create a label definition creator object from the label definitions table.

```
ldc = labelDefinitionCreator(labelDefs)
```

```
ldc =
labelDefinitionCreator contains the following labels:

    Vehicle with 0 sublabels and 3 attributes and belongs to None group.    (info)
    Pedestrian with 0 sublabels and 0 attributes and belongs to None group.    (info)
    LaneMarker with 0 sublabels and 2 attributes and belongs to None group.    (info)
    TrafficLight with 1 sublabels and 0 attributes and belongs to None group.    (info)

For more details about attributes and sublabels, use the info method.
```

Modify the Description of a Label

Display information about the label "LaneMarker".

```
info(ldc,'LaneMarker')
```

```
           Name: "LaneMarker"
           Type: Line
     LabelColor: {''}
          Group: "None"
     Attributes: ["BoundaryType"    "Location_wrt_Ego"]
      Sublabels: []
    Description: ''
```

Modify the description for the label "LaneMarker".

```
editLabelDescription(ldc,'LaneMarker','Use 5 or more points for curved lane lines.')
```

Display information about the label "LaneMarker" to verify the modified label description.

```
info(ldc,'LaneMarker')
```

```
           Name: "LaneMarker"
           Type: Line
     LabelColor: {''}
          Group: "None"
     Attributes: ["BoundaryType"    "Location_wrt_Ego"]
      Sublabels: []
    Description: 'Use 5 or more points for curved lane lines.'
```

Modify the Description of a Sublabel

Display information about the label "TrafficLight".

```
info(ldc,'TrafficLight')
```

```
           Name: "TrafficLight"
           Type: Rectangle
     LabelColor: {''}
          Group: "None"
     Attributes: []
      Sublabels: "Light"
    Description: 'Bounding box for the traffic light. Use sublabels to mark each individual ligh
```

Display information about the sublabel "Light" under the label "TrafficLight".

```
info(ldc,'TrafficLight/Light')
```

```
           Name: "Light"
           Type: Rectangle
     Attributes: ["Active"    "Color"]
      Sublabels: []
    Description: 'lights'
```

Modify the description for the sublabel "Light".

```
editLabelDescription(ldc,'TrafficLight/Light','Mark a tight bounding box around each light.')
```

Display information about the sublabel "Light" to verify the modified sublabel description.

```
info(ldc,'TrafficLight/Light')
```

```
           Name: "Light"
           Type: Rectangle
     Attributes: ["Active"    "Color"]
      Sublabels: []
    Description: 'Mark a tight bounding box around each light.'
```

Input Arguments

`ldc` — Label definition creator

`labelDefinitionCreator` object

Label definition creator, specified as a `labelDefinitionCreator` object.

`labelName` — Label or sublabel name

character vector | string scalar

Label or sublabel name, specified as a character vector or string scalar that uniquely identifies the label or sublabel for which the description is to be updated.

- To specify a label, use the form '*labelName*'.
- To specify a sublabel, use the form '*labelName/sublabelName*'.

`description` — Description
character vector | string scalar

Description, specified as a character vector or string scalar that contains the new description for the label or sublabel identified by `labelName`.

Version History

Introduced in R2018b

See Also

Objects
`labelDefinitionCreator` | `groundTruth`

Functions
`editAttributeDescription`

editLabelGroup

Modify a label group name

Syntax

```
editLabelGroup(ldc,labelName,groupName)
```

Description

`editLabelGroup(ldc,labelName,groupName)` modifies the group name that corresponds to the label identified by `labelName`. The label must be in the label definition creator object `ldc`.

Examples

Modify Group Name for Labels

Create a labelDefinitionCreator.

```
ldc = labelDefinitionCreator;
```

Add a rectangle label named `Car` in a group named `Vehicle`.

```
addLabel(ldc,'Car',labelType.Rectangle,'Group','Vehicle');
```

Add a rectangle label named `Truck` in a group named `FourWheeler`.

```
addLabel(ldc,'Truck',labelType.Rectangle,'Group','FourWheeler');
```

Move the `Car` label into the `FourWheeler` group.

```
editLabelGroup(ldc,'Car','FourWheeler');
```

Inspect the labels.

```
ldc
```

```
ldc =
labelDefinitionCreator contains the following labels:

    Car with 0 sublabels and 0 attributes and belongs to FourWheeler group.    (info)
    Truck with 0 sublabels and 0 attributes and belongs to FourWheeler group.    (info)

For more details about attributes and sublabels, use the info method.
```

Input Arguments

`ldc` — Label definition creator

`labelDefinitionCreator` object

Label definition creator, specified as a `labelDefinitionCreator` object.

`labelName` — Label name
character vector | string scalar

Label name, specified as a character vector or string scalar that uniquely identifies the label that corresponds to the `groupName` you want to modify.

`groupName` — Group name
character vector | string scalar

Group name, specified as a character vector or string scalar that identifies the group you want to modify, which corresponds to the label specified by `labelName`.

Version History

Introduced in R2019a

Objects
`labelDefinitionCreator`

Functions
`editLabelDescription` | `editGroupName`

editGroupName

Change group name

Syntax

```
editGroupName(ldc,oldname,newname)
```

Description

`editGroupName(ldc,oldname,newname)` changes the group name from `oldname` to `newname`. This function changes the group name in all the label definitions that have the `oldname`.

Examples

Rename Label Group Created with labelDefinitionCreator

Create a `labelDefinitionCreator`.

```
ldc = labelDefinitionCreator;
```

Add labels named `Car` and `Truck` in a group named `Vehicle`.

```
addLabel(ldc,'Car',labelType.Rectangle,'Group','Vehicle');
addLabel(ldc,'Truck',labelType.Rectangle,'Group','Vehicle');
```

Change the `Vehicle` group name `FourWheeler`.

```
editGroupName(ldc,'Vehicle','FourWheeler');
```

Inspect the labels.

```
ldc
```

```
ldc =
labelDefinitionCreator contains the following labels:

    Car with 0 sublabels and 0 attributes and belongs to FourWheeler group.    (info)
    Truck with 0 sublabels and 0 attributes and belongs to FourWheeler group.    (info)

For more details about attributes and sublabels, use the info method.
```

Input Arguments

`ldc` — Label definition creator

`labelDefinitionCreator` object

Label definition creator, specified as a `labelDefinitionCreator` object.

`oldname` — Old group name

character vector | string scalar

Old group name, specified as a character vector or string scalar that uniquely identifies group name you want to modify.

`newname` — New group name
character vector | string scalar

New group name, specified as a character vector or string scalar that uniquely identifies the new group name.

Version History

Introduced in R2019a

Objects
`labelDefinitionCreator`

Functions
`editLabelDescription` | `editLabelGroup`

editAttributeDescription

Modify description of attribute in label definition creator object

Syntax

`editAttributeDescription(ldc,labelName,attributeName,description)`

Description

`editAttributeDescription(ldc,labelName,attributeName,description)` modifies the description of an attribute under the label or sublabel identified by `labelName`. The label or sublabel must be in the label definition creator object `ldc`.

Examples

Modify Description of Attributes in Label Definition Creator Object

Load an existing label definitions table into the workspace.

```
labelDefFile = fullfile(toolboxdir('vision'), 'visiondata', 'labelDefsWithAttributes.mat');
ld = load(labelDefFile)
```

```
ld = struct with fields:
    labelDefs: [4×4 table]
```

Create a label definition creator object from the label definitions table.

```
ldc = labelDefinitionCreator(ld.labelDefs)
```

```
ldc =
labelDefinitionCreator contains the following labels:

    Vehicle with 0 sublabels and 3 attributes and belongs to None group.    (info)
    Pedestrian with 0 sublabels and 0 attributes and belongs to None group.    (info)
    LaneMarker with 0 sublabels and 2 attributes and belongs to None group.    (info)
    TrafficLight with 1 sublabels and 0 attributes and belongs to None group.    (info)

For more details about attributes and sublabels, use the info method.
```

Modify the Description of Attribute Under a Label

Display information about the label "Vehicle".

```
info(ldc,'Vehicle')
```

```
           Name: "Vehicle"
           Type: Rectangle
     LabelColor: {''}
          Group: "None"
     Attributes: ["Class"    "Color"    "View"]
```

```
      Sublabels: []
    Description: 'Draw a tight bounding box around the vehicle. Use this label for cars, buses ar
```

Display information about the attribute "Color" under the label "Vehicle".

```
info(ldc,'Vehicle/Color')
```

```
           Name: "Color"
           Type: String
    DefaultValue: ""
     Description: 'Color of the vehicle, specified as a string, such as red, blue, white.'
```

Modify the description of the attribute "Color" under the label "Vehicle".

```
editAttributeDescription(ldc,'Vehicle','Color','Color of the vehicle, specified as a string, e.g
```

Display information about the label "Vehicle" to verify the modified attribute description.

```
info(ldc,'Vehicle/Color')
```

```
           Name: "Color"
           Type: String
    DefaultValue: ""
     Description: 'Color of the vehicle, specified as a string, e.g. "red".'
```

Modify the Description of Attribute Under a Sublabel

Display information about the label "TrafficLight".

```
info(ldc,'TrafficLight')
```

```
          Name: "TrafficLight"
          Type: Rectangle
     LabelColor: {''}
         Group: "None"
     Attributes: []
      Sublabels: "Light"
    Description: 'Mark a tight bounding box around the traffic light. Use the sublabels to mark e
```

Display information about the sublabel "Light" under the label "TrafficLight".

```
info(ldc,'TrafficLight/Light')
```

```
          Name: "Light"
          Type: Rectangle
     Attributes: ["Active"    "Color"]
      Sublabels: []
    Description: 'Mark a tight bounding box around each light.'
```

Display information about the attribute "Active" under the sublabel "TrafficLight/Light".

```
info(ldc,'TrafficLight/Light/Active')
```

```
           Name: "Active"
           Type: Logical
    DefaultValue: 0
     Description: 'Mark true if this light is active and false if not.'
```

Modify the description of the attribute "Active" under the sublabel "TrafficLight/Light".

```
editAttributeDescription(ldc,'TrafficLight/Light','Active','Is Active: true (DefaultValue: 1), fa
```

Display information about the attribute "Active" to verify the modified attribute description.

```
info(ldc,'TrafficLight/Light/Active')
```

```
            Name: "Active"
            Type: Logical
    DefaultValue: 0
     Description: 'Is Active: true (DefaultValue: 1), false (DefaultValue: 0)'
```

Input Arguments

`ldc` — Label definition creator

`labelDefinitionCreator` object

Label definition creator, specified as a `labelDefinitionCreator` object.

`labelName` — Label or sublabel name

character vector | string scalar

Label or sublabel name, specified as a character vector or string scalar that uniquely identifies the label or sublabel to which the attribute is associated.

- To specify a label, use the form '*labelName*'.
- To specify a sublabel, use the form '*labelName/sublabelName*'. In this case, the attribute is associated with the sublabel.

`attributeName` — Attribute name

character vector | string scalar

Attribute name, specified as a character vector or string scalar that identifies the attribute for which the description is to be updated.

`description` — Description

character vector | string scalar

Description, specified as a character vector or string scalar that contains the new description for the attribute identified by `attributeName`.

Version History

Introduced in R2018b

See Also

Objects

`labelDefinitionCreator`

Functions

`editLabelDescription`

create

Create label definitions table from the label definition creator object

Syntax

```
labelDefs = create(ldc)
```

Description

`labelDefs = create(ldc)` creates a label definitions table, `labelDefs`, from the label definition creator object `ldc`. You can import the `labelDefs` table into the Image Labeler and Video Labeler apps to label ground truth data.

Examples

Create Label Definitions Table from Label Definition Creator Object

Create an empty label definition creator object.

```
ldc = labelDefinitionCreator
```

```
ldc =
labelDefinitionCreator
```

Add a label "Vehicle" to the label definition creator object. Specify the type of label as a rectangle and add a description to the label.

```
addLabel(ldc,'Vehicle','Rectangle','Description','Bounding box for the vehicle. Use this label fo
```

Add an attribute "IsCar" to the label "Vehicle". Specify the type of attribute as logical with value `true` and add description to the attribute.

```
addAttribute(ldc,'Vehicle','IsCar','logical',true,'Description','Type of vehicle')
```

Add an attribute "IsBus" to the label "Vehicle". Specify the type of attribute as logical with value `false` and add description to the attribute.

```
addAttribute(ldc,'Vehicle','IsBus','logical',false,'Description','Type of vehicle')
```

Create a label definitions table from the definitions stored in the label definition creator object.

```
labelDefs = create(ldc)
```

```
labelDefs=1×6 table
       Name          Type       LabelColor     Group                                  Description
    ___________    _________    __________    ________    ____________________________________________

    {'Vehicle'}    Rectangle    {0×0 char}    {'None'}    {'Bounding box for the vehicle. Use thi
```

Input Arguments

`ldc` — Label definition creator

`labelDefinitionCreator` object

Label definition creator, specified as a `labelDefinitionCreator` object. The object `ldc` defines the labels, sublabels, and attributes used for generating the label definitions table `labelDefs`.

Output Arguments

`labelDefs` — Label definitions

table

Label definitions, returned as a table with up to seven columns. The possible columns are *Name*, *Type*, *LabelColor*, *PixelLabelID*, *Group*, *Description*, and *Hierarchy*. This table specifies the definitions of labels, sublabels, and attributes for labeling ground truth data. For more details, see “LabelDefinitions” on page 2-0 .

Version History

Introduced in R2018b

Objects

`labelDefinitionCreator`

Functions

`addLabel` | `addSublabel` | `addAttribute` | `info`

info

Display information about a label, sublabel, or attribute stored in label definition creator object

Syntax

```
info(ldc,name)
infoStruct = info(ldc,name)
```

Description

`info(ldc,name)` displays information about the specified label, sublabel or attribute stored in the label definition creator object `ldc`.

`infoStruct = info(ldc,name)` returns the information as a structure.

Examples

Display Information About Definitions Stored in Label Definition Creator Object

Load an existing label definitions table into the workspace. Create a label definition creator object.

```
FilePath = fullfile(toolboxdir('vision'),'visiondata','labelDefsWithAttributes.mat');
Ld = load(FilePath);
ldc = labelDefinitionCreator(Ld.labelDefs)
```

```
ldc =
labelDefinitionCreator contains the following labels:

    Vehicle with 0 sublabels and 3 attributes and belongs to None group.    (info)
    Pedestrian with 0 sublabels and 0 attributes and belongs to None group.    (info)
    LaneMarker with 0 sublabels and 2 attributes and belongs to None group.    (info)
    TrafficLight with 1 sublabels and 0 attributes and belongs to None group.    (info)

For more details about attributes and sublabels, use the info method.
```

Get information about the label "TrafficLight" as a structured data.

```
trafficStruct = info(ldc,'TrafficLight')
```

```
trafficStruct = struct with fields:
           Name: "TrafficLight"
           Type: Rectangle
     LabelColor: {''}
          Group: "None"
     Attributes: []
      Sublabels: "Light"
    Description: 'Mark a tight bounding box around the traffic light. Use the sublabels to mark e
```

Get information about the sublabel "Light" under the label "TrafficLight" as a structured data.

```
lightStruct = info(ldc,'TrafficLight/Light')
```

```
lightStruct = struct with fields:
           Name: "Light"
           Type: Rectangle
     Attributes: ["Active"    "Color"]
      Sublabels: []
    Description: 'Mark a tight bounding box around each light.'
```

Get information about the attribute "Color" under the sublabel "TrafficLight/Light" as a structured data.

```
colorStruct = info(ldc,'TrafficLight/Light/Color')
```

```
colorStruct = struct with fields:
           Name: "Color"
           Type: List
      ListItems: {3×1 cell}
    Description: 'Specify the color of the light as one of Red, Yellow (amber) or Green.'
```

Display the `ListItems` field of the structure `colorStruct`.

```
colorStruct.ListItems
```

```
ans = 3×1 cell
    {'Red'   }
    {'Yellow'}
    {'Green' }
```

Input Arguments

`ldc` — Label definition creator

`labelDefinitionCreator` object

Label definition creator, specified as a `labelDefinitionCreator` object.

`name` — Name of label, sublabel, or attribute

character vector | string scalar

Name of label, sublabel, or attribute in the `ldc` object, specified as a character vector or string scalar whose form depends on the type of name you specify.

- To specify a label, use the form '*labelName*'.
- To specify a sublabel, use the form '*labelName/sublabelName*'.
- To specify an attribute, use the form '*labelName/sublabelName/attributeName*'.

Output Arguments

`infoStruct` — Information structure

structure

Information structure, returned as a structure that contains the fields `Name`, `Type`, `Attributes` (when pertinent), `Sublabels` (when pertinent), and `Description`. If `name` specifies an attribute, then `infoStruct` also contains the fields `DefaultValue` and `ListItems` (for List attributes).

Version History

Introduced in R2018b

See Also

Objects
`labelDefinitionCreator`

Functions
`addLabel` | `create`

vision.DeployableVideoPlayer

Namespace: `vision`

Display video

Description

The `DeployableVideoPlayer` object displays video frames. This player is capable of displaying high definition video at high frame rates. This video player object supports C code generation.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Creation

Syntax

```
depVideoPlayer = vision.DeployableVideoPlayer
depVideoPlayer = vision.DeployableVideoPlayer(Name,Value)
```

Description

`depVideoPlayer = vision.DeployableVideoPlayer` returns a video player `depVideoPlayer`, for displaying video frames. This object, unlike the `vision.VideoPlayer` object, can generate C code.

`depVideoPlayer = vision.DeployableVideoPlayer(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `depVideoPlayer = vision.DeployableVideoPlayer('Name','Caption title')`

Properties

`Location` — Bottom left corner of video window

[ ] (default) | two-element vector

Location of bottom left corner of video frame, specified as a two-element vector. The first and second elements are specified in pixels and represent the horizontal and vertical coordinates respectively. The coordinates `[0 0]` represent the bottom left corner of the screen. The default location depends on the screen resolution, and will result in a window positioned in the center of the screen.

`Name` — Video window title bar caption

`'Deployable Video Player'`

Video window title bar caption, specified as the comma-separated pair consisting of '`Name`' and a character vector.

`Size` — Size of video display window
`True size (1:1)` (default) | `Full-screen` | `Custom`

Size of video display window, specified as the comma-separated pair consisting of '`Size`' and `Full-screen`, `True size (1:1)` or `Custom`. When this property is set to `Full-screen`, use the `Esc` key to exit out of full-screen mode.

`CustomSize` — Custom size for video player window
`[300 410]` (default) | two-element vector

Custom size for video player window, specified as the comma-separated pair consisting of '`CustomSize`' and a two-element vector. The first and second elements are specified in pixels and represent the horizontal and vertical components respectively. The video data will be resized to fit the window. This property applies when you set the `Size` property to `Custom`.

`InputColorFormat` — Color format of input signal
`RGB` (default) | `'YCbCr 4:2:2'`

Color format of input signal, specified as the comma-separated pair consisting of '`InputColorFormat`' and `'RGB'` or `'YCbCr 4:2:2'`. The number of columns in the Cb and Cr components must be half the number of columns in Y.

Usage

Syntax

```
depVideoPlayer(videoFrame)
depVideoPlayer(videoFrame,Y,Cb,Cr)
```

Description

`depVideoPlayer(videoFrame)` displays one grayscale or truecolor RGB video frame in the video player.

`depVideoPlayer(videoFrame,Y,Cb,Cr)` displays one frame of YCbCr 4:2:2 video in the color components Y, Cb, and Cr when you set the `InputColorFormat` property to `YCbCr 4:2:2`. The number of columns in the Cb and Cr components must be half the number of columns in the Y component.

Input Arguments

`videoFrame` — Video frame
truecolor | 2-D grayscale image

Video frame, specified as a truecolor or 2-D grayscale image.

`Y,Cb,Cr` — YCbCr color format
`'YCbCr 4:2:2'`

YCbCr color format, returned in the `YCbCr 4:2:2` format.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to vision.DeployableVideoPlayer

isOpen	Visible or hidden status for player

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Play a Video from a File

Create a video reader and a video player object to read and view a video file.

```
vidReader = VideoReader('atrium.mp4');
depVideoPlayer = vision.DeployableVideoPlayer;
```

Continue to read frames of video until the last frame is read. Exit the loop if the user closes the video player window.

```
while hasFrame(vidReader)
    videoFrame = readFrame(vidReader);
    depVideoPlayer(videoFrame);
end
```

Release the video player object.

```
release(depVideoPlayer);
```

Version History

Introduced in R2012a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Generated code for this function uses a precompiled platform-specific shared library.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

Functions
`delete`

Simulink.ImageType

Specify image data type

Description

Use a `Simulink.ImageType` object to set and share image data types for signal, state, and parameter data in a model.

1. Create an instance of this class in the MATLAB base workspace.
2. Set the properties of the object to describe the image.
3. Assign the data type to supported blocks, which have a **Data type** parameter, that you want to conform to the data type.

The benefits of the `Simulink.ImageType` data type include:

- Strong typing of image data at model interfaces.
- Carrying image data attributes such as color format and pixel data type, eliminating the need to create and maintain secondary signals.
- Enabling the Simulink environment to interpret the data as an image.
- Enabling custom data type replacement with third party implementation, such as the OpenCV class `cv::Mat`.

Note To simulate a model that contains `Simulink.ImageType` signal, set the model configuration parameter **Language** (`SimTargetLang`) to `C++`.

Creation

To create a `Simulink.ImageType` object programmatically, use the `Simulink.ImageType` function described below.

Syntax

```
imageType = Simulink.ImageType
imageType = Simulink.ImageType(Rows,Columns,Channels)
imageType = Simulink.ImageType(Rows,Columns,Channels,'ClassUnderlying',
ClassUnderlying,'ColorFormat',ColorFormat,'Layout',Layout)
```

Description

`imageType = Simulink.ImageType` returns a `Simulink.Parameter` object with default property values.

`imageType = Simulink.ImageType(Rows,Columns,Channels)` returns a `Simulink.ImageType` object and initializes the `Rows`, `Columns`, and `Channels` property to the specified values.

`imageType = Simulink.ImageType(Rows,Columns,Channels,'ClassUnderlying', ClassUnderlying,'ColorFormat',ColorFormat,'Layout',Layout)` returns a `Simulink.ImageType` object and additionally initializes the optional properties `ClassUnderlying`, `ColorFormat`, and `Layout` to the specified values.

Properties

`Rows` — Number of rows in image data

`480` (default) | positive integer

Number of rows in the image data, specified as a positive integer.

Example: `480`

Data Types: `double`

`Columns` — Number of columns in image data

`640` (default) | positive integer

Number of columns in the image data, specified as a positive integer.

Example: `640`

Data Types: `double`

`Channels` — Number of color channels or samples for each pixel in array

`3` (default) | `1` | `4`

Number of color channels or samples for each pixel in the array, specified as `1`, `3`, or `4`. The number of channels must correspond to the number of color channels in the color format of the image data. These are the values of `Channels` for the supported color formats:

Color Format	Channels
`Grayscale`	1
`RGB`	3
`BGR`	3
`BGRA`	4

Example: `3`

Data Types: `double`

`ClassUnderlying` — Data type of underlying image data

`'uint8'` (default) | `'int8'` | `'uint16'` | `'int16'` | `'uint32'` | `'int32'` | `'single'` | `'double'` | `'boolean'`

Data type of the underlying image data, specified as one of these values:

- `'uint8'`
- `'int8'`
- `'uint16'`
- `'int16'`

- `'uint32'`
- `'int32'`
- `'single'`
- `'double'`
- `'boolean'`

Example: `'uint8'`

Data Types: `char` | `string`

`ColorFormat` — Color format of underlying image data
`'RGB'` (default) | `'Grayscale'` | `'BGR'` | `'BGRA'`

Color format of the underlying image data, specified as `'RGB'`, `'Grayscale'`, `'BGR'`, or `'BGRA'`. The color format determines what each color channel of a pixel in the image represents.

Example: `'RGB'`

Data Types: `char` | `string`

`Layout` — Memory arrangement of matrix data in image
`'ColumnMajor'` (default) | `'RowMajor'`

Memory arrangement of the matrix data in the image, specified as `'ColumnMajor'` or `'RowMajor'`.

Example: `'ColumnMajor'`

Data Types: `char` | `string`

Examples

Configure Data as `Simulink.ImageType` Data Type

1 Create a `Simulink.ImageType` object with default values.

```
imageType = Simulink.ImageType;
```

```
imageType =

  ImageType with properties:

              Rows: 480
              Cols: 640
          Channels: 3
    ClassUnderlying: 'uint8'
        ColorFormat: 'RGB'
             Layout: 'ColumnMajor'
```

2 Set the properties of the object to describe the image.

```
imageType.Rows = 720
imageType.Cols = 860
```

You can then reference this object from supported blocks that have a **Data type** field parameter.

Limitations

These blocks support simulation and code generation of a `Simulink.ImageType` object:

Block Library	Block Name
Sources	• Ground • From Multimedia File
Signal Routing	• Goto • From • Data Store Read • Data Store Write • Data Store Memory • Switch • Multiport Switch • Merge • Variant Source • Variant Merge (internal block added during code generation) • Mux • Demux • Vector Concatenate, Matrix Concatenate • Selector
Sinks	• Terminator • To Workspace (simulation only) • Record (simulation only) • Video Viewer (simulation only)
Ports & Subsystems	• Inport • Outport • Subsystem • Enabled Subsystem • Triggered Subsystem • Function-Call Subsystem • Resettable Subsystem • For Iterator Subsystem • Model
Discrete	• Unit Delay
Signal Attributes	• Signal Conversion • Signal Specification

Block Library	Block Name
User-Defined Functions	• Initialize Function • Reset Function • Terminate Function • Simulink Function block with side I/O and arguments

Version History

Introduced in R2021b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports C++ code generation. To generate code, set the model configuration parameter **Language** (`TargetLang`) to `C++` and the **Language standard** to `C++11 (ISO)`.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

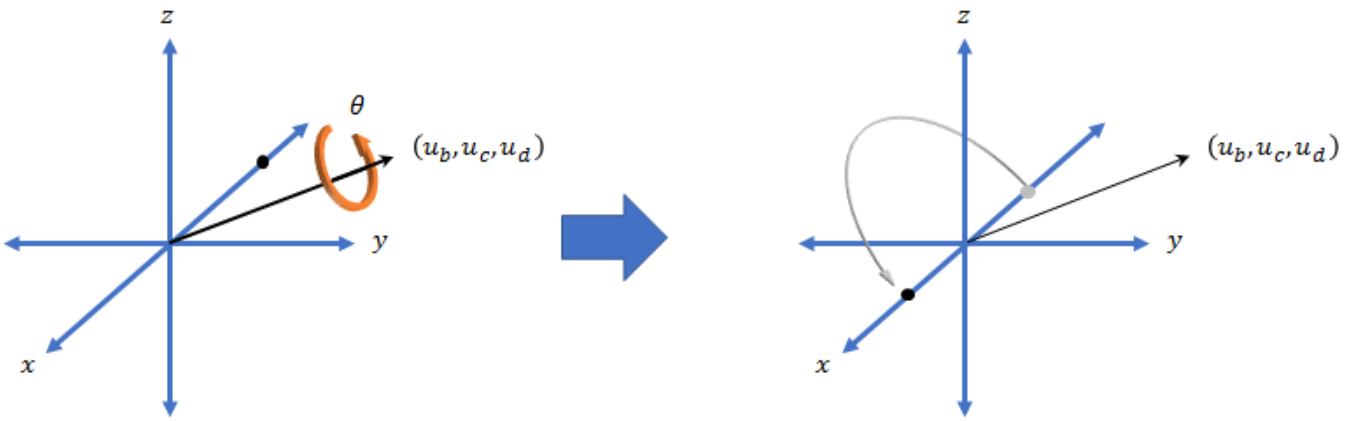
quaternion

Create quaternion array



Description

A quaternion is a four-part hyper-complex number used in three-dimensional rotations and orientations.

A quaternion number is represented in the form $a + b\mathrm{i} + c\mathrm{j} + d\mathrm{k}$, where a, b, c, and d parts are real numbers, and i, j, and k are the basis elements, satisfying the equation: $\mathrm{i}^2 = \mathrm{j}^2 = \mathrm{k}^2 = \mathrm{ijk} = -1$.

The set of quaternions, denoted by **H**, is defined within a four-dimensional vector space over the real numbers, $\mathbf{R}^4$. Every element of **H** has a unique representation based on a linear combination of the basis elements, i, j, and k.

All rotations in 3-D can be described by an axis of rotation and angle about that axis. An advantage of quaternions over rotation matrices is that the axis and angle of rotation is easy to interpret. For example, consider a point in $\mathbf{R}^3$. To rotate the point, you define an axis of rotation and an angle of rotation.

The quaternion representation of the rotation can be expressed as $q = \cos\left(\theta/2\right) + \sin\left(\theta/2\right)(u_b\mathrm{i} + u_c\mathrm{j} + u_d\mathrm{k})$, where θ is the angle of rotation and [u_b, u_c, and u_d] is the axis of rotation.

Creation

Syntax

```
quat = quaternion()
quat = quaternion(A,B,C,D)
quat = quaternion(matrix)
quat = quaternion(RV,"rotvec")
```

```
quat = quaternion(RV,"rotvecd")
quat = quaternion(RM,"rotmat",PF)
quat = quaternion(E,"euler",RS,PF)
quat = quaternion(E,"eulerd",RS,PF)
```

Description

`quat = quaternion()` creates an empty quaternion.

`quat = quaternion(A,B,C,D)` creates a quaternion array where the four quaternion parts are taken from the arrays `A`, `B`, `C`, and `D`. All the inputs must have the same size and be of the same data type.

`quat = quaternion(matrix)` creates an *N*-by-1 quaternion array from an *N*-by-4 matrix, where each column becomes one part of the quaternion.

`quat = quaternion(RV,"rotvec")` creates an *N*-by-1 quaternion array from an *N*-by-3 matrix of rotation vectors, `RV`. Each row of `RV` represents a rotation vector in radians.

`quat = quaternion(RV,"rotvecd")` creates an *N*-by-1 quaternion array from an *N*-by-3 matrix of rotation vectors, `RV`. Each row of `RV` represents a rotation vector in degrees.

`quat = quaternion(RM,"rotmat",PF)` creates an *N*-by-1 quaternion array from the 3-by-3-by-*N* array of rotation matrices, `RM`. `PF` can be either `"point"` if the Euler angles represent point rotations or `"frame"` for frame rotations.

`quat = quaternion(E,"euler",RS,PF)` creates an *N*-by-1 quaternion array from the *N*-by-3 matrix, `E`. Each row of `E` represents a set of Euler angles in radians. The angles in `E` are rotations about the axes in sequence `RS`.

`quat = quaternion(E,"eulerd",RS,PF)` creates an *N*-by-1 quaternion array from the *N*-by-3 matrix, `E`. Each row of `E` represents a set of Euler angles in degrees. The angles in `E` are rotations about the axes in sequence `RS`.

Input Arguments

`A,B,C,D` — Quaternion parts

comma-separated arrays of the same size

Parts of a quaternion, specified as four comma-separated scalars, matrices, or multi-dimensional arrays of the same size.

Example: `quat = quaternion(1,2,3,4)` creates a quaternion of the form 1 + 2i + 3j + 4k.

Example: `quat = quaternion([1,5],[2,6],[3,7],[4,8])` creates a 1-by-2 quaternion array where `quat(1,1) = 1 + 2i + 3j + 4k` and `quat(1,2) = 5 + 6i + 7j + 8k`

Data Types: `single` | `double`

`matrix` — Matrix of quaternion parts

N-by-4 matrix

Matrix of quaternion parts, specified as an *N*-by-4 matrix. Each row represents a separate quaternion. Each column represents a separate quaternion part.

Example: `quat = quaternion(rand(10,4))` creates a 10-by-1 quaternion array.

Data Types: `single` | `double`

`RV` — Matrix of rotation vectors
N-by-3 matrix

Matrix of rotation vectors, specified as an *N*-by-3 matrix. Each row of `RV` represents the [X Y Z] elements of a rotation vector. A rotation vector is a unit vector representing the axis of rotation scaled by the angle of rotation in radians or degrees.

To use this syntax, specify the first argument as a matrix of rotation vectors and the second argument as the `"rotvec"` or `"rotvecd"`.

Example: `quat = quaternion(rand(10,3),"rotvec")` creates a 10-by-1 quaternion array.

Data Types: `single` | `double`

`RM` — Rotation matrices
3-by-3 matrix | 3-by-3-by-*N* array

Array of rotation matrices, specified by a 3-by-3 matrix or 3-by-3-by-*N* array. Each page of the array represents a separate rotation matrix.

Example: `quat = quaternion(rand(3),"rotmat","point")`

Example: `quat = quaternion(rand(3),"rotmat","frame")`

Data Types: `single` | `double`

`PF` — Type of rotation matrix
`"point"` | `"frame"`

Type of rotation matrix, specified by `"point"` or `"frame"`.

Example: `quat = quaternion(rand(3),"rotmat","point")`

Example: `quat = quaternion(rand(3),"rotmat","frame")`

Data Types: `char` | `string`

`E` — Matrix of Euler angles
N-by-3 matrix

Matrix of Euler angles, specified by an *N*-by-3 matrix. If using the `"euler"` syntax, specify `E` in radians. If using the `"eulerd"` syntax, specify `E` in degrees.

Example: `quat = quaternion(E,"euler","YZY","point")`

Example: `quat = quaternion(E,"euler","XYZ","frame")`

Data Types: `single` | `double`

`RS` — Rotation sequence
character vector | scalar string

Rotation sequence, specified as a three-element character vector:

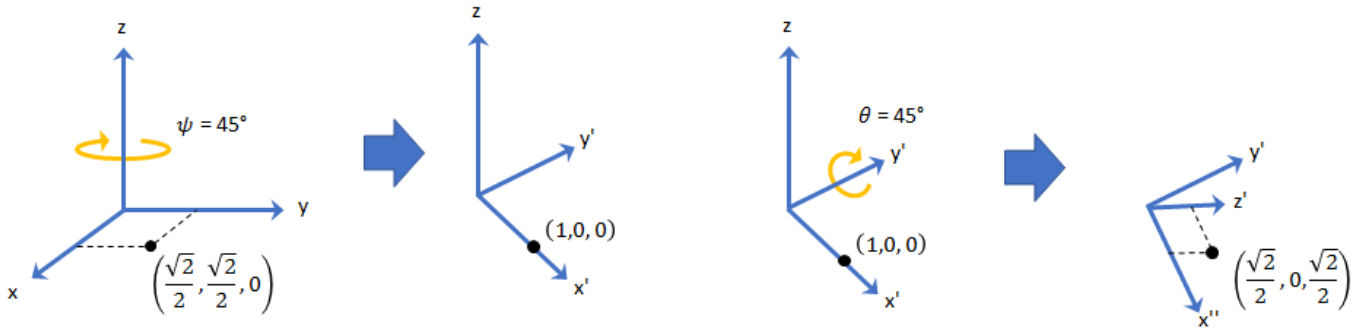
- `"YZY"`
- `"YXY"`
- `"ZYZ"`

- "ZXZ"
- "XYX"
- "XZX"
- "XYZ"
- "YZX"
- "ZXY"
- "XZY"
- "ZYX"
- "YXZ"

Assume you want to determine the new coordinates of a point when its coordinate system is rotated using frame rotation. The point is defined in the original coordinate system as:

```
point = [sqrt(2)/2,sqrt(2)/2,0];
```

In this representation, the first column represents the *x*-axis, the second column represents the *y*-axis, and the third column represents the *z*-axis.



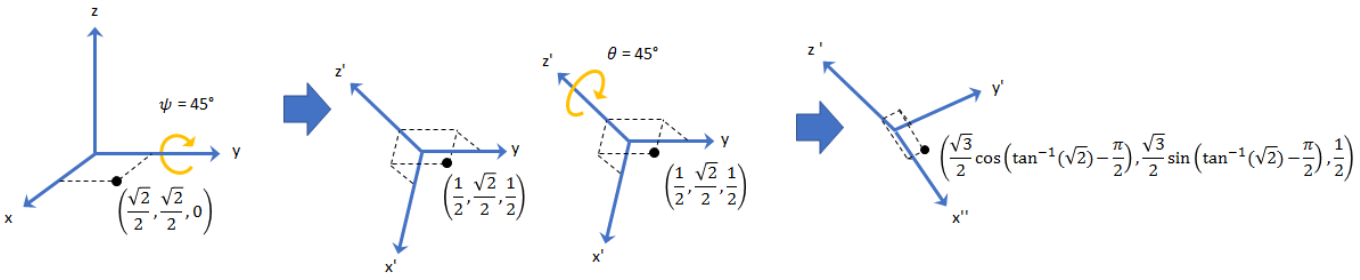
You want to rotate the point using the Euler angle representation [45,45,0]. Rotate the point using two different rotation sequences:

- If you create a quaternion rotator and specify the "ZYX" sequence, the frame is first rotated 45° around the *z*-axis, then 45° around the new *y*-axis.

  ```
  quatRotator = quaternion([45,45,0],"eulerd","ZYX","frame");
  newPointCoordinate = rotateframe(quatRotator,point)
  ```

  ```
  newPointCoordinate =

      0.7071   -0.0000    0.7071
  ```



- If you create a quaternion rotator and specify the "YZX" sequence, the frame is first rotated 45° around the *y*-axis, then 45° around the new *z*-axis.

  ```
  quatRotator = quaternion([45,45,0],"eulerd","YZX","frame");
  newPointCoordinate = rotateframe(quatRotator,point)
  ```

  ```
  newPointCoordinate =

      0.8536    0.1464    0.5000
  ```

Data Types: `char` | `string`

Object Functions

Construction and Conversion

compact	Convert quaternion array to N-by-4 matrix
eulerd	Convert quaternion to Euler angles (degrees)
euler	Convert quaternion to Euler angles (radians)
rotmat	Convert quaternion to rotation matrix
rotvec	Convert quaternion to rotation vector (radians)
rotvecd	Convert quaternion to rotation vector (degrees)
ones	Create quaternion array with real parts set to one and imaginary parts set to zero
parts	Extract quaternion parts
randrot	Uniformly distributed random rotations
zeros	Create quaternion array with all parts set to zero

Rotation

rotateframe	Quaternion frame rotation
rotatepoint	Quaternion point rotation

Normalization

norm	Quaternion norm
normalize	Quaternion normalization

Computations on Quaternions

angvel	Angular velocity from quaternion array
dist	Angular distance in radians
exp	Exponential of quaternion array
interp1	Quaternion interpolation (table lookup)
log	Natural logarithm of quaternion array
meanrot	Quaternion mean rotation
slerp	Spherical linear interpolation

Arithmetic Operations

conj	Complex conjugate of quaternion
ctranspose, '	Complex conjugate transpose of quaternion array
ldivide, .\	Element-wise quaternion left division
minus, -	Quaternion subtraction

mldivide, \	Quaternion left division for scalars
mrdivide, /	Quaternion right division for scalars
mtimes, *	Quaternion multiplication
power	Element-wise quaternion power
prod	Product of quaternion array
rdivide, ./	Element-wise quaternion right division
times	Element-wise quaternion multiplication
transpose, .'	Transpose quaternion array
uminus, -	Quaternion unary minus

Examples

Create Empty Quaternion

```
quat = quaternion()
```

```
quat =

  0×0 empty quaternion array
```

By default, the underlying class of the quaternion is a double.

```
classUnderlying(quat)
```

```
ans =
'double'
```

Create Quaternion by Specifying Individual Quaternion Parts

You can create a quaternion array by specifying the four parts as comma-separated scalars, matrices, or multidimensional arrays of the same size.

Define quaternion parts as scalars.

```
A = 1.1;
B = 2.1;
C = 3.1;
D = 4.1;
quatScalar = quaternion(A,B,C,D)
```

```
quatScalar = quaternion
     1.1 + 2.1i + 3.1j + 4.1k
```

Define quaternion parts as column vectors.

```
A = [1.1;1.2];
B = [2.1;2.2];
C = [3.1;3.2];
D = [4.1;4.2];
quatVector = quaternion(A,B,C,D)
```

```
quatVector = 2×1 quaternion array
     1.1 + 2.1i + 3.1j + 4.1k
```

```
     1.2 + 2.2i + 3.2j + 4.2k
```

Define quaternion parts as matrices.

```
A = [1.1,1.3; ...
     1.2,1.4];
B = [2.1,2.3; ...
     2.2,2.4];
C = [3.1,3.3; ...
     3.2,3.4];
D = [4.1,4.3; ...
     4.2,4.4];
quatMatrix = quaternion(A,B,C,D)
```

```
quatMatrix = 2×2 quaternion array
     1.1 + 2.1i + 3.1j + 4.1k     1.3 + 2.3i + 3.3j + 4.3k
     1.2 + 2.2i + 3.2j + 4.2k     1.4 + 2.4i + 3.4j + 4.4k
```

Define quaternion parts as three dimensional arrays.

```
A = randn(2,2,2);
B = zeros(2,2,2);
C = zeros(2,2,2);
D = zeros(2,2,2);
quatMultiDimArray = quaternion(A,B,C,D)
```

```
quatMultiDimArray = 2×2×2 quaternion array
quatMultiDimArray(:,:,1) =

     0.53767 +       0i +       0j +       0k     -2.2588 +       0i +       0j +       0k
      1.8339 +       0i +       0j +       0k     0.86217 +       0i +       0j +       0k

quatMultiDimArray(:,:,2) =

     0.31877 +       0i +       0j +       0k    -0.43359 +       0i +       0j +       0k
     -1.3077 +       0i +       0j +       0k     0.34262 +       0i +       0j +       0k
```

Create Quaternion by Specifying Quaternion Parts Matrix

You can create a scalar or column vector of quaternions by specify an *N*-by-4 matrix of quaternion parts, where columns correspond to the quaternion parts A, B, C, and D.

Create a column vector of random quaternions.

```
quatParts = rand(3,4)
```

```
quatParts = 3×4

    0.8147    0.9134    0.2785    0.9649
    0.9058    0.6324    0.5469    0.1576
    0.1270    0.0975    0.9575    0.9706
```

```
quat = quaternion(quatParts)
```

```
quat = 3×1 quaternion array
     0.81472 + 0.91338i +  0.2785j + 0.96489k
     0.90579 + 0.63236i + 0.54688j + 0.15761k
     0.12699 + 0.09754i + 0.95751j + 0.97059k
```

To retrieve the `quatParts` matrix from quaternion representation, use `compact`.

```
retrievedquatParts = compact(quat)

retrievedquatParts = 3×4

    0.8147    0.9134    0.2785    0.9649
    0.9058    0.6324    0.5469    0.1576
    0.1270    0.0975    0.9575    0.9706
```

Create Quaternion by Specifying Rotation Vectors

You can create an *N*-by-1 quaternion array by specifying an *N*-by-3 matrix of rotation vectors in radians or degrees. Rotation vectors are compact spatial representations that have a one-to-one relationship with normalized quaternions.

Rotation Vectors in Radians

Create a scalar quaternion using a rotation vector and verify the resulting quaternion is normalized.

```
rotationVector = [0.3491,0.6283,0.3491];
quat = quaternion(rotationVector,"rotvec")

quat = quaternion
     0.92124 + 0.16994i + 0.30586j + 0.16994k

norm(quat)

ans =
1.0000
```

You can convert from quaternions to rotation vectors in radians using the `rotvec` function. Recover the `rotationVector` from the quaternion, `quat`.

```
rotvec(quat)

ans = 1×3

    0.3491    0.6283    0.3491
```

Rotation Vectors in Degrees

Create a scalar quaternion using a rotation vector and verify the resulting quaternion is normalized.

```
rotationVector = [20,36,20];
quat = quaternion(rotationVector,"rotvecd")
```

```
quat = quaternion
     0.92125 + 0.16993i + 0.30587j + 0.16993k
```

```
norm(quat)

ans =
1
```

You can convert from quaternions to rotation vectors in degrees using the `rotvecd` function. Recover the `rotationVector` from the quaternion, `quat`.

```
rotvecd(quat)

ans = 1×3

   20.0000   36.0000   20.0000
```

Create Quaternion by Specifying Rotation Matrices

You can create an N-by-1 quaternion array by specifying a 3-by-3-by-N array of rotation matrices. Each page of the rotation matrix array corresponds to one element of the quaternion array.

Create a scalar quaternion using a 3-by-3 rotation matrix. Specify whether the rotation matrix should be interpreted as a frame or point rotation.

```
rotationMatrix = [1 0         0; ...
                  0 sqrt(3)/2 0.5; ...
                  0 -0.5      sqrt(3)/2];
quat = quaternion(rotationMatrix,"rotmat","frame")

quat = quaternion
     0.96593 + 0.25882i +       0j +       0k
```

You can convert from quaternions to rotation matrices using the `rotmat` function. Recover the `rotationMatrix` from the quaternion, `quat`.

```
rotmat(quat,"frame")

ans = 3×3

    1.0000         0         0
         0    0.8660    0.5000
         0   -0.5000    0.8660
```

Create Quaternion by Specifying Euler Angles

You can create an *N*-by-1 quaternion array by specifying an *N*-by-3 array of Euler angles in radians or degrees.

Euler Angles in Radians

Use the `euler` syntax to create a scalar quaternion using a 1-by-3 vector of Euler angles in radians. Specify the rotation sequence of the Euler angles and whether the angles represent a frame or point rotation.

```
E = [pi/2,0,pi/4];
quat = quaternion(E,"euler","ZYX","frame")
```

```
quat = quaternion
     0.65328 +  0.2706i +  0.2706j + 0.65328k
```

You can convert from quaternions to Euler angles using the `euler` function. Recover the Euler angles, `E`, from the quaternion, `quat`.

```
euler(quat,"ZYX","frame")
```

```
ans = 1×3

    1.5708         0    0.7854
```

Euler Angles in Degrees

Use the `eulerd` syntax to create a scalar quaternion using a 1-by-3 vector of Euler angles in degrees. Specify the rotation sequence of the Euler angles and whether the angles represent a frame or point rotation.

```
E = [90,0,45];
quat = quaternion(E,"eulerd","ZYX","frame")
```

```
quat = quaternion
     0.65328 +  0.2706i +  0.2706j + 0.65328k
```

You can convert from quaternions to Euler angles in degrees using the `eulerd` function. Recover the Euler angles, `E`, from the quaternion, `quat`.

```
eulerd(quat,"ZYX","frame")
```

```
ans = 1×3

   90.0000         0   45.0000
```

Quaternion Algebra

Quaternions form a noncommutative associative algebra over the real numbers. This example illustrates the rules of quaternion algebra.

Addition and Subtraction

Quaternion addition and subtraction occur part-by-part, and are commutative:

```
Q1 = quaternion(1,2,3,4)
```

```
Q1 = quaternion
     1 + 2i + 3j + 4k
```

```
Q2 = quaternion(9,8,7,6)

Q2 = quaternion
     9 + 8i + 7j + 6k
```

```
Q1plusQ2 = Q1 + Q2

Q1plusQ2 = quaternion
     10 + 10i + 10j + 10k
```

```
Q2plusQ1 = Q2 + Q1

Q2plusQ1 = quaternion
     10 + 10i + 10j + 10k
```

```
Q1minusQ2 = Q1 - Q2

Q1minusQ2 = quaternion
    -8 - 6i - 4j - 2k
```

```
Q2minusQ1 = Q2 - Q1

Q2minusQ1 = quaternion
     8 + 6i + 4j + 2k
```

You can also perform addition and subtraction of real numbers and quaternions. The first part of a quaternion is referred to as the *real* part, while the second, third, and fourth parts are referred to as the *vector*. Addition and subtraction with real numbers affect only the real part of the quaternion.

```
Q1plusRealNumber = Q1 + 5

Q1plusRealNumber = quaternion
     6 + 2i + 3j + 4k
```

```
Q1minusRealNumber = Q1 - 5

Q1minusRealNumber = quaternion
    -4 + 2i + 3j + 4k
```

Multiplication

Quaternion multiplication is determined by the products of the basis elements and the distributive law. Recall that multiplication of the basis elements, i, j, and k, are not commutative, and therefore quaternion multiplication is not commutative.

```
Q1timesQ2 = Q1 * Q2
```

```
Q1timesQ2 = quaternion
    -52 + 16i + 54j + 32k
```

```
Q2timesQ1 = Q2 * Q1
```

```
Q2timesQ1 = quaternion
    -52 + 36i + 14j + 52k
```

```
isequal(Q1timesQ2,Q2timesQ1)
```

```
ans = logical
   0
```

You can also multiply a quaternion by a real number. If you multiply a quaternion by a real number, each part of the quaternion is multiplied by the real number individually:

```
Q1times5 = Q1*5
```

```
Q1times5 = quaternion
      5 + 10i + 15j + 20k
```

Multiplying a quaternion by a real number is commutative.

```
isequal(Q1*5,5*Q1)
```

```
ans = logical
   1
```

Conjugation

The complex conjugate of a quaternion is defined such that each element of the vector portion of the quaternion is negated.

```
Q1
```

```
Q1 = quaternion
     1 + 2i + 3j + 4k
```

```
conj(Q1)
```

```
ans = quaternion
     1 - 2i - 3j - 4k
```

Multiplication between a quaternion and its conjugate is commutative:

```
isequal(Q1*conj(Q1),conj(Q1)*Q1)
```

```
ans = logical
   1
```

Quaternion Array Manipulation

You can organize quaternions into vectors, matrices, and multidimensional arrays. Built-in MATLAB® functions have been enhanced to work with quaternions.

Concatenate

Quaternions are treated as individual objects during concatenation and follow MATLAB rules for array manipulation.

```
Q1 = quaternion(1,2,3,4);
Q2 = quaternion(9,8,7,6);

qVector = [Q1,Q2]
```

```
qVector = 1×2 quaternion array
     1 + 2i + 3j + 4k     9 + 8i + 7j + 6k
```

```
Q3 = quaternion(-1,-2,-3,-4);
Q4 = quaternion(-9,-8,-7,-6);

qMatrix = [qVector;Q3,Q4]
```

```
qMatrix = 2×2 quaternion array
     1 + 2i + 3j + 4k     9 + 8i + 7j + 6k
    -1 - 2i - 3j - 4k    -9 - 8i - 7j - 6k
```

```
qMultiDimensionalArray(:,:,1) = qMatrix;
qMultiDimensionalArray(:,:,2) = qMatrix
```

```
qMultiDimensionalArray = 2×2×2 quaternion array
qMultiDimensionalArray(:,:,1) =

     1 + 2i + 3j + 4k     9 + 8i + 7j + 6k
    -1 - 2i - 3j - 4k    -9 - 8i - 7j - 6k

qMultiDimensionalArray(:,:,2) =

     1 + 2i + 3j + 4k     9 + 8i + 7j + 6k
    -1 - 2i - 3j - 4k    -9 - 8i - 7j - 6k
```

Indexing

To access or assign elements in a quaternion array, use indexing.

```
qLoc2 = qMultiDimensionalArray(2)
```

```
qLoc2 = quaternion
    -1 - 2i - 3j - 4k
```

Replace the quaternion at index two with a quaternion one.

```
qMultiDimensionalArray(2) = ones("quaternion")
```

```
qMultiDimensionalArray = 2×2×2 quaternion array
qMultiDimensionalArray(:,:,1) =

     1 + 2i + 3j + 4k     9 + 8i + 7j + 6k
     1 + 0i + 0j + 0k    -9 - 8i - 7j - 6k

qMultiDimensionalArray(:,:,2) =

     1 + 2i + 3j + 4k     9 + 8i + 7j + 6k
    -1 - 2i - 3j - 4k    -9 - 8i - 7j - 6k
```

Reshape

To reshape quaternion arrays, use the `reshape` function.

```
qMatReshaped = reshape(qMatrix,4,1)
```

```
qMatReshaped = 4×1 quaternion array
     1 + 2i + 3j + 4k
    -1 - 2i - 3j - 4k
     9 + 8i + 7j + 6k
    -9 - 8i - 7j - 6k
```

Transpose

To transpose quaternion vectors and matrices, use the `transpose` function.

```
qMatTransposed = transpose(qMatrix)
```

```
qMatTransposed = 2×2 quaternion array
     1 + 2i + 3j + 4k    -1 - 2i - 3j - 4k
     9 + 8i + 7j + 6k    -9 - 8i - 7j - 6k
```

Permute

To permute quaternion vectors, matrices, and multidimensional arrays, use the `permute` function.

```
qMultiDimensionalArray
```

```
qMultiDimensionalArray = 2×2×2 quaternion array
qMultiDimensionalArray(:,:,1) =

     1 + 2i + 3j + 4k     9 + 8i + 7j + 6k
     1 + 0i + 0j + 0k    -9 - 8i - 7j - 6k

qMultiDimensionalArray(:,:,2) =

     1 + 2i + 3j + 4k     9 + 8i + 7j + 6k
    -1 - 2i - 3j - 4k    -9 - 8i - 7j - 6k
```

```
qMatPermute = permute(qMultiDimensionalArray,[3,1,2])
```

```
qMatPermute = 2×2×2 quaternion array
qMatPermute(:,:,1) =
```

```
     1 + 2i + 3j + 4k     1 + 0i + 0j + 0k
     1 + 2i + 3j + 4k    -1 - 2i - 3j - 4k

qMatPermute(:,:,2) =

     9 + 8i + 7j + 6k    -9 - 8i - 7j - 6k
     9 + 8i + 7j + 6k    -9 - 8i - 7j - 6k
```

Version History

Introduced in R2023b

R2023b: Moved to Computer Vision Toolbox from Automated Driving Toolbox

The `quaternion` object and its object functions no longer require Automated Driving Toolbox.

R2025a: `interp1` object function for quaternion interpolation

Use the `interp1` object function to interpolate quaternions using interpolation methods such as SQUAD and SLERP.

R2025a: `slerp` object function supports natural interpolation

The `slerp` function now supports spherically interpolation using the `"natural"` path option, enabling smoother transitions that respect the orientation of the start and end quaternions.

Generate C and C++ code using MATLAB® Coder™.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

classUnderlying

Class of parts within quaternion

Syntax

```
underlyingClass = classUnderlying(quat)
```

Description

`underlyingClass = classUnderlying(quat)` returns the name of the class of the parts of the quaternion `quat`.

Examples

Get Underlying Class of Quaternion

A quaternion is a four-part hyper-complex number used in three-dimensional representations. The four parts of the quaternion are of data type `single` or `double`.

Create two quaternions, one with an underlying data type of `single`, and one with an underlying data type of `double`. Verify the underlying data types by calling `classUnderlying` on the quaternions.

```
qSingle = quaternion(single([1,2,3,4]))
```

```
qSingle = quaternion
     1 + 2i + 3j + 4k
```

```
classUnderlying(qSingle)
```

```
ans =
'single'
```

```
qDouble = quaternion([1,2,3,4])
```

```
qDouble = quaternion
     1 + 2i + 3j + 4k
```

```
classUnderlying(qDouble)
```

```
ans =
'double'
```

You can separate quaternions into their parts using the `parts` function. Verify the parts of each quaternion are the correct data type. Recall that `double` is the default MATLAB® type.

```
[aS,bS,cS,dS] = parts(qSingle)
```

```
aS = single

1

bS = single

2

cS = single

3

dS = single

4
```

```
[aD,bD,cD,dD] = parts(qDouble)

aD =
1

bD =
2

cD =
3

dD =
4
```

Quaternions follow the same implicit casting rules as other data types in MATLAB. That is, a quaternion with underlying data type `single` that is combined with a quaternion with underlying data type `double` results in a quaternion with underlying data type `single`. Multiply `qDouble` and `qSingle` and verify the resulting underlying data type is `single`.

```
q = qDouble*qSingle;
classUnderlying(q)

ans =
'single'
```

Input Arguments

`quat` — Quaternion to investigate

`quaternion` object | array of `quaternion` objects

Quaternion to investigate, specified as a `quaternion` object or an array of `quaternion` objects of any dimensionality.

Output Arguments

`underlyingClass` — Underlying class of quaternion object

`'single'` | `'double'`

Underlying class of quaternion, returned as the character vector `'single'` or `'double'`.

Data Types: `char`

`quaternion`

angvel

Angular velocity from quaternion array

Syntax

```
AV = angvel(quat,dt,"frame")
AV = angvel(quat,dt,"point")
[AV,qf] = angvel(quat,dt,fp,qi)
```

Description

`AV = angvel(quat,dt,"frame")` returns the angular velocity array from an array of quaternions, `quat`. The quaternions in `quat` correspond to frame rotation. The initial quaternion is assumed to represent zero rotation.

`AV = angvel(quat,dt,"point")` returns the angular velocity array from an array of quaternions, `quat`. The quaternions in `quat` correspond to point rotation. The initial quaternion is assumed to represent zero rotation.

`[AV,qf] = angvel(quat,dt,fp,qi)` allows you to specify the initial quaternion, `qi`, and the type of rotation, `fp`. It also returns the final quaternion, `qf`.

Examples

Generate Angular Velocity From Quaternion Array

Create an array of quaternions.

```
eulerAngles = [(0:10:90).',zeros(numel(0:10:90),2)];
q = quaternion(eulerAngles,'eulerd','ZYX','frame');
```

Specify the time step and generate the angular velocity array.

```
dt = 1;
av = angvel(q,dt,'frame') % units in rad/s
```

```
av = 10×3

         0         0         0
         0         0    0.1743
         0         0    0.1743
         0         0    0.1743
         0         0    0.1743
         0         0    0.1743
         0         0    0.1743
         0         0    0.1743
         0         0    0.1743
         0         0    0.1743
```

Input Arguments

`quat` — Quaternions

N-by-1 vector of `quaternion` objects

Quaternions, specified as an *N*-by-1 vector of `quaternion` objects.

`dt` — Time step

nonnegative scalar

Time step, specified as a nonnegative scalar.

Data Types: `single` | `double`

`fp` — Type of rotation

`"frame"` | `"point"`

Type of rotation, specified as `"frame"` or `"point"`.

`qi` — Initial quaternion

`quaternion` object

Initial quaternion, specified as a `quaternion` object.

Output Arguments

`AV` — Angular velocity

N-by-3 real matrix

Angular velocity, returned as an *N*-by-3 real matrix, where *N* is the number of quaternions in the `quat` argument. Each row of the matrix corresponds to an angular velocity vector.

`qf` — Final quaternion

`quaternion` object

Final quaternion, returned as a `quaternion` object. `qf` is the same as the last quaternion in the `quat` argument.

`quaternion`

compact

Convert quaternion array to *N*-by-4 matrix

Syntax

```
matrix = compact(quat)
```

Description

`matrix = compact(quat)` converts the quaternion array, `quat`, to an *N*-by-4 matrix. The columns are made from the four quaternion parts. The i^{th} row of the matrix corresponds to `quat(i)`.

Examples

Convert Quaternion Array to Compact Representation of Parts

Create a scalar quaternion with random parts. Convert the parts to a 1-by-4 vector using `compact`.

```
randomParts = randn(1,4)
```

```
randomParts = 1×4

    0.5377    1.8339   -2.2588    0.8622
```

```
quat = quaternion(randomParts)
```

```
quat = quaternion
     0.53767 +  1.8339i -  2.2588j + 0.86217k
```

```
quatParts = compact(quat)
```

```
quatParts = 1×4

    0.5377    1.8339   -2.2588    0.8622
```

Create a 2-by-2 array of quaternions, then convert the representation to a matrix of quaternion parts. The output rows correspond to the linear indices of the quaternion array.

```
quatArray = [quaternion([1:4;5:8]),quaternion([9:12;13:16])]
```

```
quatArray = 2×2 quaternion array
      1 +  2i +  3j +  4k      9 + 10i + 11j + 12k
      5 +  6i +  7j +  8k     13 + 14i + 15j + 16k
```

```
quatArrayParts = compact(quatArray)
```

```
quatArrayParts = 4×4
```

```
     1     2     3     4
     5     6     7     8
     9    10    11    12
    13    14    15    16
```

Input Arguments

`quat` — Quaternion to convert

`quaternion` object | array of `quaternion` objects

Quaternion to convert, specified as a `quaternion` object or an array of `quaternion` objects of any dimensionality.

Output Arguments

`matrix` — Quaternion in matrix form

N-by-4 numeric matrix

Quaternion in matrix form, returned as an *N*-by-4 numeric matrix, where *N* is the number of quaternions given in the input `quat`.

Data Types: `single` | `double`

Functions

`parts` | `classUnderlying`

Objects

`quaternion`

conj

Complex conjugate of quaternion

Syntax

```
quatConjugate = conj(quat)
```

Description

`quatConjugate = conj(quat)` returns the complex conjugate of the quaternion, `quat`.

If $q = a + b\mathrm{i} + c\mathrm{j} + d\mathrm{k}$, the complex conjugate of q is $q^* = a - b\mathrm{i} - c\mathrm{j} - d\mathrm{k}$. Considered as a rotation operator, the conjugate performs the opposite rotation. For example,

```
q = quaternion(deg2rad([16 45 30]),"rotvec");
a = q*conj(q);
rotatepoint(a,[0,1,0])
```

```
ans =

     0     1     0
```

Examples

Complex Conjugate of Quaternion

Create a quaternion scalar and get the complex conjugate.

```
q = normalize(quaternion([0.9 0.3 0.3 0.25]))
```

```
q = quaternion
     0.87727 + 0.29242i + 0.29242j + 0.24369k
```

```
qConj = conj(q)
```

```
qConj = quaternion
     0.87727 - 0.29242i - 0.29242j - 0.24369k
```

Verify that a quaternion multiplied by its conjugate returns a quaternion one.

```
q*qConj
```

```
ans = quaternion
     1 + 0i + 0j + 0k
```

Input Arguments

`quat` — Quaternion

`quaternion` object | array of `quaternion` objects

Quaternion to conjugate, specified as a `quaternion` object or an array of `quaternion` objects of any dimensionality.

Output Arguments

`quatConjugate` — Quaternion conjugate

`quaternion` object | array of `quaternion` objects

Quaternion conjugate, returned as a `quaternion` object or an array of `quaternion` objects of the same size as `quat`.

Objects

`quaternion`

ctranspose, '

Complex conjugate transpose of quaternion array

Syntax

```
quatTransposed = quat'
```

Description

`quatTransposed = quat'` returns the complex conjugate transpose of the quaternion, `quat`.

Examples

Vector Complex Conjugate Transpose

Create a vector of quaternions and compute its complex conjugate transpose.

```
quat = quaternion(randn(4,4))
```

```
quat = 4×1 quaternion array
      0.53767 +  0.31877i +   3.5784j +   0.7254k
       1.8339 -   1.3077i +   2.7694j - 0.063055k
      -2.2588 -  0.43359i -   1.3499j +  0.71474k
      0.86217 +  0.34262i +   3.0349j -  0.20497k
```

```
quatTransposed = quat'
```

```
quatTransposed = 1×4 quaternion array
      0.53767 -  0.31877i -   3.5784j -   0.7254k       1.8339 +   1.3077i -   2.7694j + 0.06305
```

Matrix Complex Conjugate Transpose

Create a matrix of quaternions and compute its complex conjugate transpose.

```
quat = [quaternion(randn(2,4)),quaternion(randn(2,4))]
```

```
quat = 2×2 quaternion array
      0.53767 -   2.2588i +  0.31877j -  0.43359k       3.5784 -   1.3499i +   0.7254j +  0.7147
       1.8339 +  0.86217i -   1.3077j +  0.34262k       2.7694 +   3.0349i - 0.063055j -  0.2049
```

```
quatTransposed = quat'
```

```
quatTransposed = 2×2 quaternion array
      0.53767 +   2.2588i -  0.31877j +  0.43359k       1.8339 -  0.86217i +   1.3077j -  0.3426
       3.5784 +   1.3499i -   0.7254j -  0.71474k       2.7694 -   3.0349i + 0.063055j +  0.2049
```

Input Arguments

`quat` — Quaternion to transpose

`quaternion` object | vector of `quaternion` objects | matrix of `quaternion` objects

Quaternion to transpose, specified as a `quaternion` object or a vector or matrix of `quaternion` objects. The complex conjugate transpose is defined for dimensionality up to 2.

Output Arguments

`quatTransposed` — Conjugate transposed quaternion

`quaternion` object | vector of `quaternion` objects | matrix of `quaternion` objects

Conjugate transposed quaternion, returned as a `quaternion` object or a vector or matrix of `quaternion` objects. The size of `quatTransposed` is *N*-by-*M*, where the size of `quat` is *M*-by-*N*.

dist

Angular distance in radians

Syntax

```
distance = dist(quatA,quatB)
```

Description

`distance = dist(quatA,quatB)` returns the angular distance in radians between two quaternions, `quatA` and `quatB`.

Examples

Calculate Quaternion Distance

Calculate the quaternion distance between a single quaternion and each element of a vector of quaternions. Define the quaternions using Euler angles.

```
q = quaternion([0,0,0],"eulerd","ZYX","frame")
```

```
q = quaternion
     1 + 0i + 0j + 0k
```

```
qArray = quaternion([0,45,0;0,90,0;0,180,0;0,-90,0;0,-45,0],"eulerd","ZYX","frame")
```

```
qArray = 5×1 quaternion array
       0.92388 +         0i +   0.38268j +         0k
       0.70711 +         0i +   0.70711j +         0k
    6.1232e-17 +         0i +         1j +         0k
       0.70711 +         0i -   0.70711j +         0k
       0.92388 +         0i -   0.38268j +         0k
```

```
quaternionDistance = rad2deg(dist(q,qArray))
```

```
quaternionDistance = 5×1

   45.0000
   90.0000
  180.0000
   90.0000
   45.0000
```

If both arguments to `dist` are vectors, the quaternion distance is calculated between corresponding elements. Calculate the quaternion distance between two quaternion vectors.

```
angles1 = [30,0,15; ...
           30,5,15; ...
```

```
           30,10,15; ...
           30,15,15];
angles2 = [30,6,15; ...
           31,11,15; ...
           30,16,14; ...
           30.5,21,15.5];

qVector1 = quaternion(angles1,"eulerd","ZYX","frame");
qVector2 = quaternion(angles2,"eulerd","ZYX","frame");

rad2deg(dist(qVector1,qVector2))

ans = 4×1

    6.0000
    6.0827
    6.0827
    6.0287
```

Note that a quaternion represents the same rotation as its negative. Calculate a quaternion and its negative.

```
qPositive = quaternion([30,45,-60],"eulerd","ZYX","frame")

qPositive = quaternion
     0.72332 - 0.53198i + 0.20056j +  0.3919k

qNegative = -qPositive

qNegative = quaternion
    -0.72332 + 0.53198i - 0.20056j -  0.3919k
```

Find the distance between the quaternion and its negative.

```
dist(qPositive,qNegative)

ans =
0
```

The components of a quaternion may look different from the components of its negative, but both expressions represent the same rotation.

Input Arguments

`quatA,quatB` — Quaternions to calculate distance between

`quaternion` objects | arrays of `quaternion` objects

Quaternions to calculate distance between, specified as comma-separated `quaternion` objects or arrays of `quaternion` objects of any dimensionality. `quatA` and `quatB` must have compatible sizes:

- `size(quatA) == size(quatB)`, or
- `numel(quatA) == 1`, or

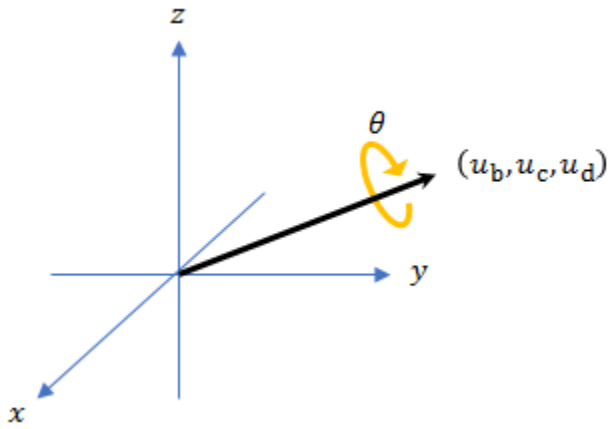
- `numel(quatB) == 1`, or
- if `[Adim1,…,AdimN] = size(quatA)` and `[Bdim1,…,BdimN] = size(quatB)`, then for `i = 1:N`, either `Adimi==Bdimi` or `Adim==1` or `Bdim==1`.

  If one of the quaternion arguments contains only one quaternion, then this function returns the distances between that quaternion and every quaternion in the other argument.

Output Arguments

`distance` — Angular distance (radians)

numeric scalar | numeric array



Angular distance in radians, returned as a numeric scalar or numeric array. The dimensions are the maximum of the union of `size(quatA)` and `size(quatB)`.

Data Types: `single` | `double`

Algorithms

The `dist` function returns the angular distance between two quaternions.

A quaternion may be defined by an axis (u_b,u_c,u_d) and angle of rotation θ_q:
$q = \cos\left(\theta_q/2\right) + \sin\left(\theta_q/2\right)(u_b\mathrm{i} + u_c\mathrm{j} + u_d\mathrm{k})$.

Given a quaternion in the form, $q = a + b\mathrm{i} + c\mathrm{j} + d\mathrm{k}$, where a is the real part, you can solve for the angle of q as $\theta_q = 2\cos^{-1}(a)$.

Consider two quaternions, p and q, and the product $z = p*\text{conjugate}(q)$. As p approaches q, the angle of z goes to 0, and z approaches the unit quaternion.

The angular distance between two quaternions can be expressed as $\theta_z = 2\cos^{-1}(\text{real}(z))$.

Using the `quaternion` data type syntax, the angular distance is calculated as:

```
angularDistance = 2*acos(abs(parts(p*conj(q))));
```

`quaternion`

euler

Convert quaternion to Euler angles (radians)

Syntax

```
eulerAngles = euler(quat,rotationSequence,rotationType)
```

Description

`eulerAngles = euler(quat,rotationSequence,rotationType)` converts the quaternion, `quat`, to an *N*-by-3 matrix of Euler angles.

Examples

Convert Quaternion to Euler Angles in Radians

Convert a quaternion frame rotation to Euler angles in radians using the "ZYX" rotation sequence.

```
quat = quaternion([0.7071 0.7071 0 0]);
eulerAnglesRandians = euler(quat,"ZYX","frame")
```

```
eulerAnglesRandians = 1×3

         0         0    1.5708
```

Input Arguments

quat — Quaternion to convert to Euler angles

`quaternion` object | array of `quaternion` objects

Quaternion to convert to Euler angles, specified as a `quaternion` object or an array of `quaternion` objects of any dimensionality.

rotationSequence — Rotation sequence

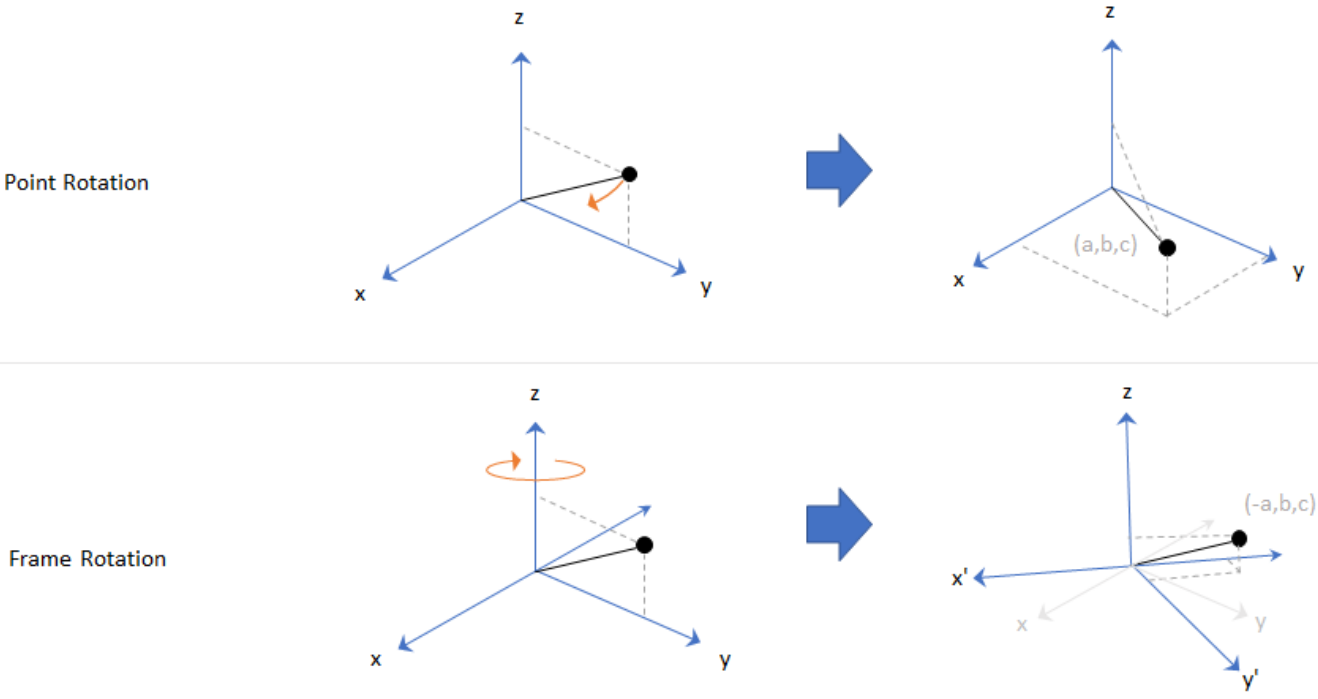
`"ZYX"` | `"ZYZ"` | `"ZXY"` | `"ZXZ"` | `"YXZ"` | `"YXY"` | `"YZX"` | `"YZY"` | `"XYZ"` | `"XYX"` | `"XZY"` | `"XZX"`

Rotation sequence of Euler angle representation, specified as one of these values.

- `"YZY"`
- `"YXY"`
- `"ZYZ"`
- `"ZXZ"`
- `"XYX"`
- `"XZX"`
- `"XYZ"`

- "YZX"
- "ZXY"
- "XZY"
- "ZYX"
- "YXZ"

The rotation sequence defines the order of rotations about the axes. For example, if you specify a rotation sequence of "YZX":



1. The first rotation is about the *y*-axis.
2. The second rotation is about the new *z*-axis.
3. The third rotation is about the new *x*-axis.

Data Types: `char` | `string`

`rotationType` — Type of rotation
`"point"` | `"frame"`

Type of rotation, specified as `"point"` or `"frame"`.

In a point rotation, the frame is static and the point moves. In a frame rotation, the point is static and the frame moves. Point rotation and frame rotation define equivalent angular displacements but in opposite directions.

Data Types: `char` | `string`

Output Arguments

`eulerAngles` — Euler angle representation (radians)

N-by-3 numeric matrix

Euler angle representation in radians, returned as an *N*-by-3 numeric matrix, where *N* is the number of quaternions in the `quat` argument.

For each row of `eulerAngles`, the first element corresponds to the first axis in the rotation sequence, the second element corresponds to the second axis in the rotation sequence, and the third element corresponds to the third axis in the rotation sequence.

The data type of the Euler angles representation is the same as the underlying data type of `quat`.

Data Types: `single` | `double`

Functions

`eulerd` | `rotateframe` | `rotatepoint`

Objects

`quaternion`

eulerd

Convert quaternion to Euler angles (degrees)

Syntax

```
eulerAngles = eulerd(quat,rotationSequence,rotationType)
```

Description

`eulerAngles = eulerd(quat,rotationSequence,rotationType)` converts the quaternion, `quat`, to an *N*-by-3 matrix of Euler angles in degrees.

Examples

Convert Quaternion to Euler Angles in Degrees

Convert a quaternion frame rotation to Euler angles in degrees using the "ZYX" rotation sequence.

```
quat = quaternion([0.7071 0.7071 0 0]);
eulerAnglesDegrees = eulerd(quat,"ZYX","frame")
```

```
eulerAnglesDegrees = 1×3

         0         0   90.0000
```

Input Arguments

`quat` — Quaternion to convert to Euler angles

`quaternion` object | array of `quaternion` objects

Quaternion to convert to Euler angles, specified as a `quaternion` object or an array of `quaternion` objects of any dimensionality.

`rotationSequence` — Rotation sequence

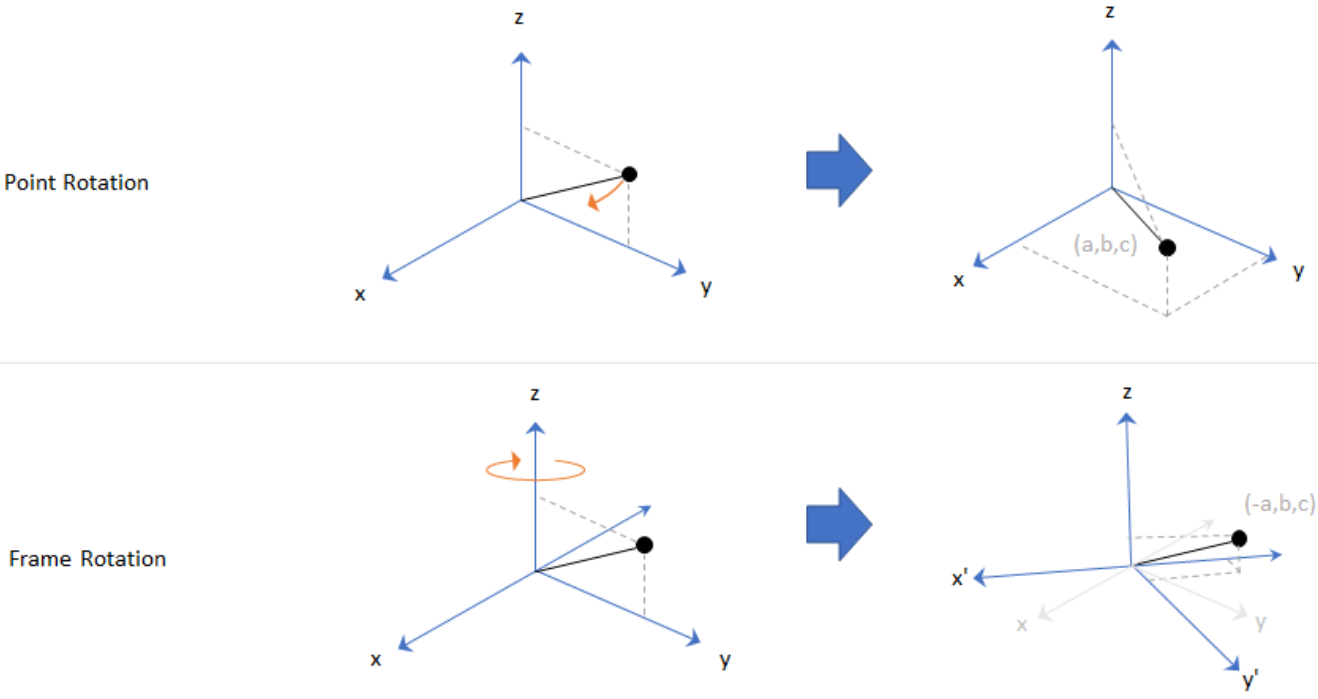
`"ZYX"` | `"ZYZ"` | `"ZXY"` | `"ZXZ"` | `"YXZ"` | `"YXY"` | `"YZX"` | `"YZY"` | `"XYZ"` | `"XYX"` | `"XZY"` | `"XZX"`

Rotation sequence of Euler angle representation, specified as one of these values.

- `"YZY"`
- `"YXY"`
- `"ZYZ"`
- `"ZXZ"`
- `"XYX"`
- `"XZX"`
- `"XYZ"`

- "YZX"
- "ZXY"
- "XZY"
- "ZYX"
- "YXZ"

The rotation sequence defines the order of rotations about the axes. For example, if you specify a rotation sequence of "YZX":



1. The first rotation is about the *y*-axis.
2. The second rotation is about the new *z*-axis.
3. The third rotation is about the new *x*-axis.

Data Types: `char` | `string`

`rotationType` — Type of rotation
`"point"` | `"frame"`

Type of rotation, specified as `"point"` or `"frame"`.

In a point rotation, the frame is static and the point moves. In a frame rotation, the point is static and the frame moves. Point rotation and frame rotation define equivalent angular displacements but in opposite directions.

Data Types: `char` | `string`

Output Arguments

`eulerAngles` — Euler angle representation (degrees)

N-by-3 numeric matrix

Euler angle representation in degrees, returned as an *N*-by-3 numeric matrix, where *N* is the number of quaternions in the `quat` argument.

For each row of `eulerAngles`, the first column corresponds to the first axis in the rotation sequence, the second column corresponds to the second axis in the rotation sequence, and the third column corresponds to the third axis in the rotation sequence.

The data type of the Euler angles representation is the same as the underlying data type of `quat`.

Functions

`euler` | `rotateframe` | `rotatepoint`

Objects

`quaternion`

exp

Exponential of quaternion array

Syntax

```
B = exp(A)
```

Description

`B = exp(A)` computes the exponential of the elements of the quaternion array `A`.

Examples

Exponential of Quaternion Array

Create a 4-by-1 quaternion array A.

```
A = quaternion(magic(4))
```

```
A = 4×1 quaternion array
     16 +  2i +  3j + 13k
      5 + 11i + 10j +  8k
      9 +  7i +  6j + 12k
      4 + 14i + 15j +  1k
```

Compute the exponential of A.

```
B = exp(A)
```

```
B = 4×1 quaternion array
     5.3525e+06 + 1.0516e+06i + 1.5774e+06j + 6.8352e+06k
        -57.359 -     89.189i -     81.081j -     64.865k
        -6799.1 +     2039.1i +     1747.8j +     3495.6k
          -6.66 +     36.931i +     39.569j +     2.6379k
```

Input Arguments

A — Input quaternion

`quaternion` object | array of `quaternion` objects

Input quaternion, specified as a `quaternion` object or an array of `quaternion` objects of any dimensionality.

Output Arguments

B — Result

`quaternion` object | array of `quaternion` objects

Result of quaternion exponential, returned as a `quaternion` object or an array of `quaternion` objects of the same size as `A`.

Algorithms

Given a quaternion $A = a + b\mathrm{i} + c\mathrm{j} + d\mathrm{k} = a + \bar{v}$, the exponential is computed by

$$\exp(A) = e^{a}\left(\cos\|\bar{v}\| + \frac{\bar{v}}{\|\bar{v}\|}\sin\|\bar{v}\|\right)$$

Functions

`.^,power` | `log`

Objects

`quaternion`

ldivide, .\

Element-wise quaternion left division

Syntax

```
C = A.\B
```

Description

`C = A.\B` performs quaternion element-wise division by dividing each element of `B` by the corresponding element of `A`.

Examples

Divide a Quaternion Array by a Real Scalar

Create a 2-by-1 quaternion array, and divide it element-by-element by a real scalar.

```
A = quaternion([1:4;5:8])
```

```
A = 2×1 quaternion array
     1 + 2i + 3j + 4k
     5 + 6i + 7j + 8k
```

```
B = 2;
C = A.\B
```

```
C = 2×1 quaternion array
     0.066667 -  0.13333i -      0.2j -  0.26667k
     0.057471 - 0.068966i -  0.08046j - 0.091954k
```

Divide a Quaternion Array by Another Quaternion Array

Create a 2-by-2 quaternion array, and divide it element-by-element by another 2-by-2 quaternion array.

```
q1 = quaternion([1:4;2:5;4:7;5:8]);
A = reshape(q1,2,2)
```

```
A = 2×2 quaternion array
     1 + 2i + 3j + 4k     4 + 5i + 6j + 7k
     2 + 3i + 4j + 5k     5 + 6i + 7j + 8k
```

```
q2 = quaternion(magic(4));
B = reshape(q2,2,2)
```

```
B = 2×2 quaternion array
     16 +  2i +  3j + 13k      9 +  7i +  6j + 12k
      5 + 11i + 10j +  8k      4 + 14i + 15j +  1k

C = A.\B

C = 2×2 quaternion array
          2.7 -      1.9i -      0.9j -      1.7k       1.5159 -  0.37302i -  0.15079j -  0.0238
       2.2778 +  0.46296i -  0.57407j + 0.092593k       1.2471 +  0.91379i -  0.33908j -   0.109
```

Input Arguments

A — Divisor

`quaternion` object | array of `quaternion` objects | real scalar | array of real numbers

Divisor, specified as a `quaternion` object, an array of `quaternion` objects of any dimensionality, a real scalar, or an array of real numbers of any dimensionality. Numeric values must be of data type `single` or `double`.

`A` and `B` must have compatible sizes. In the simplest cases, they can be the same size or one can be a scalar. Two inputs have compatible sizes if, for every dimension, the dimension sizes of the inputs are the same or one of the dimensions is 1.

B — Dividend

`quaternion` object | array of `quaternion` objects | real scalar | array of real numbers

Dividend, specified as a `quaternion` object, an array of `quaternion` objects of any dimensionality, a real scalar, or an array of real numbers of any dimensionality. Numeric values must be of data type `single` or `double`.

`A` and `B` must have compatible sizes. In the simplest cases, they can be the same size or one can be a scalar. Two inputs have compatible sizes if, for every dimension, the dimension sizes of the inputs are the same or one of the dimensions is 1.

Output Arguments

C — Result

`quaternion` object | array of `quaternion` objects

Result of quaternion division, returned as a `quaternion` object or an array of `quaternion` objects.

Algorithms

Quaternion Division

Given a quaternion $A = a_1 + a_2\mathrm{i} + a_3\mathrm{j} + a_4\mathrm{k}$ and a real scalar p,

$$C = p.\backslash A = \frac{a_1}{p} + \frac{a_2}{p}\mathrm{i} + \frac{a_3}{p}\mathrm{j} + \frac{a_4}{p}\mathrm{k}$$

Note For a real scalar p, $A./p = A.\backslash p$.

Quaternion Division by a Quaternion Scalar

Given two quaternions A and B of compatible sizes, then

$$C = A.\backslash B = A^{-1}.*B = \left(\frac{conj(A)}{norm(A)^2}\right).*B$$

Version History

Objects

`quaternion`

log

Natural logarithm of quaternion array

Syntax

```
B = log(A)
```

Description

`B = log(A)` computes the natural logarithm of the elements of the quaternion array `A`.

Examples

Logarithmic Values of Quaternion Array

Create a 3-by-1 quaternion array A.

```
A = quaternion(randn(3,4))
```

```
A = 3×1 quaternion array
     0.53767 + 0.86217i - 0.43359j +  2.7694k
      1.8339 + 0.31877i + 0.34262j -  1.3499k
     -2.2588 -  1.3077i +  3.5784j +  3.0349k
```

Compute the logarithmic values of A.

```
B = log(A)
```

```
B = 3×1 quaternion array
      1.0925 + 0.40848i - 0.20543j +  1.3121k
      0.8436 + 0.14767i + 0.15872j - 0.62533k
      1.6807 - 0.53829i +   1.473j +  1.2493k
```

Input Arguments

A — Input quaternion

`quaternion` object | array of `quaternion` objects

Input quaternion, specified as a `quaternion` object or an array of `quaternion` objects of any dimensionality.

Output Arguments

B — Natural logarithm values

`quaternion` object | array of `quaternion` objects

Natural logarithm values, returned as a `quaternion` object or an array of `quaternion` objects of the same size of the `A` argument.

Algorithms

Given a quaternion $A = a + \bar{v} = a + b\mathrm{i} + c\mathrm{j} + d\mathrm{k}$, the logarithm is computed by

$$\log(A) = \log\|A\| + \frac{\bar{v}}{\|\bar{v}\|}\arccos\frac{a}{\|A\|}$$

Functions

`exp` | `.^,power`

Objects

`quaternion`

interp1

Quaternion interpolation (table lookup)

Syntax

```
vq = interp1(x,v,xq)
vq = interp1(x,v,xq,method)
vq = interp1(x,v,xq,method,extrapolation)

vq = interp1(v,xq)
vq = interp1(v,xq,method)
vq = interp1(v,xq,method,extrapolation)
```

Description

`vq = interp1(x,v,xq)` interpolates the quaternion values of a 1-D function at specific query points using spherical linear interpolation (SLERP). `x` specifies the sample points, and `v` specifies the quaternions that contains the corresponding values *v(x)*. `xq` specifies the query points. By default, the function uses `"slerp-short"` interpolation method.

`vq = interp1(x,v,xq,method)` specifies the interpolation method.

`vq = interp1(x,v,xq,method,extrapolation)` specifies a quaternion value to return for all query points in `xq` that are outside the domain of `x`.

`vq = interp1(v,xq)` interpolates the quaternion values by assuming a default set of sample points. The default points are the sequence of numbers from 1 to *n*, where *n* depends on the shape of `v`:

- When `v` is a vector of quaternions, the default points are `1:length(v)`.
- When `v` is an array of quaternions, the default points are `1:size(v,1)`.

Use this syntax when you are not concerned about the absolute distances between sample points.

`vq = interp1(v,xq,method)` specifies the interpolation method and uses the default sample points.

`vq = interp1(v,xq,method,extrapolation)` specifies an extrapolation value and uses the default sample points.

Examples

Interpolate Quaternion Function Defined Using Sample Points

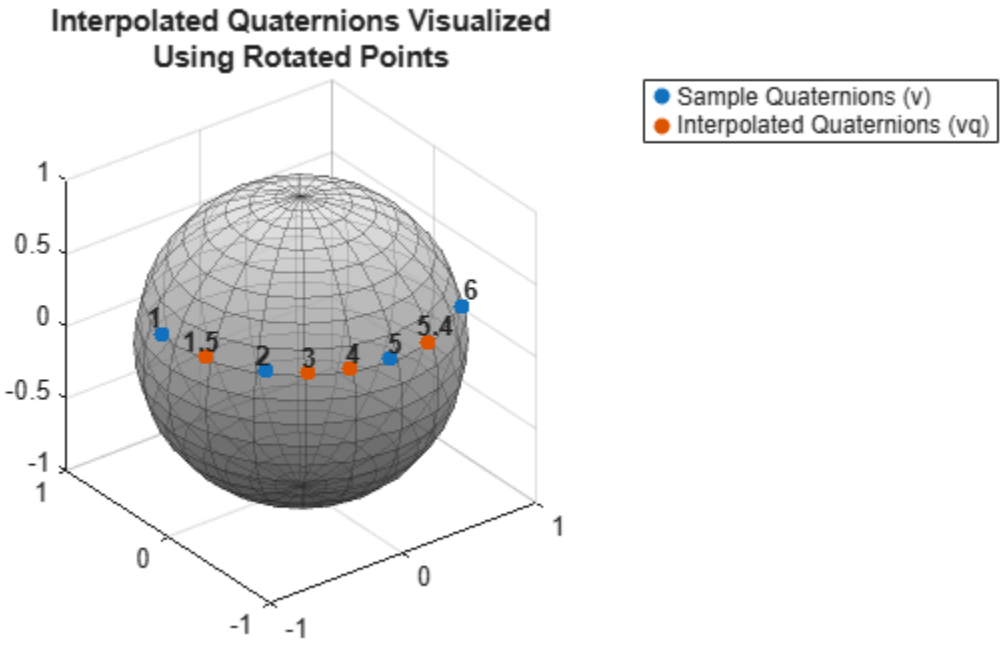
Define the sample points `x` and corresponding sample values `v`.

```
x = [1 2 5 6];
eul = [-185:45:-50; -20*ones(1,4); zeros(1,4)]';
v = quaternion(eul,"eulerd","ZYX","frame");
```

Define the query points over the range of x.

```
xq = [1.5 3 4 5.4];
```

Interpolate at the query points.



```
vq = interp1(x,v,xq);
```

To visualize the result, rotate the same point using the sample and interpolated quaternions.

```
pts_samples = rotatepoint(v,[1.05 0 0]);
pts_query = rotatepoint(vq,[1.05 0 0]);
```

Plot a unit sphere, and then plot the sample and interpolated quaternions on the sphere.

```
figure
[X,Y,Z] = sphere;
surf(X,Y,Z,FaceAlpha=0.5,EdgeAlpha=0.35)
colormap gray
hold on
scatter3(pts_samples(:,1),pts_samples(:,2),pts_samples(:,3),"filled")
scatter3(pts_query(:,1),pts_query(:,2),pts_query(:,3),"filled")
exampleHelperAnnotateQuats(pts_samples,pts_query,x,xq,10,1.05)
axis equal
title(["Interpolated Quaternions Visualized","Using Rotated Points"])
legend("","Sample Quaternions (v)","Interpolated Quaternions (vq)")
```

Interpolate Quaternions Without Specifying Sample Points

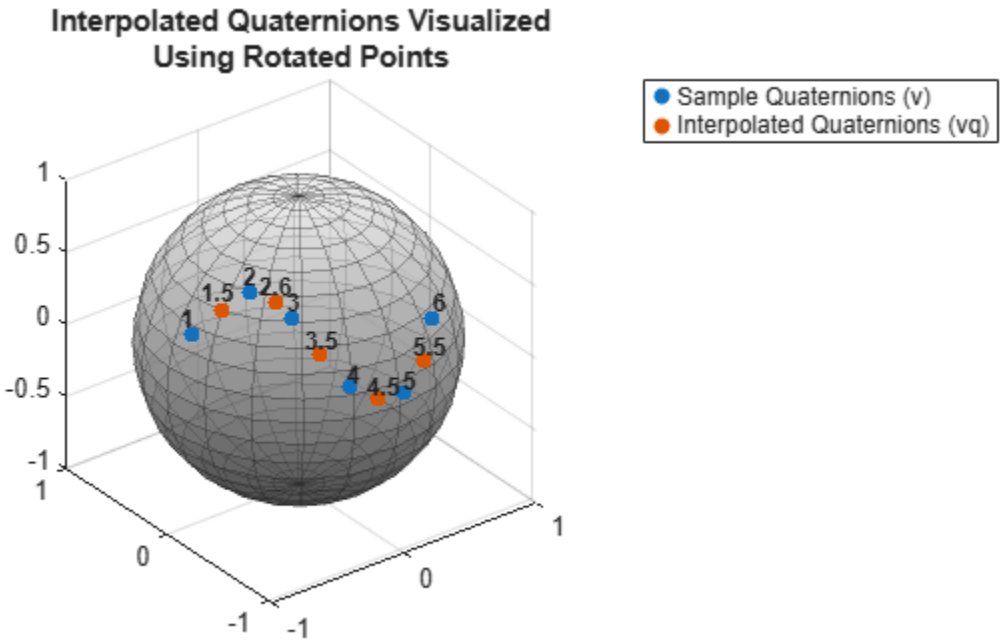
Define a set of function values.

```
eul = [-170:20:-70; -20*sind(0:72:360)-25; zeros(1,6)]';
v = quaternion(eul,"eulerd","ZYX","frame");
```

Define a set of query points that fall between the default points, `1:6`. In this case, the default points are `1:6` because `v` is a six-element quaternion array.

```
xq = [1.5 2.6 3.5 4.5 5.5];
```

Evaluate `v` at `xq` using the SQUAD natural interpolation method. Note that you could use the default `"slerp-short"` interpolation method here, but for the sine-wave rotation that this quaternion function describes, SQUAD produces a smoother interpolated path.



```
vq = interp1(v,xq,"squad-natural");
```

To visualize the result, rotate a point on the *x*-axis using the sample and interpolated quaternions.

```
pts_samples = rotatepoint(v,[1.05 0 0]);
pts_query = rotatepoint(vq,[1.05 0 0]);
```

Plot a unit sphere, and then plot the sample and interpolated quaternions on the sphere.

```
figure
[X,Y,Z] = sphere;
surf(X,Y,Z,FaceAlpha=0.5,EdgeAlpha=0.35)
colormap gray
hold on
scatter3(pts_samples(:,1),pts_samples(:,2),pts_samples(:,3),"filled")
scatter3(pts_query(:,1),pts_query(:,2),pts_query(:,3),"filled")
exampleHelperAnnotateQuats(pts_samples,pts_query,1:6,xq,9,1.05)
axis equal
title(["Interpolated Quaternions Visualized","Using Rotated Points"])
legend("","Sample Quaternions (v)","Interpolated Quaternions (vq)")
```

Get Smoother Angular Velocity Using SQUAD Interpolation

Define three quaternions representing different orientations.

```
q0 = quaternion([0 0 0],"euler","ZYX","frame");
q1 = quaternion([pi/4 pi/6 pi/3],"euler","ZYX","frame");
q2 = quaternion([pi/2 pi/4 pi/2],"euler","ZYX","frame");
```

Create a time vector for the original keyframes

```
x = [1 2 3];
```

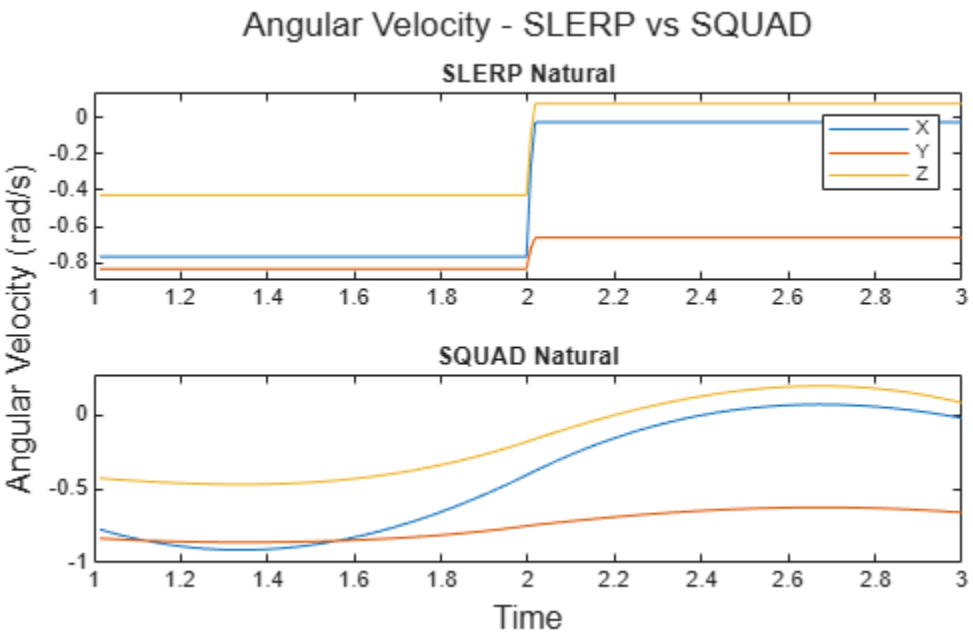
Create a time vector for interpolation

```
T = linspace(0,3,300);
```

Interpolate using `interp1` with the `"slerp-natural"` and `"squad-natural"` methods.

```
quats_slerp = interp1(x,[q0 q1 q2],T,"slerp-natural")';
quats_squad = interp1(x,[q0 q1 q2],T,"squad-natural")';
```

Calculate the angular velocities for both interpolations methods.



```
ang_vel_slerp = angvel(quats_slerp,T(2)-T(1),"frame");
ang_vel_squad = angvel(quats_squad,T(2)-T(1),"frame");
```

Plot the angular velocities.

```
tl = tiledlayout(2,1);
title(tl,"Angular Velocity - SLERP vs SQUAD")
```

Plot the angular velocities for the SLERP and SQUAD interpolations. Note that the angular velocity from the SQUAD interpolation is smoother than the interpolation using SLERP.

```
nexttile
plot(T,ang_vel_slerp)
ylim padded
title("SLERP Natural")
legend("X","Y","Z")
nexttile
plot(T,ang_vel_squad)
ylim padded
title("SQUAD Natural")
xlabel(tl,"Time")
ylabel(tl,"Angular Velocity (rad/s)")
```

Designate Constant Value for All Queries Outside Domain of x

Define the sample points `x` and corresponding sample values `v`.

```
x = [0 1 2];
eul = [0 30 60; 0 20 60; zeros(1,3)]';
v = quaternion(eul,"eulerd","ZYX","frame");
```

Specify the query points `xq` so that they extend beyond the domain of `x`.

```
xq = [-0.5 0.5 1.5 2.5];
```

Now evaluate `v` at `xq` using the `"slerp-short"` interpolation method, and assign any values outside the domain of `x` to a quaternion with all parts set to `0`.

```
vq = interp1(x,v,xq,"slerp-short",ones("quaternion"))'
```

```
vq = 4×1 quaternion array
           1 +        0i +        0j +        0k
     0.98774 + 0.022751i - 0.084907j -  0.12903k
     0.87097 +    0.151i -  0.30755j -  0.35217k
           1 +        0i +        0j +        0k
```

Input Arguments

x — Sample points

N-element vector

Sample points, specified as an *N*-element vector of real numbers. `x` must contain at least two sample points, and the values in `x` must be distinct. The length of `x` depends on the shape of `v`.

- If `v` is a vector of quaternions, then `length(x)` must equal `length(v)`.
- If `v` is an array of quaternions, then `length(x)` must equal `size(v,1)`.

Example: `[1 2 3 4 5 6 7 8 9 10]`

Example: `1:10`

Example: `[3 7 11 15 19 23 27 31]'`

`v` — Sample quaternions
N-element array of `quaternion` objects | *N*-by-*M* array of `quaternion` objects

Sample quaternions, specified as an *N*-element vector of `quaternion` objects or an *N*-by-*M* array of quaternion objects.

If you have multiple sets of data that are sampled at the same query points, then you can specify `v` as an *N*-by-*M* array. Each column of the array contains a separate set of 1-D sample values and the first dimension of the array must be of length *N*, where *N* is the number of specified sample points `x` and *M* is the number of datasets corresponding to `x`.

`xq` — Query points
scalar | vector | matrix | array

Query points, specified as a scalar, vector, matrix, or array of real numbers.

Example: `5`

Example: `1:0.05:10`

Example: `(1:0.05:10)'`

Example: `[0 1 2 7.5 10]`

`method` — Interpolation method
`"slerp-short"` (default) | `"slerp-natural"` | `"squad-natural"` | `"nearest"` | `"next"` | `"previous"`

Interpolation method, specified as one of the options in this table:

Method	Description	Continuity	Comments
`"slerp-short"`	Spherical linear interpolation between sample quaternions by an interpolation coefficient, picking the shortest interpolation path between the sample quaternions. Note that, at each sample point, the input and output quaternions might be inverted to ensure the shortest path. For more information about the SLERP algorithm, see “SLERP Algorithm” on page 2-1547.	C^0	• Requires at least 2 sample quaternions • Low memory requirements • Efficient computation time • Ensures shortest path interpolation. • Fastest computation time
`"slerp-natural"`	Spherical linear interpolation between sample quaternions by an interpolation coefficient, picking the natural interpolation path between the sample quaternions. The input and output quaternions will have the same sign at the sample points. For more information about the SLERP algorithm, see “SLERP Algorithm” on page 2-1547.	C^0	• Requires at least 2 sample quaternions • Low memory requirements • Efficient computation time • The input and output quaternions will have the same sign at the sample points.

Method	Description	Continuity	Comments
`"squad-natural"`	Spherical quadrangle interpolation between sample quaternions, providing smooth and continuous transitions with gradual changes in acceleration. The input and output quaternions will have the same sign at the sample points. For more information about the SQUAD algorithm, see “SQUAD Algorithm” on page 2-1547.	C^1	• Requires at least 2 sample quaternions • Moderate memory requirements • Efficient computation time • Ensures smooth transitions and gradual acceleration changes
`"nearest"`	Nearest neighbor interpolation. The interpolated value at a query point is the value at the nearest sample quaternion.	Discontinuous	• Requires at least 2 sample quaternions • Modest memory requirements
`"next"`	Next neighbor interpolation. The interpolated value at a query point is the value at the next sample quaternion.	Discontinuous	• Requires at least 2 sample quaternions. • Same memory requirements and computation time as `"nearest"`
`"previous"`	Previous neighbor interpolation. The interpolated value at a query point is the value at the previous sample quaternion.	Discontinuous	• Requires at least 2 sample quaternions. • Same memory requirements and computation time as `"nearest"`

`extrapolation` — Extrapolation quaternion
`nan("quaternion")` (default) | `quaternion` object

Extrapolation quaternion, specified as a `quaternion` object. `interp1` returns this quaternion for any `xq` values that query outside of domain of `x`.

Example: `interp1([0 1 2],quats,2.5,"slerp-natural")` returns a quaternion of value `NaN + NaNi + NaNj + NaNk`.

Example: `interp1([0 1 2],quats,2.5,"slerp-natural",zeros("quaternion"))` returns a quaternion of value `0 + 0i + 0j + 0k`.

Output Arguments

vq — Interpolated quaternions

scalar | vector | matrix | array

Interpolated values, returned as a scalar, vector, matrix, or array. The size of `vq` depends on the shapes of `v` and `xq`.

Shape of v	Shape of xq	Size of vq	Example
Vector	Vector	`size(xq)`	If `size(v) = [1 100]` and `size(xq) = [1 500]`, then `size(vq) = [1 500]`.
Vector	Matrix or N-D Array	`size(xq)`	If `size(v) = [1 100]` and `size(xq) = [50 30]`, then `size(vq) = [50 30]`.
Array	Vector	`[length(xq) size(v,2),...,size(v,n)]`	If `size(v) = [100 3]` and `size(xq) = [1 500]`, then `size(vq) = [500 3]`.
Array	Matrix or N-D Array	`[size(xq,1),...,size(xq, n),... size(v,2),...,size(v,m)]`	If `size(v) = [4 5 6]` and `size(xq) = [2 3 7]`, then `size(vq) = [2 3 7 5 6]`.

Algorithms

SLERP Algorithm

Quaternion spherical linear interpolation (SLERP) is an extension of linear interpolation along a plane to spherical interpolation in three dimensions. The algorithm was first proposed in [1]. Given two quaternions, q_1 and q_2, SLERP interpolates a new quaternion, q_0, along the great circle that connects q_1 and q_2. The interpolation coefficient, T, determines how close the output quaternion is to either q_1 and q_2.

The SLERP algorithm can be described in terms of sinusoids:

$$q_0 = \frac{\sin((1-T)\theta)}{\sin(\theta)} q_1 + \frac{\sin(T\theta)}{\sin(\theta)} q_2$$

where q_1 and q_2 are normalized quaternions, and θ is half the angular distance between q_1 and q_2.

SQUAD Algorithm

Quaternion spherical and quadrangle (SQUAD) interpolation is an extension of the SLERP interpolation method designed for interpolating between a sequence of quaternions [2]. It produces a continuous, smooth, angular velocity across multiple quaternion keyframes by introducing intermediate, control quaternions, much like how Bézier curves use control points to create a smooth path in Cartesian space. The SQUAD algorithm calculates two control quaternions between each consecutive pair of quaternion keyframes, specified using the input argument `v`, forming a quadrangle with each pair of quaternion keyframes. Neighboring quaternion keyframes also influence the calculation of these control quaternions to ensure smooth transitions between the interpolated paths of each quaternion keyframe pair.

The SQUAD interpolation algorithm first uses SLERP between the quaternions q_i and q_{i+1} with the interpolation coefficient h, corresponding to input argument `T` in the `slerp` function. Then, the algorithm uses SLERP to interpolate between the control quaternions s_i and s_{i+1}. Finally, the algorithm uses SLERP between these two SLERP paths, using *2h(1–h)* as the interpolation coefficient to get the SQUAD interpolated path. The *2h(1–h)* interpolation coefficient for the final SLERP is a quadratic function that ensures this interpolation is a smooth curved path instead of a linear straight path.

In equation form, the SQUAD interpolation between q_i and q_{i+1} with the interpolation coefficient h is defined as:

$$Squad(q_i, q_{i+1}, s_i, s_{i+1}, h) = Slerp(Slerp(q_i, q_{i+1}, h), Slerp(s_i, s_{i+1}, h), 2h(1-h)),$$

where s_i and s_{i+1} are the control quaternions defined using the equation:

$$s_i = q_i \exp\left(-\frac{\log(q_i^{-1}q_{i+1}) + \log(q_i^{-1}q_{i-1})}{4}\right)$$

`quaternion` | `slerp`

meanrot

Quaternion mean rotation

Syntax

```
quatAverage = meanrot(quat)
quatAverage = meanrot(quat,dim)
quatAverage = meanrot( ___ ,nanflag)
```

Description

`quatAverage = meanrot(quat)` returns the average rotation of the elements of `quat` along the first array dimension whose size not does equal 1.

- If `quat` is a vector, `meanrot(quat)` returns the average rotation of the elements.
- If `quat` is a matrix, `meanrot(quat)` returns a row vector containing the average rotation of each column.
- If `quat` is a multidimensional array, then `mearot(quat)` operates along the first array dimension whose size does not equal 1, treating the elements as vectors. This dimension becomes 1 while the sizes of all other dimensions remain the same.

The `meanrot` function normalizes the input quaternions, `quat`, before calculating the mean.

`quatAverage = meanrot(quat,dim)` return the average rotation along dimension `dim`. For example, if `quat` is a matrix, then `meanrot(quat,2)` is a column vector containing the mean of each row.

`quatAverage = meanrot( ___ ,nanflag)` specifies whether to include or omit `NaN` values from the calculation for any of the previous syntaxes. `meanrot(quat,"includenan")` includes all `NaN` values in the calculation while `mean(quat,"omitnan")` ignores them.

Examples

Quaternion Mean Rotation

Create a matrix of quaternions corresponding to three sets of Euler angles.

```
eulerAngles = [40 20 10; ...
               50 10 5; ...
               45 70 1];

quat = quaternion(eulerAngles,"eulerd","ZYX","frame");
```

Determine the average rotation represented by the quaternions. Convert the average rotation to Euler angles in degrees for readability.

```
quatAverage = meanrot(quat)
```

```
quatAverage = quaternion
      0.88863 - 0.062598i +  0.27822j +  0.35918k

eulerAverage = eulerd(quatAverage,"ZYX","frame")

eulerAverage = 1×3

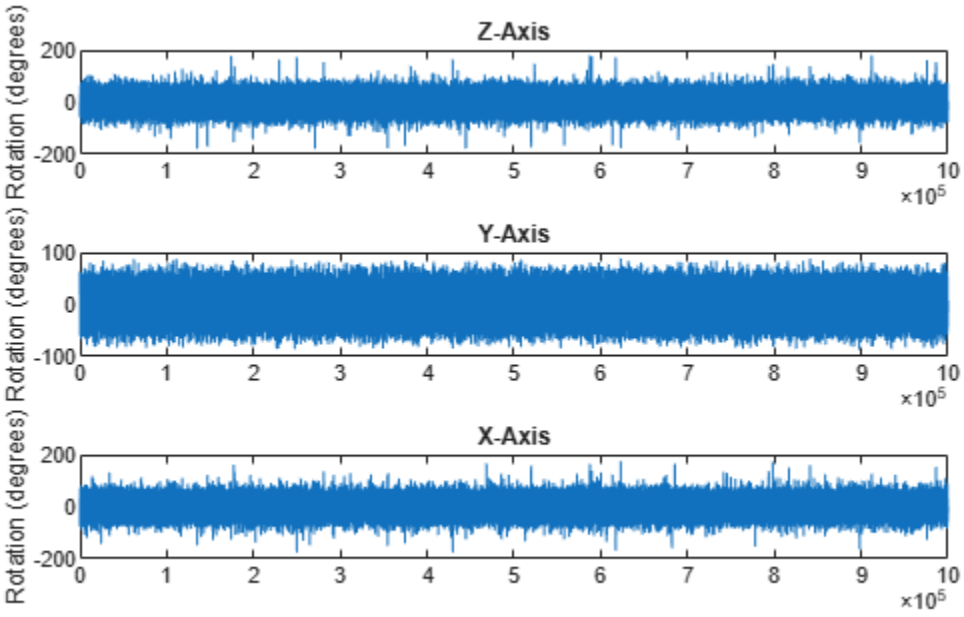
   45.7876   32.6452    6.0407
```

Average Out Rotational Noise

Use `meanrot` over a sequence of quaternions to average out additive noise.

Create a vector of 1e6 quaternions whose distance, as defined by the `dist` function, from quaternion(1,0,0,0) is normally distributed. Plot the Euler angles corresponding to the noisy quaternion vector.

```
nrows = 1e6;
ax = 2*rand(nrows,3) - 1;
ax = ax./sqrt(sum(ax.^2,2));
ang = 0.5*randn(size(ax,1),1);
q = quaternion(ax.*ang ,"rotvec");



noisyEulerAngles = eulerd(q,"ZYX","frame");

figure(1)

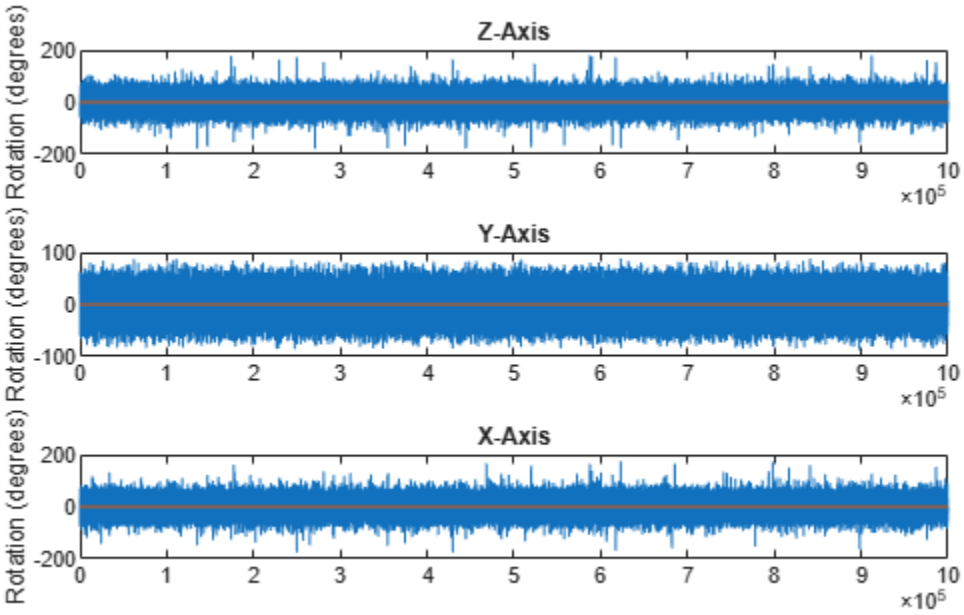
subplot(3,1,1)
plot(noisyEulerAngles(:,1))
title("Z-Axis")
ylabel("Rotation (degrees)")
hold on

subplot(3,1,2)
plot(noisyEulerAngles(:,2))
title("Y-Axis")
ylabel("Rotation (degrees)")
hold on

subplot(3,1,3)
plot(noisyEulerAngles(:,3))
title("X-Axis")
ylabel("Rotation (degrees)")
hold on
```

Use `meanrot` to determine the average quaternion given the vector of quaternions. Convert to Euler angles and plot the results.

```
qAverage = meanrot(q);



qAverageInEulerAngles = eulerd(qAverage,"ZYX","frame");

figure(1)

subplot(3,1,1)
plot(ones(nrows,1)*qAverageInEulerAngles(:,1))
title("Z-Axis")

subplot(3,1,2)
plot(ones(nrows,1)*qAverageInEulerAngles(:,2))
title("Y-Axis")

subplot(3,1,3)
plot(ones(nrows,1)*qAverageInEulerAngles(:,3))
title("X-Axis")
```

The `meanrot` Algorithm and Limitations

The `meanrot` Algorithm

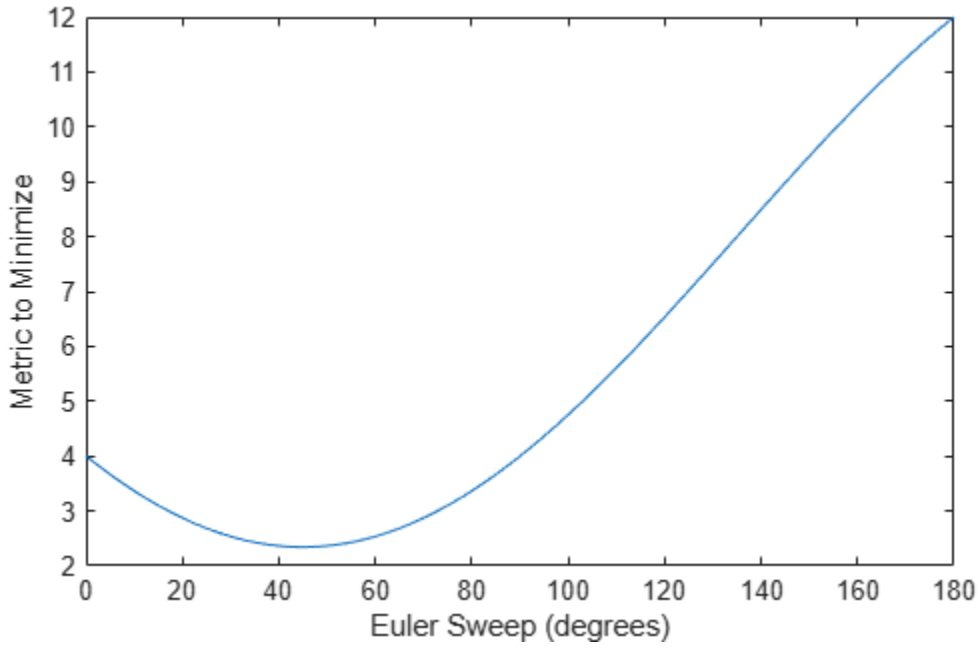
The `meanrot` function outputs a quaternion that minimizes the squared Frobenius norm of the difference between rotation matrices. Consider two quaternions:

- `q0` represents no rotation.
- `q90` represents a 90 degree rotation about the *x*-axis.

```
q0 = quaternion([0 0 0],"eulerd","ZYX","frame");
q90 = quaternion([0 0 90],"eulerd","ZYX","frame");
```

Create a quaternion sweep, `qSweep`, that represents rotations from 0 to 180 degrees about the *x*-axis.

```
eulerSweep = (0:1:180)';
qSweep = quaternion([zeros(numel(eulerSweep),2),eulerSweep], ...
    "eulerd","ZYX","frame");
```



Convert `q0`, `q90`, and `qSweep` to rotation matrices. In a loop, calculate the metric to minimize for each member of the quaternion sweep. Plot the results and return the value of the Euler sweep that corresponds to the minimum of the metric.

```
r0     = rotmat(q0,"frame");
r90    = rotmat(q90,"frame");
rSweep = rotmat(qSweep,"frame");

metricToMinimize = zeros(size(rSweep,3),1);
for i = 1:numel(qSweep)
    metricToMinimize(i) = norm((rSweep(:,:,i) - r0),"fro").^2 + ...
```

```
                        norm((rSweep(:,:,i) - r90),"fro").^2;
end

plot(eulerSweep,metricToMinimize)
xlabel("Euler Sweep (degrees)")
ylabel("Metric to Minimize")
```

```
[~,eulerIndex] = min(metricToMinimize);
eulerSweep(eulerIndex)
```

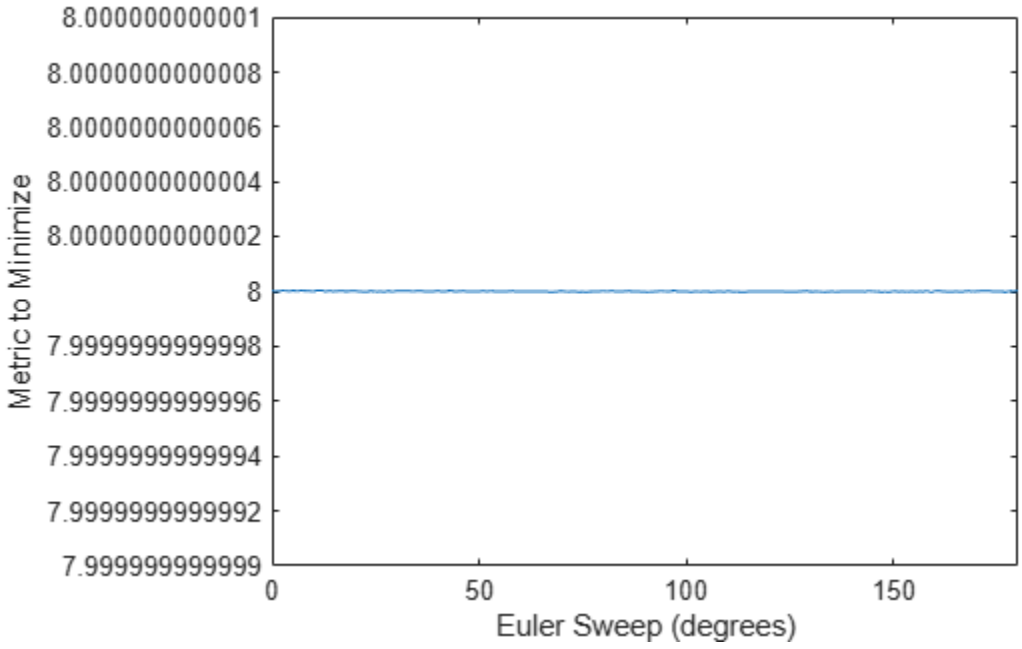
```
ans =
45
```

The minimum of the metric corresponds to the Euler angle sweep at 45 degrees. That is, `meanrot` defines the average between `quaterion([0 0 0],"ZYX","frame")` and `quaternion([0 0 90],"ZYX","frame")` as `quaternion([0 0 45],"ZYX","frame")`. Call `meanrot` with `q0` and `q90` to verify the same result.

```
eulerd(meanrot([q0,q90]),"ZYX","frame")
```

```
ans = 1×3

         0         0   45.0000
```



Limitations

The metric that `meanrot` uses to determine the mean rotation is not unique for quaternions significantly far apart. Repeat the experiment above for quaternions that are separated by 180 degrees.

```
q180 = quaternion([0 0 180],"eulerd","ZYX","frame");
r180 = rotmat(q180,"frame");
```

```
for i = 1:numel(qSweep)
    metricToMinimize(i) = norm((rSweep(:,:,i) - r0),"fro").^2 + ...
                          norm((rSweep(:,:,i) - r180),"fro").^2;
end

plot(eulerSweep,metricToMinimize)
xlabel("Euler Sweep (degrees)")
ylabel("Metric to Minimize")
```

```
[~,eulerIndex] = min(metricToMinimize);
eulerSweep(eulerIndex)
```

```
ans =
159
```

Quaternion means are usually calculated for rotations that are close to each other, which makes the edge case shown in this example unlikely in real-world applications. To average two quaternions that are significantly far apart, use the `slerp` function. Repeat the experiment using `slerp` and verify that the quaternion mean returned is more intuitive for large distances.

```
qMean = slerp(q0,q180,0.5);
q0_q180 = eulerd(qMean,"ZYX","frame")
```

```
q0_q180 = 1×3
```

```
         0         0   90.0000
```

Input Arguments

`quat` — Quaternion

`quaternion` object | array of `quaternion` objects

Quaternion for which to calculate the mean, specified as a `quaternion` object or an array of `quaternion` objects of any dimensionality.

`dim` — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to 1. The `size(quatAverage,dim)` is `1`, while the sizes of all other dimensions remain the same.

Data Types: `double` | `single`

`nanflag` — `NaN` condition

`"includenan"` (default) | `"omitnan"`

`NaN` condition, specified as one of these values:

- `"includenan"` –– Include `NaN` values when computing the mean rotation, resulting in `NaN`.
- `"omitnan"` –– Ignore all `NaN` values in the input.

Data Types: `char` | `string`

Output Arguments

`quatAverage` — Quaternion average rotation

`quaternion` object | array of `quaternion` objects

Quaternion average rotation, returned as a `quaternion` object or an array of `quaternion` objects.

Algorithms

`meanrot` determines a quaternion mean, $\bar{q}$, according to [1]. $\bar{q}$ is the quaternion that minimizes the squared Frobenius norm of the difference between rotation matrices:

$$\bar{q} = \arg \min_{q \in \mathrm{S}^3} \sum_{i=1}^{n} \| A(q) - A(q_i) \|_F^2$$

Quaternion subtraction

Syntax

```
C = A - B
```

Description

`C = A - B` subtracts quaternion `B` from quaternion `A` using quaternion subtraction. Either `A` or `B` may be a real number, in which case subtraction is performed with the real part of the quaternion argument.

Examples

Subtract a Quaternion from a Quaternion

Quaternion subtraction is defined as the subtraction of the corresponding parts of each quaternion. Create two quaternions and perform subtraction.

```
Q1 = quaternion([1,0,-2,7]);
Q2 = quaternion([1,2,3,4]);

Q1minusQ2 = Q1 - Q2
```

```
Q1minusQ2 = quaternion
     0 - 2i - 5j + 3k
```

Subtract a Real Number from a Quaternion

Addition and subtraction of real numbers is defined for quaternions as acting on the real part of the quaternion. Create a quaternion and then subtract 1 from the real part.

```
Q = quaternion([1,1,1,1])
```

```
Q = quaternion
     1 + 1i + 1j + 1k
```

```
Qminus1 = Q - 1
```

```
Qminus1 = quaternion
     0 + 1i + 1j + 1k
```

Input Arguments

A — Input

`quaternion` object | array of `quaternion` objects | real scalar | array of real numbers

Input, specified as a `quaternion` object, an array of `quaternion` objects of any dimensionality, a real scalar, or an array of real numbers of any dimensionality. Numeric values must be of data type `single` or `double`.

`A` and `B` must have compatible sizes. In the simplest cases, they can be the same size or one can be a scalar. Two inputs have compatible sizes if, for every dimension, the dimension sizes of the inputs are the same or one of the dimensions is 1.

B — Input

`quaternion` object | array of `quaternion` objects | real scalar | array of real numbers

Input, specified as a `quaternion` object, an array of `quaternion` objects of any dimensionality, a real scalar, or an array of real numbers of any dimensionality. Numeric values must be of data type `single` or `double`.

`A` and `B` must have compatible sizes. In the simplest cases, they can be the same size or one can be a scalar. Two inputs have compatible sizes if, for every dimension, the dimension sizes of the inputs are the same or one of the dimensions is 1.

Output Arguments

C — Result

`quaternion` object | array of `quaternion` objects

Result of quaternion subtraction, returned as a `quaternion` object or an array of `quaternion` objects.

```
C = 2×2 quaternion array
       0.18493 +   0.13014i +  0.061644j +   0.11644k        0.2871 +  0.074194i +  0.080645j +
        0.2871 -  0.054839i +   0.10645j - 0.0032258k       0.18493 -   0.14384i +   0.11644j + 0
```

Input Arguments

A — Divisor

`quaternion` object | array of `quaternion` objects | real scalar | array of real numbers

Divisor, specified as a `quaternion` object, an array of `quaternion` objects, a real numeric scalar, or an array of real numbers. Numeric values must be of data type `single` or `double`.

At least one of `A` and `B` must a scalar.

B — Dividend

`quaternion` object | array of `quaternion` objects | real scalar | array of real numbers

Dividend, specified as a `quaternion` object, an array of `quaternion` objects, a real numeric scalar, or an array of real numbers. Numeric values must be of data type `single` or `double`.

At least one of `A` and `B` must a scalar.

Output Arguments

C — Result

`quaternion` object | array of `quaternion` objects

Result of quaternion left division, returned as a `quaternion` object or an array of `quaternion` objects.

Algorithms

Quaternion Division

Given a quaternion $A = a_1 + a_2\mathrm{i} + a_3\mathrm{j} + a_4\mathrm{k}$ and a real numeric scalar p,

$$C = p\backslash A = \frac{a_1}{p} + \frac{a_2}{p}\mathrm{i} + \frac{a_3}{p}\mathrm{j} + \frac{a_4}{p}\mathrm{k}$$

Note For a real numeric scalar p, $A\backslash p = p/A$.

Quaternion Division by a Quaternion Scalar

Given two quaternions A and B,

$$C = A\backslash B = A^{-1} * B = \left(\frac{conj(A)}{norm(A)^2}\right) * B$$

`quaternion`

mtimes, *

Quaternion multiplication

Syntax

```
quatC = A*B
```

Description

`quatC = A*B` implements quaternion multiplication if either `A` or `B` is a quaternion. Either `A` or `B` must be a scalar.

You can use quaternion multiplication to compose rotation operators:

- To compose a sequence of frame rotations, multiply the quaternions in the order of the desired sequence of rotations. For example, to apply a p quaternion followed by a q quaternion, multiply in the order pq. The rotation operator becomes $(pq)^*v(pq)$, where v represents the object to rotate specified in quaternion form. * represents conjugation.
- To compose a sequence of point rotations, multiply the quaternions in the reverse order of the desired sequence of rotations. For example, to apply a p quaternion followed by a q quaternion, multiply in the reverse order, qp. The rotation operator becomes $(qp)v(qp)^*$.

Examples

Multiply Quaternion Scalar and Quaternion Vector

Create a 4-by-1 column vector, `A`, and a scalar, `b`. Multiply `A` times `b`.

```
A = quaternion(randn(4,4))
```

```
A = 4×1 quaternion array
      0.53767 +  0.31877i +   3.5784j +   0.7254k
       1.8339 -   1.3077i +   2.7694j - 0.063055k
      -2.2588 -  0.43359i -   1.3499j +  0.71474k
      0.86217 +  0.34262i +   3.0349j -  0.20497k
```

```
b = quaternion(randn(1,4))
```

```
b = quaternion
    -0.12414 +  1.4897i +   1.409j +  1.4172k
```

```
C = A*b
```

```
C = 4×1 quaternion array
      -6.6117 +   4.8105i +  0.94224j -   4.2097k
      -2.0925 +   6.9079i +   3.9995j -   3.3614k
       1.8155 -   6.2313i -    1.336j -     1.89k
      -4.6033 +   5.8317i + 0.047161j -    2.791k
```

Input Arguments

A — Input to multiply

`quaternion` object | array of `quaternion` objects | real scalar | array of real numbers

Input to multiply, specified as a `quaternion` object, an array of `quaternion` objects of any dimensionality, a real scalar, or an array of real numbers of any dimensionality. Numeric values must be of data type `single` or `double`.

If `B` is nonscalar, then `A` must be scalar.

B — Input to multiply

`quaternion` object | array of `quaternion` objects | real scalar | array of real numbers

Input to multiply, specified as a `quaternion` object, an array of `quaternion` objects of any dimensionality, a real scalar, or an array of real numbers of any dimensionality. Numeric values must be of data type `single` or `double`.

If `A` is nonscalar, then `B` must be scalar.

Output Arguments

quatC — Quaternion product

`quaternion` object | array of `quaternion` objects

Quaternion product, returned as a `quaternion` object or an array of `quaternion` objects.

Algorithms

Quaternion Multiplication by a Real Scalar

Given a quaternion

$$q = a_q + b_q\mathrm{i} + c_q\mathrm{j} + d_q\mathrm{k},$$

the product of q and a real scalar β is

$$\beta q = \beta a_q + \beta b_q\mathrm{i} + \beta c_q\mathrm{j} + \beta d_q\mathrm{k}$$

Quaternion Multiplication by a Quaternion Scalar

The definition of the basis elements for quaternions,

$$\mathrm{i}^2 = \mathrm{j}^2 = \mathrm{k}^2 = \mathrm{ijk} = -1,$$

can be expanded to populate a table summarizing quaternion basis element multiplication:

	1	**i**	**j**	**k**
1	1	i	j	k
i	i	−1	k	−j

j	j	−k	−1	i
k	k	j	−i	−1

When reading the table, the rows are read first, for example: ij = k and ji = −k.

Given two quaternions, $q = a_q + b_q i + c_q j + d_q k$, and $p = a_p + b_p i + c_p j + d_p k$, the multiplication can be expanded as:

$$\begin{aligned} z = pq &= \left(a_p + b_p i + c_p j + d_p k\right)\left(a_q + b_q i + c_q j + d_q k\right) \\ &= a_p a_q + a_p b_q i + a_p c_q j + a_p d_q k \\ &+ b_p a_q i + b_p b_q i^2 + b_p c_q ij + b_p d_q ik \\ &+ c_p a_q j + c_p b_q ji + c_p c_q j^2 + c_p d_q jk \\ &+ d_p a_q k + d_p b_q ki + d_p c_q kj + d_p d_q k^2 \end{aligned}$$

You can simplify the equation using the quaternion multiplication table:

$$\begin{aligned} z = pq &= a_p a_q + a_p b_q i + a_p c_q j + a_p d_q k \\ &+ b_p a_q i - b_p b_q + b_p c_q k - b_p d_q j \\ &+ c_p a_q j - c_p b_q k - c_p c_q + c_p d_q i \\ &+ d_p a_q k + d_p b_q j - d_p c_q i - d_p d_q \end{aligned}$$

Functions

`.*,times`

Objects

`quaternion`

norm

Quaternion norm

Syntax

```
N = norm(quat)
```

Description

`N = norm(quat)` returns the quaternion's norm, `quat`, as the square root of the sum of its component squared.

Given a quaternion of the form $Q = a + b\mathrm{i} + c\mathrm{j} + d\mathrm{k}$, the norm of the quaternion is defined as $\mathrm{norm}(Q) = \sqrt{a^2 + b^2 + c^2 + d^2}$.

Examples

Calculate Quaternion Norm

Create a scalar quaternion and calculate its norm.

```
quat = quaternion(1,2,3,4);
norm(quat)
```

```
ans =
5.4772
```

The quaternion norm is defined as the square root of the sum of the quaternion parts squared. Calculate the quaternion norm explicitly to verify the result of the `norm` function.

```
[a,b,c,d] = parts(quat);
sqrt(a^2+b^2+c^2+d^2)
```

```
ans =
5.4772
```

Input Arguments

quat — Quaternion

`quaternion` object | array of `quaternion` objects

Quaternion for which to calculate the norm, specified as a `quaternion` object or an array of `quaternion` objects of any dimensionality.

Output Arguments

N — Quaternion norm

real scalar | array of real numbers

Quaternion norm, returned as a real scalar or an array of real numbers of the same size as the `quat` argument. Elements of `N` are of the same data type as the underlying data type of `quat`.

Data Types: `single` | `double`

Functions

`normalize` | `parts` | `conj`

Objects

`quaternion`

normalize

Quaternion normalization

Syntax

```
quatNormalized = normalize(quat)
```

Description

`quatNormalized = normalize(quat)` normalizes the quaternion.

Given a quaternion of the form $Q = a + b\mathrm{i} + c\mathrm{j} + d\mathrm{k}$, the normalized quaternion is defined as $Q/\sqrt{a^2 + b^2 + c^2 + d^2}$.

Examples

Normalize Elements of Quaternion Vector

Quaternions can represent rotations when normalized. You can use `normalize` to normalize a scalar, elements of a matrix, or elements of a multi-dimensional array of quaternions. Create a column vector of quaternions, then normalize them.

```
quatArray = quaternion([1,2,3,4; ...
                        2,3,4,1; ...
                        3,4,1,2]);
quatArrayNormalized = normalize(quatArray)
```

```
quatArrayNormalized = 3×1 quaternion array
     0.18257 + 0.36515i + 0.54772j +  0.7303k
     0.36515 + 0.54772i +  0.7303j + 0.18257k
     0.54772 +  0.7303i + 0.18257j + 0.36515k
```

Input Arguments

quat — Quaternion to normalize

`quaternion` object | array of `quaternion` objects

Quaternion to normalize, specified as a `quaternion` object or an array of `quaternion` objects of any dimensionality.

Output Arguments

quatNormalized — Normalized quaternion

`quaternion` object | array of `quaternion` objects

Normalized quaternion, returned as a `quaternion` object or an array of `quaternion` objects of the same size as the `quat` argument.

Functions

`norm` | `.*,times` | `conj`

Objects

`quaternion`

ones

Create quaternion array with real parts set to one and imaginary parts set to zero

Syntax

```
quatOnes = ones("quaternion")
quatOnes = ones(n,"quaternion")
quatOnes = ones(sz,"quaternion")
quatOnes = ones(sz1,...,szN,"quaternion")

quatOnes = ones( ___ ,"like",prototype,"quaternion")
```

Description

`quatOnes = ones("quaternion")` returns a scalar quaternion with the real part set to 1 and the imaginary parts set to 0.

Given a quaternion of the form $Q = a + b\mathrm{i} + c\mathrm{j} + d\mathrm{k}$, a quaternion one is defined as $Q = 1 + 0\mathrm{i} + 0\mathrm{j} + 0\mathrm{k}$.

`quatOnes = ones(n,"quaternion")` returns an `n`-by-`n` quaternion matrix with the real parts set to 1 and the imaginary parts set to 0.

`quatOnes = ones(sz,"quaternion")` returns an array of quaternion ones where the size vector, `sz`, defines `size(qOnes)`.

Example: `ones([1,4,2],"quaternion")` returns a 1-by-4-by-2 array of quaternions with the real parts set to `1` and the imaginary parts set to `0`.

`quatOnes = ones(sz1,...,szN,"quaternion")` returns a `sz1`-by-...-by-`szN` array of ones where `sz1,…,szN` indicates the size of each dimension.

`quatOnes = ones( ___ ,"like",prototype,"quaternion")` specifies the underlying class of the returned quaternion array to be the same as the underlying class of the quaternion prototype.

Examples

Quaternion Scalar One

Create a quaternion scalar one.

```
quatOnes = ones("quaternion")
```

```
quatOnes = quaternion
     1 + 0i + 0j + 0k
```

Square Matrix of Quaternion Ones

Create an n-by-n matrix of quaternion ones.

```
n = 3;
quatOnes = ones(n,"quaternion")
```

```
quatOnes = 3×3 quaternion array
     1 + 0i + 0j + 0k     1 + 0i + 0j + 0k     1 + 0i + 0j + 0k
     1 + 0i + 0j + 0k     1 + 0i + 0j + 0k     1 + 0i + 0j + 0k
     1 + 0i + 0j + 0k     1 + 0i + 0j + 0k     1 + 0i + 0j + 0k
```

Multidimensional Array of Quaternion Ones

Create a multidimensional array of quaternion ones by defining array dimensions in order. In this example, you create a 3-by-1-by-2 array. You can specify dimensions using a row vector or comma-separated integers. Specify the dimensions using a row vector and display the results:

```
dims = [3,1,2];
quatOnesSyntax1 = ones(dims,"quaternion")
```

```
quatOnesSyntax1 = 3×1×2 quaternion array
quatOnesSyntax1(:,:,1) =

     1 + 0i + 0j + 0k
     1 + 0i + 0j + 0k
     1 + 0i + 0j + 0k

quatOnesSyntax1(:,:,2) =

     1 + 0i + 0j + 0k
     1 + 0i + 0j + 0k
     1 + 0i + 0j + 0k
```

Specify the dimensions using comma-separated integers, and then verify the equivalency of the two syntaxes:

```
quatOnesSyntax2 = ones(3,1,2,"quaternion");
isequal(quatOnesSyntax1,quatOnesSyntax2)
```

```
ans = logical
   1
```

Underlying Class of Quaternion Ones

A quaternion is a four-part hyper-complex number used in three-dimensional rotations and orientations. You can specify the underlying data type of the parts as `single` or `double`. The default is `double`.

Create a quaternion array of ones with the underlying data type set to `single`.

```
quatOnes = ones(2,"like",single(1),"quaternion")
```

```
quatOnes = 2×2 quaternion array
     1 + 0i + 0j + 0k     1 + 0i + 0j + 0k
     1 + 0i + 0j + 0k     1 + 0i + 0j + 0k
```

Verify the underlying class using the `classUnderlying` function.

```
classUnderlying(quatOnes)
```

```
ans =
'single'
```

Input Arguments

`n` — Size of square quaternion matrix

integer value

Size of square quaternion matrix, specified as an integer value.

If `n` is zero or negative, then `quatOnes` is returned as an empty matrix.

Example: `ones(4,"quaternion")` returns a 4-by-4 matrix of quaternions with the real parts set to `1` and the imaginary parts set to `0`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`sz` — Output size

row vector of integer values

Output size, specified as a row vector of integer values. Each element of `sz` indicates the size of the corresponding dimension in `quatOnes`. If the size of any dimension is `0` or negative, then `quatOnes` is returned as an empty array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`prototype` — Quaternion prototype

`quaternion` object

Quaternion prototype, specified as a `quaternion` object.

Example: `ones(2,"like",quat,"quaternion")` returns a 2-by-2 matrix of quaternions with the same underlying class as the prototype quaternion, `quat`.

`sz1,...,szN` — Size of each dimension

two or more integer values

Size of each dimension, specified as two or more comma-separated integers. If the size of any dimension is `0` or negative, then `quatOnes` is returned as an empty array.

Example: `ones(2,3,"quaternion")` returns a 2-by-3 matrix of quaternions with the real parts set to `1` and the imaginary parts set to `0`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`quatOnes` — Quaternion ones
`quaternion` object | array of `quaternion` objects

Quaternion ones, returned as a `quaternion` object or an array of `quaternion` objects.

Given a quaternion of the form $Q = a + b\mathrm{i} + c\mathrm{j} + d\mathrm{k}$, a quaternion one is defined as $Q = 1 + 0\mathrm{i} + 0\mathrm{j} + 0\mathrm{k}$.

Functions
`zeros`

Objects
`quaternion`

parts

Extract quaternion parts

Syntax

```
[a,b,c,d] = parts(quat)
```

Description

`[a,b,c,d] = parts(quat)` returns the parts of the quaternion array as arrays, each the same size as `quat`.

Examples

Convert Quaternion to Matrix of Quaternion Parts

Convert a quaternion representation to parts using the `parts` function.

Create a two-element column vector of quaternions by specifying the parts.

```
quat = quaternion([1:4;5:8])
```

```
quat = 2×1 quaternion array
     1 + 2i + 3j + 4k
     5 + 6i + 7j + 8k
```

Recover the parts from the quaternion matrix using the `parts` function. The parts are returned as separate output arguments, each the same size as the input 2-by-1 column vector of quaternions.

```
[qA,qB,qC,qD] = parts(quat)
```

```
qA = 2×1

     1
     5

qB = 2×1

     2
     6

qC = 2×1

     3
     7

qD = 2×1
```

```
     4
     8
```

Input Arguments

`quat` — Quaternion

`quaternion` object | array of `quaternion` objects

Quaternion, specified as a `quaternion` object or an array of `quaternion` objects of any dimensionality.

Output Arguments

`[a,b,c,d]` — Quaternion parts

numeric array

Quaternion parts, returned as four comma-separated numeric arrays: `a`, `b`, `c`, and `d`. Each part is the same size as `quat`.

Data Types: `single` | `double`

Functions

`classUnderlying` | `compact`

Objects

`quaternion`

power, .^

Element-wise quaternion power

Syntax

```
C = A.^b
```

Description

`C = A.^b` raises each element of `A` to the corresponding power in `b`.

Examples

Raise a Quaternion to a Real Scalar Power

Create a quaternion and raise it to a real scalar power.

```
A = quaternion(1,2,3,4)
```

```
A = quaternion
     1 + 2i + 3j + 4k
```

```
b = 3;
C = A.^b
```

```
C = quaternion
     -86 -  52i -  78j - 104k
```

Raise a Quaternion Array to Powers from a Multidimensional Array

Create a 2-by-1 quaternion array and raise it to powers from a 2-D array.

```
A = quaternion([1:4;5:8])
```

```
A = 2×1 quaternion array
     1 + 2i + 3j + 4k
     5 + 6i + 7j + 8k
```

```
b = [1 0 2; 3 2 1]
```

```
b = 2×3

     1     0     2
     3     2     1
```

```
C = A.^b
```

```
C = 2×3 quaternion array
        1 +    2i +    3j +    4k        1 +    0i +    0j +    0k      -28 +    4i +    6j +
    -2110 -  444i -  518j -  592k     -124 +   60i +   70j +   80k        5 +    6i +    7j +
```

Input Arguments

A — Base

`quaternion` object | array of `quaternion` objects

Base, specified as a `quaternion` object or an array of `quaternion` objects of any dimensionality.

`A` and `b` must have compatible sizes. In the simplest cases, they can be the same size or one can be a scalar. Two inputs have compatible sizes if, for every dimension, the dimension sizes of the inputs are the same or one of the dimensions is 1.

b — Exponent

real scalar | array of real numbers

Exponent, specified as a real scalar or an array of real numbers.

`A` and `b` must have compatible sizes. In the simplest cases, they can be the same size or one can be a scalar. Two inputs have compatible sizes if, for every dimension, the dimension sizes of the inputs are the same or one of the dimensions is 1.

Data Types: `single` | `double`

Output Arguments

C — Result

`quaternion` object | array of `quaternion` objects

Each element of quaternion `A` raised to the corresponding power in `b`, returned as a `quaternion` object or an array of `quaternion` objects.

Algorithms

The polar representation of a quaternion $A = a + b\mathrm{i} + c\mathrm{j} + d\mathrm{k}$ is given by

$$A = \|A\|(\cos\theta + \widehat{u}\sin\theta)$$

where θ is the angle of rotation, and $\hat{u}$ is the unit quaternion.

Quaternion A raised by a real exponent b is given by

$$P = A.\hat{}\,b = \|A\|^{b}(\cos(b\theta) + \widehat{u}\sin(b\theta))$$

Functions
`log` | `exp`

Objects
`quaternion`

prod

Product of quaternion array

Syntax

```
quatProd = prod(quat)
quatProd = prod(quat,dim)
```

Description

`quatProd = prod(quat)` returns the quaternion product of the elements of the array.

`quatProd = prod(quat,dim)` calculates the quaternion product along dimension `dim`.

Examples

Product of Quaternions in Each Column

Create a 3-by-3 array whose elements correspond to their linear indices.

```
A = reshape(quaternion(randn(9,4)),3,3)
```

```
A = 3×3 quaternion array
      0.53767 +   2.7694i +    1.409j -  0.30344k      0.86217 +   0.7254i -   1.2075j +   0.888
       1.8339 -   1.3499i +   1.4172j +  0.29387k      0.31877 - 0.063055i +  0.71724j -   1.147
      -2.2588 +   3.0349i +   0.6715j -  0.78728k      -1.3077 +  0.71474i +   1.6302j -   1.068
```

Find the product of the quaternions in each column. The length of the first dimension is `1`, and the length of the second dimension matches `size(A,2)`.

```
B = prod(A)
```

```
B = 1×3 quaternion array
     -19.837 -  9.1521i +  15.813j -  19.918k     -5.4708 - 0.28535i +   3.077j -  1.2295k      -
```

Product of Specified Dimension of Quaternion Array

You can specify which dimension of a quaternion array to take the product of.

Create a 2-by-2-by-2 quaternion array.

```
A = reshape(quaternion(randn(8,4)),2,2,2);
```

Find the product of the elements in each page of the array. The length of the first dimension matches `size(A,1)`, the length of the second dimension matches `size(A,2)`, and the length of the third dimension is `1`.

```
dim = 3;
B = prod(A,dim)

B = 2×2 quaternion array
     -2.4847 +  1.1659i - 0.37547j +  2.8068k     0.28786 - 0.29876i - 0.51231j -  4.2972k
     0.38986 -  3.6606i -  2.0474j -   6.047k      -1.741 - 0.26782i +  5.4346j +  4.1452k
```

Input Arguments

`quat` — Quaternions

array of `quaternion` objects

Quaternions, specified as an array of `quaternion` objects of any dimensionality.

Example: `qProd = prod(quat)` calculates the quaternion product along the first non-singleton dimension of `quat`.

`dim` — Dimension

positive integer

Dimension along which to calculate the quaternion product, specified as a positive integer. If `dim` is not specified, `prod` operates along the first non-singleton dimension of `quat`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`quatProd` — Quaternion product

array of `quaternion` objects

Quaternion product, returned as an array of `quaternion` objects. `quatProd` has one less non-singleton dimension than `quat`.

For example, if `quat` is a 2-by-2-by-5 array,

- `prod(quat,1)` returns a 1-by-2-by-5 array.
- `prod(quat,2)` returns a 2-by-1-by-5 array.
- `prod(quat,3)` returns a 2-by-2 array.

Functions
`mtimes, *` | `times, .*`

Objects
`quaternion`

rdivide, ./

Element-wise quaternion right division

Syntax

```
C = A./B
```

Description

`C = A./B` performs quaternion element-wise division by dividing each element of quaternion `A` by the corresponding element of quaternion `B`.

Examples

Divide a Quaternion Array by a Real Scalar

Create a 2-by-1 quaternion array, and divide it element-by-element by a real scalar.

```
A = quaternion([1:4;5:8])
```

```
A = 2×1 quaternion array
     1 + 2i + 3j + 4k
     5 + 6i + 7j + 8k
```

```
B = 2;
C = A./B
```

```
C = 2×1 quaternion array
     0.5 +   1i + 1.5j +   2k
     2.5 +   3i + 3.5j +   4k
```

Divide a Quaternion Array by Another Quaternion Array

Create a 2-by-2 quaternion array, and divide it element-by-element by another 2-by-2 quaternion array.

```
q1 = quaternion(magic(4));
A = reshape(q1,2,2)
```

```
A = 2×2 quaternion array
     16 +  2i +  3j + 13k      9 +  7i +  6j + 12k
      5 + 11i + 10j +  8k      4 + 14i + 15j +  1k
```

```
q2 = quaternion([1:4;3:6;2:5;4:7]);
B = reshape(q2,2,2)
```

```
B = 2×2 quaternion array
     1 + 2i + 3j + 4k     2 + 3i + 4j + 5k
     3 + 4i + 5j + 6k     4 + 5i + 6j + 7k

C = A./B

C = 2×2 quaternion array
          2.7 -      0.1i -      2.1j -      1.7k       2.2778 + 0.092593i -  0.46296j -  0.5740
       1.8256 - 0.081395i +  0.45349j -  0.24419k       1.4524 -      0.5i +   1.0238j -   0.261
```

Input Arguments

A — Dividend

`quaternion` object | array of `quaternion` objects | real scalar | array of real numbers

Dividend, specified as a `quaternion` object, an array of `quaternion` objects of any dimensionality, a real scalar, or an array of real numbers of any dimensionality. Numeric values must be of data type `single` or `double`.

`A` and `B` must have compatible sizes. In the simplest cases, they can be the same size or one can be a scalar. Two inputs have compatible sizes if, for every dimension, the dimension sizes of the inputs are the same or one of the dimensions is 1.

B — Divisor

`quaternion` object | array of `quaternion` objects | real scalar | array of real numbers

Divisor, specified as a `quaternion` object, an array of `quaternion` objects of any dimensionality, a real scalar, or an array of real numbers of any dimensionality. Numeric values must be of data type `single` or `double`.

`A` and `B` must have compatible sizes. In the simplest cases, they can be the same size or one can be a scalar. Two inputs have compatible sizes if, for every dimension, the dimension sizes of the inputs are the same or one of the dimensions is 1.

Output Arguments

C — Result

`quaternion` object | array of `quaternion` objects

Result of quaternion division, returned as a `quaternion` object or an array of `quaternion` objects.

Algorithms

Quaternion Division

Given a quaternion $A = a_1 + a_2\mathrm{i} + a_3\mathrm{j} + a_4\mathrm{k}$ and a real scalar p,

$$C = A./p = \frac{a_1}{p} + \frac{a_2}{p}\mathrm{i} + \frac{a_3}{p}\mathrm{j} + \frac{a_4}{p}\mathrm{k}$$

Note For a real scalar p, $A./p = p.\backslash A$.

Quaternion Division by a Quaternion Scalar

Given two quaternions A and B of compatible sizes,

$$C = A./B = A.*B^{-1} = A.*\left(\frac{conj(B)}{norm(B)^2}\right)$$

Objects

`quaternion`

randrot

Uniformly distributed random rotations

Syntax

```
R = randrot
R = randrot(m)
R = randrot(m1,...,mN)
R = randrot([m1,...,mN])
```

Description

`R = randrot` returns a unit quaternion drawn from a uniform distribution of random rotations.

`R = randrot(m)` returns an `m`-by-`m` matrix of unit quaternions drawn from a uniform distribution of random rotations.

`R = randrot(m1,...,mN)` returns an `m1`-by-...-by-`mN` array of random unit quaternions, where `m1`, ..., `mN` indicate the size of each dimension. For example, `randrot(3,4)` returns a 3-by-4 matrix of random unit quaternions.

`R = randrot([m1,...,mN])` returns an `m1`-by-...-by-`mN` array of random unit quaternions, where `m1`,..., `mN` indicate the size of each dimension. For example, `randrot([3,4])` returns a 3-by-4 matrix of random unit quaternions.

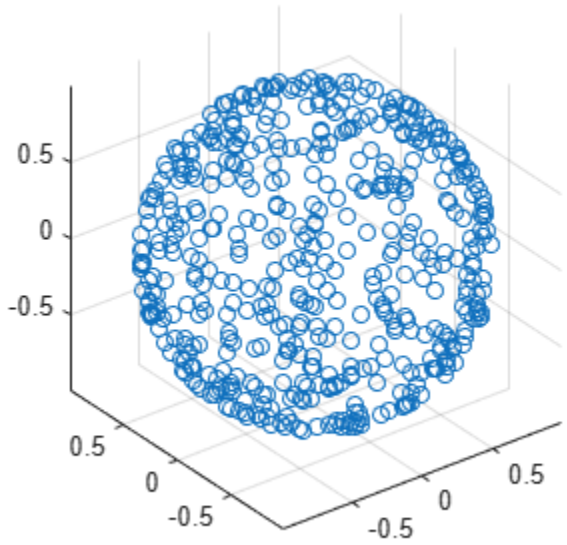
Examples

Matrix of Random Rotations

Generate a 3-by-3 matrix of uniformly distributed random rotations.

```
r = randrot(3)
```

```
r = 3×3 quaternion array
      0.17446 +  0.59506i -  0.73295j +  0.27976k      0.69704 - 0.060589i +  0.68679j -  0.1969
      0.21908 -  0.89875i -    0.298j +  0.23548k    -0.049744 +  0.59691i +  0.56459j +  0.5678
       0.6375 +  0.49338i -  0.24049j +  0.54068k       0.2979 -  0.53568i +  0.31819j +  0.7232
```



Create Uniform Distribution of Random Rotations

Create a vector of 500 random quaternions. Use `rotatepoint` to visualize the distribution of the random rotations applied to point (1, 0, 0).

```
q = randrot(500,1);

pt = rotatepoint(q, [1 0 0]);
```

```
figure
scatter3(pt(:,1), pt(:,2), pt(:,3))
axis equal
```

Input Arguments

`m` — Size of square matrix

integer

Size of square quaternion matrix, specified as an integer value. If `m` is `0` or negative, then `R` is returned as an empty matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`m1,...,mN` — Size of each dimension

two or more integer values

Size of each dimension, specified as two or more comma-separated integer values. If the size of any dimension is `0` or negative, then `R` is returned as an empty array.

Example: `randrot(2,3)` returns a 2-by-3 matrix of random quaternions.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`[m1,...,mN]` — Vector of size of each dimension

row vector of integer values

Vector of size of each dimension, specified as a row vector of two or more integer values. If the size of any dimension is `0` or negative, then `R` is returned as an empty array.

Example: `randrot([2,3])` returns a 2-by-3 matrix of random quaternions.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

R — Random quaternions
`quaternion` object | array of `quaternion` objects

Random quaternions, returned as a `quaternion` object or an array of `quaternion` objects.

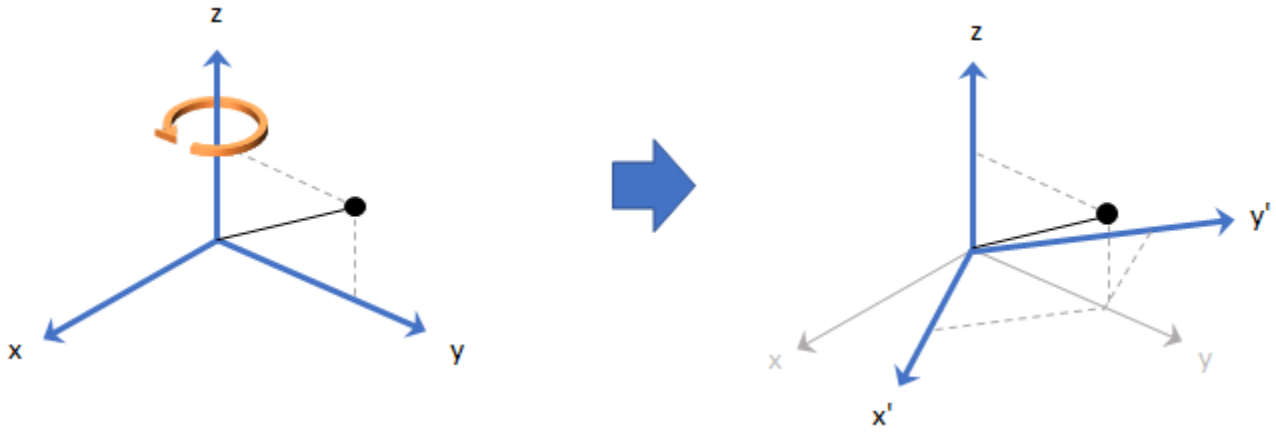
`quaternion`

rotateframe



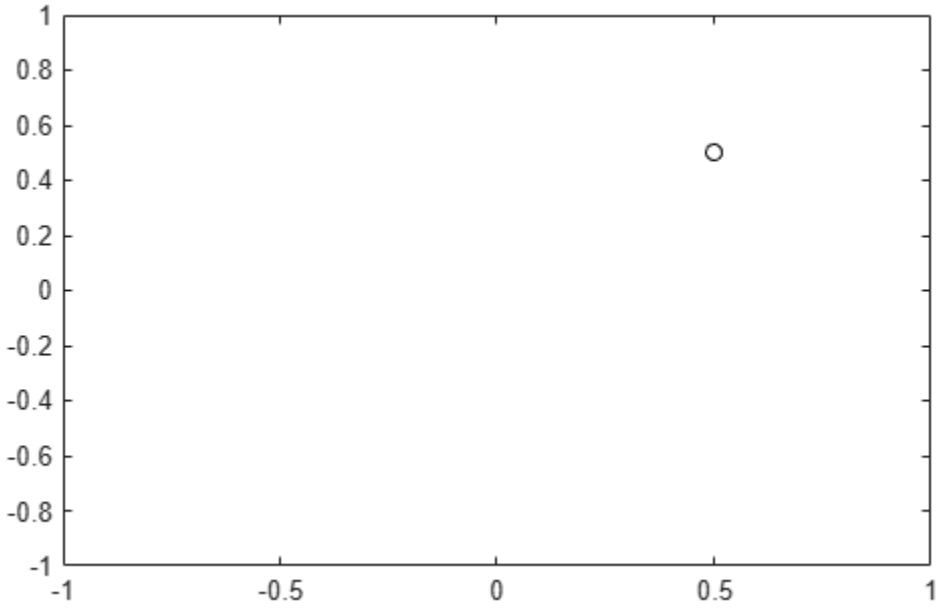
Quaternion frame rotation

Syntax

```
rotationResult = rotateframe(quat,cartesianPoints)
```

Description

`rotationResult = rotateframe(quat,cartesianPoints)` rotates the frame of reference for the Cartesian points using the quaternion, `quat`. The elements of the quaternion are normalized before use in the rotation.



Examples

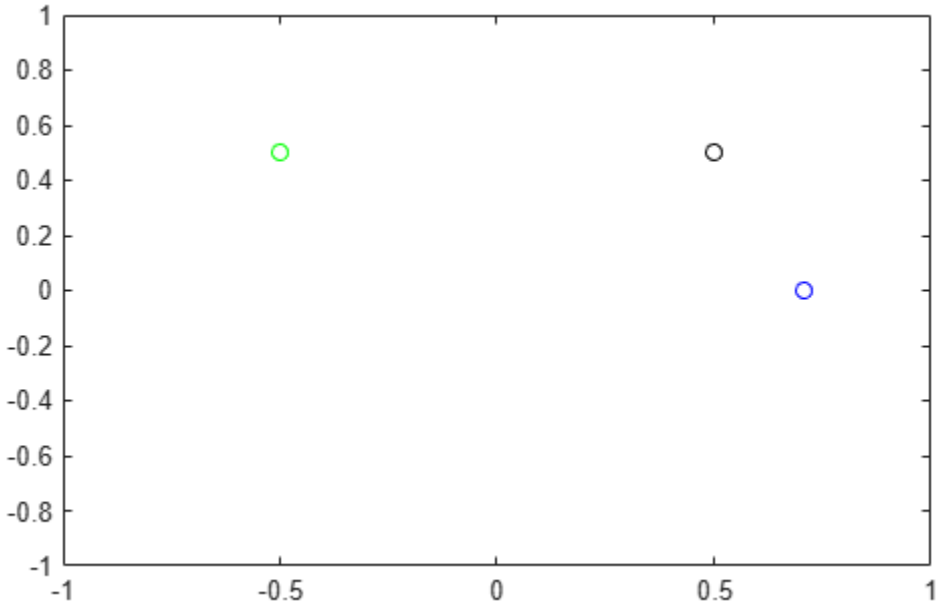
Rotate Frame Using Quaternion Vector

Define a point in three dimensions. The coordinates of a point are always specified in the order *x*, *y*, and *z*. For convenient visualization, define the point on the *x*-*y* plane.

```
x = 0.5;
y = 0.5;
z = 0;
plot(x,y,"ko")
hold on
axis([-1 1 -1 1])
```

Create a quaternion vector specifying two separate rotations, one to rotate the frame 45 degrees and another to rotate the point -90 degrees about the *z*-axis. Use `rotateframe` to perform the rotations.

```
quat = quaternion([0,0,pi/4; ...
                   0,0,-pi/2],"euler","XYZ","frame");



rereferencedPoint = rotateframe(quat,[x,y,z])
```

```
rereferencedPoint = 2×3

    0.7071   -0.0000         0
   -0.5000    0.5000         0
```

Plot the re-referenced points.

```
plot(rereferencedPoint(1,1),rereferencedPoint(1,2),"bo")
plot(rereferencedPoint(2,1),rereferencedPoint(2,2),"go")
```

Re-reference Group of Points using Quaternion

Define two points in three-dimensional space. Define a quaternion to re-reference the points by first rotating the reference frame about the *z*-axis 30 degrees and then about the new *y*-axis 45 degrees.

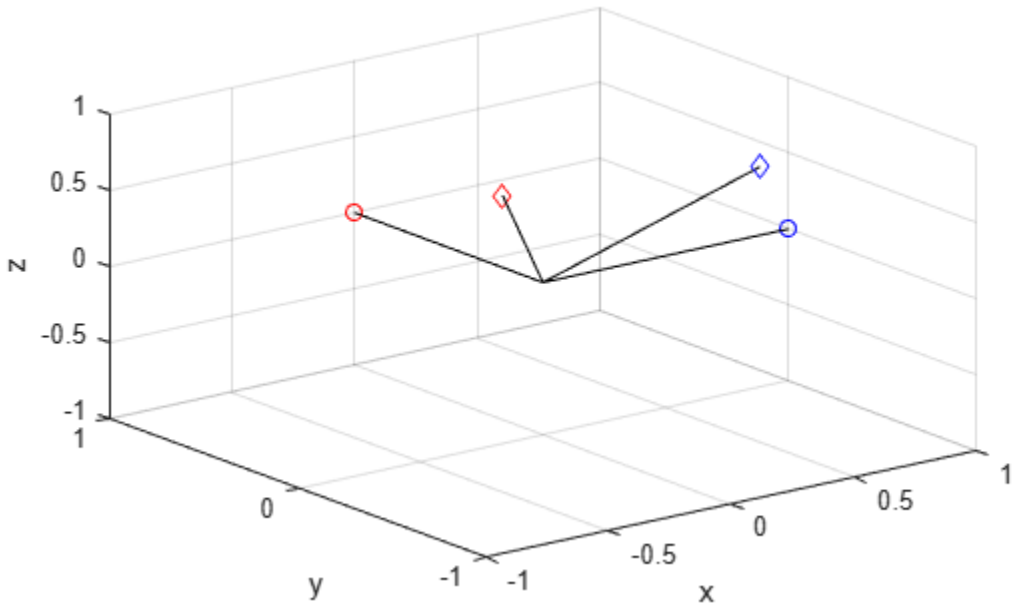
```
a = [1,0,0];
b = [0,1,0];
quat = quaternion([30,45,0],"eulerd","ZYX","point");
```

Use `rotateframe` to reference both points using the quaternion rotation operator. Display the result.

```
rP = rotateframe(quat,[a;b])
```

```
rP = 2×3

    0.6124   -0.3536    0.7071
    0.5000    0.8660   -0.0000
```



Visualize the original orientation and the rotated orientation of the points. Draw lines from the origin to each of the points for visualization purposes.

```
plot3(a(1),a(2),a(3),"bo");

hold on
grid on
axis([-1 1 -1 1 -1 1])
xlabel("x")
ylabel("y")
zlabel("z")
```

```
plot3(b(1),b(2),b(3),"ro");
plot3(rP(1,1),rP(1,2),rP(1,3),"bd")
plot3(rP(2,1),rP(2,2),rP(2,3),"rd")

plot3([0;rP(1,1)],[0;rP(1,2)],[0;rP(1,3)],"k")
plot3([0;rP(2,1)],[0;rP(2,2)],[0;rP(2,3)],"k")
plot3([0;a(1)],[0;a(2)],[0;a(3)],"k")
plot3([0;b(1)],[0;b(2)],[0;b(3)],"k")
```

Input Arguments

quat — Quaternion that defines rotation

`quaternion` object | vector of `quaternion` objects

Quaternion that defines rotation, specified as a `quaternion` object or a vector of `quaternion` objects. `quat` and `cartesianPoints` must have compatible sizes:

- `length(quat) == size(cartesianPoints,1)`, or
- `length(quat) == 1`, or
- `size(cartesianPoints,1) == 1`

cartesianPoints — Three-dimensional Cartesian points

1-by-3 numeric vector | *N*-by-3 numeric matrix

Three-dimensional Cartesian points, specified as a 1-by-3 numeric vector representing a single point or an *N*-by-3 numeric matrix representing *N* points. `quat` and `cartesianPoints` must have compatible sizes:

- `length(quat) == size(cartesianPoints,1)` or

- `length(quat) == 1`, or
- `size(cartesianPoints,1) == 1`

Data Types: `single` | `double`

Output Arguments

`rotationResult` — Re-referenced Cartesian points

1-by-3 numeric vector | numeric matrix

Cartesian points defined in reference to rotated reference frame, returned as a 1-by-3 numeric vector or a numeric matrix.

`rotationResult` is a 1-by-3 vector when `quat` is a scalar `quaternion` object and `cartesianPoints` is a 1-by-3 vector representing a single point. Otherwise, `rotationResult` is an *M*-by-3 matrix, where *M* is the maximum of `length(quat)` and `size(cartesianPoints,1)`.

Data Types: `single` | `double`

Algorithms

Quaternion frame rotation re-references a point specified in $\mathbf{R}^3$ by rotating the original frame of reference according to a specified quaternion:

$$L_q(u) = q^*uq$$

where q is the quaternion, * represents conjugation, and u is the point to rotate, specified as a quaternion.

For convenience, the `rotateframe` function takes a point in $\mathbf{R}^3$ and returns a point in $\mathbf{R}^3$. Given a function call with some arbitrary quaternion, $q = a + b\mathrm{i} + c\mathrm{j} + d\mathrm{k}$, and arbitrary coordinate, $[x,y,z]$,

```
point = [x,y,z];
rereferencedPoint = rotateframe(q,point)
```

the `rotateframe` function performs the following operations:

1. Converts point $[x,y,z]$ to a quaternion:

   $$u_q = 0 + xi + yj + zk$$

2. Normalizes the quaternion, q:

   $$q_n = \frac{q}{\sqrt{a^2 + b^2 + c^2 + d^2}}$$

3. Applies the rotation:

   $$v_q = q^*u_qq$$

4. Converts the quaternion output, v_q, back to $\mathbf{R}^3$

plot3([0;b(1)],[0;b(2)],[0;b(3)],"k")
```

Input Arguments

quat — Quaternion that defines rotation

`quaternion` object | vector of `quaternion` objects

Quaternion that defines rotation, specified as a `quaternion` object or a vector of `quaternion` objects. `quat` and `cartesianPoints` must have compatible sizes:

- `length(quat) == size(cartesianPoints,1)`, or
- `length(quat) == 1`, or
- `size(cartesianPoints,1) == 1`

cartesianPoints — Three-dimensional Cartesian points

1-by-3 numeric vector | *N*-by-3 numeric matrix

Three-dimensional Cartesian points, specified as a 1-by-3 numeric vector representing a single point or an *N*-by-3 numeric matrix representing *N* points. `quat` and `cartesianPoints` must have compatible sizes:

- `length(quat) == size(cartesianPoints,1)` or

- `length(quat) == 1`, or
- `size(cartesianPoints,1) == 1`

Data Types: `single` | `double`

Output Arguments

`rotationResult` — Repositioned Cartesian points

1-by-3 numeric vector | numeric matrix

Rotated Cartesian points defined using the quaternion rotation, returned as a 1-by-3 numeric vector or a numeric matrix.

`rotationResult` is a 1-by-3 vector when `quat` is a scalar `quaternion` object and `cartesianPoints` is a 1-by-3 vector representing a single point. Otherwise, `rotationResult` is an *M*-by-3 matrix, where *M* is the maximum of `length(quat)` and `size(cartesianPoints,1)`.

Data Types: `single` | `double`

Algorithms

Quaternion point rotation rotates a point specified in $\mathbf{R}^3$ according to a specified quaternion:

$$L_q(u) = quq^*$$

where q is the quaternion, * represents conjugation, and u is the point to rotate, specified as a quaternion.

For convenience, the `rotatepoint` function takes in a point in $\mathbf{R}^3$ and returns a point in $\mathbf{R}^3$. Given a function call with some arbitrary quaternion, $q = a + b\mathrm{i} + c\mathrm{j} + d\mathrm{k}$, and arbitrary coordinate, $[x,y,z]$, for example,

```
rereferencedPoint = rotatepoint(q,[x,y,z])
```

the `rotatepoint` function performs the following operations:

1. Converts point $[x,y,z]$ to a quaternion:

   $$u_q = 0 + xi + yj + zk$$

2. Normalizes the quaternion, q:

   $$q_n = \frac{q}{\sqrt{a^2 + b^2 + c^2 + d^2}}$$

3. Applies the rotation:

   $$v_q = qu_qq^*$$

4. Converts the quaternion output, v_q, back to $\mathbf{R}^3$

Functions

`rotateframe`

Objects

`quaternion`

rotmat

Convert quaternion to rotation matrix

Syntax

```
rotationMatrix = rotmat(quat,rotationType)
```

Description

`rotationMatrix = rotmat(quat,rotationType)` converts the quaternion, `quat`, to an equivalent rotation matrix representation.

Examples

Convert Quaternion to Rotation Matrix for Point Rotation

Define a quaternion for use in point rotation.

```
theta = 45;
gamma = 30;
quat = quaternion([0,theta,gamma],"eulerd","ZYX","point")
```

```
quat = quaternion
       0.8924 +  0.23912i +  0.36964j + 0.099046k
```

Convert the quaternion to a rotation matrix.

```
rotationMatrix = rotmat(quat,"point")
```

```
rotationMatrix = 3×3

    0.7071   -0.0000    0.7071
    0.3536    0.8660   -0.3536
   -0.6124    0.5000    0.6124
```

To verify the rotation matrix, directly create two rotation matrices corresponding to the rotations about the *y*- and *x*-axes. Multiply the rotation matrices and compare to the output of `rotmat`.

```
theta = 45;
gamma = 30;

ry = [cosd(theta)   0           sind(theta) ; ...
      0             1           0           ; ...
     -sind(theta)   0           cosd(theta)];

rx = [1             0           0           ;      ...
      0             cosd(gamma) -sind(gamma) ;     ...
      0             sind(gamma) cosd(gamma)];

rotationMatrixVerification = rx*ry
```

```
rotationMatrixVerification = 3×3

    0.7071         0    0.7071
    0.3536    0.8660   -0.3536
   -0.6124    0.5000    0.6124
```

Convert Quaternion to Rotation Matrix for Frame Rotation

Define a quaternion for use in frame rotation.

```
theta = 45;
gamma = 30;
quat = quaternion([0,theta,gamma],"eulerd","ZYX","frame")
```

```
quat = quaternion
       0.8924 +  0.23912i +  0.36964j - 0.099046k
```

Convert the quaternion to a rotation matrix.

```
rotationMatrix = rotmat(quat,"frame")
```

```
rotationMatrix = 3×3

    0.7071   -0.0000   -0.7071
    0.3536    0.8660    0.3536
    0.6124   -0.5000    0.6124
```

To verify the rotation matrix, directly create two rotation matrices corresponding to the rotations about the *y*- and *x*-axes. Multiply the rotation matrices and compare to the output of `rotmat`.

```
theta = 45;
gamma = 30;

ry = [cosd(theta)   0           -sind(theta) ; ...
      0             1           0            ; ...
     sind(theta)   0           cosd(theta)];

rx = [1             0           0            ;      ...
      0             cosd(gamma) sind(gamma) ;     ...
      0             -sind(gamma) cosd(gamma)];

rotationMatrixVerification = rx*ry
```

```
rotationMatrixVerification = 3×3

    0.7071         0   -0.7071
    0.3536    0.8660    0.3536
    0.6124   -0.5000    0.6124
```

Convert Quaternion Vector to Rotation Matrices

Create a 3-by-1 normalized quaternion vector.

```
qVec = normalize(quaternion(randn(3,4)));
```

Convert the quaternion array to rotation matrices. The pages of `rotmatArray` correspond to the linear index of `qVec`.

```
rotmatArray = rotmat(qVec,"frame");
```

Assume `qVec` and `rotmatArray` correspond to a sequence of rotations. Combine the quaternion rotations into a single representation, then apply the quaternion rotation to arbitrarily initialized Cartesian points.

```
loc = normalize(randn(1,3));
quat = prod(qVec);
rotateframe(quat,loc)
```

```
ans = 1×3

    0.9524    0.5297    0.9013
```

Combine the rotation matrices into a single representation, then apply the rotation matrix to the same initial Cartesian points. Verify the quaternion rotation and rotation matrix result in the same orientation.

```
totalRotMat = eye(3);
for i = 1:size(rotmatArray,3)
    totalRotMat = rotmatArray(:,:,i)*totalRotMat;
end
totalRotMat*loc'
```

```
ans = 3×1

    0.9524
    0.5297
    0.9013
```

Input Arguments

`quat` — Quaternion to convert

`quaternion` object | array of `quaternion` objects

Quaternion to convert, specified as a `quaternion` object or an array of `quaternion` objects of any dimensionality.

`rotationType` — Type or rotation

`"frame"` | `"point"`

Type of rotation represented by the `rotationMatrix` output, specified as `"frame"` or `"point"`.

Data Types: `char` | `string`

Output Arguments

`rotationMatrix` — Rotation matrix representation
3-by-3 numeric matrix | 3-by-3-by-*N* numeric array

Rotation matrix representation, returned as a 3-by-3 numeric matrix or 3-by-3-by-*N* numeric array.

- If `quat` is a scalar, `rotationMatrix` is returned as a 3-by-3 matrix.
- If `quat` is non-scalar, `rotationMatrix` is returned as a 3-by-3-by-*N* array, where `rotationMatrix(:,:,i)` is the rotation matrix corresponding to `quat(i)`.

The data type of the rotation matrix is the same as the underlying data type of `quat`.

Data Types: `single` | `double`

Algorithms

Given a quaternion of the form

$$q = a + bi + cj + dk\,,$$

the equivalent rotation matrix for frame rotation is defined as

$$\begin{bmatrix} 2a^2 - 1 + 2b^2 & 2bc + 2ad & 2bd - 2ac \\ 2bc - 2ad & 2a^2 - 1 + 2c^2 & 2cd + 2ab \\ 2bd + 2ac & 2cd - 2ab & 2a^2 - 1 + 2d^2 \end{bmatrix}.$$

The equivalent rotation matrix for point rotation is the transpose of the frame rotation matrix:

$$\begin{bmatrix} 2a^2 - 1 + 2b^2 & 2bc - 2ad & 2bd + 2ac \\ 2bc + 2ad & 2a^2 - 1 + 2c^2 & 2cd - 2ab \\ 2bd - 2ac & 2cd + 2ab & 2a^2 - 1 + 2d^2 \end{bmatrix}.$$

Functions
`rotvec` | `rotvecd` | `euler` | `eulerd`

Objects
`quaternion`

rotvec

Convert quaternion to rotation vector (radians)

Syntax

```
rotationVector = rotvec(quat)
```

Description

`rotationVector = rotvec(quat)` converts the quaternion array, `quat`, to an *N*-by-3 matrix of equivalent rotation vectors in radians. The elements of `quat` are normalized before conversion.

Examples

Convert Quaternion to Rotation Vector in Radians

Convert a random quaternion scalar to a rotation vector in radians

```
quat = quaternion(randn(1,4));
rotvec(quat)
```

```
ans = 1×3

    1.6866   -2.0774    0.7929
```

Input Arguments

`quat` — Quaternion to convert

`quaternion` object | array of `quaternion` objects

Quaternion to convert, specified as a `quaternion` object or an array of `quaternion` objects of any dimensionality.

Output Arguments

`rotationVector` — Rotation vector (radians)

N-by-3 numeric matrix

Rotation vector representation, in radians, returned as an *N*-by-3 numeric matrix of rotation vectors, where *N* is the number of quaternions in the `quat` argument.

Each row represents the [*X Y Z*] angles of the rotation vectors. The *i*th row of `rotationVector` corresponds to the element `quat(i)`.

The data type of the rotation vector is the same as the underlying data type of `quat`.

Data Types: `single` | `double`

Algorithms

All rotations in 3-D can be represented by a three-element axis of rotation and a rotation angle, for a total of four elements. If the rotation axis is constrained to be unit length, the rotation angle can be distributed over the vector elements to reduce the representation to three elements.

Recall that a quaternion can be represented in axis-angle form

$$q = \cos\left(\theta/2\right) + \sin\left(\theta/2\right)(\mathrm{xi} + y\mathrm{j} + z\mathrm{k}),$$

where θ is the angle of rotation and $[x,y,z]$ represent the axis of rotation.

Given a quaternion of the form

$$q = a + bi + cj + dk\,,$$

you can solve for the rotation angle using the axis-angle form of quaternions:

$$\theta = 2\cos^{-1}(a)\,.$$

Assuming a normalized axis, you can rewrite the quaternion as a rotation vector without loss of information by distributing θ over the parts b, c, and d. The rotation vector representation of q is

$$q_{\mathrm{rv}} = \frac{\theta}{\sin\left(\theta/2\right)}[b, c, d]\,.$$

Functions

`rotvecd` | `euler` | `eulerd`

Objects

`quaternion`

rotvecd

Convert quaternion to rotation vector (degrees)

Syntax

```
rotationVector = rotvecd(quat)
```

Description

`rotationVector = rotvecd(quat)` converts the quaternion array, `quat`, to an *N*-by-3 matrix of equivalent rotation vectors in degrees. The elements of `quat` are normalized before conversion.

Examples

Convert Quaternion to Rotation Vector in Degrees

Convert a random quaternion scalar to a rotation vector in degrees.

```
quat = quaternion(randn(1,4));
rotvecd(quat)
```

```
ans = 1×3

   96.6345 -119.0274   45.4312
```

Input Arguments

`quat` — Quaternion to convert

`quaternion` object | array of `quaternion` objects

Quaternion to convert, specified as a `quaternion` object or an array of `quaternion` objects of any dimensionality.

Output Arguments

`rotationVector` — Rotation vector representation (degrees)

N-by-3 numeric matrix

Rotation vector representation, in degrees, returned as an *N*-by-3 numeric matrix of rotation vectors, where *N* is the number of quaternions in the `quat` argument.

Each row represents the [*X Y Z*] angles of the rotation vectors in degrees. The *i*th row of `rotationVector` corresponds to the element `quat(i)`.

The data type of the rotation vector is the same as the underlying data type of `quat`.

Data Types: `single` | `double`

Algorithms

All rotations in 3-D can be represented by four elements: a three-element axis of rotation and a rotation angle. If the rotation axis is constrained to be unit length, the rotation angle can be distributed over the vector elements to reduce the representation to three elements.

Recall that a quaternion can be represented in axis-angle form

$$q = \cos\left(\theta/2\right) + \sin\left(\theta/2\right)(\mathrm{xi} + y\mathrm{j} + z\mathrm{k}),$$

where θ is the angle of rotation in degrees, and $[x,y,z]$ represent the axis of rotation.

Given a quaternion of the form

$$q = a + bi + cj + dk\,,$$

you can solve for the rotation angle using the axis-angle form of quaternions:

$$\theta = 2\cos^{-1}(a)\,.$$

Assuming a normalized axis, you can rewrite the quaternion as a rotation vector without loss of information by distributing θ over the parts b, c, and d. The rotation vector representation of q is

$$q_{\mathrm{rv}} = \frac{\theta}{\sin\left(\theta/2\right)}[b, c, d]\,.$$

Functions

`rotvec` | `euler` | `eulerd`

Objects

`quaternion`

slerp

Spherical linear interpolation

Syntax

```
q0 = slerp(q1,q2,T)
q0 = slerp(q1,q2,T,method)
```

Description

`q0 = slerp(q1,q2,T)` spherically interpolates between `q1` and `q2` by the interpolation coefficient `T`. This syntax chooses the shorter interpolation path, between `q1` and `q2`.

`q0 = slerp(q1,q2,T,method)` interpolates between `q1` and `q2` using the specified interpolation method.

Examples

Interpolate Between Two Quaternions

Create two quaternions with the following interpretation:

1. `a` = 45 degree rotation around the *z*-axis
2. `c` = -45 degree rotation around the *z*-axis

```
a = quaternion([45,0,0],"eulerd","ZYX","frame");
c = quaternion([-45,0,0],"eulerd","ZYX","frame");
```

Call `slerp` with the quaternions `a` and `c` and specify an interpolation coefficient of 0.5.

```
interpolationCoefficient = 0.5;

b = slerp(a,c,interpolationCoefficient);
```

The output of `slerp`, `b`, represents an average rotation of `a` and `c`. To verify, convert `b` to Euler angles in degrees.

```
averageRotation = eulerd(b,"ZYX","frame")
```

```
averageRotation = 1×3

     0     0     0
```

The interpolation coefficient is specified as a normalized value between `0` and `1`, inclusive. An interpolation coefficient of `0` corresponds to the `a` quaternion, and an interpolation coefficient of `1` corresponds to the `c` quaternion. Call `slerp` with coefficients `0` and `1` to confirm.

```
b = slerp(a,c,[0,1]);
eulerd(b,"ZYX","frame")
```

```
ans = 2×3

   45.0000         0         0
  -45.0000         0         0
```

You can create smooth paths between quaternions by specifying arrays of equally spaced interpolation coefficients.

```
path = 0:0.1:1;

interpolatedQuaternions = slerp(a,c,path);
```

For quaternions that represent rotation only about a single axis, specifying interpolation coefficients as equally spaced results in quaternions equally spaced in Euler angles. Convert `interpolatedQuaternions` to Euler angles and verify that the difference between the angles in the path is constant.

```
k = eulerd(interpolatedQuaternions,"ZYX","frame");
abc = abs(diff(k))
```

```
abc = 10×3

    9.0000         0         0
    9.0000         0         0
    9.0000         0         0
    9.0000         0         0
    9.0000         0         0
    9.0000         0         0
    9.0000         0         0
    9.0000         0         0
    9.0000         0         0
    9.0000         0         0
```

Alternatively, you can use the `dist` function to verify that the distance between the interpolated quaternions is consistent. The `dist` function returns angular distance in radians; convert to degrees for easy comparison.

```
def = rad2deg(dist(interpolatedQuaternions(2:end),interpolatedQuaternions(1:end-1)))
```

```
def = 1×10

    9.0000    9.0000    9.0000    9.0000    9.0000    9.0000    9.0000    9.0000    9.0000    9.0
```

SLERP Minimizes Great Circle Path

The SLERP algorithm interpolates along a great circle path connecting two quaternions. This example shows how the SLERP algorithm minimizes the great circle path.

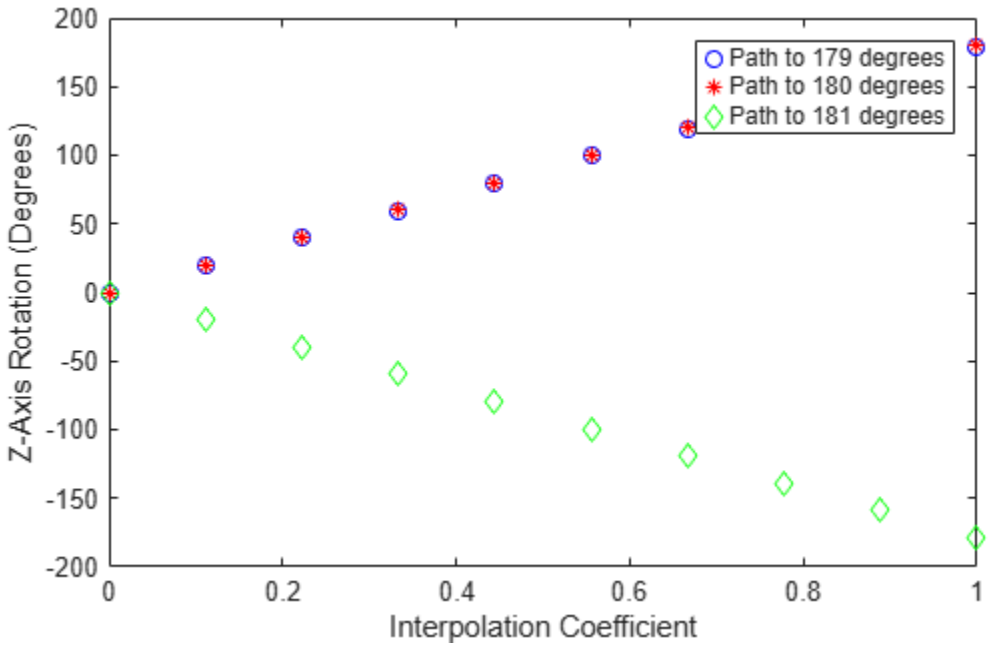
Define four quaternions:

1. `q0` - quaternion indicating no rotation from the global frame

2. `q179` - quaternion indicating a 179 degree rotation about the *z*-axis
3. `q180` - quaternion indicating a 180 degree rotation about the *z*-axis
4. `q181` - quaternion indicating a 181 degree rotation about the *z*-axis

```
q0 = ones(1,"quaternion");
q179 = quaternion([179,0,0],"eulerd","ZYX","frame");
q180 = quaternion([180,0,0],"eulerd","ZYX","frame");
q181 = quaternion([181,0,0],"eulerd","ZYX","frame");
```

Use `slerp` to interpolate between `q0` and the three quaternion rotations. Specify that the paths are traveled in 10 steps.



```
T = linspace(0,1,10);

q179path = slerp(q0,q179,T);
q180path = slerp(q0,q180,T);
q181path = slerp(q0,q181,T);
```

Plot each path in terms of Euler angles in degrees.

```
q179pathEuler = eulerd(q179path,"ZYX","frame");
q180pathEuler = eulerd(q180path,"ZYX","frame");
q181pathEuler = eulerd(q181path,"ZYX","frame");

plot(T,q179pathEuler(:,1),"bo", ...
     T,q180pathEuler(:,1),"r*", ...
     T,q181pathEuler(:,1),"gd");
legend("Path to 179 degrees", ...
       "Path to 180 degrees", ...
       "Path to 181 degrees")
xlabel("Interpolation Coefficient")
ylabel("Z-Axis Rotation (Degrees)")
```

The path between `q0` and `q179` is clockwise to minimize the great circle distance. The path between `q0` and `q181` is counterclockwise to minimize the great circle distance. The path between `q0` and `q180` can be either clockwise or counterclockwise, depending on numerical rounding.

Show Interpolated Quaternions on Sphere

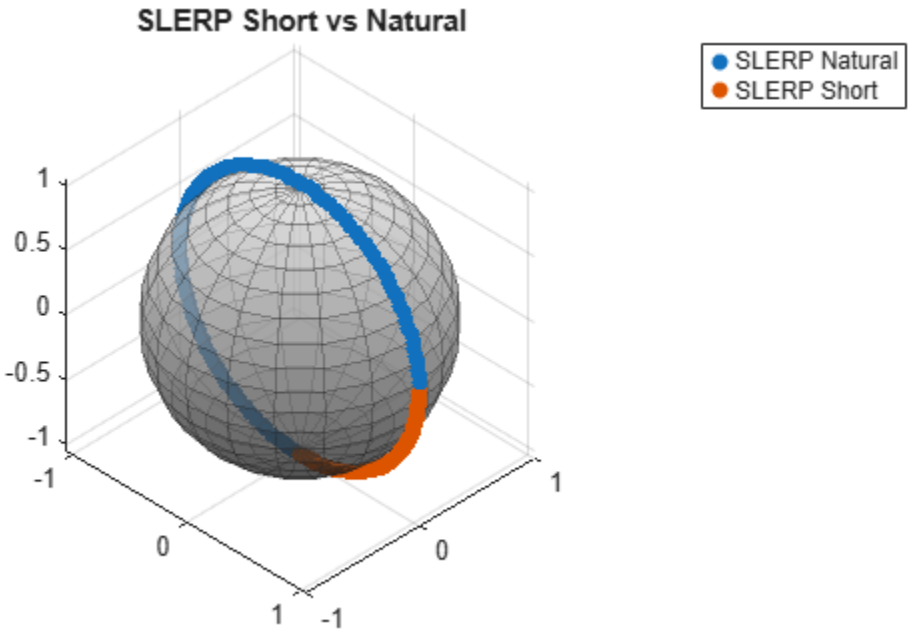
Create two quaternions.

```
q1 = quaternion([0 0 0],"eulerd","ZYX","frame");
q2 = quaternion([-180 90 180],"eulerd","ZYX","frame");
```

Define the interpolation coefficient.

```
T = 0:0.01:1;
```

Interpolate quaternions using both the `"short"` and `"natural"` interpolation methods.



```
quats_natural = slerp(q1,q2,T,"natural");
quats_short = slerp(q1,q2,T,"short");
```

Obtain the corresponding rotate points.

```
pts_natural = rotatepoint(quats_natural,[1.05 0 0]);
pts_short = rotatepoint(quats_short,[1.05 0 0]);
```

Show the interpolated quaternions on a unit sphere.

```
figure
[X,Y,Z] = sphere;
surf(X,Y,Z,FaceAlpha=0.5,EdgeAlpha=0.35)
colormap gray
hold on
scatter3(pts_natural(:,1),pts_natural(:,2),pts_natural(:,3),"filled")
scatter3(pts_short(:,1),pts_short(:,2),pts_short(:,3),"filled")
view([45 36.60])
axis equal
title("SLERP Short vs Natural")
legend("","SLERP Natural","SLERP Short")
```

Input Arguments

q1 — Quaternion to interpolate

`quaternion` object | array of `quaternion` objects

Quaternion to interpolate, specified as a `quaternion` object, an array of `quaternion` objects of any dimensionality.

`q1`, `q2`, and `T` must have compatible sizes. In the simplest cases, they can be the same size or any one can be a scalar. Two inputs have compatible sizes if, for every dimension, the dimension sizes of the inputs are either the same or one of them is 1.

q2 — Quaternion to interpolate

`quaternion` object | array of `quaternion` objects

Quaternion to interpolate, specified as a scalar, vector, matrix, or multidimensional array of quaternions.

`q1`, `q2`, and `T` must have compatible sizes. In the simplest cases, they can be the same size or any one can be a scalar. Two inputs have compatible sizes if, for every dimension, the dimension sizes of the inputs are either the same or one of the dimension sizes is 1.

T — Interpolation coefficient

scalar | vector | matrix | multidimensional array

Interpolation coefficient, specified as a scalar, vector, matrix, or multidimensional array of numbers with each element in the range [0, 1].

`q1`, `q2`, and `T` must have compatible sizes. In the simplest cases, they can be the same size or any one can be a scalar. Two inputs have compatible sizes if, for every dimension, the dimension sizes of the inputs are either the same or one of the dimension sizes is 1.

Data Types: `single` | `double`

`method` — Spherical interpolation method
`"short"` (default) | `"natural"`

Spherical interpolation method, specified as either `"short"` or `"natural"`.

- `"short"` — Interpolates along the shortest path on the great circle between `q1` and `q2`, ensuring the minimal angular distance.
- `"natural"` — Skips shortest path optimization, following the natural path determined by the dot product of `q1` and `q2`, which may not be the shortest.

Data Types: `single` | `double`

Output Arguments

`q0` — Interpolated quaternion
`quaternion` object | array of `quaternion` objects

Interpolated quaternion, returned as a `quaternion` object or an array of `quaternion` objects.

Algorithms

Quaternion spherical linear interpolation (SLERP) is an extension of linear interpolation along a plane to spherical interpolation in three dimensions. The algorithm was first proposed in [1]. Given two quaternions, q_1 and q_2, SLERP interpolates a new quaternion, q_0, along the great circle that connects q_1 and q_2. The interpolation coefficient, T, determines how close the output quaternion is to either q_1 and q_2.

The SLERP algorithm can be described in terms of sinusoids:

$$q_0 = \frac{\sin((1-T)\theta)}{\sin(\theta)}q_1 + \frac{\sin(T\theta)}{\sin(\theta)}q_2$$

where q_1 and q_2 are normalized quaternions, and θ is half the angular distance between q_1 and q_2.

Version History

Introduced in R2023b

R2025a: Natural interpolation path

Spherically interpolate using the `"natural"` path option, enabling smoother transitions that respect the orientation of the start and end quaternions. Use the `method` argument to specify the interpolation method.

Functions

`dist` | `meanrot`

Objects

`quaternion`

times, .*

Element-wise quaternion multiplication

Syntax

```
quatC = A.*B
```

Description

`quatC = A.*B` returns the element-by-element quaternion multiplication of quaternion arrays.

You can use quaternion multiplication to compose rotation operators:

- To compose a sequence of frame rotations, multiply the quaternions in the same order as the desired sequence of rotations. For example, to apply a p quaternion followed by a q quaternion, multiply in the order pq. The rotation operator becomes $(pq)^*v(pq)$, where v represents the object to rotate in quaternion form. * represents conjugation.
- To compose a sequence of point rotations, multiply the quaternions in the reverse order of the desired sequence of rotations. For example, to apply a p quaternion followed by a q quaternion, multiply in the reverse order, qp. The rotation operator becomes $(qp)v(qp)^*$.

Examples

Multiply Two Quaternion Vectors

Create two vectors, `A` and `B`, and multiply them element by element.

```
A = quaternion([1:4;5:8]);
B = A;
C = A.*B
```

```
C = 2×1 quaternion array
     -28 +   4i +   6j +   8k
    -124 +  60i +  70j +  80k
```

Multiply Two Quaternion Arrays

Create two 3-by-3 arrays, `A` and `B`, and multiply them element by element.

```
A = reshape(quaternion(randn(9,4)),3,3);
B = reshape(quaternion(randn(9,4)),3,3);
C = A.*B
```

```
C = 3×3 quaternion array
     0.60169 +  2.4332i -  2.5844j + 0.51646k    -0.49513 +  1.1722i +  4.4401j -   1.217k      2
     -4.2329 +  2.4547i +  3.7768j + 0.77484k    -0.65232 - 0.43112i -  1.4645j - 0.90073k     -1
```

```
     -4.4159 +  2.1926i +  1.9037j -  4.0303k     -2.0232 +  0.4205i - 0.17288j +  3.8529k     -2
```

Note that quaternion multiplication is not commutative:

```
isequal(C,B.*A)
```

```
ans = logical
   0
```

Multiply Quaternion Row and Column Vectors

Create a row vector `a` and a column vector `b`, then multiply them. The 1-by-3 row vector and 4-by-1 column vector combine to produce a 4-by-3 matrix with all combinations of elements multiplied.

```
a = [zeros("quaternion"),ones("quaternion"),quaternion(randn(1,4))]
```

```
a = 1×3 quaternion array
          0 +       0i +       0j +       0k           1 +       0i +       0j +       0k     0
```

```
b = quaternion(randn(4,4))
```

```
b = 4×1 quaternion array
      0.31877 +   3.5784i +   0.7254j -  0.12414k
      -1.3077 +   2.7694i - 0.063055j +   1.4897k
     -0.43359 -   1.3499i +  0.71474j +    1.409k
      0.34262 +   3.0349i -  0.20497j +   1.4172k
```

```
a.*b
```

```
ans = 4×3 quaternion array
            0 +        0i +        0j +        0k      0.31877 +   3.5784i +   0.7254j -  0.1241
            0 +        0i +        0j +        0k      -1.3077 +   2.7694i - 0.063055j +   1.489
            0 +        0i +        0j +        0k     -0.43359 -   1.3499i +  0.71474j +    1.40
            0 +        0i +        0j +        0k      0.34262 +   3.0349i -  0.20497j +   1.417
```

Input Arguments

A — Input to multiply

`quaternion` object | array of `quaternion` objects | real scalar | array of real numbers

Input to multiply, specified as a `quaternion` object, an array of `quaternion` objects of any dimensionality, a real scalar, or an array of real numbers of any dimensionality. Numeric values must be of data type `single` or `double`.

`A` and `B` must have compatible sizes. In the simplest cases, they can be the same size or one can be a scalar. Two inputs have compatible sizes if, for every dimension, the dimension sizes of the inputs are the same or one of them is 1.

B — Input to multiply
`quaternion` object | array of `quaternion` objects | real scalar | array of real numbers

Input to multiply, specified as a `quaternion` object, an array of `quaternion` objects of any dimensionality, a real scalar, or an array of real numbers of any dimensionality. Numeric values must be of data type `single` or `double`.

`A` and `B` must have compatible sizes. In the simplest cases, they can be the same size or one can be a scalar. Two inputs have compatible sizes if, for every dimension, the dimension sizes of the inputs are the same or one of them is 1.

Output Arguments

quatC — Quaternion product
`quaternion` object | array of `quaternion` objects

Quaternion product, returned as a `quaternion` object or an array of `quaternion` objects.

Algorithms

Quaternion Multiplication by a Real Scalar

Given a quaternion,

$$q = a_q + b_q\mathrm{i} + c_q\mathrm{j} + d_q\mathrm{k},$$

the product of q and a real scalar β is

$$\beta q = \beta a_q + \beta b_q\mathrm{i} + \beta c_q\mathrm{j} + \beta d_q\mathrm{k}$$

Quaternion Multiplication by a Quaternion Scalar

The definition of the basis elements for quaternions,

$$\mathrm{i}^2 = \mathrm{j}^2 = \mathrm{k}^2 = \mathrm{ijk} = -1,$$

can be expanded to populate a table summarizing quaternion basis element multiplication:

	1	**i**	**j**	**k**
1	1	i	j	k
i	i	−1	k	−j
j	j	−k	−1	i
k	k	j	−i	−1

When reading the table, the rows are read first, for example: ij = k and ji = −k.

Given two quaternions, $q = a_q + b_q\mathrm{i} + c_q\mathrm{j} + d_q\mathrm{k}$, and $p = a_p + b_p\mathrm{i} + c_p\mathrm{j} + d_p\mathrm{k}$, the multiplication can be expanded as:

$$
\begin{aligned}
z = pq &= \left(a_p + b_p\mathrm{i} + c_p\mathrm{j} + d_p\mathrm{k}\right)\left(a_q + b_q\mathrm{i} + c_q\mathrm{j} + d_q\mathrm{k}\right) \\
&= a_p a_q + a_p b_q\mathrm{i} + a_p c_q\mathrm{j} + a_p d_q\mathrm{k} \\
&+ b_p a_q\mathrm{i} + b_p b_q\mathrm{i}^2 + b_p c_q\mathrm{ij} + b_p d_q\mathrm{ik} \\
&+ c_p a_q\mathrm{j} + c_p b_q\mathrm{ji} + c_p c_q\mathrm{j}^2 + c_p d_q\mathrm{jk} \\
&+ d_p a_q k + d_p b_q\mathrm{ki} + d_p c_q\mathrm{kj} + d_p d_q\mathrm{k}^2
\end{aligned}
$$

You can simplify the equation using the quaternion multiplication table.

$$
\begin{aligned}
z = pq &= a_p a_q + a_p b_q\mathrm{i} + a_p c_q\mathrm{j} + a_p d_q\mathrm{k} \\
&+ b_p a_q\mathrm{i} - b_p b_q + b_p c_q\mathrm{k} - b_p d_q\mathrm{j} \\
&+ c_p a_q\mathrm{j} - c_p b_q\mathrm{k} - c_p c_q + c_p d_q\mathrm{i} \\
&+ d_p a_q k + d_p b_q\mathrm{j} - d_p c_q\mathrm{i} - d_p d_q
\end{aligned}
$$

Objects

`quaternion`

transpose, .'

Transpose quaternion array

Syntax

```
Y = quat.'
```

Description

`Y = quat.'` returns the non-conjugate transpose of the quaternion array, `quat`.

Examples

Vector Transpose

Create a vector of quaternions and compute its nonconjugate transpose.

```
quat = quaternion(randn(4,4))
```

```
quat = 4×1 quaternion array
      0.53767 +  0.31877i +   3.5784j +   0.7254k
       1.8339 -   1.3077i +   2.7694j - 0.063055k
      -2.2588 -  0.43359i -   1.3499j +  0.71474k
      0.86217 +  0.34262i +   3.0349j -  0.20497k
```

```
quatTransposed = quat.'
```

```
quatTransposed = 1×4 quaternion array
      0.53767 +  0.31877i +   3.5784j +   0.7254k       1.8339 -   1.3077i +   2.7694j - 0.06305
```

Matrix Transpose

Create a matrix of quaternions and compute its nonconjugate transpose.

```
quat = [quaternion(randn(2,4)),quaternion(randn(2,4))]
```

```
quat = 2×2 quaternion array
      0.53767 -   2.2588i +  0.31877j -  0.43359k       3.5784 -   1.3499i +   0.7254j +  0.7147
       1.8339 +  0.86217i -   1.3077j +  0.34262k       2.7694 +   3.0349i - 0.063055j -  0.2049
```

```

       3.5784 -   1.3499i +   0.7254j +  0.71474k       2.7694 +   3.0349i - 0.063055j -  0.2049
```

Input Arguments

quat — Quaternion array to transpose

vector of `quaternion` objects | matrix of `quaternion` objects

Quaternion array to transpose, specified as a vector or matrix of `quaternion` objects. `transpose` is defined for 1-D and 2-D arrays. For higher-order arrays, use `permute`.

Output Arguments

Y — Transposed quaternion array

vector of `quaternion` objects | matrix of `quaternion` objects

Transposed quaternion array, returned as a vector or matrix of `quaternion` objects. The size of `Y` is *N*-by-*M*, where the size of `quat` is *M*-by-*N*.

Functions

`ctranspose, '`

Objects

`quaternion`

uminus, -

Quaternion unary minus

Syntax

```
mQuat = -quat
```

Description

`mQuat = -quat` negates the elements of `quat` and stores the result in `mQuat`.

Examples

Negate Elements of Quaternion Matrix

Unary minus negates each part of a the quaternion. Create a 2-by-2 matrix, `Q`.

```
Q = quaternion(randn(2),randn(2),randn(2),randn(2))
```

```
Q = 2×2 quaternion array
      0.53767 +  0.31877i +   3.5784j +   0.7254k      -2.2588 -  0.43359i -   1.3499j +  0.7147
       1.8339 -   1.3077i +   2.7694j - 0.063055k      0.86217 +  0.34262i +   3.0349j -  0.2049
```

Negate the parts of each quaternion in `Q`.

```
R = -Q
```

```
R = 2×2 quaternion array
     -0.53767 -  0.31877i -   3.5784j -   0.7254k       2.2588 +  0.43359i +   1.3499j -  0.7147
      -1.8339 +   1.3077i -   2.7694j + 0.063055k     -0.86217 -  0.34262i -   3.0349j +  0.2049
```

Input Arguments

`quat` — Input quaternion

`quaternion` object | array of `quaternion` objects

Input quaternion, specified as a `quaternion` object, an array of `quaternion` objects of any dimensionality.

Output Arguments

`mQuat` — Negated quaternion

`quaternion` object | array of `quaternion` objects

Negated quaternion, returned as a `quaternion` object or an array of `quaternion` objects of the same size as `quat`.

Version History

Functions

`minus, -`

Objects

`quaternion`

zeros

Create quaternion array with all parts set to zero

Syntax

```
quatZeros = zeros("quaternion")
quatZeros = zeros(n,"quaternion")
quatZeros = zeros(sz,"quaternion")
quatZeros = zeros(sz1,...,szN,"quaternion")

quatZeros = zeros( ___ ,"like",prototype,"quaternion")
```

Description

`quatZeros = zeros("quaternion")` returns a scalar quaternion with all parts set to zero.

`quatZeros = zeros(n,"quaternion")` returns an `n`-by-`n` matrix of quaternions.

`quatZeros = zeros(sz,"quaternion")` returns an array of quaternions where the size vector, `sz`, defines `size(quatZeros)`.

`quatZeros = zeros(sz1,...,szN,"quaternion")` returns a `sz1`-by-...-by-`szN` array of quaternions where `sz1,…,szN` indicates the size of each dimension.

`quatZeros = zeros( ___ ,"like",prototype,"quaternion")` specifies the underlying class of the returned quaternion array to be the same as the underlying class of the quaternion prototype.

Examples

Quaternion Scalar Zero

Create a quaternion scalar zero.

```
quatZeros = zeros("quaternion")
```

```
quatZeros = quaternion
     0 + 0i + 0j + 0k
```

Square Matrix of Quaternions

Create an n-by-n array of quaternion zeros.

```
n = 3;
quatZeros = zeros(n,"quaternion")
```

```
quatZeros = 3×3 quaternion array
     0 + 0i + 0j + 0k     0 + 0i + 0j + 0k     0 + 0i + 0j + 0k
```

```
     0 + 0i + 0j + 0k     0 + 0i + 0j + 0k     0 + 0i + 0j + 0k
     0 + 0i + 0j + 0k     0 + 0i + 0j + 0k     0 + 0i + 0j + 0k
```

Multidimensional Array of Quaternion Zeros

Create a multidimensional array of quaternion zeros by defining array dimensions in order. In this example, you create a 3-by-1-by-2 array. You can specify dimensions using a row vector or comma-separated integers.

Specify the dimensions using a row vector and display the results:

```
dims = [3,1,2];
quatZerosSyntax1 = zeros(dims,"quaternion")
```

```
quatZerosSyntax1 = 3×1×2 quaternion array
quatZerosSyntax1(:,:,1) =

     0 + 0i + 0j + 0k
     0 + 0i + 0j + 0k
     0 + 0i + 0j + 0k

quatZerosSyntax1(:,:,2) =

     0 + 0i + 0j + 0k
     0 + 0i + 0j + 0k
     0 + 0i + 0j + 0k
```

Specify the dimensions using comma-separated integers, and then verify the equivalence of the two syntaxes:

```
quatZerosSyntax2 = zeros(3,1,2,"quaternion");
isequal(quatZerosSyntax1,quatZerosSyntax2)
```

```
ans = logical
   1
```

Underlying Class of Quaternion Zeros

A quaternion is a four-part hyper-complex number used in three-dimensional representations. You can specify the underlying data type of the parts as `single` or `double`. The default is `double`.

Create a quaternion array of zeros with the underlying data type set to `single`.

```
quatZeros = zeros(2,"like",single(1),"quaternion")
```

```
quatZeros = 2×2 quaternion array
     0 + 0i + 0j + 0k     0 + 0i + 0j + 0k
     0 + 0i + 0j + 0k     0 + 0i + 0j + 0k
```

Verify the underlying class using the `classUnderlying` function.

```
classUnderlying(quatZeros)
```

```
ans =
'single'
```

Input Arguments

`n` — Size of square quaternion matrix

integer value

Size of square quaternion matrix, specified as an integer value. If `n` is `0` or negative, then `quatZeros` is returned as an empty matrix.

Example: `zeros(4,"quaternion")` returns a 4-by-4 matrix of quaternion zeros.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`sz` — Output size

row vector of integer values

Output size, specified as a row vector of integer values. Each element of `sz` indicates the size of the corresponding dimension in `quatZeros`. If the size of any dimension is `0` or negative, then `quatZeros` is returned as an empty array.

Example: `zeros([1,4,2],"quaternion")` returns a 1-by-4-by-2 array of quaternion zeros.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`prototype` — Quaternion prototype

`quaternion` object

Quaternion prototype, specified as a `quaternion` object.

Example: `zeros(2,"like",quat,"quaternion")` returns a 2-by-2 matrix of quaternions with the same underlying class as the prototype quaternion, `quat`.

`sz1,...,szN` — Size of each dimension

two or more integer values

Size of each dimension, specified as two or more comma-separated integers.

- If the size of any dimension is `0`, then `quatZeros` is returned as an empty array.
- If the size of any dimension is negative, then it is treated as `0`.

Example: `zeros(2,3,"quaternion")` returns a 2-by-3 matrix of quaternion zeros.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`quatZeros` — Quaternion zeros

`quaternion` object | array of `quaternion` objects

Quaternion zeros, returned as a `quaternion` object or an array of `quaternion` objects.

Given a quaternion of the form $Q = a + b\mathrm{i} + c\mathrm{j} + d\mathrm{k}$, a quaternion zero is defined as $Q = 0 + 0\mathrm{i} + 0\mathrm{j} + 0\mathrm{k}$.

Data Types: `quaternion`

efficientADAnomalyDetector

Detect anomalies using EfficientAD network

Description

The `efficientADAnomalyDetector` object detects images of anomalies using an EfficientAD anomaly detector network. Train the detector using the `trainEfficientADAnomalyDetector` function. To detect anomalous images, pass the trained detector to the `classify` function.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Creation

Syntax

```
detector = efficientADAnomalyDetector
detector = efficientADAnomalyDetector(Name=Value)
```

Description

`detector = efficientADAnomalyDetector` creates an EfficientAD anomaly detector from a base patch description network (PDN).

`detector = efficientADAnomalyDetector(Name=Value)` specifies options for the EfficientAD anomaly detector creation using one or more name-value arguments.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `efficientADAnomalyDetector(PDNnet="pdn-small")` specifies the patch description network as `"pdn-small"`.

`PDNnet` — Name of patch description network
`"pdn-small"` (default) | `"pdn-medium"`

Name of the patch description network (PDN), a convolutional network that serves as the base feature extraction network, specified as one of these values:

- `"pdn-small"` — PDN of reduced depth that has a teacher and student network architecture.
- `"pdn-medium"` — PDN that uses twice as many filters in the middle layers of both its teacher and student networks. This network has a higher capacity to extract and learn detailed and nuanced features from image patches, at the expense of more computation time.

For images of variable size, the PDN generates all feature vectors in a single forward pass.

Data Types: `char` | `string`

`UseGlobalAnomalyMap` — Global anomaly map autoencoder toggle for tile-based training
`true` or `1` (default) | `false` or `0`

Global anomaly map autoencoder toggle for tile-based training, specified as a numeric or logical `1` (`true`) or `0` (`false`). If you specify `UseGlobalAnomalyMap` as `false`, the `efficientADAnomalyDetector` object creates an EfficientAD anomaly detector that uses the student-teacher model to generate the local anomaly map, and turns off the autoencoder, which primarily detects global anomalies. To perform inference on full-size images after tile-based training on patches of images, turn off the autoencoder by specifying `UseGlobalAnomalyMap` as `false`.

Tip When you perform tile-based training and GPU memory is limited, reduce the mini-batch size using the `MiniBatchSize` argument of the `trainingOptions` function, at the expense of slower computation speed.

`OptimizeScoreForLogicalAnomalies` — Optimize anomaly score for logical anomalies
`false` or `0` (default) | `true` or `1`

Optimize anomaly score for logical anomalies, specified as a numeric or logical `0` (`false`) or `1` (`true`) . If you specify `OptimizeScoreForLogicalAnomalies` as `true`, the `efficientADAnomalyDetector` object creates an EfficientAD anomaly detector that uses both picturable and unpicturable anomaly scores to optimize logical anomaly detection. Logical anomalies result from missing, misplaced, extraneous, or geometrically faulty features. Specify this option to improve detector performance in images with logical anomalies at the expense of increased computation cost from calculating normalization statistics and additional anomaly scores. To learn more, see “Logical Anomaly Detection Method” on page 2-1632.

Properties

`Threshold` — Anomaly threshold
`[]` (default) | numeric scalar

Anomaly threshold, stored as a numeric scalar. You must set the value of the threshold before calling the `classify` function. You can calculate a threshold using the `anomalyThreshold` function.

`ImageSize` — Image size
`[]` (default) | three-element numeric row vector

This property is read-only.

Image size of images used for training and inference, stored as a three-element numeric row vector. The `trainEfficientADAnomalyDetector` function sets the `ImageSize` property during training, which indicates the size of the training images. The image size can be different from the input layer size of the base feature extraction PDN.

Note When using the detector, the image size at inference must match the image size used during training.

Object Functions

predict	Predict unnormalized anomaly scores
classify	Classify image as normal or anomalousJAB
anomalyMap	Predict per-pixel anomaly score map

Examples

Create EfficientAD Anomaly Detector

Create an `efficientADAnomalyDetector` object from a medium-sized base patch description network (PDN).

```
detector = efficientADAnomalyDetector(Network="pdn-medium")
```

```
detector =
  efficientADAnomalyDetector with properties:

    Threshold: []
    ImageSize: []
      Network: "pdn-medium"
```

More About

EfficientAD Student-teacher Network Architecture

The EfficientAD anomaly detector operates on the principle of a student-teacher model, where the *teacher* is a pre-trained deep neural network that understands normal data behavior, and the *student* is a smaller network that learns to mimic the teacher's responses on normal data. During training, only normal data (without anomalies) is used, allowing the student to learn a compact representation of what is considered normal. At inference, both the student and teacher evaluate incoming data; anomalies are detected based on the discrepancy between the student's and teacher's outputs, as the student will likely fail to accurately replicate the teacher's behavior on anomalous data, highlighting instances that deviate from the learned normal behavior.

Logical Anomaly Detection Method

Picturable, or structural, anomalies are anomalies whose location can be clearly depicted on a ground truth map. *Unpicturable* anomalies are logical anomalies which result from missing, misplaced, extraneous, or geometrically faulty features, and are not easily represented by spatial feature maps. The Picturable and Unpicturable Anomaly Scores (PUAD) method uses EfficientAD to detect picturable anomalies, and a feature-based method to detect unpicturable anomalies. The out-of-distribution approach calculates the unpicturable anomalies as Mahalanobis distances using the student’s former half output [2].

Version History

Introduced in R2024b

R2025a: Option to specify EfficientAD detector to optimize anomaly score for logical anomaly detection

Specify the `OptimizeScoreForLogicalAnomalies` name-value argument as `true` (or `1`) to optimize the anomaly score for logical anomaly detection.

fastFlowAnomalyDetector

Detect anomalies using FastFlow network

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

The `fastFlowAnomalyDetector` object detects images of anomalies using a FastFlow anomaly detector network. Train the detector using the `trainFastFlowAnomalyDetector` function. To detect anomalous images, pass the trained detector to the `classify` function.

Note This functionality requires Deep Learning Toolbox. This functionality also requires the Deep Learning Toolbox Model for ResNet-18 Network and the Automated Visual Inspection Library for Computer Vision Toolbox, which you can install from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Creation

Syntax

```
detector = fastFlowAnomalyDetector
detector = fastFlowAnomalyDetector(Name=Value)
```

Description

`detector = fastFlowAnomalyDetector` creates a FastFlow anomaly detector from a ResNet-18 backbone network.

`detector = fastFlowAnomalyDetector(Name=Value)` specifies the `Backbone`, `NumFlowSteps` and `FlowModelChannelRatio` properties of the FastFlow anomaly detector using name-value arguments.

For example, `NumFlowSteps=10` sets the number of steps in the flow network of the FastFlow detector to 10.

Properties

Backbone — Pretrained backbone network

`dlnetwork` object

This property is read-only.

Pretrained backbone network that serves as the base feature extraction network, specified as a `dlnetwork` object. The network must accept a single input and produce one or more outputs. If you do not specify the `Backbone` property, `fastFlowAnomalyDetector` uses a ResNet-18 network as the backbone feature extraction network.

To set the value of this property, you must specify it at object creation.

Data Types: `dlnetwork`

`NumFlowSteps` — Number of steps in flow network
`8` (default) | positive integer

This property is read-only.

Number of steps in the flow network of the FastFlow detector, specified as a positive integer. Increase the number of flow network steps to obtain more trainable parameters at the possible expense of increasing memory cost and using more computing resources.

To set the value of this property, you must specify it at object creation.

`FlowModelChannelRatio` — Ratio of input channels to hidden channels
`1.0` (default) | positive numeric scalar

This property is read-only.

Ratio of input channels to hidden channels used in the input and output subnet layers after the channels are split in the flow network, specified as a positive numeric scalar. Increase the value of `FlowModelChannelRatio` to improve detection metrics at the possible expense of increasing memory cost and using more computing resources.

To set the value of this property, you must specify it at object creation.

`Threshold` — Anomaly threshold
`[]` (default) | numeric scalar

Anomaly threshold, specified as a numeric scalar. You must set the value of the threshold before calling the `classify` function. You can calculate a threshold using the `anomalyThreshold` function.

`Layers` — Network layers
array of `Layer` objects

This property is read-only.

Network layers, specified as an array of `Layer` objects.

`InputNames` — Network input layer names
`[]` (default) | cell array of character vectors

This property is read-only.

Network input layer names, specified as a cell array of character vectors.

`OutputNames` — Network output layer names
`[]` (default) | cell array of character vectors

This property is read-only.

Network output layer names, specified as a cell array of character vectors.

`State` — Network state
table

This property is read-only.

Network state, specified as a table with three columns.

- `Layer` — Layer name, specified as a string scalar
- `Parameter` — State parameter name, specified as a string scalar
- `Value` — Value of state parameter, specified as a `dlarray` object

Layer states contain information calculated during the layer operation to be retained for use in subsequent forward passes of the layer. For example, the cell state and hidden state of LSTM layers, or running statistics in batch normalization layers.

`Learnables` — Network learnable parameters
table

This property is read-only.

Network learnable parameters, specified as a table with three columns.

- `Layer` — Layer name, specified as a string scalar
- `Parameter` — Parameter name, specified as a string scalar
- `Value` — Value of parameter, specified as a `dlarray` object

The network learnable parameters contain the features that the network learns. For example, the parameters include the weights of convolution and fully connected layers.

Object Functions

predict	Predict unnormalized anomaly scores
classify	Classify image as normal or anomalousJAB
anomalyMap	Predict per-pixel anomaly score map

Examples

Create FastFlow Anomaly Detector

Create a `fastFlowAnomalyDetector` object.

```
detector = fastFlowAnomalyDetector
```

```
detector =
  fastFlowAnomalyDetector with properties:

    Threshold: []
```

Version History

Introduced in R2023a

R2024b: Use `coder.loadDeepLearningNetwork` for code generation

Starting in R2024b, you can use the `coder.loadDeepLearningNetwork` function to load a `fastFlowAnomalyDetector` object for CPU and GPU code generation.

R2024a: Option to specify custom backbone network, number of steps in flow network, and ratio of input channels to hidden channels used in subnetwork

Specify the backbone feature extraction network as a `dlnetwork` object by using the `Backbone` name-value argument.

Specify the number of steps in the flow network by using the `NumFlowSteps` name-value argument. For example, `NumFlowSteps=10` sets the number of steps in the flow network of the FastFlow detector to 10.

Specify the ratio of input channels to hidden channels in the input and output subnet layers of the FastFlow detector by using the `FlowModelChannelRatio` name-value argument.

fcddAnomalyDetector

Detect anomalies using fully convolutional data description (FCDD) network for anomaly detection

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

The `fcddAnomalyDetector` object detects images of anomalies using a fully convolutional data description (FCDD) network. To detect anomalous images, pass the trained detector to the `classify` function.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Creation

Syntax

```
detector = fcddAnomalyDetector(network)
```

Description

`detector = fcddAnomalyDetector(network)` creates an FCDD anomaly detector from a base feature extraction backbone network.

Input Arguments

`network` — Network
`dlnetwork` object

Network that serves as the base feature extraction backbone, specified as a `dlnetwork` object. You can create a `dlnetwork` for several common named pretrained networks, such as GoogLeNet and ResNet-18, using the `pretrainedEncoderNetwork` function.

Properties

`Threshold` — Anomaly threshold
`[]` (default) | numeric scalar

Anomaly threshold, specified as a numeric scalar. You must set the value of the threshold before calling the `classify` function. You can calculate a threshold using the `anomalyThreshold` function.

`Layers` — Network layers
array of `Layer` objects

This property is read-only.

Network layers, specified as an array of `Layer` objects.

`InputNames` — Network input layer names
`[ ]` (default) | cell array of character vectors

This property is read-only.

Network input layer names, specified as a cell array of character vectors.

`OutputNames` — Network output layer names
`[ ]` (default) | cell array of character vectors

This property is read-only.

Network output layer names, specified as a cell array of character vectors.

`State` — Network state
table

This property is read-only.

Network state, specified as a table with three columns:

- `Layer` – Layer name, specified as a string scalar.
- `Parameter` – State parameter name, specified as a string scalar.
- `Value` – Value of state parameter, specified as a `dlarray` object.

Layer states contain information calculated during the layer operation to be retained for use in subsequent forward passes of the layer. For example, the cell state and hidden state of LSTM layers, or running statistics in batch normalization layers.

`Learnables` — Network learnable parameters
table

This property is read-only.

Network learnable parameters, specified as a table with three columns:

- `Layer` – Layer name, specified as a string scalar.
- `Parameter` – Parameter name, specified as a string scalar.
- `Value` – Value of parameter, specified as a `dlarray` object.

The network learnable parameters contain the features learned by the network. For example, the weights of convolution and fully connected layers.

Object Functions

predict	Predict unnormalized anomaly scores
classify	Classify image as normal or anomalousJAB
anomalyMap	Predict per-pixel anomaly score map

Examples

Create FCDD Anomaly Detector

Create an `fcddAnomalyDetector` object with a ResNet-18 backbone.

```
backbone = pretrainedEncoderNetwork("resnet18",3);
detector = fcddAnomalyDetector(backbone)
```

```
detector =
  fcddAnomalyDetector with properties:

      Threshold: []
         Layers: [43×1 nnet.cnn.layer.Layer]
     InputNames: {'data'}
    OutputNames: {'fcddHeadPseudoHuber'}
          State: [4×3 table]
     Learnables: [10×3 table]
```

Version History

Introduced in R2022b

R2024b: Use `coder.loadDeepLearningNetwork` for code generation

Starting in R2024b, you can use the `coder.loadDeepLearningNetwork` function to load a `fcddAnomalyDetector` object for CPU and GPU code generation.

R2023a: Support for C and GPU code generation

`fcddAnomalyDetector` now supports the generation of C code (requires MATLAB Coder) and optimized CUDA code (requires GPU Coder).

patchCoreAnomalyDetector

Detect anomalies using PatchCore network

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

The `patchCoreAnomalyDetector` object detects images of anomalies using a PatchCore anomaly detector network. Train the detector using the `trainPatchCoreAnomalyDetector` function. To detect anomalous images, pass the trained detector to the `classify` function.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Creation

Syntax

```
detector = patchCoreAnomalyDetector
detector = patchCoreAnomalyDetector(Backbone=backbone)
```

Description

`detector = patchCoreAnomalyDetector` creates a PatchCore anomaly detector from a ResNet-18 backbone network.

`detector = patchCoreAnomalyDetector(Backbone=backbone)` specifies the base feature extraction backbone network from which to create the PatchCore anomaly detector.

Input Arguments

backbone — Name of pretrained backbone network
`"resnet18"` (default) | `"resnet50"` | `"resnet101"` | `dlnetwork` object

Name of the pretrained backbone network that serves as the base feature extraction network, specified as a `dlnetwork` object or one of these values:

- `"resnet18"` — ResNet-18 convolutional neural network.
- `"resnet50"` — ResNet-50 convolutional neural network.
- `"resnet101"` — ResNet-101 convolutional neural network.

To learn more about each network, see “Pretrained Deep Neural Networks” (Deep Learning Toolbox). You must install the associated add-on for the selected pretrained network.

If you specify the network as a `dlnetwork` object, it must accept a single input and return one or more outputs.

Data Types: `char` | `string` | `dlnetwork`

Properties

`Threshold` — Anomaly threshold

`[]` (default) | numeric scalar

Anomaly threshold, specified as a numeric scalar. You must set the value of the threshold before calling the `classify` function. You can calculate a threshold using the `anomalyThreshold` function.

`ImageSize` — Image size

`[]` (default) | three-element numeric row vector

This property is read-only.

Image size of images used for training and inference, stored as a three-element numeric row vector. The `trainPatchCoreAnomalyDetector` function sets the `ImageSize` property during training, which indicates the size of the training images. The image size can be different from the input layer size of `backbone`.

Note When using the detector, the image size at inference must match the image size used during training.

Object Functions

predict	Predict unnormalized anomaly scores
classify	Classify image as normal or anomalousJAB
anomalyMap	Predict per-pixel anomaly score map

Examples

Create PatchCore Anomaly Detector

Create a `patchCoreAnomalyDetector` object from a ResNet-50 backbone network.

```
detector = patchCoreAnomalyDetector(Backbone="resnet50")
```

```
detector =
  patchCoreAnomalyDetector with properties:

    Threshold: []
    ImageSize: []
```

Version History

Introduced in R2023a

R2024b: Use `coder.loadDeepLearningNetwork` for code generation

Starting in R2024b, you can use the `coder.loadDeepLearningNetwork` function to load a `patchCoreAnomalyDetector` object for CPU and GPU code generation.

R2026a: Option to specify ResNet-101 backbone network

You can now specify the backbone feature extraction network as a ResNet-101 convolutional neural network by specifying the `backbone` input argument as `"resnet101"`.

R2024a: Option to specify backbone network as a `dlnetwork` object

Specify the backbone feature extraction network as a `dlnetwork` object by using the `backbone` input argument. For example, given a custom `dlnetwork` object, `dlnet`, the argument `Backbone` specifies `dlnet` as the backbone feature extraction network.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- To prepare a `patchCoreAnomalyDetector` object for code generation, you can use either `vision.loadPatchCoreAnomalyDetector` or `coder.loadDeepLearningNetwork` function. The recommended approach is to use `coder.loadDeepLearningNetwork`. For information on how to load the detector for code generation, see “Load Pretrained Networks for Code Generation” (MATLAB Coder).
- The `predict`, `classify`, and `anomalyMap` object functions are supported.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- To prepare a `patchCoreAnomalyDetector` object for GPU code generation, you can use either `vision.loadPatchCoreAnomalyDetector` or `coder.loadDeepLearningNetwork` function. The recommended approach is to use `coder.loadDeepLearningNetwork`. For information on how to load the detector for code generation, see “Load Pretrained Networks for Code Generation” (GPU Coder).
- The `predict`, `classify`, and `anomalyMap` object functions are supported.

percentileNormalizer

Create percentile normalizer for anomaly map normalization

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

The `percentileNormalizer` object creates a percentile anomaly map normalizer for a specified anomaly detector using the calculated percentile statistics of normal, or non-anomalous, images in a datastore. Use this object along with its object function `normalize`, to normalize anomaly score maps from different detectors to the same range, or to normalize anomaly scores for an anomaly map or a set of anomaly maps to a specified range.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Creation

Syntax

```
normalizer = percentileNormalizer(dsNormal,detector)
normalizer = percentileNormalizer(dsNormal,detector,Name=Value)
```

Description

`normalizer = percentileNormalizer(dsNormal,detector)` creates a percentile anomaly map normalizer for a specified anomaly detector, `detector`, using the calculated percentile statistics of normal, or non-anomalous, images in a datastore, `dsNormal`.

`normalizer = percentileNormalizer(dsNormal,detector,Name=Value)` specifies additional options for normalization parameters using name-value arguments. For example, `NormalPercentileRange=[0.95 0.99]` sets the lower and upper percentile statistics range for normal images to `[0.95, 0.99]`.

Input Arguments

`dsNormal` — Normal image data
datastore

Normal image data, specified as a datastore that contains image data. Do not include anomalous images in this datastore.

`detector` — Anomaly detector
`efficientADAnomalyDetector` object | `fcddAnomalyDetector` object | `fastFlowAnomalyDetector` object | `patchCoreAnomalyDetector` object

Anomaly detector, specified as an `efficientADAnomalyDetector` object, an `fcddAnomalyDetector` object, a `fastFlowAnomalyDetector` object, or a `patchCoreAnomalyDetector` object.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `percentileNormalizer(dsNormal,detector,NormalPercentileRange=[0.95 0.99])` sets the lower and upper percentile statistics range for normal images to `[0.95, 0.99]`.

`NormalPercentileRange` — Normal image percentile range
`[0.9 0.99]` (default) | vector of form $[p_1\ p_2]$

Normal image percentile range, specified as a vector of the form $[p_1\ p_2]$, where p_1 and p_2 are the lower and upper percentile bounds, respectively. The lower and upper percentile values must be in the range [0, 1].

p_1 and p_2 define the slope of the linear mapping from the anomaly score input to the normalized anomaly score values. To learn more, see “Linear Mapping for Anomaly Map Normalization” on page 2-1648.

`Verbose` — Training progress information display
`true` or `1` (default) | `false` or `0`

Training progress information display in the command window, specified as a logical `1` (`true`) or `0` (`false`).

Properties

`PercentileStatistics` — Anomaly map percentile values
vector of form [*P1 P2*]

Anomaly map percentile values, *P1* and *P2*, stored as a two-element numeric vector of the form [*P1 P2*].

Object Functions

normalize Normalize anomaly score map using percentiles

More About

Linear Mapping for Anomaly Map Normalization

The `percentileNormalizer` object maps the upper range of the normal image percentile to the bottom end of the anomaly map output values. The object considers image pixels with anomaly scores higher than the upper percentile of the normal image to be anomalous. p_1 and p_2 are the normal image upper percentile range lower and upper bounds, respectively, and the object bounds the anomaly map output by the lower and upper values v_1 and v_2, respectively. Therefore, this function defines the linear mapping between the anomaly score input x and the normalized anomaly score output y:

$$y = \frac{x(v2 - v1)}{(p2 - p1)} - \frac{p1(v2 - v1)}{(p2 - p1)} + v1$$

The upper range values of the normal image percentile, p_2 and p_2, define the slope of the linear mapping from the anomaly score input to the normalized anomaly score values.

The normalized anomaly score from the linear mapping, y, is unbounded. To confine the normalization to a range of values, specify the range using the `OutputClipRange` name-value argument of the `normalize` object function.

counTRObjectCounter

Count objects using CounTR deep learning model

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

The `counTRObjectCounter` object creates a Counting TRansformer (CounTR) object counter model for counting the number of objects from arbitrary semantic categories in an image, without the need for training. Using this object, you can:

- Create a CounTR object counter model using exemplar patches. Exemplar patches are small image patches that contain examples of the objects to be counted. These patches serve as reference examples that help the model identify and count similar objects in the larger input image.
- Create a CounTR object counter model using an exemplar image with exemplar bounding box locations from which the model extracts exemplar patches.

After creating the CounTR model using the `counTRObjectCounter` object, count the number of objects in an image based on the exemplar patches you specify using the `countObjects` object function. Compute the density map of the object count in the image, based on specified exemplar patches, using the `densityMap` object function.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Creation

Syntax

```
counter = counTRObjectCounter(exemplarPatches)
counter = counTRObjectCounter(exemplarImage,exemplarBBoxes)
```

Description

`counter = counTRObjectCounter(exemplarPatches)` creates a CounTR object counter model using exemplar patches containing objects to count, `exemplarPatches`.

`counter = counTRObjectCounter(exemplarImage,exemplarBBoxes)` creates a CounTR object counter model using exemplar patches of objects obtained from an exemplar image, `exemplarImage`, at the exemplar bounding box locations, `exemplarBBoxes`.

Input Arguments

`exemplarPatches` — Exemplar patches

cell array

Exemplar patches containing examples of objects of interest, specified as *numPatches*-by-1 cell array where each cell contains a patch of size *P*-by-*Q*-by-3. The `counTRObjectCounter` object resizes patches to 64-by-64-by-3 and stacks them to form an input of size 64-by-64-by-3-by-*numPatches* to the object counter model. *numPatches* is the number of patches.

Tip To select exemplar patches, crop sections of an image that contain clear, non-overlapping instances of the objects of interest. The patches you specify should be representative of the object class, capturing key features that distinguish the objects from the background or other classes.

`exemplarImage` — Exemplar image

H-by-*W* matrix | *H*-by-*W*-by-*3* numeric array

Exemplar image containing examples of objects of interest, specified as one of these options:

Image Type	Data Format
Grayscale	*H*-by-*W* numeric matrix
Binary	*H*-by-*W* logical matrix
RGB	*H*-by-*W*-by-*3* numeric array

`exemplarBBoxes` — Exemplar bounding boxes

numShots-by-4 numeric matrix

Exemplar bounding boxes containing sample objects of interest to count, specified as a *numShots*-by-4 numeric matrix. *numShots* is the number of axis-aligned rectangles. The rows of the matrix have the form [*x y w h*]. *x* and `y` specify the upper-left corner of the rectangle, *w* specifies the width of the rectangle, which is its length along the *x*-axis, and *h* specifies the height of the rectangle, which is its length along the *y*-axis.

Properties

`ExemplarPatches` — Exemplar patches

64-by-64-by-3-by-*numPatches*

This property is read-only.

Exemplar patches used by the CounTR model, represented as a 64-by-64-by-3-by-*numPatches* array. *numPatches* is the number of created patches.

You can create exemplar parches from an image using the `patchextractor` function.

`NumShots` — Number of exemplar bounding boxes

positive numeric scalar

Number of exemplar bounding boxes, represented as a positive integer.

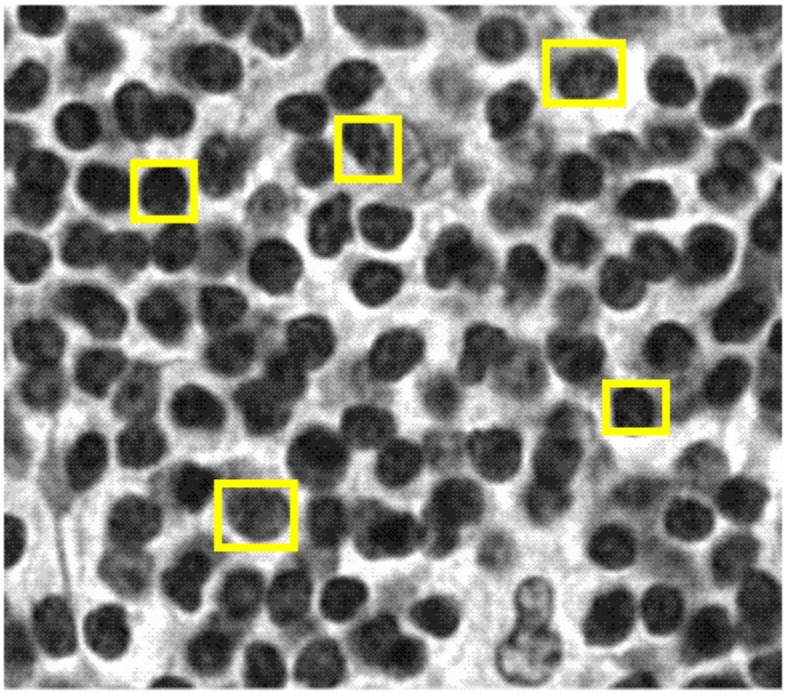
Object Functions

countObjects	Count objects using CounTR deep learning model
densityMap	Density map of object count generated using CounTR deep learning model

Examples

Count Objects in Cell Microscopy Image Using CounTR

Load an exemplar image that contains objects to count, cell nuclei, into the workspace. The exemplar image and the test image in this example are cropped from an image of lymph node cells (`patient_000_node_1.tif`) in the CAMELYON-17 data set.



```
exemplarI = imread("nuclei.png");
```

Define exemplar bounding boxes, which signify the locations of sample cells to count.

```
exemplarBoxes = ...
         [272   23   38   30
          302  193   30   24
          66   83   30   28
          108  243   38   32
          168   61   30   30];
```

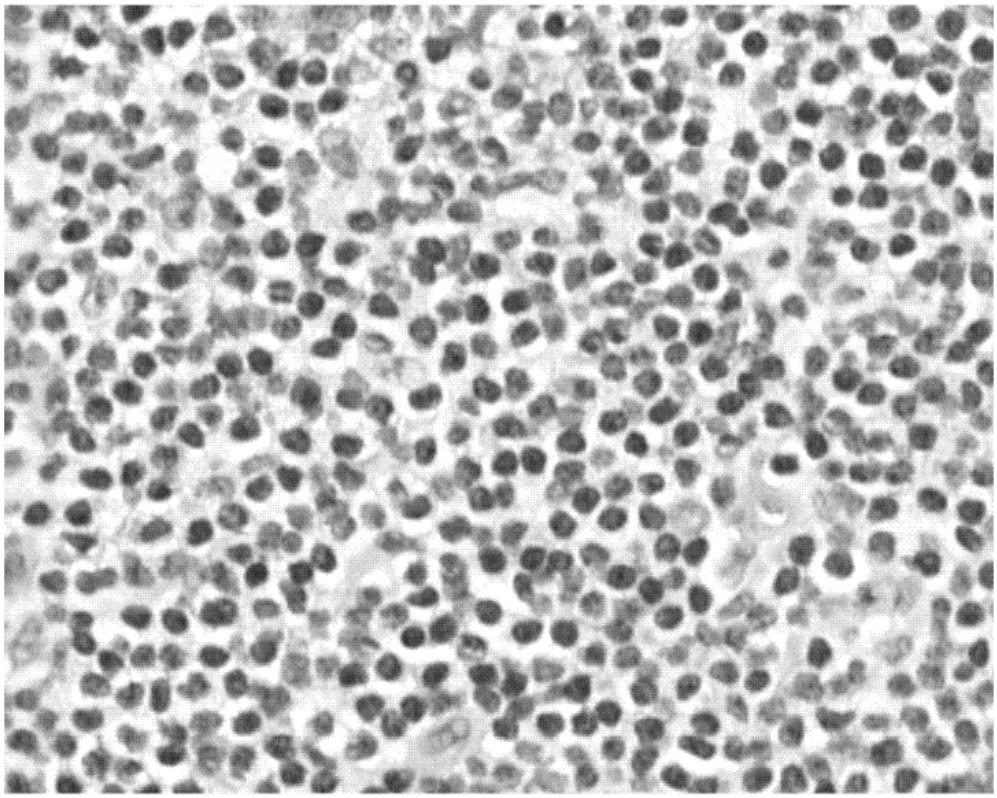
Display the exemplar image together and the exemplar bounding boxes using the `insertShape` function.

```
annotatedImage = insertShape(exemplarI,"rectangle",exemplarBoxes,"LineWidth",4);
imshow(annotatedImage)
```

Create CounTR Model

Create a CounTR object counter model using the exemplar image and exemplar bounding boxes.

```
counter = counTRObjectCounter(exemplarI,exemplarBoxes);
```



Count Objects in Test Image

Load a test image containing more cell nuclei into the workspace.

```
I = imread("nucleiTest.png");
```

Display the test timage in which to count objects.

```
imshow(I)
```

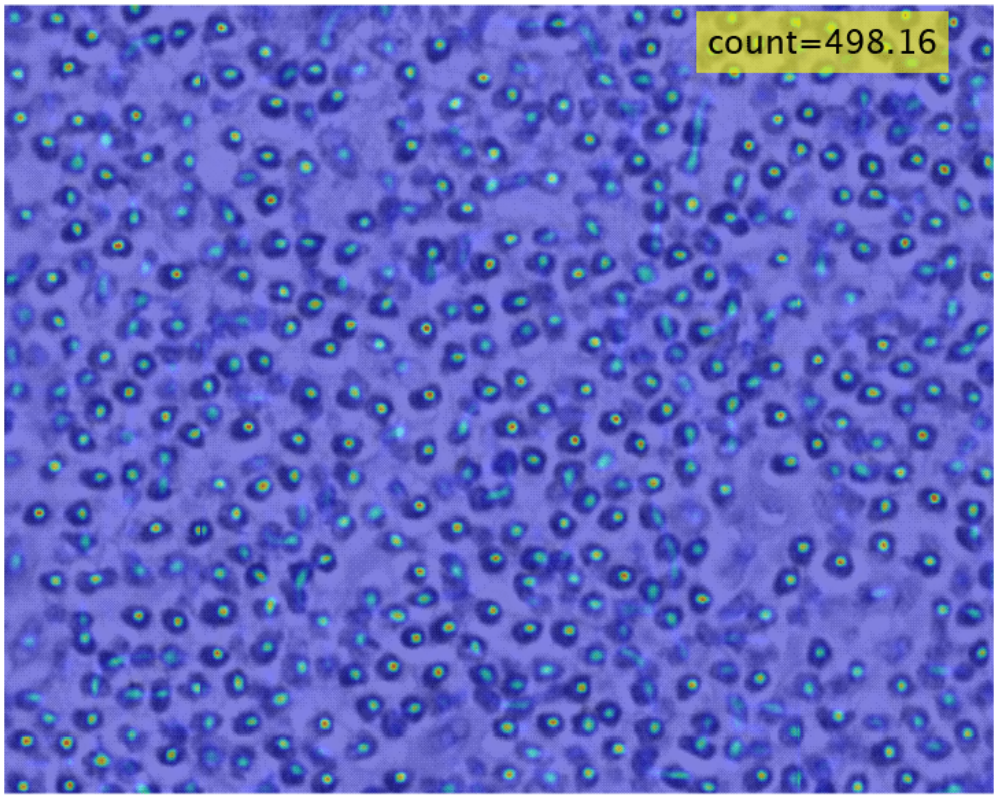
Compute the number of objects in the test image using the `countObjects` object function.

```
count = countObjects(counter,I);
count
```

```
count = single

498.1617
```

Create Density Map of Object Count



Compute the density map of the object count in the test image using the `densityMap` object function.

```
densMap = densityMap(counter,I);
```

Display the object count density map overlaid over the test image using the `anomalyMapOverlay` function. Display the approximate object count on the overlaid image using the `insertText` function.

```
densityOverlayImage = anomalyMapOverlay(I,densMap,"Blend","equal");
fontSize = min(floor(size(densityOverlayImage,2)/30),200);
```

```
gutterWidth = fontSize*9;
densityOverlayImageWText = insertText(densityOverlayImage,[size(densityOverlayImage,2)-gutterWid
sprintf("count=%0.2f",count),FontSize=fontSize);
imshow(densityOverlayImageWText)
```

Tips

- To select exemplar patches from many images for the CountTR model creation, specify the patches to the `exemplarPatches` input argument. To select exemplar patches from a single image, specify the exemplar image and the object bounding boxes it contains to the `exemplarImage` and `exemplarBBoxes` input argument, respectively.
- To count objects in a datastore of images using the `countObjects` object function, or compute a count density map using the `densityMap` object function, use exemplars in the form of patches or images and bounding boxes. For best model performance, specify exemplars to the `counTRObjectCounter` object that are general enough to apply to the series of images in a datastore.
- For best model performance, use images with well-separated, non-overlapping, objects. To improve performance in images that contain overlapping or occluded objects, crop the image to include only the non-overlapping objects of interest before running the CounTR model. This

ensures that CounTR counts objects only in this region of interest and provides a more accurate count for your specific target objects.

Version History

Introduced in R2025a

Topics

“Count Objects Using CounTR Model”

countObjects

Count objects using CounTR deep learning model

Syntax

```
count = countObjects(counter,I)
count = countObjects(counter,ds)
count = countObjects( ___ ,Name=Value)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`count = countObjects(counter,I)` counts objects within an image `I` based on exemplar image patches containing objects.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

`count = countObjects(counter,ds)` counts the number of objects within images in a datastore `ds` based on exemplar patches containing objects.

`count = countObjects( ___ ,Name=Value)` specifies options using additional name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `MiniBatchSize=4` specifies the mini-batch size as `4`.

Input Arguments

`counter` — CounTR object counter model

`counTRObjectCounter` object

CounTR object counter model, specified as a `counTRObjectCounter` object.

`I` — Image

H-by-*W* matrix | *H*-by-*W*-by-*3* numeric array

Image in which to count objects, specified as one of these values:

Image Type	Data Format
Grayscale	*H*-by-*W* numeric matrix
Binary	*H*-by-*W* logical matrix
RGB	*H*-by-*W*-by-*3* numeric array

`ds` — Datastore of images

datastore

Datastore of images, specified as a datastore such as an `ImageDatastore` or `CombinedDatastore` object, in which to count objects. If calling the datastore with the `read` function returns a cell array, then the image data must be in the first cell.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `countObjects(counter,ds,MiniBatchSize=4)` specifies the mini-batch size as 4.

Options for All Image Formats

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to process images with the network, specified as one of the execution environment options in this table.

`ExecutionEnvironment`	Description
`"auto"`	Use a GPU if available. Otherwise, use the CPU. The use of a GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
`"gpu"`	Use the GPU. If a suitable GPU is not available, the function returns an error message. Using a GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If Parallel Computing Toolbox or a suitable GPU is not available, then the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
`"cpu"`	Use the CPU.

Options for Datastore Inputs

`MiniBatchSize` — Number of observations returned in each batch
128 (default) | positive integer

Number of observations returned in each batch, specified as a positive integer. If you set a higher `MiniBatchSize`, computation requires more memory, which can cause errors if your system does not have sufficient memory.

You can specify this argument only when you specify an input datastore of images, `ds`.

`Verbose` — Visible progress display
`true` or `1` (default) | `false` or `0`

Visible progress display, specified as a numeric or logical `1` (`true`) or `0` (`false`).

You can specify this argument only when you specify an input datastore of images, `ds`.

Output Arguments

`count` — Object count
positive numeric scalar | *R*-by-1 vector

Object count, returned as a positive numeric scalar for a single image input, or an *R*-by-1 vector for a datastore input. *R* is the number of images in the input datastore, `ds`.

Version History

Introduced in R2025a

densityMap

Density map of object count generated using CounTR deep learning model

Syntax

```
densMap = densityMap(counter,I)
dsDensMap = densityMap(counter,ds)
densMap = densityMap( ___ ,Name=Value)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`densMap = densityMap(counter,I)` computes the object count density map for an image `I`.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

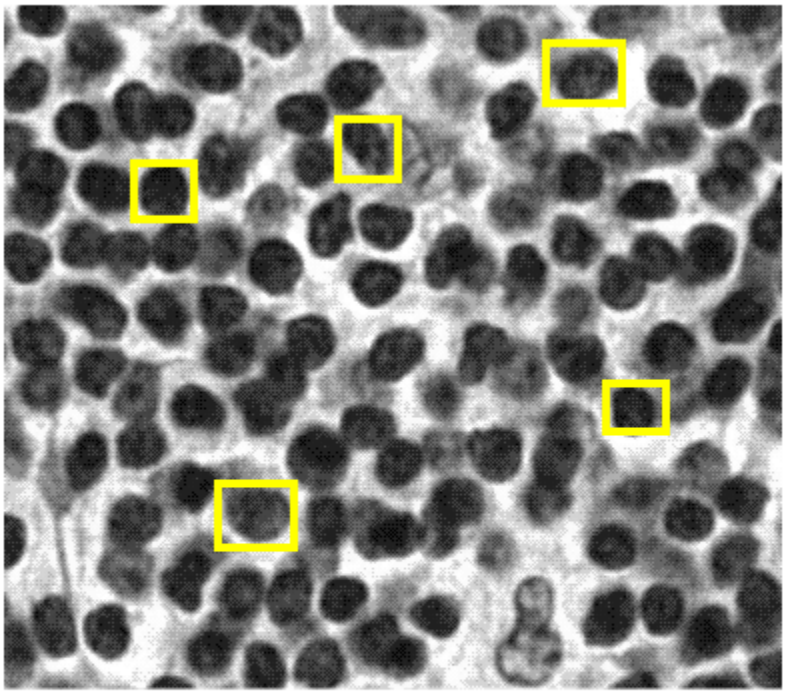
`dsDensMap = densityMap(counter,ds)` computes the object count density map for datastores of images, `ds`.

`densMap = densityMap( ___ ,Name=Value)` specifies options using additional name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `MiniBatchSize=4` specifies the mini-batch size as 4 when you specify an input datastore of images, `ds`.

Examples

Count Objects in Cell Microscopy Image Using CounTR

Load an exemplar image that contains objects to count, cell nuclei, into the workspace. The exemplar image and the test image in this example are cropped from an image of lymph node cells (`patient_000_node_1.tif`) in the CAMELYON-17 data set.



```
exemplarI = imread("nuclei.png");
```

Define exemplar bounding boxes, which signify the locations of sample cells to count.

```
exemplarBoxes = ...
         [272   23   38   30
          302  193   30   24
          66   83   30   28
          108  243   38   32
          168   61   30   30];
```

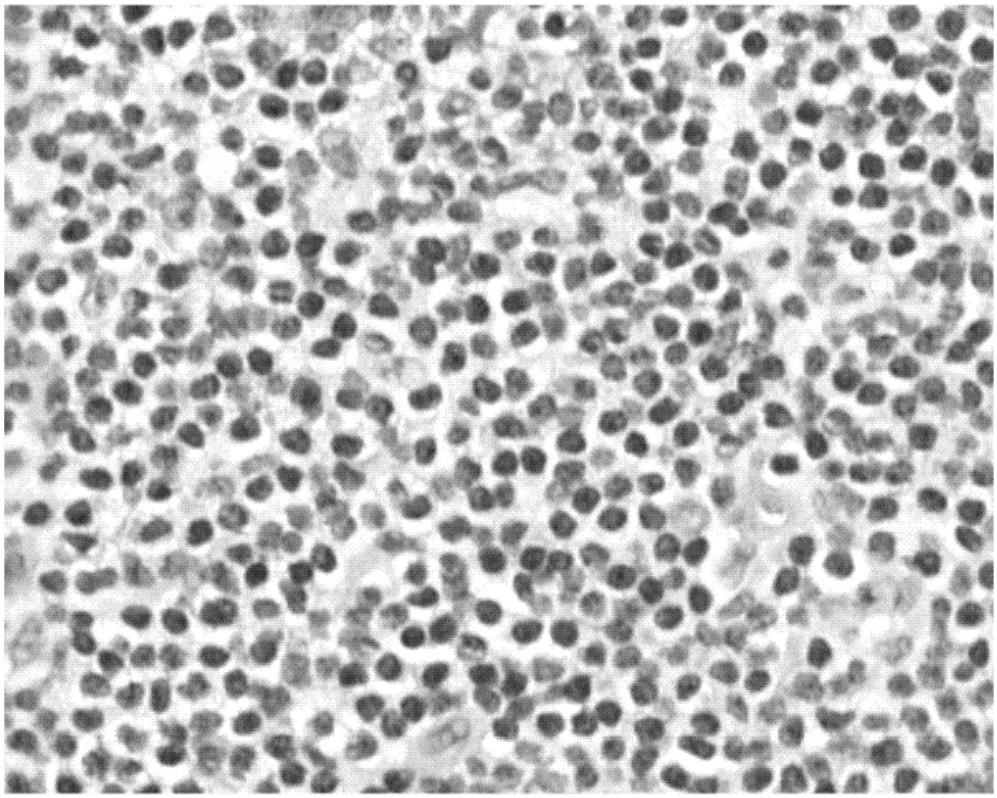
Display the exemplar image together and the exemplar bounding boxes using the `insertShape` function.

```
annotatedImage = insertShape(exemplarI,"rectangle",exemplarBoxes,"LineWidth",4);
imshow(annotatedImage)
```

Create CounTR Model

Create a CounTR object counter model using the exemplar image and exemplar bounding boxes.

```
counter = counTRObjectCounter(exemplarI,exemplarBoxes);
```



Count Objects in Test Image

Load a test image containing more cell nuclei into the workspace.

```
I = imread("nucleiTest.png");
```

Display the test timage in which to count objects.

```
imshow(I)
```

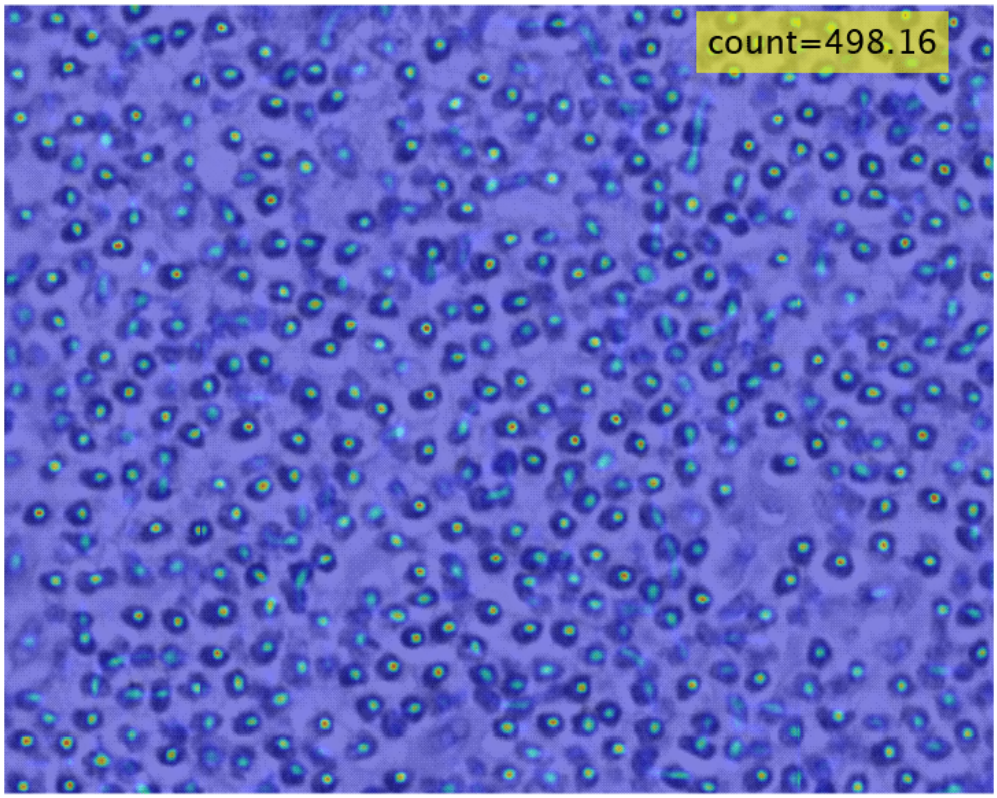
Compute the number of objects in the test image using the `countObjects` object function.

```
count = countObjects(counter,I);
count
```

```
count = single

498.1617
```

Create Density Map of Object Count



Compute the density map of the object count in the test image using the `densityMap` object function.

```
densMap = densityMap(counter,I);
```

Display the object count density map overlaid over the test image using the `anomalyMapOverlay` function. Display the approximate object count on the overlaid image using the `insertText` function.

```
densityOverlayImage = anomalyMapOverlay(I,densMap,"Blend","equal");
fontSize = min(floor(size(densityOverlayImage,2)/30),200);
```

```
gutterWidth = fontSize*9;
densityOverlayImageWText = insertText(densityOverlayImage,[size(densityOverlayImage,2)-gutterWid
sprintf("count=%0.2f",count),FontSize=fontSize);
imshow(densityOverlayImageWText)
```

Input Arguments

`counter` — CounTR object counter model

`counTRObjectCounter` object

CounTR object counter model, specified as a `counTRObjectCounter` object.

`I` — Image

H-by-*W* matrix | *H*-by-*W*-by-*3* numeric array

Image for which to create an object count density map, specified as one of these values:

Image Type	Data Format
Grayscale	*H*-by-*W* numeric matrix

Image Type	Data Format
Binary	*H*-by-*W* logical matrix
RGB	*H*-by-*W*-by-*3* numeric array

`ds` — Datastore of images
datastore

Datastore of images, specified as a datastore such as an `ImageDatastore` or `CombinedDatastore` object, for which to create object count density maps. If calling the datastore with the `read` function returns a cell array, then the image data must be in the first cell.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `densityMap(counter,ds,MiniBatchSize=4)` specifies the mini-batch size as 4 when you specify an input datastore of images, `ds`.

Options for All Image Formats

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to process images with the network, specified as one of the execution environment options in this table.

`ExecutionEnvironment`	Description
`"auto"`	Use a GPU if available. Otherwise, use the CPU. The use of a GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
`"gpu"`	Use the GPU. If a suitable GPU is not available, the function returns an error message. Using a GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If Parallel Computing Toolbox or a suitable GPU is not available, then the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
`"cpu"`	Use the CPU.

Options for Datastore Inputs

`MiniBatchSize` — Number of observations returned in each batch
128 (default) | positive integer

Number of observations returned in each batch, specified as a positive integer. If you set a higher `MiniBatchSize`, density map computation requires more memory, which can cause errors if your system does not have sufficient memory.

You can specify this argument only when you specify an input datastore of images, `ds`.

`WriteLocation` — Location to store writable data
string scalar | character vector

Location to store writable data, specified as a string scalar or character vector. The specified folder must have write permissions. If the folder already exists, the `densityMap` function creates a new folder and adds a suffix to the folder name with the next available number. The default write location is `fullfile(pwd,OutputFolderName)`, where `pwd` is the current working directory and `OutputFolderName` is specified by the `OutputFolderName` name-value argument.

You can specify this argument only when you specify an input datastore of images, `ds`.

Data Types: `char` | `string`

`OutputFolderName` — Output folder name
`"densityMapOutput"` (default) | string scalar | character vector

Output folder name for density map results, specified as a string scalar or a character vector. This folder is in the location specified by the value of the `WriteLocation` name-value argument.

If the output folder already exists, the function creates a new folder with the string `"_1"` appended to the end of the name. Set `OutputFoldername` to `""` to write all the results to the folder specified by `WriteLocation`.

You can specify this argument only when you specify an input datastore of images, `ds`.

`NamePrefix` — Prefix applied to output filenames
`"densityMap"` (default) | string scalar | character vector

Prefix applied to output filenames, specified as a string scalar or character vector. The image files are named as follows:

- *<prefix>*`_`*<N>*`.png`, where *N* corresponds to the index of the input image file, `imds.Files`(*N*).

You can specify this argument only when you specify an input datastore of images, `ds`.

`NameSuffix` — Suffix to add to the output image filename
string scalar | character vector

Suffix to add to the output image filename, specified as a string scalar or a character vector. The function appends the specified suffix to the output filename as:

- *<prefix>*`_`*<N>*`<`*suffix*`>.png`, where *N* corresponds to the index of the input image file, `ds.Files`(*N*).

If you do not specify the suffix, the function uses the input filenames as the output file suffixes. The function extracts the input filenames from the `info` output of the `read` object function of the datastore. When the datastore does not provide the filename, the function does not add a suffix.

You can specify this argument only when you specify an input datastore of images, `ds`.

`Verbose` — Visible progress display
`true` or `1` (default) | `false` or `0`

Visible progress display, specified as a numeric or logical `1` (`true`) or `0` (`false`).

You can specify this argument only when you specify an input datastore of images, `ds`.

Output Arguments

densMap — Density map

P-by-*Q* numeric matrix | datastore

Density map of object count, returned as a *P*-by-*Q* numeric matrix when you specify an input image `I`, or a datastore containing *R* density maps of size *P*-by-*Q* when you specify a datastore input `ds`. *R* is the number of images in the datastore.

Version History

Introduced in R2025a

objectInsertionDatastore

Create synthetic labeled datastore for training an instance segmentation or object detection network

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

The `objectInsertionDatastore` object blends datastores of labeled images containing foreground objects with destination images containing the background. Using this object, you can create a synthetic labeled datastore for training an instance segmentation or object detection network.

To insert an object into a single background image at a randomized or specified location, use the `insertObjectInImage` function.

Note This functionality requires Deep Learning Toolbox and the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Creation

Syntax

```
dsNew = objectInsertionDatastore(dsDestination,dsObject,numNewImages)
dsNew = objectInsertionDatastore( ___ ,PropertyName=Value)
```

Description

`dsNew = objectInsertionDatastore(dsDestination,dsObject,numNewImages)` creates an augmented datastore `dsNew` by inserting objects from the source datastore `dsObject` into the destination datastore containing image data, `dsDestination`. The objects from the source images are inserted at randomized locations on the destination images. You must specify the number of images synthetic images to create, `numNewImages`.

`dsNew = objectInsertionDatastore( ___ ,PropertyName=Value)` sets writeable properties using one or more name-value arguments, in addition to the input argument from the previous syntax. For example, `NumObjectsToInsert=2` specifies the number of objects to insert as 2.

Input Arguments

`dsDestination` — Destination datastore
datastore

Destination datastore of images, specified as a datastore such as an `ImageDatastore` or `CombinedDatastore` object.

To insert objects at specific image locations using a region constraint mask, specify the `dsDestination` argument as a datastore that returns a cell array with two columns, `{Image`

`ObjectMask}`, when called with the `read` function. `Image` is an array of RGB or grayscale images, and `ObjectMask` is a logical array of masks which span object regions to insert.

`dsObject` — Datastore of source images containing objects
datastore

Datastore of source images containing objects, specified as a datastore such as an `ImageDatastore` or `CombinedDatastore` object. You must set up your data so that calling the `read` and `readall` functions on the datastore returns a cell array with these columns.

Image Data	Boxes	Labels	Masks
RGB or grayscale image containing objects to insert, specified as an *H*-by-*W*-by-3 or *H*-by-*W*-by-1 numeric array, respectively.	Bounding boxes, defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and `y` specify the upper-left corner of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis. • *h* specifies the height of the rectangle, which is its length along the *y*-axis.	Object class names, specified as an *M*-by-1 categorical vector, where *M* is the number of specified bounding boxes. All categorical data read from the datastore must contain the same categories.	Binary masks, specified as a logical array of size *H*-by-*W*-by-*M*, where *M* is the number of specified bounding boxes. Each channel is a mask, and each mask is the segmentation of one object in the image.

`numNewImages` — Number of augmented images
positive integer

Number of augmented images to create, specified as a positive integer. In every call to the datastore with the `read` function, the `objectInsertionDatastore` object inserts random object from the datastore `dsObject` into a random image from the datastore `dsDestination`.

Properties

`NumObjectsToInsert` — Number of objects to insert
1 (default) | positive integer | range of positive integers

Number of objects to insert from the source datastore, `dsObject`, specified as a positive integer or a range of positive integers [*minNum*,*maxNum*]. If you specify a range of positive integers [*minNum*,*maxNum*], the `objectInsertionDatastore` object inserts a random number of objects into each image in the destination datastore `dsDestination`.

`OutputFormat` — Output format
`"InstanceSegmentation"` (default) | `"ObjectDetection"` | `"SceneClassification"`

Output format of the data returned by calling the augmented datastore `dsNew` with the `read` function, specified as one of these options:

- `"InstanceSegmentation"` – Instance segmentation data containing image data, bounding boxes, masks, and labels
- `"ObjectDetection"` – Object detection data containing image data, bounding boxes and labels
- `"SceneClassification"` – Scene classification, or semantic segmentation data, containing image data and masks

`ObjectsInSceneMaxOverlap` — Maximum object overlap
`1` (default) | positive scalar in range `[0, 1]`

Maximum object overlap between an object in an image from the datastore `dsObject` and a previously inserted object, specified as a positive scalar in range `[0, 1]`. Specify the `ObjectsInSceneMaxOverlap` value as `1` to insert new objects on top of existing objects. Decrease this value to decrease the overlap between the newly inserted objects and existing objects.

`BoundaryConstraintMode` — Boundary constraint mode
`"inbounds-bbox"` (default) | `"inbounds-exact"` | `"center"`

Boundary constraint mode used to constrain objects at the boundaries of images in the destination datastore `dsDestination`, specified as one of these options:

Value	Edge Detection Mechanism
`"inbounds-bbox"`	To insert an object, the entire bounding box containing the object must be completely within the destination image.
`"inbounds-exact"`	To insert an object, the object mask must be completely within the destination image.
`"center"`	Objects are inserted when the object centroid lies inside the destination image, so objects can be partially visible and clipped at the image boundary.

`MaxInsertionAttempts` — Maximum insertion attempts
`10` (default) | positive scalar

Maximum insertion attempts to satisfy the overlap value, specified as a positive scalar. The overlap value is represented by the `ObjectsInSceneMaxOverlap` property. If no insertion location can be found on the destination image after `MaxInsertionAttempts` iterations, the object from the source datastore image will not be inserted into the destination datastore image.

`BlendMethod` — Blend method
`"guidedfilter"` (default) | `"poisson"` | `"none"`

Blend method to use for inserting objects from the images in the source datastore `dsObject` into the images in the destination datastore `dsDestination`, specified as a one of these options:

BlendMethod Value	Blend Method
"guidedfilter"	Guided filter blending [1] – Blur the object mask of the source image at the mask-object boundary. Guided image filtering uses edge context from the source image to filter the mask prior to blending the object image with the destination image.
"poisson"	Poisson blending [2] – Blend the source object into the destination image by matching the color distribution of the source object to that of the boundary between the destination image and source object mask.
"none"	No blending – At insertion locations of the destination image, replace pixels of the destination image by the source image pixel values.

`GeometricAugmentation` — Geometric augmentation
`[]` (default) | function handle

Geometric augmentation, specified as a function handle that returns an `affinetform2d` object. The geometric augmentation warps a source image and the mask associated with each object in the image before it is inserted into the destination image. For example, specify the `GeometricAugmentation` value as `@() randomAffine2d("Scale",[0.9,1.1])` to apply a randomized scale transformation to each inserted object.

Version History
Introduced in R2025a

uicaliper

Interactively measure distances in images using caliper tool

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

The `uicaliper` object displays a caliper tool on an image object that you create using the `imageshow` function. You can use the caliper tool to interactively detect edges and measure distances in the image.

Note This functionality requires the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Creation

Syntax

```
hCaliper = uicaliper(hImage)
hCaliper = uicaliper(hImage,PropertyName=Value)
```

Description

`hCaliper = uicaliper(hImage)` configures a caliper tool on the displayed image `hImage`.

`hCaliper = uicaliper(hImage,PropertyName=Value)` sets writable properties using one or more name-value arguments.

For example, `Width=10` specifies the width of the profile scan as 10 pixels.

Input Arguments

`hImage` — Input image

`Image` object

Input image, specified as an `Image` object. To create an `Image` object, use the `imageshow` function.

Properties

`Position` — Profile center line position

2-by-2 numeric matrix

Profile center line position, in pixels, specified as a 2-by-2 numeric matrix of the form $[x_1\ y_1; x_2\ y_2]$, where the $[x_1\ ,\ y_1]$ and $[x_2\ ,y_2]$ are the first and last coordinates defining the line, respectively.

You can specify `Position` programmatically in the MATLAB Command Window, or interactively by clicking a start point in the specified image `hImage` and dragging to your desired end point.

`Width` — Profile scan width
non-negative scalar

Profile scan width, specified as a positive scalar. The width is the area within which the `uicaliper` object computes profile scan lines measurements. The caliper tool scans in lines orthogonal to the profile centerline and using these measurements, computes a mean 1-D profile for gradient detection. If you specify `Width` as `0`, the caliper tool scans the profile along a single line, with no additional sampling scan lines that smooth out the results. By default, the profile scan width is 10% of the length of the caliper tool.

To interactively adjust the profile scan width, configure the caliper tool on a displayed image by dragging the tool between a start and end point. Once you release the tool, you can click and drag the handles perpendicular to the tool to adjust the scan width.

`EdgeTransition` — Edge transition type
`"both"` (default) | `"rising"` | `"falling"`

Edge transition type used in edge detection, specified as one of these options:

- `"rising"` — Detect darker-to-brighter edge transitions.
- `"falling"` — Detect brighter-to-darker edge transitions.
- `"both"` — Detect both brighter-to-darker and darker-to brighter-edge transitions.

Tip When you set the `MeasurementMode` property to `"edge-pairs"`, specify the edge transition with respect to the first edge in the profile scan line. For example, to detect edge pairs in which the first edge is rising and the second edge is falling, specify `EdgeTransition` as `"rising"`.

`GradientThreshold` — Gradient threshold selection
`0.1` (default) | positive scalar in range [0, 1]

Gradient threshold for a gradient to be considered an edge, specified as a positive scalar in range [0, 1]. The gradient at each scan point is the normalized average gradient across the profile line width, `Width`. The `uicaliper` object function evaluates this value at each point along the scan line. Increase the gradient threshold value to detect fewer false positive edges.

`MeasurementMode` — Measurement mode
`"edge-pair"` (default) | `"single-edge"`

Measurement mode used to compute edge data, specified as `"edge-pair"` or `"single-edge"`. This argument determines how the `measurementData` argument outputs distance.

Value	Edge Detection Mode
`"edge-pair"`	Detect edge pairs of the type specified by the `EdgeTransition` property. When the profile scan line spans multiple edges, the caliper tool pairs each starting edge with the spatially closest ending edge to form a pair.

Value	Edge Detection Mode
`"single-edge"`	Detect single edges of the type specified by the `EdgeTransition` property.

`Sigma` — Standard deviation for Gaussian smoothing of 1-D profile data
`1.0` (default) | positive scalar

Standard deviation for Gaussian smoothing of the 1-D profile data, specified as a positive scalar. Increase this value to increase the amount of Gaussian smoothing and reduce measurement noise at the possible expense of lower accuracy in detecting edge positions.

`Color` — Caliper tool color
`[0.0 0.5610 1.0]` (default) | short or long color name | RGB triplet

Caliper tool color, specified as an RGB triplet, or a long or short color name.

`DisplayProfile` — Option to display 1-D profile scan lines
`true` or `1` (default) | `false` or `0`

Option to display 1-D profile scan lines, specified as a numeric or logical `1` (`true`) or `0` (`false`). By default, the `uicaliper` function overlays the 1-D profile scan line over the displayed image.

`DisplayDistance` — Option to display distance measurement value as text
`true` or `1` (default) | `false` or `0`

Option to display the distance measurement value as text overlaid on the image, specified as a numeric or logical `1` (`true`) or `0` (`false`).

`EdgeDistance` — Distance from each detected edge to profile scan line origin
row vector

This property is read-only.

Distance from each detected edge profile scan line origin, represented as a row vector.

`IntraEdgeDistance` — Distance between start and end of each edge pair
row vector

This property is read-only.

Distance between the start and end of each edge pair, represented as a row vector.

`InterEdgeDistance` — Distance between edge pairs
row vector

This property is read-only.

Distance between edge pairs, represented as a row vector. The caliper tool measures this distance from the end of each edge pair to the start of the next edge pair.

`GradientValue` — Gradient value corresponding to each detected edge
N-element row vector

This property is read-only.

Gradient value corresponding to each detected edge, represented as an *N*-element row vector. Each element of the row vector is the gradient value associated with each detected edge. *N* depends on the `MeasurementMode` value.

- `"single-edge"` — *N* is the number of total detected edges.
- `"edge-pair"` — *N* is the number of edges that comprise edge pairs.

`ProfileData` — 1-D profile data that determines detected edges
row vector

This property is read-only.

1-D profile data that determines detected edges, represented as an *M*-element numeric vector. *M* is the integer length of the profile scan, in pixels, and each element of the vector is the mean gradient value at each scan point.

This profile data determines the gradient values for each edge, stored in the `GradientValue` property.

Note Specify the amount of Gaussian smoothing of the profile data using the `Sigma` property.

Examples

Interactively Measure Distances on Image Using Caliper Tool

Load an image into the workspace.

```
I = imread("coins.png");
```

Display the image using the `imageshow` function.

```
hIm = imageshow(I);
```

To interactively measure distances, configure the caliper tool on the displayed image using the `uicaliper` object. Click a start point in the image and drag the end point of the caliper tool to a desired location.

```
hCal = uicaliper(hIm)
```

This GIF shows how to perform multiple measurements by dragging the end points of the caliper tool to different positions on the image.

anomalyDetectionMetrics

Anomaly detection metrics

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

An `anomalyDetectionMetrics` object encapsulates anomaly detection quality metrics for a set of images. Images of anomalies belong to the positive (`true`) class. Normal images belong to the negative (`false`) class.

Note This functionality requires the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

Creation

Create an `anomalyDetectionMetrics` object using the `evaluateAnomalyDetection` function.

Properties

`ConfusionMatrix` — Confusion matrix
table

This property is read-only.

Confusion matrix, specified as a 2-by-2 table. Each table element (*i*, *j*) is the count of images known to belong to class *i* but predicted to belong to class *j*.

`NormalizedConfusionMatrix` — Normalized confusion matrix
table

This property is read-only.

Normalized confusion matrix, specified as a 2-by-2 table. `NormalizedConfusionMatrix` represents a confusion matrix normalized by the number of images known to belong to each class. Each table element (*i*, *j*) is the count of images known to belong to class *i* but predicted to belong to class *j*, divided by the total number of images predicted in class *i*. Elements are in the range [0, 1].

`DataSetMetrics` — Metrics aggregated over data set
table

This property is read-only.

Metrics aggregated over the data set, specified as a 1-by-8 table with columns corresponding to these metrics:

- `GlobalAccuracy` — Ratio of correctly classified images to total images, regardless of class
- `MeanAccuracy` — Ratio of correctly classified images of each class to total images, averaged over all classes
- `Precision` — Positive predictive value
- `Recall` — True positive (TP) rate
- `Specificity` — True negative (TN) rate
- `F1Score` — Harmonic mean of precision and recall
- `FalsePositiveRate` — False positive (FP) rate, or fallout
- `FalseNegativeRate` — False negative (FN) rate, or miss

`ClassMetrics` — Class metrics
table

This property is read-only.

Anomaly detection metrics for each class, specified as a 2-by-2 table. The table has rows "Normal" and "Anomaly" and columns corresponding to these metrics:

- `Accuracy` — Fraction of correctly classified images for each class (normal or anomaly).
- `AccuracyPerSubClass` — Fraction of correctly classified images for each subclass within the normal and anomaly classes. The value of `AccuracyPerSubClass` is a table with *C* rows and one column, where *C* is the number of subclasses.

Examples

Calculate Metrics for Trained FCDD Anomaly Detector

Load test images and corresponding labels, then create a datastore that reads the test data. The data set consists of grayscale images of handwritten digits 0–9.

```
[Xtest,gtLabels] = digitTest4DArrayData;
dsTest = arrayDatastore(Xtest,IterationDimension=4);
```

Load a pretrained FCDD anomaly detector. This detector has been trained to classify the digit 8 as normal and all other digits as anomalies. Therefore, specify the set of anomaly labels as the set of digits between 0 and 9, excluding 8.

```
load("digit8AnomalyDetector.mat");
anomalyLabels = setdiff(string(0:9),"8");
```

Classify each test image as normal or anomalous.

```
predLabels = classify(detector,dsTest);
```

Calculate metrics for the anomaly detection results.

```
metrics = evaluateAnomalyDetection(predLabels,gtLabels,anomalyLabels)
```

```
Evaluating anomaly detection results

`evaluateAnomalyDetection`

clipNetwork

Create pretrained CLIP deep learning neural network for vision-language tasks

Description

Add-On Required: This feature requires the Computer Vision Toolbox Model for OpenAI CLIP Network add-on.

The `clipNetwork` object configures a pretrained Contrastive Language-Image Pre-Training (CLIP) network. Use the CLIP network to connect and compare images and text for tasks like image classification, retrieval, and zero-shot learning.

Use the CLIP network for image retrieval and image classification.

- Image retrieval — To search for images that best match a text query, first extract embeddings for each of the images in the data set using the `extractImageEmbeddings` object function. Then, extract the embeddings for the text search terms using the `extractTextEmbeddings` object function, compute the similarity between the text embeddings and the image embeddings, and select the classes with the closest match.
- Zero-shot classification without retraining — To classify images by comparing extracted image features to the features of candidate class names or descriptions, use the `classify` object function and select the classes with the closest match.

To perform a forward pass on the image and text encoders prior to training the CLIP network, use the `forward` object function.

Note This functionality requires Deep Learning Toolbox.

Creation

Syntax

```
net = clipNetwork(backbone)
net = clipNetwork(backbone,Name=Value)
```

Description

`net = clipNetwork(backbone)` creates a pretrained CLIP network with a pretrained image encoder, `backbone`.

`net = clipNetwork(backbone,Name=Value)` sets writable properties using one or more name-value arguments. For example, `ModelName="TrainedCLIP"` specifies the CLIP network name as `"TrainedCLIP"`.

Input Arguments

backbone — Pretrained image encoder backbone
`"vit-b-16"` | `"vit-l-14"` | `"resnet50`

Pretrained image encoder backbone of the CLIP network, specified as one of these options:

- `"vit-b-16"` — ViT-B/16 (Vision Transformer Base with 16-by-16 input patches).
- `"vit-l-14"` — ViT-L/14 (Vision Transformer Large with 14-by-14 input patches).
- `"resnet50"` — ResNet-50 deep convolutional neural network, scaled by 16 times.

The `clipNetwork` function uses the backbone image encoder to process input images and convert them into high-dimensional feature vectors.

Data Types: `char` | `string`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `clipNetwork("resnet50",ModelName="trainedCLIP")` specifies the CLIP network model name as `"TrainedCLIP"`.

`ModelName` — Name of pretrained CLIP network model
`""` (default) | string scalar | character vector

Name of the pretrained CLIP network model, specified as a string scalar or a character vector.

`ImageNormalizationStatistics` — *Z*-score normalization statistics
`[]` (default) | structure

Z-score normalization statistics, specified as a structure with these fields:

Field	Description	Default Value
`Mean`	1-by-*C* vector of means per channel.	`[122.7709 116.7460 104.0937]`
`StandardDeviation`	1-by-*C* vector of standard deviations per channel.	`[68.5005 66.6321 70.3232]`

C is the number of channels in each image.

Properties

`ModelName` — Name of pretrained CLIP network model
`""` (default) | string scalar | character vector

This property is read-only after object creation. To set this property, use the `ModelName` argument during object creation.

Name of the pretrained CLIP network model, represented as a string scalar or a character vector.

`ImageNormalizationStatistics` — *Z*-score normalization statistics
`[]` (default) | structure

This property is read-only after object creation. To set this property, use the `ImageNormalizationStatistics` argument during object creation.

Z-score normalization statistics, represented as a structure with these fields:

Field	Description	Default Value
`Mean`	1-by-*C* vector of means per channel.	`[122.7709 116.7460 104.0937]`
`StandardDeviation`	1-by-*C* vector of standard deviations per channel.	`[68.5005 66.6321 70.3232]`

The number of channels *C* must match the number of channels in each image.

`TextEncoderNetwork` — Network containing CLIP text encoder parameters
`dlnetwork` object

This property is read-only.

Network containing the CLIP text encoder parameters, represented as a `dlnetwork` object.

`ImageEncoderNetwork` — Network containing CLIP image encoder parameters
`dlnetwork` object

This property is read-only.

Network containing the CLIP image encoder parameters, represented as a `dlnetwork` object.

Object Functions

classify	Classify image using CLIP network
extractImageEmbeddings	Extract feature embeddings from image using CLIP network image encoder
extractTextEmbeddings	Extract text embeddings from search text using CLIP network text encoder
forward	Run forward pass on CLIP network

Examples

Create CLIP Network

Create a pretrained CLIP network.

```
clip = clipNetwork("resnet50")
```

```
clip =
  clipNetwork with properties:

                     ModelName: "resnet50"
            ImageEncoderNetwork: [1×1 dlnetwork]
             TextEncoderNetwork: [1×1 dlnetwork]
   ImageNormalizationStatistics: [1×1 struct]
```

Perform Image Retrieval using CLIP Network

Create a pretrained CLIP network with the ViT-B/16 backbone.

```
clip = clipNetwork("vit-b-16");
```

Create a datastore of images, `imds`, and display a montage of the images.

```
pathToImages = fullfile(toolboxdir("vision"),"visiondata","imageSets");
imds = imageDatastore(pathToImages,IncludeSubfolders=true);
montage(imds)
```

Extract Image Embeddings

Extract the feature embeddings for each image in the datastore.

```
imageEmbeddings = extractImageEmbeddings(clip,imds);
```

Extract Text Embeddings

Define a search text search term, and extract the text embeddings using the CLIP network encoder. You can modify the search term to empirically test image retrieval.

```
search = "A photo of a children's book.";
textEmbeddings = extractTextEmbeddings(clip,search);
```

Retrieve Images Related to Search Text

Compute the cosine similarity between the text embeddings and all image embeddings.

```
function simScores = cosineSim(x,y)
    simScores = (x'*y)'./(vecnorm(x)*norm(y));
end
simScores = cosineSim(imageEmbeddings,textEmbeddings)
```

```
simScores = 1×12 single row vector

    0.3019    0.3202    0.2359    0.2261    0.1954    0.2838    0.1628    0.1735    0.2029    0.1
```

Identify the three highest similarity scores.

```
[~,topIdx] = maxk(simScores,3);
```

Display the images with the highest similarity scores related to the search text.

```
imageFiles = imds.Files(topIdx);
montage(imageFiles)
```

Topics

“Get Started with Vision-Language Models”

classify

Classify image using CLIP network

Syntax

```
classes = classify(clip,I,classNames)
[classes,scores] = classify(clip,I,classNames)
[___] = classify(___,Name=Value)
```

Description

Add-On Required: This feature requires the Computer Vision Toolbox Model for OpenAI CLIP Network add-on.

`classes = classify(clip,I,classNames)` assigns each image in `I` to one of the suggested classes `classNames` using a Contrastive Language-Image Pre-Training (CLIP) network.

Note This functionality requires Deep Learning Toolbox.

`[classes,scores] = classify(clip,I,classNames)` additionally returns the CLIP network prediction scores corresponding to the predicted classes `classes`.

`[___] = classify(___,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `MiniBatchSize=32` limits the batch size to 32 images.

Examples

Classify Images in Datastore Using CLIP Network

Create a pretrained CLIP network.

```
clip = clipNetwork("vit-b-16");
```

Create a datastore of test images.

```
imageFiles = ["kobi.png","baby.jpg","flamingos.jpg","saturn.png"];
imds = imageDatastore(imageFiles);
```

Define the list of class suggestions for the test images.

```
classNames = ["baby","dog","flamingo","planet"];
```

Obtain the predicted classes for each image in the datastore.

```
class = classify(clip,imds,classNames);
```

Display the images along with their predicted classes.

```
figure
tiledlayout(2,2)
```

```
for i = 1:length(imageFiles)
    nexttile
    imshow(read(imds))
    title(class(i))
end
```

Classify Image Using CLIP Network

Create a pretrained CLIP network with a RestNet-50 backbone.

```
clip = clipNetwork("resnet50")
```

```
clip =
  clipNetwork with properties:

                      ModelName: "resnet50"
             ImageEncoderNetwork: [1×1 dlnetwork]
              TextEncoderNetwork: [1×1 dlnetwork]
    ImageNormalizationStatistics: [1×1 struct]
```

Load an image that contains the object to classify into the workspace, and display the image.

```
I = imread("kobi.png");
imshow(I)
```

Define the list of potential classes for the image.

```
classNames = ["aardvark","bee","cat","dog"];
```

Obtain the predicted class and prediction scores from the image.

```
[class,scores] = classify(clip,I,classNames)
```

```
class = categorical
     dog

scores = 1×4 single row vector

    0.5309    0.5131    0.5337    0.7217
```

Classify Image with Custom Descriptions Using CLIP Network

Create a pretrained CLIP network.

```
clip = clipNetwork("vit-l-14");
```

Load a satellite photo of the town of Concord, Massachusetts into the workspace, and display the image.

```
I = imread("concordaerial.png");
imshow(I)
```

Define the list of class suggestions for the image. These classes are town or city names.

```
classNames = ["Boston","Concord","Plymouth","Falmouth"];
```

Define class descriptions that provide more context to the CLIP model for more accurate classification.

```
classDescriptions = [ ...
    "A satellite photo of Boston, a city in Massachusetts."
    "A satellite photo of Concord, a suburb in Massachusetts."
    "A satellite photo of Plymouth, a town on the coast of Massachusetts."
    "A satellite photo of Falmouth, a town on Cape Cod in Massachusetts."
    ];
```

Specify the suggested class names for each of the towns, as well as the more detailed class descriptions, to predict the town shown in the image using the CLIP network.

```
class = classify(clip,I,classNames,ClassDescriptions=classDescriptions)
```

```
class = categorical
     Concord
```

Input Arguments

`clip` — CLIP network

`clipNetwork` object

CLIP network, specified as a `clipNetwork` object.

`I` — Image data

numeric array | datastore | formatted `dlarray` object

Image data, specified in one of these formats:

- *H*-by-*W*-by-3-by-*B* numeric array representing a batch of *B* truecolor images.
- *H*-by-*W*-by-1-by-*B* numeric array representing a batch of *B* grayscale images.
- Datastore that reads and returns truecolor images.
- Formatted `dlarray` object with two spatial dimensions of the format `"SSCB"`. You can specify multiple test images by including a batch dimension.

`classNames` — Names of class suggestions
categorical vector | vector of strings

Names of class suggestions, specified as a vector of strings or a categorical vector. You must specify class names in English using ASCII characters. The function automatically pads or truncates each text input so that it contains exactly 77 tokens.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `classify(clip,I,classNames,MiniBatchSize=32)` limits the batch size to 32 images.

`MiniBatchSize` — Size of batches
8 (default) | positive integer

Size of batches for processing large collections of images, specified as a positive integer. Larger batch sizes reduce processing time, but require more memory.

`ClassDescriptions` — Class descriptions
`"auto"` (default) | *C*-element string array

Class descriptions used for classification by the CLIP network, specified as a *C*-element string array. *C* is the number of classes in `classNames`. By default, the CLIP model generates class descriptions from the labels specified by the `classNames` input argument.

Use the `ClassDescriptions` name-value argument to create custom class descriptions. The `classify` function pads each description string with zeros or shortens it so that it contains exactly 77 tokens.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as `"auto"`, `"gpu"`, or `"cpu"`. The table shows the valid hardware resource values.

Resource	Action
`"auto"`	Use a GPU if it is available. Otherwise, use the CPU.

Resource	Action
`"gpu"`	Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
`"cpu"`	Use the CPU.

Output Arguments

`classes` — Predicted classes

B-element categorical vector

Predicted classes, returned as a *B*-element categorical vector. *B* is the number of images in the batch.

`scores` — Prediction scores

B-by-*C* numeric matrix

Prediction scores, returned as a *B*-by-*C* numeric matrix. *B* is the number of images in the batch, and *C* is the number of suggested classes specified using the `classNames` input argument.

The `classify` function computes the scores using the CLIPScore algorithm. For an input image *I* and associated text *T*, the algorithm computes the score using the equation

$$\text{CLIPScore}(I, T) = 2.5 \cdot \max(\cos(I, T), 0) .$$

`clipNetwork`

extractImageEmbeddings

Extract feature embeddings from image using CLIP network image encoder

Syntax

```
imageEmbeddings = extractImageEmbeddings(clip,I)
imageEmbeddings = extractImageEmbeddings(clip,I,Name=Value)
```

Description

Add-On Required: This feature requires the Computer Vision Toolbox Model for OpenAI CLIP Network add-on.

`imageEmbeddings = extractImageEmbeddings(clip,I)` extracts the feature embeddings from the image data `I` using the image encoder of a Contrastive Language-Image Pre-Training (CLIP) network, `clip`, by running a forward pass on the neural network.

Note This functionality requires Deep Learning Toolbox.

`imageEmbeddings = extractImageEmbeddings(clip,I,Name=Value)` specifies options using one or more name-value arguments. For example, `MiniBatchSize=32` limits the batch size to 32 images.

Examples

Extract Image Embeddings Using CLIP Network Encoder

Create a pretrained CLIP network with a ViT-B/16 backbone.

```
clip = clipNetwork("vit-b-16");
```

Create a datastore of images, `imds`, and display a montage of the images.

```
pathToImages = fullfile(toolboxdir("vision"),"visiondata","imageSets");
imds = imageDatastore(pathToImages,IncludeSubfolders=true);
montage(imds)
```

Extract the feature embeddings for each image in the datastore.

```
imageEmbeddings = extractImageEmbeddings(clip,imds);
```

Display the size of the feature embeddings.

```
size(imageEmbeddings)
```

```
ans = 1×2

   512    12
```

Input Arguments

`clip` — CLIP network

`clipNetwork` object

CLIP network, specified as a `clipNetwork` object.

`I` — Input image data

numeric array | datastore | formatted `dlarray` object

Input image data, specified in one of these formats:

- *H*-by-*W*-by-3-by-*B* numeric array representing a batch of *B* truecolor images.
- *H*-by-*W*-by-1-by-*B* numeric array representing a batch of *B* grayscale images.
- Datastore that reads and returns truecolor images.
- Formatted `dlarray` object with two spatial dimensions of the format `"SSCB"`. You can specify multiple test images by including a batch dimension.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `extractImageEmbeddings(clip,I,MiniBatchSize=32)` limits the batch size to 32 images.

`MiniBatchSize` — Size of batches
8 (default) | positive integer

Size of batches for processing large collections of images, specified as a positive integer. Larger batch sizes reduce processing time, but require more memory.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as `"auto"`, `"gpu"`, or `"cpu"`. The table shows the valid hardware resource values.

Resource	Action
`"auto"`	Use a GPU if it is available. Otherwise, use the CPU.
`"gpu"`	Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
`"cpu"`	Use the CPU.

Output Arguments

`imageEmbeddings` — Feature embeddings
512-by-*B* matrix | 768-by-*B* matrix

Feature embeddings extracted from the CLIP model encoder, returned as a 512-by-*B* or 768-by-*B* matrix, depending on the value of the `backbone` argument of the `clipNetwork` object.

Image Encoder backbone Value	Image Embeddings Format
`"vit-b-16"`	512-by-*B* matrix
`"vit-l-14"` or `"resnet50"`	768-by-*B* matrix

The `extractImageEmbeddings` function resizes the input images to 224-by-224 pixels for the ViT-L/14 and ViT-B/16 backbones, or to 384-by-384 pixels for the ResNet-50 backbone.

`clipNetwork` | `extractTextEmbeddings` | `classify`

extractTextEmbeddings

Extract text embeddings from search text using CLIP network text encoder

Syntax

```
textEmbeddings = extractTextEmbeddings(clip,text)
textEmbeddings = extractTextEmbeddings(clip,text,Name=Value)
```

Description

Add-On Required: This feature requires the Computer Vision Toolbox Model for OpenAI CLIP Network add-on.

`textEmbeddings = extractTextEmbeddings(clip,text)` extracts text embeddings from the search text `text` using the text encoder of a Contrastive Language-Image Pre-Training (CLIP) network, `clip`, by running a forward pass on the neural network.

Note This functionality requires Deep Learning Toolbox.

`textEmbeddings = extractTextEmbeddings(clip,text,Name=Value)` specifies options using one or more name-value arguments. For example, `MiniBatchSize=32` limits the batch size to 32 text strings.

Examples

Extract Text Embeddings Using CLIP Network Encoder

Create a pretrained CLIP network with a ViT-B/16 backbone.

```
clip = clipNetwork("vit-b-16");
```

Define a text search term.

```
search = "A photo of a children's book.";
```

Extract the text embeddings for the search term using the CLIP network encoder.

```
textEmbeddings = extractTextEmbeddings(clip,search);
```

Display the size of the text embeddings.

```
size(textEmbeddings)
```

```
ans = 1×2

   512     1
```

Input Arguments

`clip` — CLIP network

`clipNetwork` object

CLIP network, specified as a `clipNetwork` object.

`text` — Input text

B-element string array | datastore

Input text, specified as a *B*-element string array or a datastore containing *B* strings. *B* is the number of strings in the batch. You must specify the text in English using ASCII characters. The function automatically pads or truncates each text input so that it contains exactly 77 tokens.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `extractTextEmbeddings(clip,text,MiniBatchSize=32)` limits the batch size to 32 text strings.

`MiniBatchSize` — Number of strings in each batch

64 (default) | positive integer

Number of strings in each batch, specified as a positive integer. Larger batch sizes reduce processing time, but require more memory.

`ExecutionEnvironment` — Hardware resource

`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource on which to run the detector, specified as `"auto"`, `"gpu"`, or `"cpu"`. The table shows the valid hardware resource values.

Resource	Action
`"auto"`	Use a GPU if it is available. Otherwise, use the CPU.
`"gpu"`	Use the GPU. To use a GPU, you must have Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. If a suitable GPU is not available, the function returns an error. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).
`"cpu"`	Use the CPU.

Output Arguments

`textEmbeddings` — Text embeddings

512-by-*B* matrix | 768-by-*B* matrix

Text embeddings extracted from the CLIP model encoder, returned as a 512-by-*B* or 768-by-*B* matrix, depending on the value of the `backbone` argument of the `clipNetwork` object.

Image Encoder Backbone backbone Value	Text Embeddings Format
`"vit-b-16"`	512-by-*B* matrix
`"vit-l-14"` or `"resnet50"`	768-by-*B* matrix

`clipNetwork` | `classify` | `extractImageEmbeddings`

forward

Run forward pass on CLIP network

Syntax

```
[imageEmbeddings,textEmbeddings,state] = forward(clip,I,text)
```

Description

Add-On Required: This feature requires the Computer Vision Toolbox Model for OpenAI CLIP Network add-on.

`[imageEmbeddings,textEmbeddings,state] = forward(clip,I,text)` computes the feature embeddings of the images `I` and text embeddings of the text `text` from the output layers of the CLIP network, and returns the updated network state `state`.

Note This functionality requires Deep Learning Toolbox.

Input Arguments

`clip` — CLIP network

`clipNetwork` object

CLIP network, specified as a `clipNetwork` object.

`I` — Image data

numeric array | datastore | formatted `dlarray` object

Image data, specified in one of these formats:

- *H*-by-*W*-by-3-by-*B* numeric array representing a batch of *B* truecolor images.
- *H*-by-*W*-by-1-by-*B* numeric array representing a batch of *B* grayscale images.
- Datastore that reads and returns truecolor images.
- Formatted `dlarray` object with two spatial dimensions of the format `"SSCB"`. You can specify multiple test images by including a batch dimension.

`text` — Input text corresponding to each image

B-element string array

Input text corresponding to each image, specified as a *B*-element string array. *B* is the number of images in the batch. You must specify the text in English using ASCII characters. The function automatically pads or truncates each text input so that it contains exactly 77 tokens.

Output Arguments

`imageEmbeddings` — Image feature embeddings

`dlarray` object

Image feature embeddings extracted from the CLIP model encoder, returned as a `dlarray` object. The dimensions of the `dlarray` are 512-by-*B* or 768-by-*B*, depending on the value of the `backbone` argument of the `clipNetwork` object.

Image Encoder Backbone `backbone` Value	Image Embeddings `dlarray` Size
`"vit-b-16"`	512-by-*B*
`"vit-l-14"` or `"resnet50"`	768-by-*B*

`textEmbeddings` — Text embeddings
`dlarray` object

Text embeddings extracted from the CLIP model encoder, returned as a `dlarray` object. The dimensions of the `dlarray` are 512-by-*B* or 768-by-*B*, depending on the value of the `backbone` argument of the `clipNetwork` object.

Image Encoder Backbone `backbone` Value	Text Embeddings `dlarray` Size
`"vit-b-16"`	512-by-*B*
`"vit-l-14"` or `"resnet50"`	768-by-*B*

`state` — Updated network state
table

Updated network state, returned as a table. The network state is a table with these columns:

- `Layer` – Layer name, returned as a string scalar.
- `Parameter` – Parameter name, returned as a string scalar.
- `Value` – Parameter value, returned as a numeric array.

The network state contains information remembered by the network between iterations. Use the state to update the network parameters for training.

`clipNetwork` | `classify`

moondream

Create pretrained Moondream vision-language model (VLM)

Description

Add-On Required: This feature requires the Computer Vision Toolbox Model for Moondream Vision Language Model add-on.

The `moondream` object configures a pretrained Moondream™ vision-language model (VLM).

Use the Moondream model to quickly understand image content by generating descriptive captions. Due to the lightweight design and speed of the model, you can use it for downstream low-latency tasks like alt-text generation, image-text retrieval, and basic scene description.

To generate image captions using Moondream, use the `captionImage` object function.

Creation

Syntax

```
mdModel = moondream
```

Description

`mdModel = moondream` loads a pretrained Moondream vision-language model with 2 billion parameters.

Properties

`ModelName` — Name of pretrained Moondream vision-language model
`""` (default) | string scalar | character vector

Name of the pretrained Moondream vision-language model, specified as a string scalar or a character vector.

Object Functions

captionImage Caption images using Moondream vision-language model (VLM)

Examples

Caption Image Using Moondream Vision-Language Model

Load the Moondream vision-language model.

```
mdModel = moondream;
```

Load an image to caption into the workspace, and display the image.

```
I = imread("peppers.png");
imshow(I)
```

Caption the image using the `captionImage` object function.

```
captions = captionImage(mdModel,I);
```

Display the generated image caption.

```
display(captions)
```

```
captions =
" A purple tablecloth holds a vibrant array of red, green, yellow, and white peppers, onions, and
```

Tips

- The quality of Moondream outputs can vary across different data domains. Validate its predictions using a data set from a domain similar to your intended application.

Version History

captionImage

Caption images using Moondream vision-language model (VLM)

Syntax

```
captions = captionImage(mdModel,I)
captionsDS = captionImage(mdModel,imds)
[___] = captionImage(___,CaptionVerbosity=verbosity)
```

Description

Add-On Required: This feature requires the Computer Vision Toolbox Model for Moondream Vision Language Model add-on.

`captions = captionImage(mdModel,I)` generates a caption for image input `I` using the Moondream™ vision-language model `mdModel`.

`captionsDS = captionImage(mdModel,imds)` generates captions for images in the input image datastore `imds` using the Moondream vision-language model `mdModel`.

`[___] = captionImage(___,CaptionVerbosity=verbosity)` specifies the length of the generated captions, in addition to the arguments from previous syntaxes.

Examples

Caption Image Using Moondream Vision-Language Model

Load the Moondream vision-language model.

```
mdModel = moondream;
```

Load an image to caption into the workspace, and display the image.

```
I = imread("peppers.png");
imshow(I)
```

Caption the image using the `captionImage` object function.

```
captions = captionImage(mdModel,I);
```

Display the generated image caption.

```
display(captions)
```

```
captions =
" A purple tablecloth holds a vibrant array of red, green, yellow, and white peppers, onions, and
```

Generate Descriptive Image Caption Using Moondream Vision-Language Model

Load the Moondream vision-language model.

```
mdModel = moondream;
```

Load an image to caption into the workspace, and display the image.

```
I = imread("visionteam.jpg");
imshow(I)
```

Generate a detailed caption for the image by specifying the `CaptionVerbosity` argument of the `captionImage` object function.

```
captions = captionImage(mdModel,I,CaptionVerbosity="detail");
```

Display the generated image caption.

```
display(captions)
```

```
captions =
" The image shows six individuals standing in a row in what appears to be an office setting. The
```

Input Arguments

`mdModel` — Moondream vision-language model

`moondream` object

Moondream vision-language model, specified as a `moondream` object.

`I` — Input RGB image data

H-by-*W*-by-3 numeric array | *H*-by-*W*-by-3-by-*B* numeric array

Input RGB image data, specified as one of these options:

- *H*-by-*W*-by-3 numeric array representing a single truecolor image.
- *H*-by-*W*-by-3-by-*B* numeric array representing a batch of *B* truecolor images. *B* is the number of images in the batch.

`imds` — Datastore of images

datastore

Datastore of images, specified as any type of datastore that returns image data. If calling the datastore with the `read` function returns a cell array, then the image data must be in the first cell.

`verbosity` — Caption length

`"brief"` (default) | `"detail"`

Caption length, specified as one of these options:

- `"brief"` — Returns a caption containing approximately 25 words or less.
- `"detail"` — Returns a caption containing up to 60 words.

Output Arguments

`captions` — Image captions

string scalar | 1-by-*B* string array

Image captions, returned as one of these options, depending on the format of the input image `I`.

- `I` is a single RGB image — String scalar.
- `I` is a batch of RGB images — 1-by-*B* string array, in which each element is the caption for the corresponding image from the batch. *B* is the number of images in the batch.

`captionsDS` — Datastore image captions

N-element string array

Datastore image captions, returned as an *N*-element string array. *N* is the number of images in the image datastore `imds`.

Tips

- The quality of Moondream outputs can vary across different data domains. Validate its predictions using a data set from a domain similar to your intended application.

nerfacto

Dense reconstruction and novel view synthesis using Nerfacto Neural Radiance Field (NeRF) model

Description

Add-On Required: This feature requires the Computer Vision Toolbox Interface for Nerfstudio Library add-on.

Use the `nerfacto` object to reconstruct a 3-D representation of a scene, as a dense, colored point cloud, from 2-D images by using the Nerfacto Neural Radiance Field (NeRF) model [1] from the Nerfstudio library [2]. To generate a dense, colored point cloud of a scene, use the `generatePointCloud` function. You can synthesize novel views of the scene by using the `generateViews` function.

Note This feature requires the Computer Vision Toolbox Interface for Nerfstudio Library add-on, a Deep Learning Toolbox license, a Parallel Computing Toolbox license, and a CUDA enabled NVIDIA GPU with at least 16 GB of available GPU memory.

Creation

Create and train a `nerfacto` object on a collection of 2-D images taken from different camera poses by using the `trainNerfacto` function. The `trainNerfacto` function also generates the model folder that contains the model weights and other parameters in the path that is returned in the `ModelFolder` property.

Properties

`ModelFolder` — Model folder path

string scalar | character vector

This property is read-only.

Model folder path, represented as a string scalar or character vector in accordance with the `outputFolder` argument of the `trainNerfacto` that you use to train the `nerfacto` object. The model folder must be present and accessible for the `nerfacto` object to generate a dense, colored point cloud and create novel views of a scene.

Tip Use the `changePath` function to update the `ModelFolder` property of a trained `nerfacto` object, such as if you move the model folder to a new location.

`MaxIterations` — Maximum number of training iterations

positive integer

This property is read-only.

Maximum number of training iterations, represented as a positive integer in accordance with the `MaxIterations` argument of the `trainNerfacto` that you use to train the `nerfacto` object.

Data Types: `single` | `double`

`Intrinsics` — Camera intrinsic parameters of training images
`cameraIntrinsics` object

This property is read-only.

Camera intrinsic parameters of the training images, represented as a `cameraIntrinsics` object.

Object Functions

generatePointCloud	Generate dense, colored point cloud using trained Nerfacto Neural Radiance Field (NeRF) model
generateViews	Generate novel views using Nerfacto Neural Radiance Field (NeRF) model
writeViews	Write novel views from Nerfacto Neural Radiance Field (NeRF) model to image files
changePath	Update model folder property of trained Nerfacto NeRF model

Examples

Generate Point Cloud Using Neural Radiance Field Model

Download Pretrained NeRF Model

The `tum_rgbd_nerfacto.zip` file contains the `trainedNerfactoTUMRGBD` folder. The folder contains the `saved-nerfacto-tum-rgbd.mat` supporting file, which contains a `nerfacto` object that has been trained on a sequence of indoor images from the TUM RGB-D data set [1 on page 2-1709], and the `nerfactoModelFolder` folder, which contains the data and configuration files required for the Nerfstudio Library [2 on page 2-1709] to load and execute the trained NeRF model [3 on page 2-1709].

Download and extract `tum_rgbd_nerfacto.zip`.

```
if ~exist("tum_rgbd_nerfacto.zip","file")
    websave("tum_rgbd_nerfacto.zip","https://ssd.mathworks.com/supportfiles/3DReconstruction/tum_
    unzip("tum_rgbd_nerfacto.zip",pwd);
end
```

Specify the path to the folder containing the `saved-nerfacto-tum-rgbd` MAT file, and then load the pretrained `nerfacto` object into the workspace.

```
modelRoot = fullfile(pwd, "trainedNerfactoTUMRGBD");
load(fullfile(modelRoot, "saved-nerfacto-tum-rgbd.mat"))
```

```
Warning: The model folder for the nerfacto object could not be loaded. Update the model folder lo
  '\\mathworks\devel\sandbox\user\Shared\EX_25b\EX_nerfacto_feature\train_nerfacto_small'
```

MATLAB® displays a warning when you first load the pretrained `nerfacto` object into the workspace because the path to the model folder associated with the object, `nerfactoModelFolder`, changes when you extract the `nerfacto_saved_model.zip`.

To resolve this issue, use the `changePath` function to update the `ModelFolder` property of the trained `nerfacto` object to the current path of `nerfactoModelFolder`. This process can take a few minutes.

```
nerf = changePath(nerf, fullfile(modelRoot, "nerfactoModelFolder"));
```

```
Changing nerfacto object model folder path.
nerfacto object model folder path change complete.
```

Display the `nerfacto` object properties to verify that the `ModelFolder` property is set to the current path of `nerfactoModelFolder` on your system.

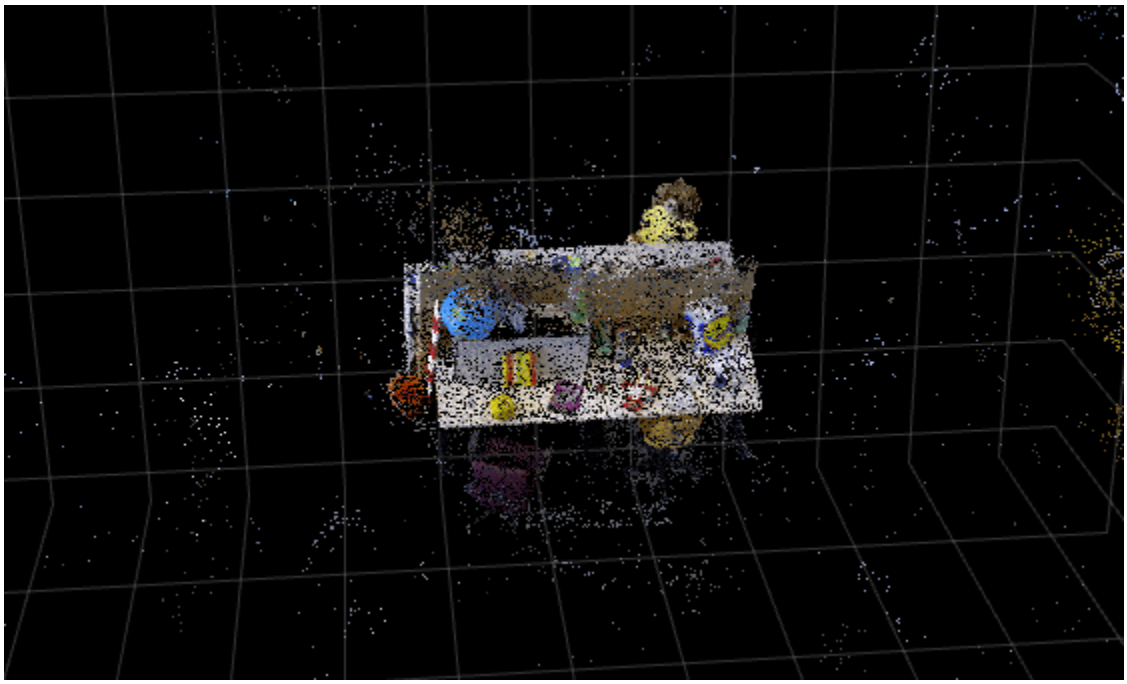
```
disp(nerf)
```

```
  nerfacto with properties:

      ModelFolder: "/home/user/Documents/MATLAB/ExampleManager/user.Bdoc.EX_26a_v1/vision-ex9089
    MaxIterations: 30000
       Intrinsics: [1×1 cameraIntrinsics]
```

Generate Point Cloud with Pretrained NeRF Model

Use the `generatePointCloud` function to generate a dense, colored point cloud of the scene. Set the maximum number of points in the point cloud to 100,000 by specifying the `MaxNumPoints` name-value argument. This value achieves a balance between the quality of the point cloud, the computing time, and storage space.



```
ptCloud = generatePointCloud(nerf, MaxNumPoints=100000);
```

```
Generating point cloud from nerfacto object.
Loading latest checkpoint from load_dir
Setting up the Nerfstudio pipeline...
[12:27:23 PM] Auto image downscale factor of 1                                                  nerfs
Setting up training dataset...
Caching all 104 images.
Loading latest checkpoint from load_dir
nerfacto object point cloud generation complete.
```

Visualize Point Cloud

Visualize the point cloud by using the `pcshow` function, and specify the vertical axis and vertical axis direction to match the coordinate system of the TUM RGB-D data set used to train the `nerfacto` object. Modify the view of the point cloud visualization to focus on the scene region of interest by specifying the of low-level camera properties of the axes object. For more information on configuring these properties, see “Low-Level Camera Properties”.

```
figure
ax = pcshow(ptCloud, VerticalAxis="y",VerticalAxisDir="down");
ax.CameraPosition = [-1.5185 -6.5178 -11.9106];
ax.CameraUpVector = [0.0520 -0.8878 0.4572];
ax.CameraViewAngle = 15;
xlabel("X")
ylabel("Y")
zlabel("Z")
title("Point Cloud from NeRF")
```

Tip: You can use the `pcdenoise` function to clean up the outliers and noise in the point cloud.

Generate Novel Views using Neural Radiance Field Model

Download Pretrained NeRF Model

The `tum_rgbd_nerfacto.zip` file contains the `trainedNerfactoTUMRGBD` folder. The folder contains the `saved-nerfacto-tum-rgbd.mat` supporting file, which contains a `nerfacto` object that has been trained on a sequence of indoor images from the TUM RGB-D data set [1 on page 2-1712], and the `nerfactoModelFolder` folder, which contains the data and configuration files

required for the Nerfstudio Library [2 on page 2-1712] to load and execute the trained NeRF model [3 on page 2-1712].

Download and extract `tum_rgbd_nerfacto.zip`.

```
if ~exist("tum_rgbd_nerfacto.zip","file")
    websave("tum_rgbd_nerfacto.zip","https://ssd.mathworks.com/supportfiles/3DReconstruction/tum_
    unzip("tum_rgbd_nerfacto.zip", pwd);
end
```

Specify the path to the folder containing the `saved-nerfacto-tum-rgbd` MAT file, and then load the pretrained `nerfacto` object into the workspace.

```
modelRoot = fullfile(pwd, "trainedNerfactoTUMRGBD");
load(fullfile(modelRoot, "saved-nerfacto-tum-rgbd.mat"))
```

```
Warning: The model folder for the nerfacto object could not be loaded. Update the model folder lo
  '\\mathworks\devel\sandbox\user\Shared\EX_25b\EX_nerfacto_feature\train_nerfacto_small'
```

MATLAB® displays a warning when you first load the pretrained `nerfacto` object into the workspace because the path to the model folder associated with the object, `nerfactoModelFolder`, changes when you extract the `nerfacto_saved_model.zip`.

To resolve this issue, use the `changePath` function to update the `ModelFolder` property of the trained `nerfacto` object to the current path of `nerfactoModelFolder`. This process can take a few minutes.

```
nerf = changePath(nerf, fullfile(modelRoot, "nerfactoModelFolder"));
```

```
Changing nerfacto object model folder path.
nerfacto object model folder path change complete.
```

Display the `nerfacto` object properties to verify that the `ModelFolder` property is set to the current path of `nerfactoModelFolder` on your system.

```
disp(nerf)
```

```
  nerfacto with properties:

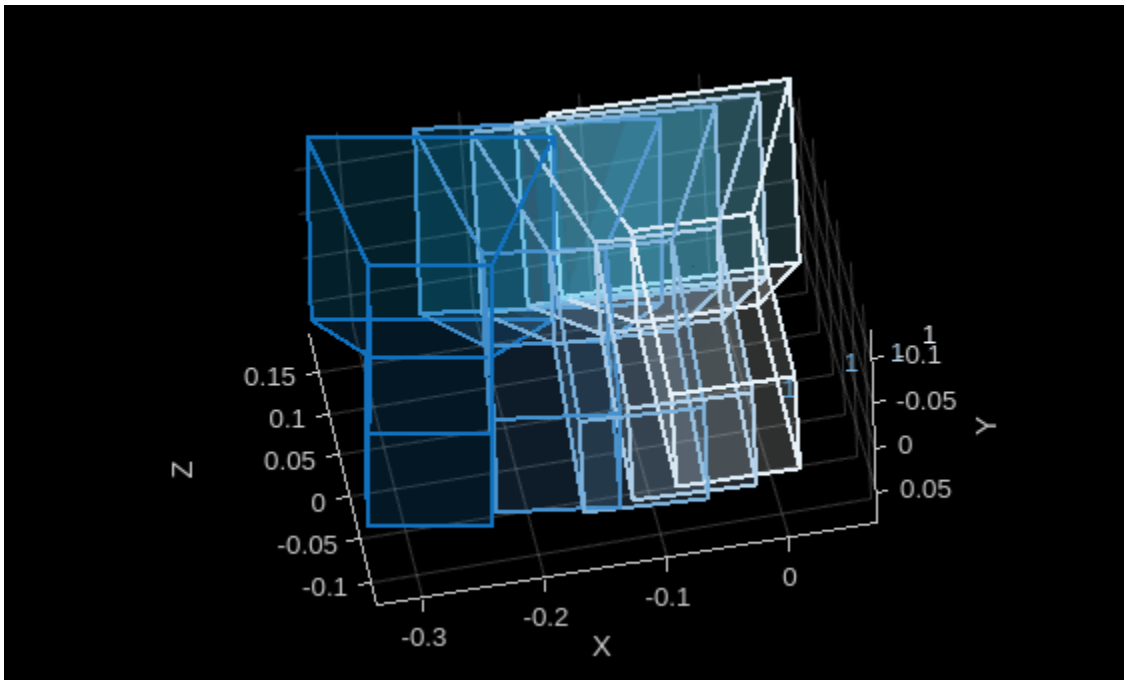
      ModelFolder: "/home/user/Documents/MATLAB/ExampleManager/user.Bdoc.EX_26a_v1/vision-ex3949
    MaxIterations: 30000
       Intrinsics: [1×1 cameraIntrinsics]
```

Load Camera Poses

This example contains a set of predefined camera poses that are stored as an array of `rigidtform3d` objects in the `camera-poses-tum.mat` file. These represent the position and orientation of the camera in the 3-D world coordinate system of the scene.

Load the `camera-poses-tum.mat` file into workspace, which contains the camera poses `camPoses`.

```
load("camera-poses-tum.mat","camPoses");
```



Display the camera poses by using the `plotCamera` function.

```
figure
pcshow([NaN NaN NaN], VerticalAxis="y", VerticalAxisDir="down");
xlabel("X")
```

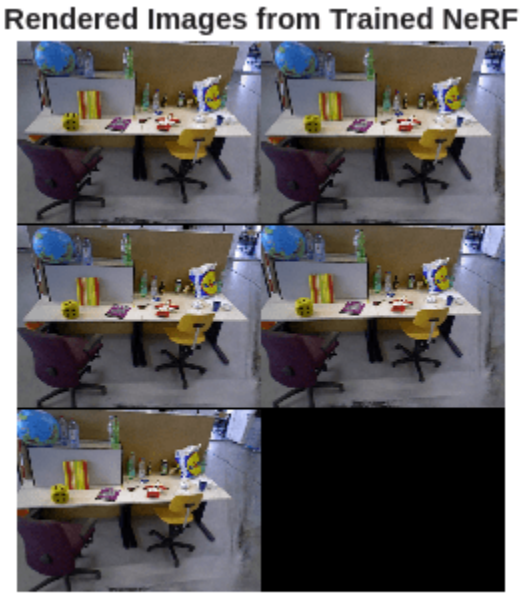
```
ylabel("Y")
zlabel("Z")
hold on

colors = sky(length(camPoses));
for i = 1:length(camPoses)
plotCamera(camPoses(i), Size=0.1, Color=colors(i,:), Opacity=0.1);
end

hold off
```

Generate Novel Views with Pretrained NeRF Model

Generate the views captured by the camera poses `camPoses` by using the `generateViews` function.



```
images = generateViews(nerf,camPoses);
```

```
Generating views from nerfacto object.
Loading latest checkpoint from load_dir
nerfacto object view generation complete.
```

Tip: If you want to generate a large number of novel views, use the `writeViews` function instead of `generateViews` to avoid an out-of-memory error.

Display the generated images. The images show the globe and chairs in front of the desk that are present in the images used to train this NeRF model.

```
figure
montage(images, BorderSize=[2 2])
title("Rendered Images from Trained NeRF")
```

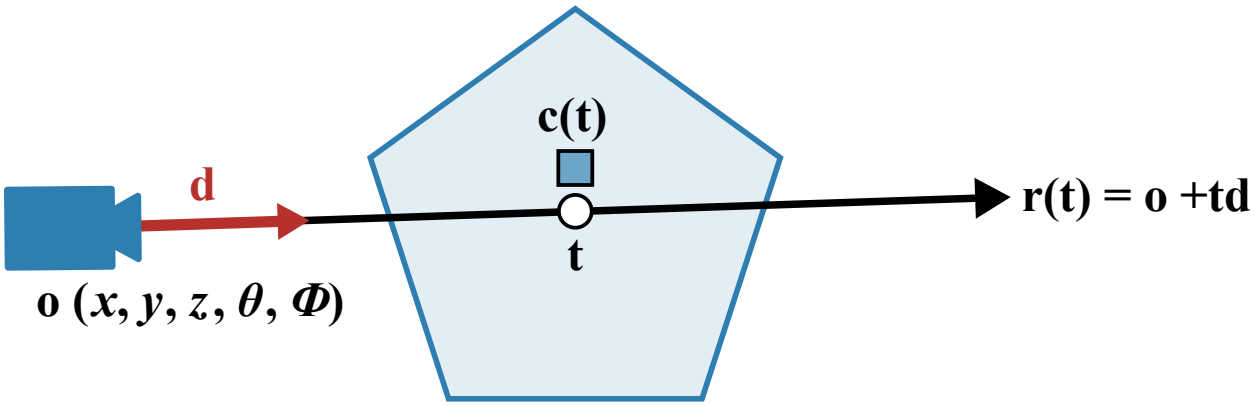
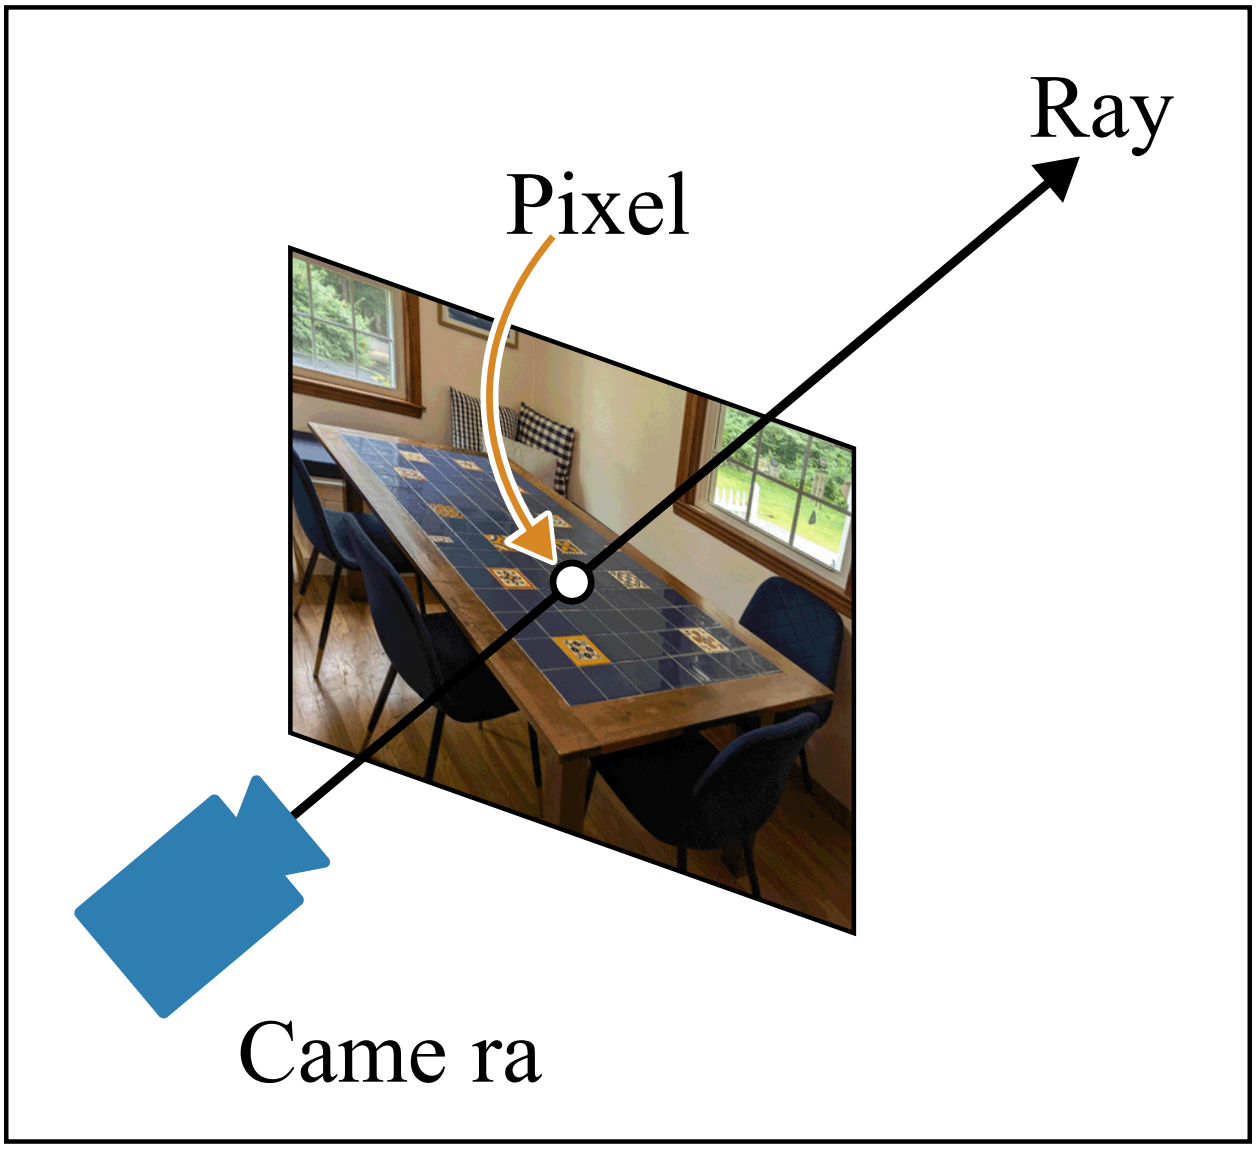
Algorithms

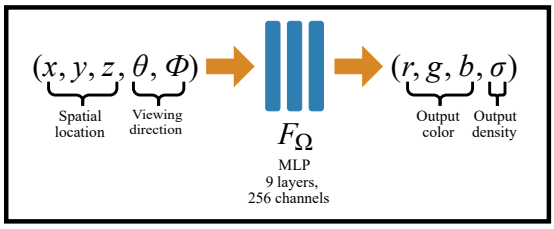


By training a NeRF model on a set of sparse input images and camera poses, you can create an internal representation of a 3D scene. You can use a trained NeRF model to generate a dense, colored point cloud, and render images from novel viewpoints.



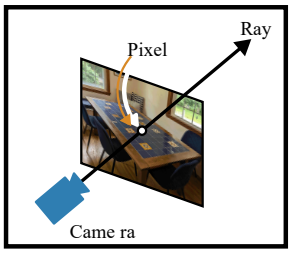
Input Images
Optimize NeRF
Render New Views

A NeRF model represents a scene as a continuous 5D vector-valued function instantiated as a neural network with weights Ω. The function accepts the position and direction of a light ray and returns the color and density of 3D points along the ray.



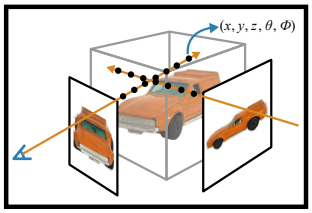
(x, y, z, θ, Φ)
Spatial location
Viewing direction
F_Ω
MLP
9 layers,
256 channels
(r, g, b, σ)
Output color
Output density

When generating a novel view, the NeRF model first uses the neural network to calculate the color and density of 3D points along each ray from a virtual camera. The ray is defined as $r(t) = o + td$, where o is the origin coordinates of the ray, and d is the unit vector in the ray direction defined by the camera angles θ and ϕ. The neural network return the color $c(t)$ if the ray $r(t)$ hits a particle at distance t along the ray. The model then uses volumetric rendering to project the output colors and densities into an image.



c(t)
d
r(t) = o +td
t
o (x, y, z, θ, Φ)

Ray
Pixel
Came ra



During training, a NeRF model first samples a batch of rays that consist of multiple spatial locations and viewing directions. The neural network F_Ω then predicts the color and density at 3D points along each ray, and the NeRF model uses volumetric rendering to project the output colors and densities onto an image. The model calculates the training loss by matching the image pixels of the rendered image against the captured images in the training data.

Predict color and density at 3D points along ray using neu ral net

Calculate color at each pixel using volumetric rendering

Calculate t raining loss by comparing rendered vs actual image pixels

Version History

Introduced in R2026a

Functions

axang

Convert transformation or rotation into axis-angle rotations

Syntax

```
angles = axang(transformation)
angles = axang(rotation)
```

Description

`angles = axang(transformation)` converts the rotation of the transformation `transformation` to the axis-angle rotations `angles`.

`angles = axang(rotation)` converts the rotation `rotation` to the axis-angle rotations `angles`.

Examples

Convert SE(3) Transformation to Axis-Angle Rotation

Create SE(3) transformation with no translation but with a rotation defined by an axis-angle rotation. Define the axis-rotation with vector of `[0.5 0.25 0.5]` to be the axis and a `pi/2` rotation about that axis.

```
axa1 = [0.5 0.25 0.5 pi/2];
T = se3(axa1,"axang");
```

Get the axis-angle rotation from the transformation.

```
axa2 = axang(T)
```

```
axa2 = 1×4

    0.6667    0.3333    0.6667    1.5708
```

Convert SO(3) Rotation to Axis-Angle Rotation

Create SO(3) transformation with a rotation defined by an axis-angle rotation. Define the axis-rotation with vector of `[0.5 0.25 0.5]` to be the axis and a `pi/2` rotation about that axis.

```
axa1 = [0.5 0.25 0.5 pi/2];
R = so3(axa1,"axang");
```

Get the axis-angle rotation from the transformation. Note that the vector of the axis-angle rotation has a different magnitude from the axis-angle rotation specified to the transformation but the defined axis and rotation are the same.

```
axa2 = axang(R)
```

```
axa2 = 1×4

    0.6667    0.3333    0.6667    1.5708
```

Input Arguments

`transformation` — Transformation

`se3` object | *N*-element array of `se3` objects

Transformation, specified as an `se3` object or as an *N*-element array of `se3` objects. *N* is the total number of transformations.

`rotation` — Rotation

`so3` object | *N*-element array of `so3` objects

Rotation, specified as an `so3` object or as an *N*-element array of `so3` objects. *N* is the total number of rotations.

Output Arguments

`angles` — Axis-angle rotation angles

N-by-4 matrix

Axis-angle rotation angles, specified as an *N*-by-4 matrix of *N* axis-angle rotations. The first three elements of every row specify the rotation axes, and the last element defines the rotation angle, in radians.

`se3` | `so3`

detectMultiPatternPoints

Detect keypoints of multiple calibration patterns

Syntax

```
imagePoints = detectMultiPatternPoints(imageFileNames,patternCount,"charuco-
board",patternDims,markerFamily,checkerSize,markerSize)
imagePoints = detectMultiPatternPoints(imageFileNames,
patternCount,"aprilgrid",patternDims,tagFamily)

imagePoints = detectMultiPatternPoints(imageFileNames,patternCount,
patternDetector,numKeyPoints)

imagePoints = detectMultiPatternPoints( ___ ,Name=Value)
```

Description

Natively Supported Patterns

`imagePoints = detectMultiPatternPoints(imageFileNames,patternCount,"charuco-board",patternDims,markerFamily,checkerSize,markerSize)` detects the keypoints of two or more ChArUco board calibration patterns in images `imageFileNames`, with dimensions specified by `patternDims`, `markerFamily`, and `checkerSize`. `patternCount` specifies the number of patterns to detect.

`imagePoints = detectMultiPatternPoints(imageFileNames, patternCount,"aprilgrid",patternDims,tagFamily)` detects the keypoints of two or more AprilGrid calibration patterns in images `imageFileNames`, with dimensions specified by `patternDims`.

Custom Pattern Detector

`imagePoints = detectMultiPatternPoints(imageFileNames,patternCount, patternDetector,numKeyPoints)` detects the specified number of uniquely detectable keypoints `numKeyPoints` of two or more custom calibration patterns of same type that can be detected in an image using the specified detector function `patternDetector`.

Optional Arguments

`imagePoints = detectMultiPatternPoints( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `Verbose=true` displays the progress of the detection process.

Examples

Calibrate a Multi-Camera System using Multiple ChArUco Boards

Estimate the relative position and orientation of eight cameras with overlapping fields of view by using calibration images that contain multiple ChArUco boards.

Download the calibration images.

```
calibImagesURL = "https://www.mathworks.com/supportfiles/vision/data/overlapping-cameras-multiple
calibImagesDir = fullfile(pwd,"overlapping-cameras-multiple-charuco");
calibImagesZip = fullfile(pwd,"overlapping-cameras-multiple-charuco.zip");
if ~exist(calibImagesZip,"file")
    disp("Downloading calibration images (86 MB)...")
    websave(calibImagesZip,calibImagesURL);
end
if ~exist(calibImagesDir,"dir")
    unzip(calibImagesZip,pwd)
end
```

Specify calibration image filenames for each camera.

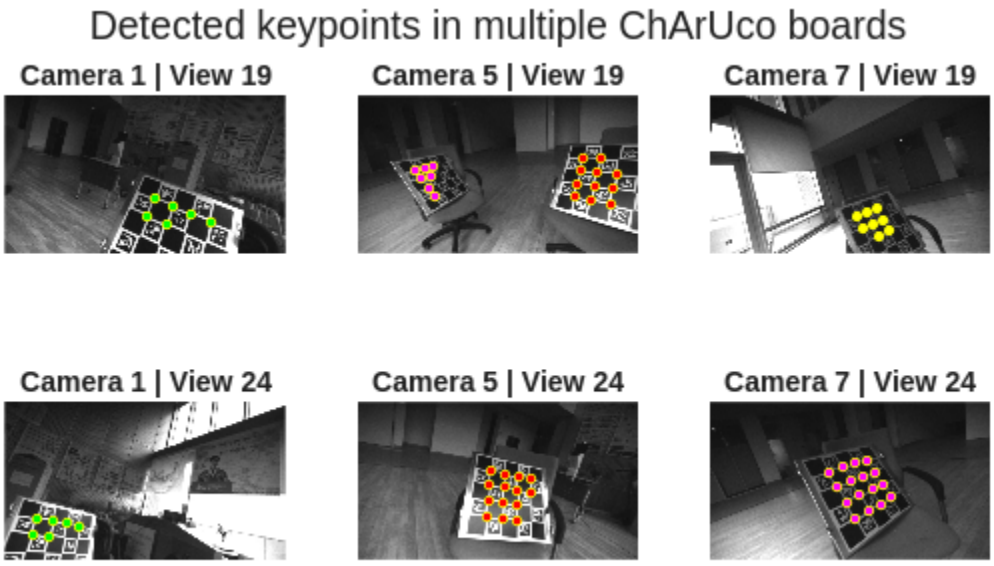
```
numCameras = 8;
camDirPrefix = "Cam00";
imageFiles = cell(1,numCameras);
for i = 1:numCameras
    camDir = fullfile(calibImagesDir,camDirPrefix+i);
    imds = imageDatastore(camDir);
    imageFiles{i} = imds.Files;
end
imageFiles = [imageFiles{:}];
```

Define the ChArUco board properties. Specify checker size and marker size in centimeters.

```
markerFamily = "DICT_6X6_1000";
patternDims = [5 5];
markerSize = 6.8;   % in cm
checkerSize = 9.15; % in cm
```

Detect the keypoints of the eight ChArUco boards captured in the calibration images using the `detectMultiPatternPoints` function. Specify the MinMarkerID for each pattern.

```
patternCount = 8;
patternIDs = 144:12:228;



imagePoints = detectMultiPatternPoints(imageFiles,patternCount,"charuco-board",patternDims,marke
    checkerSize,markerSize,MinMarkerID=patternIDs);
```

```
[==================================================] 100%
Elapsed time: 00:00:14
Estimated time remaining: 00:00:00
```

Display the detected keypoints in a couple of views and three of the eight cameras.

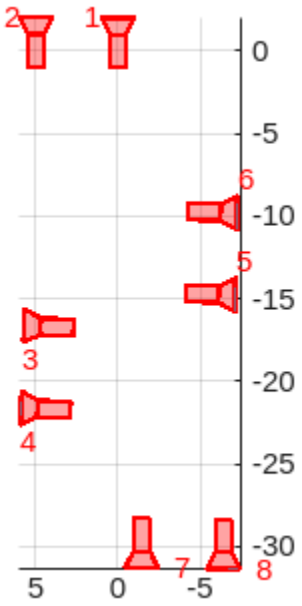
```
t = tiledlayout(2,3,TileSpacing="compact",Padding="compact");
colors = ["red","green","cyan","black","magenta","yellow","blue","white"];
for viewIdx = [19,24]
    for camIdx = [1,5,7]
        nexttile
        imshow(imageFiles{viewIdx,camIdx})
        title("Camera " + camIdx + " | View " + viewIdx)
        hold on
        for patternIdx = 1:patternCount
            plot(imagePoints(:,1,viewIdx,camIdx,patternIdx),imagePoints(:,2,viewIdx,camIdx,patte
                MarkerSize=3,MarkerFaceColor=colors(patternIdx))
        end
```

```
    end
end
title(t,"Detected keypoints in multiple ChArUco boards")
```

Generate the world coordinates of each pattern points in their respective pattern coordinate system.

```
worldPoints = patternWorldPoints("charuco-board",patternDims,checkerSize);
```

Load the intrinsic parameters of the eight cameras. These parameters have been estimated using the “Using the Single Camera Calibrator App”.



```
ld = load("eightCameraIntrinsics.mat");
```

Perform multi-camera calibration.

```
params = estimateMultiCameraParameters(imagePoints,worldPoints,ld.intrinsics,WorldUnits="cm");
```

Plot the estimated camera poses.

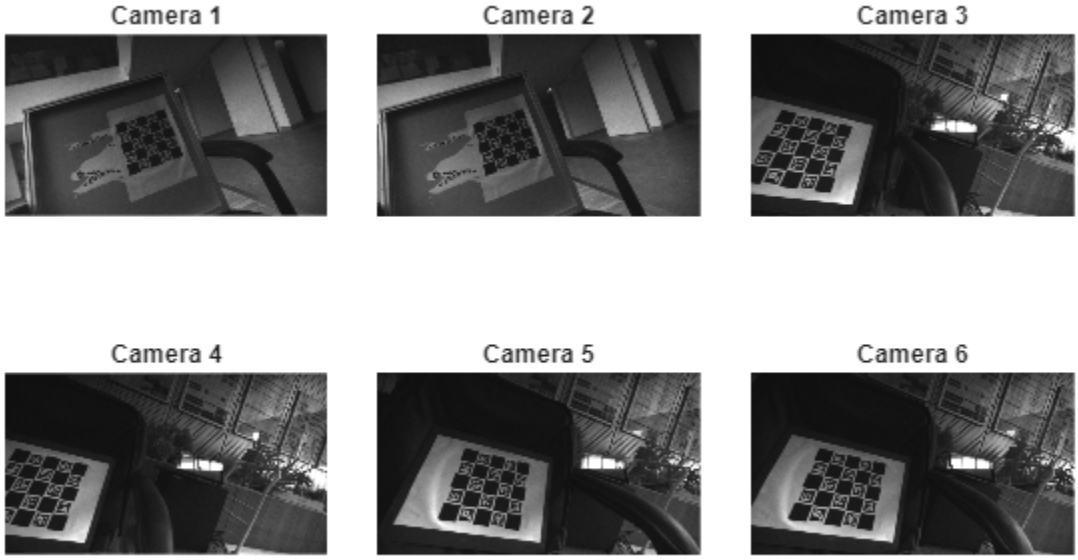
```
figure
plotCamera(params.CameraPoses)
axis equal
grid on
view([0 1 0])
```

Multi-Camera Calibration with Overlapping and Non-Overlapping Cameras

Calibrate multiple cameras that have some cameras sharing fields-of-view and some cameras not sharing any field-of-view.

Download the calibration images containing two ChArUco boards that were captured from six cameras as per the guidelines outlined in “Prepare Cameras and Capture Images for Multi-Camera Calibration”. The calibration images were captured by moving the multi-camera system around the stationary ChArUco boards.

```
calibImagesURL = "https://www.mathworks.com/supportfiles/vision/data/non-overlapping-cameras-cha
calibImagesDir = fullfile(pwd,"non-overlapping-cameras-charuco");
calibImagesZip = fullfile(pwd,"non-overlapping-cameras-charuco.zip");
if ~exist(calibImagesZip,"file")
    disp("Downloading calibration images (68 MB)...")
    websave(calibImagesZip,calibImagesURL);
end
if ~exist(calibImagesDir,"dir")
    unzip(calibImagesZip,pwd)
end
```



Specify calibration image filenames for each camera.

```
numCameras = 6;
camDirPrefix = "Cam00";
imageFiles = cell(1,numCameras);
for i = 1:numCameras
    camDir = fullfile(calibImagesDir,camDirPrefix+i);
    imds = imageDatastore(camDir);
    imageFiles{i} = imds.Files;
```

```
end
imageFiles = [imageFiles{:}];
```

Display images captured by the six cameras from one of the views.

```
figure
t = tiledlayout(2,3,TileSpacing="tight", Padding="tight");
for i = 1:numCameras
    nexttile
    imshow(imageFiles{25,i})
    title("Camera " + i)
end
```

Define the ChArUco board properties. Specify checker size and marker size in centimeters.

```
markerFamily = "DICT_6X6_1000";
patternDims = [5 5];
markerSize = 2.55;   % in cm
checkerSize = 3.40; % in cm
```

Detect the key points of the two ChArUco boards captured in the calibration images using the `detectMultiPatternPoints` function.

```
patternCount = 2;
imagePoints = detectMultiPatternPoints(imageFiles,patternCount,"charuco-board",patternDims,marke
    checkerSize,markerSize);
```

```
[==================================================] 100%
Elapsed time: 00:00:09
Estimated time remaining: 00:00:00
```

Generate the world coordinates of each pattern points in their respective pattern coordinate system.

```
worldPoints = patternWorldPoints("charuco-board",patternDims,checkerSize);
```

Load the intrinsic parameters of the six cameras. These parameters have been estimated using the "Using the Single Camera Calibrator App".

```
ld = load("sixCameraIntrinsicsNoOverlap.mat");
```

Perform multi-camera calibration. Enable verbose mode to track the progress of the calibration process.

```
params = estimateMultiCameraParameters(imagePoints,worldPoints,ld.intrinsics,WorldUnits="cm",Verb
```

```
Estimating multi-camera extrinsic parameters

* Refining all camera poses and pattern poses...done.
* Finished calibrating cameras.
```

Visualize the camera extrinsic parameters along with the patterns from a couple of views.

```
figure
showExtrinsics(params,"CameraCentric",ViewIndex=21:22)
```

Input Arguments

`imageFileNames` — Filenames of camera calibration patterns

numViews-by-*numCameras* string array | *numViews*-by-*numCameras* cell array

Filenames of the camera calibration patterns, specified as a *numViews*-by-*numCameras* string or cell array. *numViews* is the number of calibration pattern views for each camera, and *numCameras* is the number of cameras. Because you must specify more than two cameras, *numCameras* must be greater than 2. Any missing views can be specified by an empty string in the array.

Organize your calibration data into folders that contain synchronized images for each camera, ensuring that the filenames are consistent across all camera folders. This arrangement aligns images from different cameras that correspond to the same scene or subject. By using identical filenames in the folder for each camera, you can ensure that the images are properly synchronized.

CalibrationData
Camera-1
image1.ext
image2.ext
image N.ext
Camera-2
image1.ext
image2.ext
image N.ext
Camera-numCameras
image1.ext
image2.ext
image N.ext

`patternCount` — Number of unique calibration patterns captured in calibration images
scalar

Number of unique calibration patterns captured in the calibration images, specified as a scalar. The `patternCount` value must be greater than 1. For single pattern, you can use the `detectPatternPoints` function to detect keypoints.

`patternDims` — Pattern dimensions
two-element vector

Pattern dimensions, specified as a two-element vector that represents the number of checkers in the rows (*dim1*) and columns (*dim2*) of the pattern. For an AprilGrid pattern, ensure that the pattern is oriented with the origin at the top-left as you count the rows and columns. For more information on patterns, see “Calibration Patterns”.

`checkerSize` — ChArUco board checker box side length
scalar

ChArUco board checker box side length, specified as a scalar in world units, such as millimeters or inches. You must specify `checkerSize` and `markerSize` in the same world units, and `checkerSize` must be a larger value than `markerSize`.

`markerSize` — Size of ArUco marker
positive integer

Size of ArUco marker, specified as a positive integer. This value sets the length of one side of a square ArUco marker in world units such as millimeters, centimeters, meters, or inches. The value of `checkerSize` must be greater than the value of `markerSize`.

`markerFamily` — ArUco marker family
`"DICT_ARUCO_ORIGINAL"` | `"DICT_4X4_1000"` | `"DICT_5X5_1000"` | `"DICT_6X6_1000"` | `"DICT_7X7_1000"`

ArUco marker family, specified as one of these options:

- `"DICT_ARUCO_ORIGINAL"`
- `"DICT_4X4_1000"`
- `"DICT_5X5_1000"`
- `"DICT_6X6_1000"`
- `"DICT_7X7_1000"`

`tagFamily` — AprilTag family
`"tag36h11"` | `"tag25h9"` | `"tag16h5"`

AprilTag family, specified as `"tag36h11"`, `"tag25h9"`, or `"tag16h5"`.

`patternDetector` — Custom pattern detector
function handle

Custom pattern detector, specified as a function handle with this syntax:

`[imagePoints,hasDetected] = patternDetector(filename,patternID)`.

Input

- `filename` — Name of the image to be processed, specified as a string scalar or character vector.
- `patternID` — Scalar identifier assigned to the pattern to be detected. This serves the same purpose as the `minMarkerID` of a ChArUco board or an AprilGrid pattern.

Output

- `imagePoints` — Coordinates of the detected keypoints in the image, returned as a *numKeyPoints*-by-2 matrix. *N* is the number of keypoints.
- `hasDetected` — Logical that indicates whether the function detected the pattern, returned as `true` when the function detects the pattern and `false` when it does not.

`numKeyPoints` — Number of keypoints that can be detected

positive integer

Number of keypoints that can be detected in the custom pattern, specified as a positive integer.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `detectMultiPatternPoints(imageFileNames,patternCount,"charuco-board",patternDims,markerFamily,checkerSize,markerSize,Verbose=1)` enables progress display to the screen.

`MinMarkerID` — Minimum marker ID to detect in each pattern

N-element vector

Minimum marker ID to detect in each pattern, specified as an *N*-element vector of non-negative integers. The number of elements *N* is equal to the number of calibration patterns, `patternCount`.

`Verbose` — Display detection progress information

`true` or `1` (default) | `false` or `0`

Display detection progress information in the Command Window, specified as a numeric or logical `1` (`true`) or `0` (`false`). Set `Verbose` to `true` to display progress information.

Output Arguments

`imagePoints` — Image coordinates for keypoints found in each image

numKeyPoints-by-*2*-by-*numViews*-by-*numCameras*-by-*patternCount* array

Image coordinates for the keypoints found in each image, returned as a *numKeyPoints*-by-2-*numViews*-by-*numCameras*-by-*patternCount* array.

- *numKeyPoints* is the number of keypoints found for each image.
- *numViews* is the number of views with respect to the camera.
- *numCameras* is the number of cameras. For example, `imagePoints(:,:,i,j,k)` contains the points from camera *j* when the k^{th} pattern is located at the i^{th} view.

- *patternCount* is the number of unique calibration patterns captured in the calibration images.

For images where a camera fails to detect a pattern, the corresponding keypoint values are assigned as NaNs (Not a Number).

Version History

Introduced in R2026a

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set `'UseParallel'` to `true` or enable this by default using the Computer Vision Toolbox preferences.

For more information, see “Parallel Computing Toolbox Support”.

Thread-Based Environment

Run code in the background using MATLAB® `backgroundPool` or accelerate code with Parallel Computing Toolbox™ `ThreadPool`.

The `detectMultiPatternPoints` function supports thread-based environments with these usage notes and limitations:

Support for running in a thread-based environment on a background pool is available only when you set `Verbose` to `false`. For more information, see “Run MATLAB Functions in Thread-Based Environment”.

groundTruthFromCOCO

Convert COCO JSON file into ground truth object

Syntax

```
gTruth = groundTruthFromCOCO(pathToJSON,pathToImages)
```

Description

`gTruth = groundTruthFromCOCO(pathToJSON,pathToImages)` converts the COCO-formatted JSON file `pathToJSON` and the image files in the folder `pathToImages` into a ground truth object, `gTruth`.

You can use this function to convert data stored in the COCO JSON format into a ground truth object, and then use the ground truth object to create a datastore for training deep learning models for semantic segmentation, object detection, and instance segmentation tasks.

Examples

Import JSON File to Ground Truth Object

Define the location for annotations and images.

```
pathToJSON = "cupGtruthCOCO.json";
pathToImages = fullfile(matlabroot,"toolbox","vision","visiondata","imageSets","cups");
```

Import JSON file to a `groundTruth` object.

```
gTruth = groundTruthFromCOCO(pathToJSON,pathToImages);
```

Open the Image Labeler app with the imported data.

```
imageLabeler(gTruth)
```

Input Arguments

`pathToJSON` — Path to JSON file

character vector | string scalar

Path to a JSON file, specified as a character vector or string scalar. The JSON file contains the annotations for the image data.

`pathToImages` — Folder containing images

character vector | string scalar

Folder containing images, specified as a character vector or string scalar.

Output Arguments

`gTruth` — Ground truth object
`groundTruth` object

Ground truth object, returned as a `groundTruth`.

Version History

Introduced in R2025a

estimateMultiCameraParameters

Calibrate extrinsic parameters of multiple cameras with overlapping views

Syntax

```
[cameraParams,imagesUsed] = estimateMultiCameraParameters(imagePoints,
worldPoints,intrinsics)
cameraParams = estimateMultiCameraParameters( ___ ,Name=Value)
```

Description

`[cameraParams,imagesUsed] = estimateMultiCameraParameters(imagePoints, worldPoints,intrinsics)` estimates extrinsic parameters of multiple cameras using images of one or more calibration patterns. The keypoints of the patterns in each image are specified in `imagePoints`. The keypoints of the calibration patterns in world coordinates is specified in `worldPoints`. The function adjusts all image points for distortion according to the lens distortion parameters specified in the `intrinsics` input. The function also returns the images you used, `imagesUsed`, to estimate the camera parameters.

Use this function to calibrate the extrinsic parameters of two cameras without overlapping fields of view. To calibrate the extrinsic parameters of two cameras with overlapping fields of view, use the `estimateStereoBaseline` function.

`cameraParams = estimateMultiCameraParameters( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `WorldUnits="mm"` sets the world units to millimeters.

Examples

Calibrate a Multi-Camera System using a ChArUco board

Estimate the relative position and orientation of six cameras with overlapping fields of view by using calibration images that contain a single ChArUco board.

Download the calibration images.

```
calibImagesURL = "https://www.mathworks.com/supportfiles/vision/data/overlapping-cameras-charuco
calibImagesDir = fullfile(pwd,"overlapping-cameras-charuco");
calibImagesZip = fullfile(pwd,"overlapping-cameras-charuco.zip");
if ~exist(calibImagesZip,"file")
    disp("Downloading calibration images (52 MB)...")
    websave(calibImagesZip,calibImagesURL);
end
```

```
Downloading calibration images (52 MB)...
```

```
if ~exist(calibImagesDir,"dir")
    unzip(calibImagesZip,pwd)
end
```

Specify calibration image filenames for each camera.

```
numCameras = 6;
camDirPrefix = "Cam00";
imageFiles = cell(1,numCameras);
for i = 1:numCameras
    camDir = fullfile(calibImagesDir,camDirPrefix+i);
    imds = imageDatastore(camDir);
    imageFiles{i} = imds.Files;
end
imageFiles = [imageFiles{:}];
```

Define the ChArUco board properties. Specify checker size and marker size in centimeters.

```
markerFamily = "DICT_6X6_1000";
patternDims = [5 5];
markerSize = 6.8;   % in cm
checkerSize = 9.15; % in cm
numKeyPoints = prod(patternDims - 1);
minMarkerId = 144;
```

Detect the key points of the ChArUco board in the calibration images.

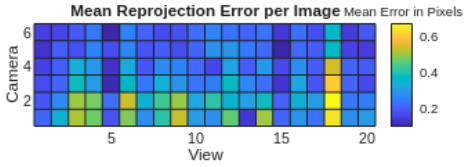
```
imagePoints = detectPatternPoints(imageFiles,"charuco-board",patternDims, ...
    markerFamily,checkerSize,markerSize,MinMarkerID=minMarkerId);
```

```
[==================================================] 100%
Elapsed time: 00:00:09
Estimated time remaining: 00:00:00
```

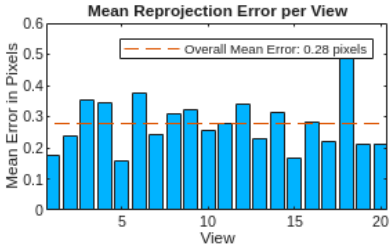
Generate the world points for the pattern.

```
worldPoints = patternWorldPoints("charuco-board",patternDims,checkerSize);
```

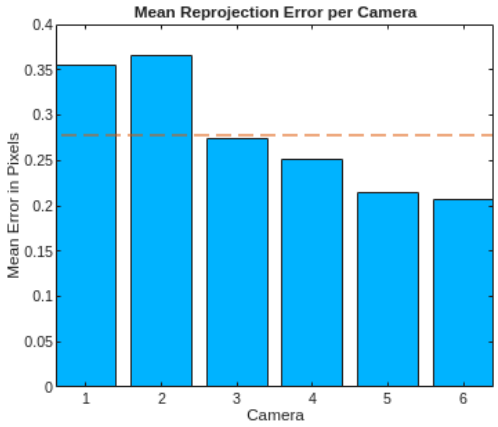
Load the intrinsic parameters of the six cameras. These parameters have been estimated using the “Using the Single Camera Calibrator App”.



```
ld = load("sixCameraIntrinsics.mat");
```



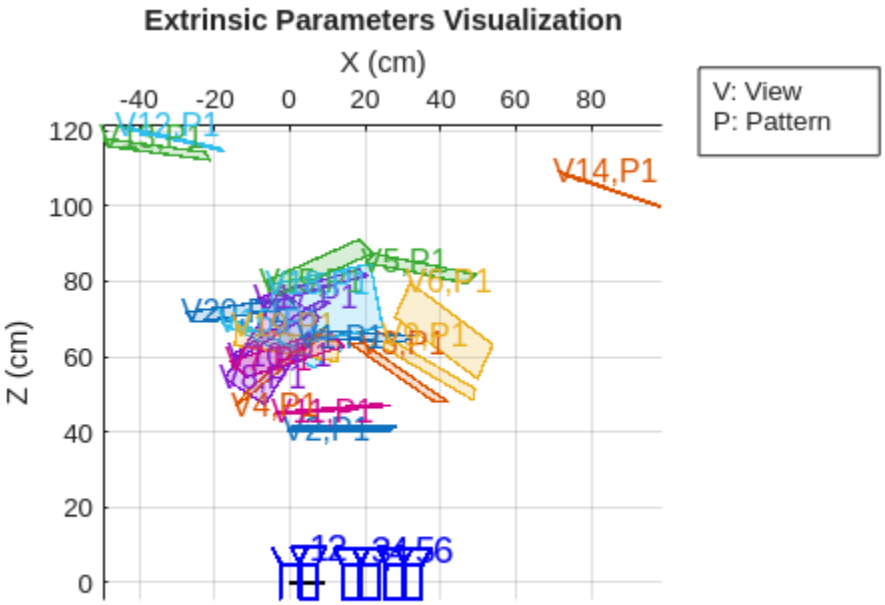
Perform multi-camera calibration.



```
params = estimateMultiCameraParameters(imagePoints,worldPoints,ld.intrinsics,WorldUnits="cm");
```

Visualize the calibration accuracy.

```
figure(Position=[100,100,1000,400])
showReprojectionErrors(params)
```



Visualize the camera extrinsic parameters.

```
figure
showExtrinsics(params)
view(2)
```

Multi-Camera Calibration with Overlapping and Non-Overlapping Cameras

Calibrate multiple cameras that have some cameras sharing fields-of-view and some cameras not sharing any field-of-view.

Download the calibration images containing two ChArUco boards that were captured from six cameras as per the guidelines outlined in “Prepare Cameras and Capture Images for Multi-Camera Calibration”. The calibration images were captured by moving the multi-camera system around the stationary ChArUco boards.

```
calibImagesURL = "https://www.mathworks.com/supportfiles/vision/data/non-overlapping-cameras-cha
calibImagesDir = fullfile(pwd,"non-overlapping-cameras-charuco");
calibImagesZip = fullfile(pwd,"non-overlapping-cameras-charuco.zip");
if ~exist(calibImagesZip,"file")
    disp("Downloading calibration images (68 MB)...")
    websave(calibImagesZip,calibImagesURL);
end
if ~exist(calibImagesDir,"dir")
    unzip(calibImagesZip,pwd)
end
```

Specify calibration image filenames for each camera.

```
numCameras = 6;
camDirPrefix = "Cam00";
imageFiles = cell(1,numCameras);
for i = 1:numCameras
    camDir = fullfile(calibImagesDir,camDirPrefix+i);
    imds = imageDatastore(camDir);
    imageFiles{i} = imds.Files;
end
imageFiles = [imageFiles{:}];
```

Display images captured by the six cameras from one of the views.

```
figure
t = tiledlayout(2,3,TileSpacing="tight", Padding="tight");
for i = 1:numCameras
    nexttile
    imshow(imageFiles{25,i})
    title("Camera " + i)
end
```

Define the ChArUco board properties. Specify checker size and marker size in centimeters.

```
markerFamily = "DICT_6X6_1000";
patternDims = [5 5];
markerSize = 2.55;   % in cm
checkerSize = 3.40; % in cm
```

Detect the key points of the two ChArUco boards captured in the calibration images using the `detectMultiPatternPoints` function.

```
patternCount = 2;
imagePoints = detectMultiPatternPoints(imageFiles,patternCount,"charuco-board",patternDims,marke
    checkerSize,markerSize);
```

```
[==================================================] 100%
Elapsed time: 00:00:09
Estimated time remaining: 00:00:00
```

Generate the world coordinates of each pattern points in their respective pattern coordinate system.

```
worldPoints = patternWorldPoints("charuco-board",patternDims,checkerSize);
```

Load the intrinsic parameters of the six cameras. These parameters have been estimated using the “Using the Single Camera Calibrator App”.

```
ld = load("sixCameraIntrinsicsNoOverlap.mat");
```

Perform multi-camera calibration. Enable verbose mode to track the progress of the calibration process.

```
params = estimateMultiCameraParameters(imagePoints,worldPoints,ld.intrinsics,WorldUnits="cm",Verb
```

```
Estimating multi-camera extrinsic parameters
--------------------------------------------
```

```
* Number of cameras: 6

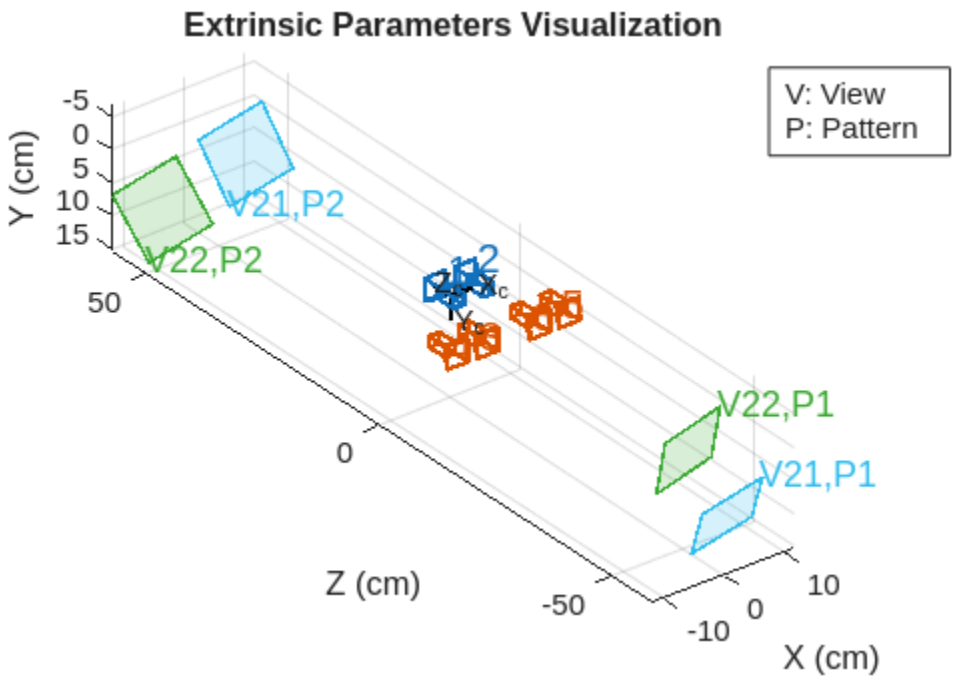
* Number of views: 30
* Number of images used: 110

* Undistorting image points...done.

* Grouping cameras with overlapping field-of-view....done.
* Group 1: camera 3 4 5 6
* Group 2: camera 1 2



* Refining camera poses of each group:
* Group 1...done.
* Group 2...done.

* Estimating relative pose between camera groups:
* [Pair 1/1] Group 1 and 2...done.

* Refining all camera poses and pattern poses...done.
* Finished calibrating cameras.
```

Visualize the camera extrinsic parameters along with the patterns from a couple of views.

```
figure
showExtrinsics(params,"CameraCentric",ViewIndex=21:22)
```

Calibrate a Multi-Camera System using Multiple ChArUco Boards

Estimate the relative position and orientation of eight cameras with overlapping fields of view by using calibration images that contain multiple ChArUco boards.

Download the calibration images.

```
calibImagesURL = "https://www.mathworks.com/supportfiles/vision/data/overlapping-cameras-multiple
calibImagesDir = fullfile(pwd,"overlapping-cameras-multiple-charuco");
calibImagesZip = fullfile(pwd,"overlapping-cameras-multiple-charuco.zip");
if ~exist(calibImagesZip,"file")
    disp("Downloading calibration images (86 MB)...")
    websave(calibImagesZip,calibImagesURL);
end
if ~exist(calibImagesDir,"dir")
    unzip(calibImagesZip,pwd)
end
```

Specify calibration image filenames for each camera.

```
numCameras = 8;
camDirPrefix = "Cam00";
imageFiles = cell(1,numCameras);
for i = 1:numCameras
    camDir = fullfile(calibImagesDir,camDirPrefix+i);
    imds = imageDatastore(camDir);
    imageFiles{i} = imds.Files;
end
imageFiles = [imageFiles{:}];
```

Define the ChArUco board properties. Specify checker size and marker size in centimeters.

```
markerFamily = "DICT_6X6_1000";
patternDims = [5 5];
markerSize = 6.8;   % in cm
checkerSize = 9.15; % in cm
```

Detect the keypoints of the eight ChArUco boards captured in the calibration images using the `detectMultiPatternPoints` function. Specify the MinMarkerID for each pattern.

```
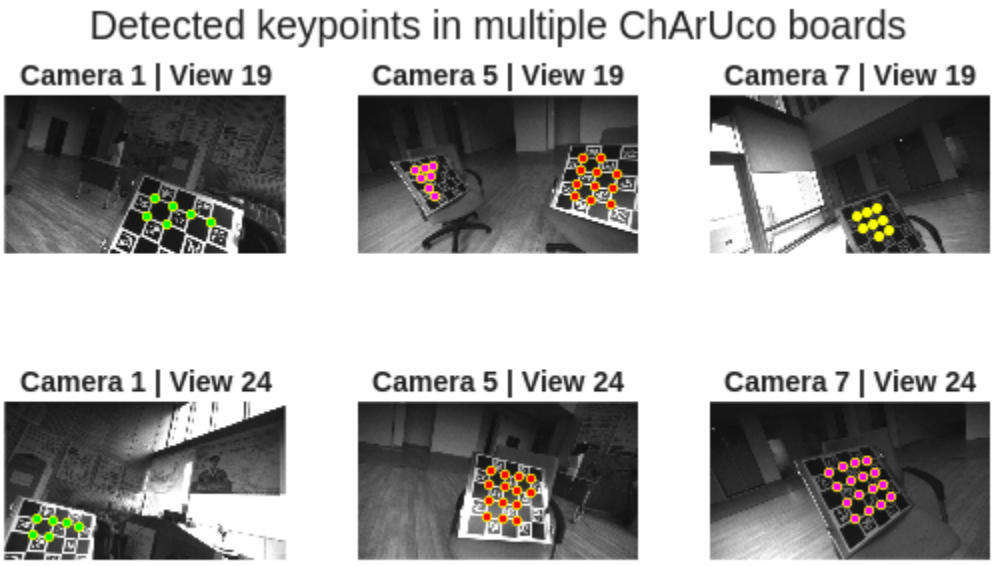
patternCount = 8;
patternIDs = 144:12:228;



imagePoints = detectMultiPatternPoints(imageFiles,patternCount,"charuco-board",patternDims,marke
    checkerSize,markerSize,MinMarkerID=patternIDs);
```

```
[==================================================] 100%
Elapsed time: 00:00:14
Estimated time remaining: 00:00:00
```

Display the detected keypoints in a couple of views and three of the eight cameras.

```
t = tiledlayout(2,3,TileSpacing="compact",Padding="compact");
colors = ["red","green","cyan","black","magenta","yellow","blue","white"];
for viewIdx = [19,24]
    for camIdx = [1,5,7]
        nexttile
        imshow(imageFiles{viewIdx,camIdx})
        title("Camera " + camIdx + " | View " + viewIdx)
        hold on
        for patternIdx = 1:patternCount
            plot(imagePoints(:,1,viewIdx,camIdx,patternIdx),imagePoints(:,2,viewIdx,camIdx,patte
                MarkerSize=3,MarkerFaceColor=colors(patternIdx))
        end
```

```
    end
end
title(t,"Detected keypoints in multiple ChArUco boards")
```

Generate the world coordinates of each pattern points in their respective pattern coordinate system.

```
worldPoints = patternWorldPoints("charuco-board",patternDims,checkerSize);
```

Load the intrinsic parameters of the eight cameras. These parameters have been estimated using the “Using the Single Camera Calibrator App”.

```
ld = load("eightCameraIntrinsics.mat");
```

Perform multi-camera calibration.

```
params = estimateMultiCameraParameters(imagePoints,worldPoints,ld.intrinsics,WorldUnits="cm");
```

Plot the estimated camera poses.

```
figure
plotCamera(params.CameraPoses)
axis equal
grid on
view([0 1 0])
```

Input Arguments

`imagePoints` — Image coordinates of keypoints in calibration pattern

numKeyPoints-by-2-by-*numViews*-by-*numCameras* array | *numKeyPoints*-by-2-by-*numViews*-by-*numCameras*-by-*patternCount* array

Image coordinates of keypoints in calibration pattern, specified as a *numKeyPoints*-by-2-by-*numViews*-by-*numCameras* 4-D array or a *numKeyPoints*-by-2-by-*numViews*-by-*numCameras*-by-*patternCount* 5-D array of *x*-*y* image coordinates.

- *numKeyPoints* — Number of keypoints in each view, which must be greater than 3.
- *numViews* — Number of unique views of the calibration patterns with respect to each camera. At each view, the pattern must be visible to at least two cameras. Each camera should observe the pattern at least once along with some other cameras. This index represents the points from camera *j* when the pattern is located at the i^{th} view.
  - `imagePoints(:,:,i,j)`
- *numCameras* — Number of cameras to calibrate, which must be greater than 2.
- *patternCount* — Number of calibration patterns. When using multiple calibration patterns, each pattern must either be visible to at least two cameras in a view or be seen by a camera along with another pattern in the same view. Additionally, each camera must observe at least one pattern that is also seen by another camera in one of the views.

To include partially detected patterns, use `[NaN,NaN]` as x-y coordinates for missing keypoints. For calibration with a single pattern, you can create a 4-D array of keypoints using the `detectPatternPoints` function. For calibration with multiple patterns, you can create a 5-D array of keypoints using the `detectMultiPatternPoints` function.

Data Types: `double`

`worldPoints` — World coordinates of keypoints on calibration pattern
numKeyPoints-by-2 array

World coordinates of keypoints on calibration pattern, specified as an *numKeyPoints*-by-2 array. *numKeyPoints* is the number of keypoints. Each keypoint is of the form [*x*,*y*]. The pattern must be planar, so all *z*-coordinates are assumed to be `0`.

Data Types: `double`

`intrinsics` — Intrinsic parameters of each camera
numCameras-element array

Intrinsic parameters of each camera, specified as a *numCameras*-element array. *numCameras* is the number of cameras and each element is either a `cameraIntrinsics` or `fisheyeIntrinsics` object.

- If all cameras share the same model (lens characteristics), the array is contains `cameraIntrinsics` or `fisheyeIntrinsics` objects.
- If different models are used across the cameras, the array is a cell array, with each cell containing a different type of camera intrinsics object.

The intrinsic parameters of the cameras are not refined by this function. By default, all the keypoints are corrected for distortion based on the lens distortion specified in the `intrinsics` input. To enhance speed, you can use the `undistortImage` or `undistortFisheyeImage` function to correct lens distortion of the images. After correcting the images, detect keypoints on these undistorted images. Then, use the undistorted keypoints along with the corresponding intrinsics object to perform calibration.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `estimateMultiCameraParameters(imagePoints,worldPoints,intrinsics,WorldUnits="mm")` sets the world units to millimeters.

`WorldUnits` — Units of world points
`"mm"` (default) | character vector | string scalar

Units of world points, specified as a character vector or string scalar.

`ReferenceCameraIndex` — Index of camera that defines reference coordinate system
`1` (default) | integer

Index of the camera that defines the reference coordinate system, specified as an integer. All other camera poses are defined relative to the reference camera. Use the `ReferenceCameraPose` name-value argument to specify the reference camera pose.

`ReferenceCameraPose` — Pose of reference camera
`rigidtform3d(eye(4))` (default) | `rigidtform3d` scalar

Pose of reference camera with respect to a world coordinate system, specified as a `rigidtform3d` scalar.

`Verbose` — Display detection progress information
`false` or`0` (default) | `true` or `1`

Display detection progress information in the Command Window, specified as a numeric or logical `1` (`true`) or `0` (`false`). Set `Verbose` to `true` to display progress information.

Output Arguments

`cameraParams` — Parameters of multi-camera system
`multiCameraParameters` object

Parameters of a multi-camera system, returned as a `multiCameraParameters` object. The extrinsic parameters include the rotation and translation that describe the position and orientation of each camera with respect to the reference camera.

`imagesUsed` — Images used to estimate camera parameters
numViews-by-*numCameras* logical array

Images you use to estimate camera parameters, returned as a *numViews*-by-*numCameras* logical array. *numViews* corresponds to the number of camera views used and *numCameras* is the number of cameras. The array indicates which images you used to estimate the camera parameters. A logical `true` value in the array indicates which images you used to estimate the camera parameters.

Version History

Introduced in R2025a

R2026a: Added support for multiple calibration patterns and cameras with non-overlapping fields of view

You can now specify a 5-D array for `imagePoints` to include the number of calibration patterns and from multiple cameras with or without overlapping fields of view. Use the `ReferenceCameraPose` name-value argument to specify the camera pose with respect to a world coordinate system.

detectPatternPoints

Detect keypoints of calibration pattern in images from multiple cameras

Syntax

```
imagePoints = detectPatternPoints(imageFileNames,"charuco-board",patternDims,
markerFamily,checkerSize,markerSize)
imagePoints = detectPatternPoints(imageFileNames,"aprilgrid",patternDims,
tagFamily)
imagePoints = detectPatternPoints(imageFileNames,"checkerboard",patternDims)
imagePoints = detectPatternPoints(imageFileNames,"circle-grid-asymmetric",
patternDims)

imagePoints = detectPatternPoints(imageFileNames,patternDetector,
numKeyPoints)

imagePoints = detectPatternPoints( ___ ,Name=Value)
```

Description

Natively Supported Patterns

`imagePoints = detectPatternPoints(imageFileNames,"charuco-board",patternDims, markerFamily,checkerSize,markerSize)` detects the keypoints of a ChArUco board calibration pattern in images `imageFileNames`, with dimensions specified by `patternDims`, `markerFamily`, and `checkerSize`.

`imagePoints = detectPatternPoints(imageFileNames,"aprilgrid",patternDims, tagFamily)` detects the keypoints of an AprilGrid calibration pattern in images `imageFileNames`, with dimensions specified by `patternDims`.

`imagePoints = detectPatternPoints(imageFileNames,"checkerboard",patternDims)` detects the keypoints of a fully visible checkerboard calibration pattern in images `imageFileNames`, with dimensions specified by `patternDims`. The values of the elements of `patternDims` must not be equal.

`imagePoints = detectPatternPoints(imageFileNames,"circle-grid-asymmetric", patternDims)` detects keypoints of a circle grid calibration pattern in images `imageFileNames`, with dimensions specified by `patternDims`.

Custom Pattern Detector

`imagePoints = detectPatternPoints(imageFileNames,patternDetector, numKeyPoints)` detects the specified number of uniquely detectable keypoints `numKeyPoints` of a custom calibration pattern that can be detected in an image using the specified detector function `patternDetector`.

Optional Arguments

`imagePoints = detectPatternPoints( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `Verbose=true` displays the progress of the detection process.

Examples

Detect AprilGrid in Images from Multiple Cameras

Download the calibration images.

```
calibImagesURL = "https://www.mathworks.com/supportfiles/vision/data/overlapping-cameras-aprilgr
calibImagesDir = fullfile(pwd,"overlapping-cameras-aprilgrid");
calibImagesZip = fullfile(pwd,"overlapping-cameras-aprilgrid.zip");
if ~exist(calibImagesZip,"file")
    disp("Downloading calibration images (54 MB)...")
    websave(calibImagesZip,calibImagesURL);
end
```

```
Downloading calibration images (54 MB)...
```

```
if ~exist(calibImagesDir,"dir")
    unzip(calibImagesZip,pwd)
end
```

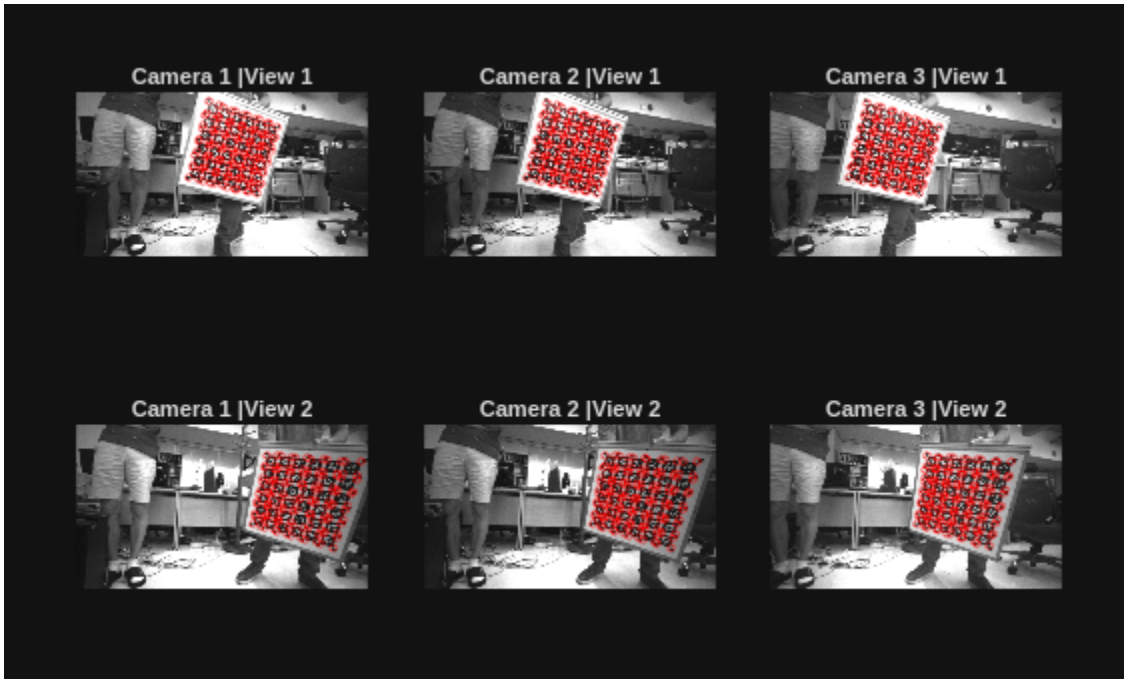
Specify calibration image filenames for each camera.

```
numCameras = 6;
camDirPrefix = "Cam00";
imageFiles = cell(1,numCameras);
for i = 1:numCameras
    camDir = fullfile(calibImagesDir,camDirPrefix+i);
    imds = imageDatastore(camDir);
    imageFiles{i} = imds.Files;
end
imageFiles = [imageFiles{:}];
```

Define the AprilGrid properties.

```
patternDims = [6 6];
tagFamily = "tag36h11";
```

Detect the key points of the AprilGrid in the calibration images.



```
imagePoints = detectPatternPoints(imageFiles, "aprilgrid", ...
    patternDims,tagFamily);
```

```
[==================================================] 100%
Elapsed time: 00:00:32
Estimated time remaining: 00:00:00
```

Display the detected keypoints of the AprilGrid in the first two views for three of the six cameras.

```
tiledlayout(2,3,TileSpacing="compact",Padding="compact");
for viewIdx = 1:2
    for camIdx = 1:3
        nexttile
        imshow(imageFiles{viewIdx,camIdx})
        title("Camera " + camIdx + "|View " + viewIdx)
        hold on
        plot(imagePoints(:,1,viewIdx,camIdx),imagePoints(:,2,viewIdx,camIdx), ...
            "ro",MarkerSize=3)
```

```
    end
end
```

Calibrate a Multi-Camera System using a ChArUco board

Estimate the relative position and orientation of six cameras with overlapping fields of view by using calibration images that contain a single ChArUco board.

Download the calibration images.

```
calibImagesURL = "https://www.mathworks.com/supportfiles/vision/data/overlapping-cameras-charuco
calibImagesDir = fullfile(pwd,"overlapping-cameras-charuco");
calibImagesZip = fullfile(pwd,"overlapping-cameras-charuco.zip");
if ~exist(calibImagesZip,"file")
    disp("Downloading calibration images (52 MB)...")
    websave(calibImagesZip,calibImagesURL);
end
```

```
Downloading calibration images (52 MB)...
```

```
if ~exist(calibImagesDir,"dir")
    unzip(calibImagesZip,pwd)
end
```

Specify calibration image filenames for each camera.

```
numCameras = 6;
camDirPrefix = "Cam00";
imageFiles = cell(1,numCameras);
for i = 1:numCameras
    camDir = fullfile(calibImagesDir,camDirPrefix+i);
```

```
    imds = imageDatastore(camDir);
    imageFiles{i} = imds.Files;
end
imageFiles = [imageFiles{:}];
```

Define the ChArUco board properties. Specify checker size and marker size in centimeters.

```
markerFamily = "DICT_6X6_1000";
patternDims = [5 5];
markerSize = 6.8;   % in cm
checkerSize = 9.15; % in cm
numKeyPoints = prod(patternDims - 1);
minMarkerId = 144;
```

Detect the key points of the ChArUco board in the calibration images.

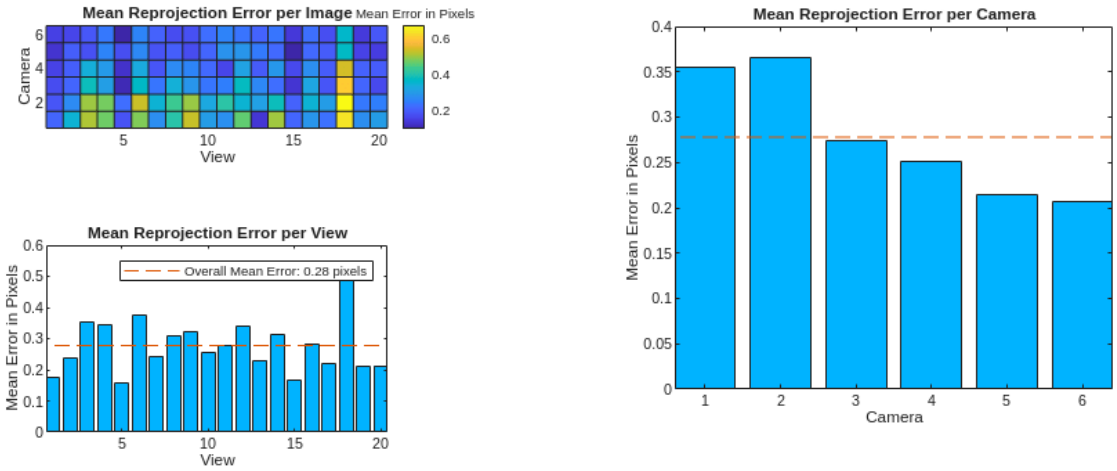
```
imagePoints = detectPatternPoints(imageFiles,"charuco-board",patternDims, ...
    markerFamily,checkerSize,markerSize,MinMarkerID=minMarkerId);
```

```
[==================================================] 100%
Elapsed time: 00:00:09
Estimated time remaining: 00:00:00
```

Generate the world points for the pattern.

```
worldPoints = patternWorldPoints("charuco-board",patternDims,checkerSize);
```

Load the intrinsic parameters of the six cameras. These parameters have been estimated using the “Using the Single Camera Calibrator App”.



```
ld = load("sixCameraIntrinsics.mat");
```

Perform multi-camera calibration.

```
params = estimateMultiCameraParameters(imagePoints,worldPoints,ld.intrinsics,WorldUnits="cm");
```

Visualize the calibration accuracy.

```
figure(Position=[100,100,1000,400])
showReprojectionErrors(params)
```

Visualize the camera extrinsic parameters.

```
figure
showExtrinsics(params)
view(2)
```

Input Arguments

`imageFileNames` — Filenames of camera calibration patterns

numViews-by-*numCameras* string array | *numViews*-by-*numCameras* cell array

Filenames of the camera calibration patterns, specified as a *numViews*-by-*numCameras* string or cell array. *numViews* is the number of calibration pattern views for each camera, and *numCameras* is the number of cameras. Because you must specify more than two cameras, *numCameras* must be greater than 2.

Organize your calibration data into folders that contain synchronized images for each camera, ensuring that the filenames are consistent across all camera folders. This arrangement aligns images from different cameras that correspond to the same scene or subject. By using identical filenames in the folder for each camera, you can ensure that the images are properly synchronized.

CalibrationData

image1.ext
image2.ext
image N.ext
Camera-2
image1.ext
image2.ext
image N.ext
Camera-numCameras
image1.ext
image2.ext
image N.ext

`patternDims` — Pattern dimensions
two-element vector

Pattern dimensions, specified as a two-element vector that represents the number of checker boxes or circles along the rows (*dim1*) and columns (*dim2*) of the pattern. For an AprilGrid pattern, ensure that the pattern is oriented with the origin at the top-left as you count the rows and columns. For more information on patterns, see “Calibration Patterns”.

`markerFamily` — ArUco marker family
`"DICT_ARUCO_ORIGINAL"` | `"DICT_4X4_1000"` | `"DICT_5X5_1000"` | `"DICT_6X6_1000"` | `"DICT_7X7_1000"`

ArUco marker family, specified as one of these options:

- `"DICT_ARUCO_ORIGINAL"`
- `"DICT_4X4_1000"`
- `"DICT_5X5_1000"`
- `"DICT_6X6_1000"`
- `"DICT_7X7_1000"`

`checkerSize` — ChArUco board checker box side length
scalar

ChArUco board checker box side length, specified as a scalar in world units, such as millimeters or inches. You must specify `checkerSize` and `markerSize` in the same world units, and `checkerSize` must be a larger value than `markerSize`.

`markerSize` — Size of ArUco marker
positive integer

Size of ArUco marker, specified as a positive integer. This value sets the length of one side of a square ArUco marker in world units such as millimeters, centimeters, meters, or inches. The value of `checkerSize` must be greater than the value of `markerSize`.

`tagFamily` — AprilTag family
`"tag36h11"` | `"tag25h9"` | `"tag16h5"`

AprilTag family, specified as `"tag36h11"`, `"tag25h9"`, or `"tag16h5"`.

`patternDetector` — Custom pattern detector
function handle

Custom pattern detector, specified as a function handle with this syntax:

`[imagePoints,hasDetected] = patternDetector(filename)`.

Input

- `filename` — Name of the image to be processed, specified as a string scalar or character vector.

Output

- `imagePoints` — Coordinates of the detected keypoints in the image, returned as a *numKeyPoints*-by-2 matrix. *N* is the number of keypoints.

- `hasDetected` — Logical that indicates whether the function detected the pattern, returned as `true` when the function detects the pattern and `false` when it does not.

`numKeyPoints` — Number of keypoints that can be detected
positive integer

Number of keypoints that can be detected in the custom pattern, specified as a positive integer.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `detectPatternPoints(imageFileNames,"circle-grid-asymmetric",patternDims,Verbose=1)` enables progress display to the screen.

`Verbose` — Display detection progress information
`true` or `1` (default) | `false` or `0`

Display detection progress information in the Command Window, specified as a numeric or logical `1` (`true`) or `0` (`false`). Set `Verbose` to `true` to display progress information.

`MinMarkerID` — Minimum marker ID of pattern to detect
`0` (default) | non-negative integer

Minimum marker ID of the pattern to detect, specified as a non-negative integer. This argument applies only to ChArUco and AprilGrid patterns.

Output Arguments

`imagePoints` — Image coordinates for keypoints found in each image
numKeyPoints-by-2-by-*numViews*-by-*numCameras* array

Image coordinates for the keypoints found in each image, returned as a *numKeyPoints*-by-2-by-*numViews*-by-*numCameras* matrix. *numKeyPoints* is the number of keypoints found for each image. *numViews* is the number of views with respect to the camera, and *numCameras* is the number of cameras. For example, `imagePoints(:,:,i,j)` contains the points from camera *j* when the pattern is located at the i^{th} view. For images in which a camera does not detect a pattern, the corresponding keypoint values are `NaN`s.

Version History

Introduced in R2025a

R2026a: Specify minimum marker ID for ChArUco and AprilGrid patterns

Use the `MinMarkerID` name-value argument to specify the minimum marker ID for ChArUco or AprilGrid patterns.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set `'UseParallel'` to `true` or enable this by default using the Computer Vision Toolbox preferences.

For more information, see “Parallel Computing Toolbox Support”.

Thread-Based Environment

Run code in the background using MATLAB® `backgroundPool` or accelerate code with Parallel Computing Toolbox™ `ThreadPool`.

The `detectPatternPoints` function supports thread-based environments with these usage notes and limitations:

Support for running in a thread-based environment on a background pool is available only when you set `Verbose` to `false`. For more information, see “Run MATLAB Functions in Thread-Based Environment”.

estimateCameraRobotTransform

Estimate pose of camera relative to robot using hand-eye calibration

Syntax

```
relativePose = estimateCameraRobotTransform(cameraExtrinsics,gripperPose,
configuration)
```

Description

`relativePose = estimateCameraRobotTransform(cameraExtrinsics,gripperPose, configuration)` estimates the pose `relativePose` of a camera relative to a robot frame using hand-eye calibration for a moving or stationary `configuration`. The value of `cameraExtrinsics` is the pose of the calibration object relative to the camera. `gripperPose` is the pose of the robot gripper relative to the robot base.

Examples

Robot Hand-Eye Calibration for Stationary-Camera Configuration

Load a MAT file that contains this robot hand-eye calibration data.

- `intrinsics`— Intrinsic parameters of the camera, stored as a `cameraIntrinsics` object. These parameters have been estimated using the process from the “Using the Single Camera Calibrator App” topic.
- `camExtrinsics`: Positions and orientations of the calibration pattern relative to the camera in 15 calibration images, stored as a 15-by-1 vector of `rigidtform3d` objects. These extrinsic parameters have been computed from the images containing the calibration pattern by using the `estimateExtrinsics` function with the estimated `intrinsics`.
- `gripperPoses`: Positions and orientations of the robot gripper, relative to the robot base, while capturing the 15 calibration images, stored as a 15-by-1 vector of `rigidtform3d` objects.

```
ld = load("stationaryCameraCalibrationData.mat");
```

Perform robot hand-eye calibration for the stationary-camera configuration to estimate the camera pose relative to robot base.

```
camPose = estimateCameraRobotTransform(ld.camExtrinsics,ld.gripperPoses,"stationary-camera");
```

To verify the calibration results, follow these steps:

1. Place a detectable object, such a checkerboard calibration pattern, near the robot and record the distance from the object to the robot base.
2. Capture an image of the object from the camera.
3. Estimate the camera extrinsic parameters for the captured image.
4. Transform object keypoints detected in image coordinates to world coordinates.
5. Verify that the transformed world coordinates match the distance recorded in the first step.

This stationary camera configuration has already been used to capture an image of a calibration checkerboard. Load the captured checkerboard image. Load the captured checkerboard image.

```
I = imread("stationaryCameraSampleImage.jpg");
```

Detect checkerboard keypoints, generate corresponding world points in the checkerboard coordinate system, and estimate the camera extrinsic parameters for the captured image.

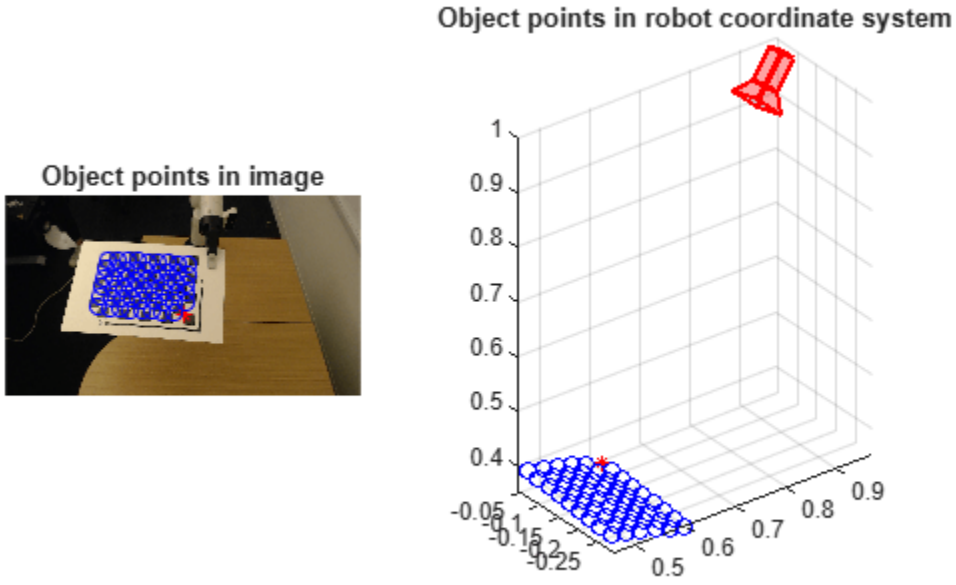
```
[imagePts,patternDims] = detectCheckerboardPoints(I);
squareSize = 0.029; % in meters
patternWorldPts2D = patternWorldPoints("checkerboard",patternDims,squareSize);
cameraExtrinsics = estimateExtrinsics(imagePts,patternWorldPts2D,ld.intrinsics);
```

Using the cameraExtrinsics and `camPose` objects, transform any image coordinates on the same plane as the calibration pattern to world coordinates in the robot coordinate system. Use the checkerboard keypoints is used as the object of interest.

Transform object points from the image coordinate system to the camera coordinate system.

```
objectWorldPts2D = img2world2d(imagePts,cameraExtrinsics,ld.intrinsics);
objectWorldPts3D = padarray(objectWorldPts2D,[0 1],"post");
```

Use `camPose` to find the transformation of the camera relative to the robot base frame, and transform the object points to the robot base frame.



```
pointsToBasePose = rigidtform3d(camPose.A * cameraExtrinsics.A);
objectPts = transformPointsForward(pointsToBasePose,objectWorldPts3D);
```

Visualize the object keypoints detected in the image and transformed to the robot coordinate system. Display the first checkerboard keypoint with a different marker and color.

```
tiledlayout(1,2)

nexttile
imshow(I)
hold on
plot(imagePts(1,1),imagePts(1,2),"r*");
plot(imagePts(2:end,1),imagePts(2:end,2),"bo");
title("Object points in image")

nexttile
plotCamera(AbsolutePose=camPose,Size=.03)
hold on
plot3(objectPts(1,1),objectPts(1,2),objectPts(1,3),"r*")
plot3(objectPts(2:end,1),objectPts(2:end,2),objectPts(2:end,3),"bo")
axis equal
grid on
title("Object points in robot coordinate system")
```

Robot Hand-Eye Calibration for Moving-Camera Configuration

Load a MAT file that contains this robot hand-eye calibration data.

- `intrinsics`— Intrinsic parameters of the camera, stored as a `cameraIntrinsics` object. These parameters have been estimated using the process from the “Using the Single Camera Calibrator App” topic.
- `camExtrinsics`: Positions and orientations of the calibration pattern relative to the camera in 15 calibration images, stored as a 15-by-1 vector of `rigidtform3d` objects. These extrinsic parameters have been computed from the images containing the calibration pattern by using the `estimateExtrinsics` function with the estimated `intrinsics`.
- `gripperPoses`: Positions and orientations of the robot gripper, relative to the robot base, while capturing the 15 calibration images, stored as a 15-by-1 vector of `rigidtform3d` objects.

```
ld1 = load("movingCameraCalibrationData.mat");
```

Perform robot hand-eye calibration for the moving-camera configuration to estimate the camera pose relative to the robot gripper.

```
camPose = estimateCameraRobotTransform(ld1.camExtrinsics,ld1.gripperPoses,"moving-camera");
```

To verify the calibration results, follow these steps:

1. Place a detectable object, such a checkerboard calibration pattern, near the robot and record the distance from the object to the robot base.
2. Capture an image of the object from the camera.
3. Record the robot gripper pose relative to the robot base while capturing that image.

4. Estimate the camera extrinsic parameters for the captured image.
5. Transform object keypoints detected in image coordinates to world coordinates.
6. Verify that the transformed world coordinates match the distance recorded in the first step.

This moving camera configuration has already been used to capture an image of a calibration checkerboard and record the pose of the robot gripper relative to the robot base. Load the captured checkerboard image and the corresponding robot gripper pose.

```
I = imread("movingCameraSampleImage.jpg");
ld2 = load("movingCameraSamplePose.mat");
```

Detect checkerboard keypoints, generate corresponding world points in the checkerboard coordinate system, and estimate the camera extrinsic parameters for the captured image.

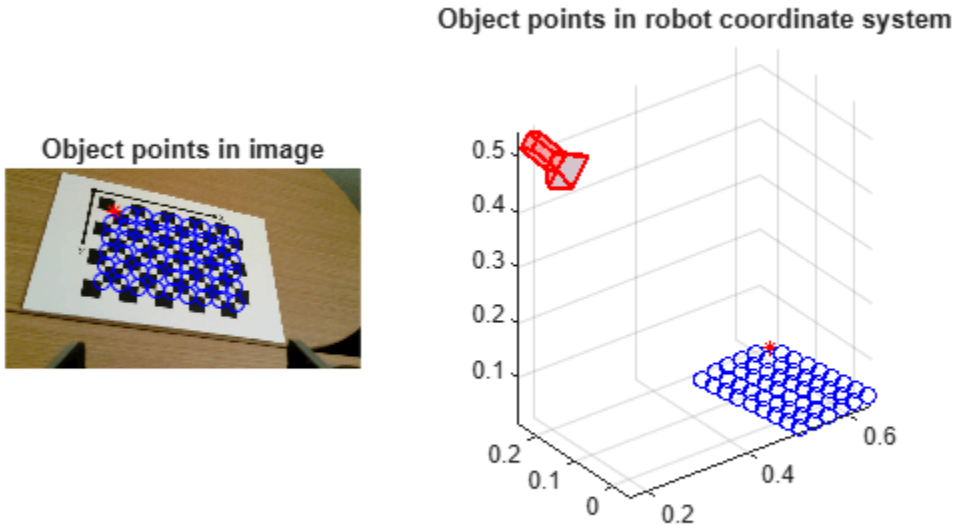
```
[imagePts,patternDims] = detectCheckerboardPoints(I);
squareSize = 0.029; % in meters
patternWorldPts2D = patternWorldPoints("checkerboard",patternDims,squareSize);
cameraExtrinsics = estimateExtrinsics(imagePts,patternWorldPts2D,ld1.intrinsics);
```

Using the cameraExtrinsics and `camPose` objects, transform any image coordinates on the same plane as the calibration pattern to world coordinates in the robot coordinate system. Use the checkerboard keypoints is used as the object of interest.

Transform object points from the image coordinate system to the camera coordinate system.

```
objectWorldPts2D = img2world2d(imagePts,cameraExtrinsics,ld1.intrinsics);
objectWorldPts3D = padarray(objectWorldPts2D,[0 1],"post");
```

Use `camPose` to find the transformation of the camera relative to the robot base frame, and transform the object points to the robot base frame.



```
camToBasePose = rigidtform3d(ld2.gripperPose * camPose.A);
pointsToBasePose = rigidtform3d(camToBasePose.A * cameraExtrinsics.A);
objectPts = transformPointsForward(pointsToBasePose, objectWorldPts3D);
```

Visualize the object keypoints detected in the image and transformed to the robot coordinate system. Display the first checkerboard keypoint with a different marker and color.

```
tiledlayout(1,2)

nexttile
imshow(I)
hold on
plot(imagePts(1,1),imagePts(1,2),"r*");
plot(imagePts(2:end,1),imagePts(2:end,2),"bo");
title("Object points in image")

nexttile
plotCamera(AbsolutePose=camToBasePose,Size=.03)
hold on
plot3(objectPts(1,1),objectPts(1,2),objectPts(1,3),"r*")
plot3(objectPts(2:end,1),objectPts(2:end,2),objectPts(2:end,3),"bo")
axis equal
grid on
title("Object points in robot coordinate system")
```

Input Arguments

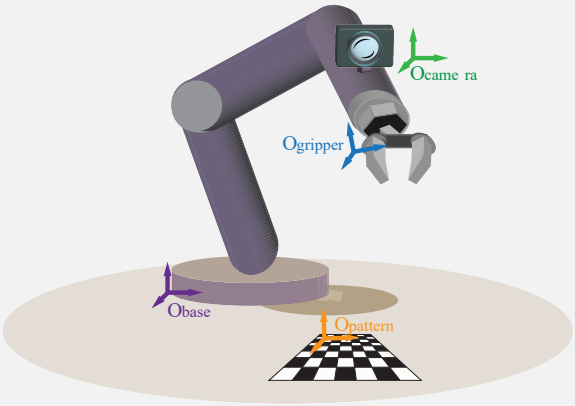
`cameraExtrinsics` — Camera extrinsic parameters

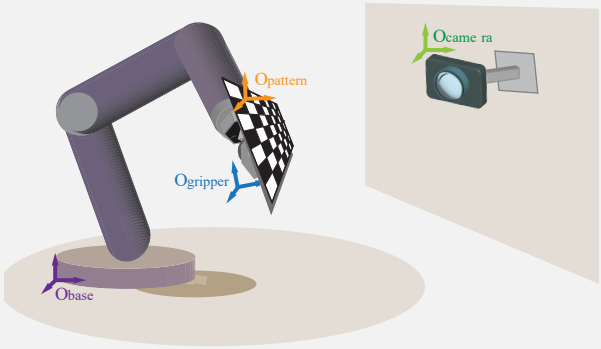
M-by-1 vector of `rigidtform3d` objects.

Camera extrinsic parameters, specified as an *M*-by-1 vector of `rigidtform3d` objects. The extrinsic parameters represent the transformation from the calibration object to the camera coordinate frame.

`gripperPose` — Pose of robot gripper relative to robot base

M-by-1 vector of `rigidtform3d` objects





Pose of the robot gripper relative to the robot base, specified as an *M*-by-1 vector of `rigidtform3d` objects.

`configuration` — Robot camera configuration

`"moving-camera"` | `"stationary-camera"`

Robot camera configuration, specified as `"moving-camera"` or `"stationary-camera"`.

- `"moving-camera"` — Also referred to as "eye-in-hand," a setup where the camera is mounted on the robot manipulator, allowing it to move with the robot while the calibration target is fixed in the world coordinate frame.
- `"stationary-camera"` — Also referred to as "eye-to-hand," a setup where the camera is fixed in the world coordinate frame while the robot manipulator moves the calibration target within the camera field of view.

"moving-camera"	"stationary-camera"
	

Output Arguments

`relativePose` — Pose of camera relative to robot frame
`rigidtform3d` object

Pose of the camera relative to the robot frame, returned as a `rigidtform3d` object. In a `"moving-camera"` configuration, `relativePose` returns the transformation of position and orientation from the camera to the robot gripper. In a `"stationary-camera"` configuration, `relativePose` returns the transformation of position and orientation from the camera to robot base.

Algorithms

The hand-eye calibration method originated from a seminal paper by Tsai and Lenz [1 on page 3-44]. Their approach is based on solving the equation $AX = XB$, where:

- A is the transformation of the robot gripper from one position to the next.
- B is the transformation of the camera or the calibration target (whichever is moving with the robot gripper) from one position to the next.
- X is the unknown transformation.

The approach uses the least squares method to solve the equation $AX = XB$. To obtain the intermediate transformations A and B, you must have information about the robot gripper pose and the camera pose at two different locations. In general, you can calibrate any sensors that can establish the relationship $AX = XB$ using the hand-eye calibration method.

Version History

Introduced in R2025a

select

Select point or region features during code generation

Syntax

```
indexedPoints = select(points,ind)
```

Description

`indexedPoints = select(points,ind)` selects one or more sets of point or region features using the specified indices `ind`.

Examples

Select Point Features During Code Generation

Read an image into MATLAB® the workspace.

```
I = imread("cameraman.tif");
```

Define the `helperGetSubsetOfPoints` function which, detects and selects SURF points. You must save the helper function as a MATLAB script file with a `.m` extension.

```
function indexedLocation = helperGetSubsetOfPoints(I)
    points = detectSURFFeatures(I);
    indexedPoints = select(points,30:100);
    indexedLocation = indexedPoints.Location;
end
```

Create a configuration object for generating a MEX function.

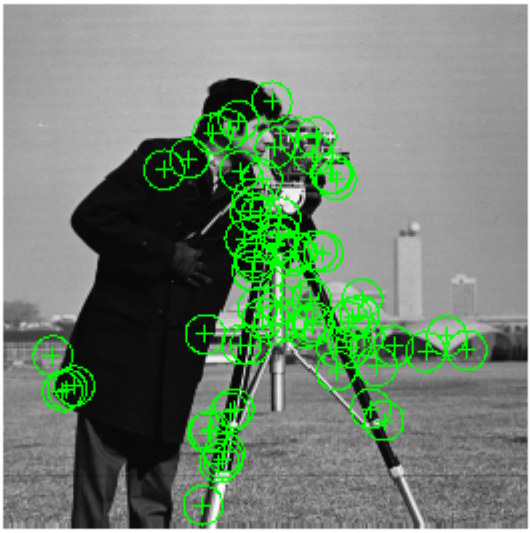
```
cfg = coder.config("mex");
```

Generate the MEX function from the helper function `helperGetSubsetOfPoints` using the configuration `cfg`. The `helperGetSubsetOfPoints` function detects SURF features in the input image and selects a specified set of point features using the `select` object function of the `SURFPoints` object. The `helperGetSubsetOfPoints` function outputs the locations of the selected SURF point features in the image. You can use the `select` function only for code generation.

```
codegen -config cfg helperGetSubsetOfPoints -args {I}
```

```
Code generation successful.
```

Call the generated MEX function with the image `I` as input. Objects cannot be returned as outputs during code generation. Therefore, the `helperGetSubsetOfPoints` function outputs the locations of the selected SURF point features.



```
locations = helperGetSubsetOfPoints_mex(I);
```

Convert the output locations to `SURFPoints` objects.

```
points = SURFPoints(locations);
```

Display the selected SURF point features.

```
figure
imshow(I)
hold on
plot(points)
hold off
```

Input Arguments

`points` — Input features

`MSERRegions` object | `SURFPoints` object | `ORBPoints` object | `KAZEPoints` object | `BRISKPoints` object | `SIFTPoints` object | `cornerPoints` object

Input features, specified as an `MSERRegions`, `SURFPoints`, `ORBPoints`, `KAZEPoints`, `BRISKPoints`, `SIFTPoints`, or `cornerPoints` object.

`ind` — Indices of features to be selected

scalar | vector

Indices of the features to be selected from the input, specified as a scalar or vector.

Output Arguments

`indexedPoints` — Output features
`MSERRegions` object | `SURFPoints` object | `ORBPoints` object | `KAZEPoints` object | `BRISKPoints` object | `SIFTPoints` object | `cornerPoints` object

Output features, returned as an `MSERRegions`, `SURFPoints`, `ORBPoints`, `KAZEPoints`, `BRISKPoints`, `SIFTPoints`, or `cornerPoints` object. The `indexedPoints` output object type matches the type of object specified to the `points` input argument.

Version History

Introduced in R2024b

compareTrajectories

Compare estimated trajectory against ground truth

Syntax

```
metrics = compareTrajectories(estimatedPoses,groundTruthPose)
metrics = compareTrajectories( ___ ,Name=Value)
```

Description

`metrics = compareTrajectories(estimatedPoses,groundTruthPose)` returns metrics for the accuracy of an estimated trajectory, `estimatedPoses`, against a ground truth trajectory `groundTruthPose`, to assess the performance of an odometry or a Simultaneous Localization and Mapping (SLAM) system.

The function aligns the estimated trajectory to the ground truth trajectory by performing a least-square fitting between the translation components of poses in the two trajectories.

`metrics = compareTrajectories( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to the previous syntaxes. For example, `AlignmentType="none"` sets the transformation type to `"none"` when aligning the estimated trajectory to the ground truth trajectory.

Input Arguments

`estimatedPoses` — Estimated poses

M-element array | `se3` object

Estimated poses, specified as an *M*-element array of `rigidtform3d` or `se3` objects. The estimated poses can be obtained from an odometry or a SLAM system.

`groundTruthPose` — Ground truth poses

M-element array | `se3` object

Ground truth poses, specified as an *M*-element array of `rigidtform3d` or `se3` objects. The ground truth poses are obtained from an external ground truth system.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `compareTrajectories(estimatedPoses,groundTruthPose,AlignmentType="none")` sets the transformation type to `"none"` when aligning the estimated trajectory to the ground truth trajectory.

`AlignmentType` — Transformation type

`"rigid"` (default) | `"similarity"` | `"none"`

Transformation type to align the estimated trajectory to the ground truth trajectory, specified as `"rigid"`, `"similarity"`, or `"none"`. To disable trajectory alignment, set `AlignmentType` to `"none"`.

`EvaluationInterval` — Fixed distance to compute relative trajectory error
1 (default) | scalar

Fixed distance to compute relative trajectory error for each pose within the estimated trajectory, specified as a scalar in world units.

Output Arguments

`metrics` — Error metrics object
`trajectoryErrorMetrics` object

Error metrics object, returned as an `trajectoryErrorMetrics` object. The object stores error metrics including the absolute trajectory error and the relative trajectory error.

Version History

Introduced in R2024b

generateCharucoBoard

Generate ChArUco board image

Syntax

```
I = generateCharucoBoard(imageSize,patternDims,markerFamily,checkerSize,
markerSize)
I = generateCharucoBoard( ___ ,Name=Value)
```

Description

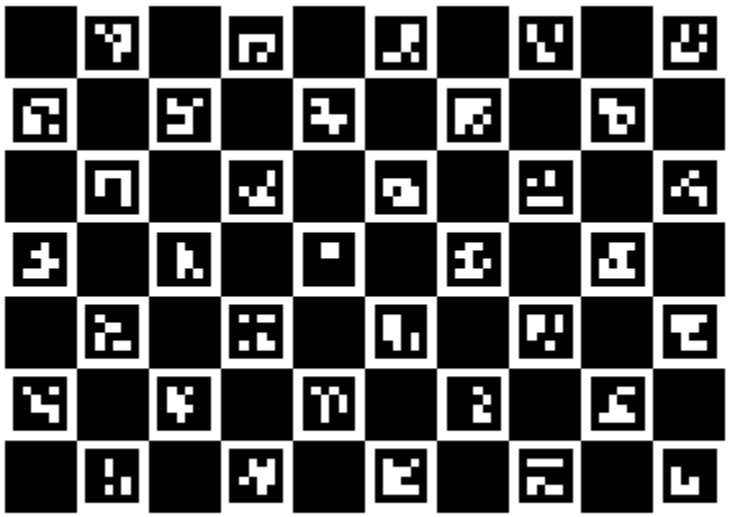
`I = generateCharucoBoard(imageSize,patternDims,markerFamily,checkerSize, markerSize)` returns a grayscale ChArUco board image.

`I = generateCharucoBoard( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to the previous syntax. For example, `MinMarkerID=3` sets the lowest marker ID in the board to 3.

Examples

Generate ChArUco Board Image for Single Camera Calibration

Specify properties to generate the ChArUco board. Image, checker, and marker size are in pixels.



```
patternDims = [7 10];
family = "DICT_4X4_1000";
imageSize = [900 1200];
checkerSize = 100;
markerSize = 75;
```

Generate the ChArUco board based on specified properties.

```
I = generateCharucoBoard(imageSize,patternDims,family,checkerSize,markerSize);
```

Display the generated ChArUco board image.

```
imshow(I)
```

Write the ChArUco board image to a file.

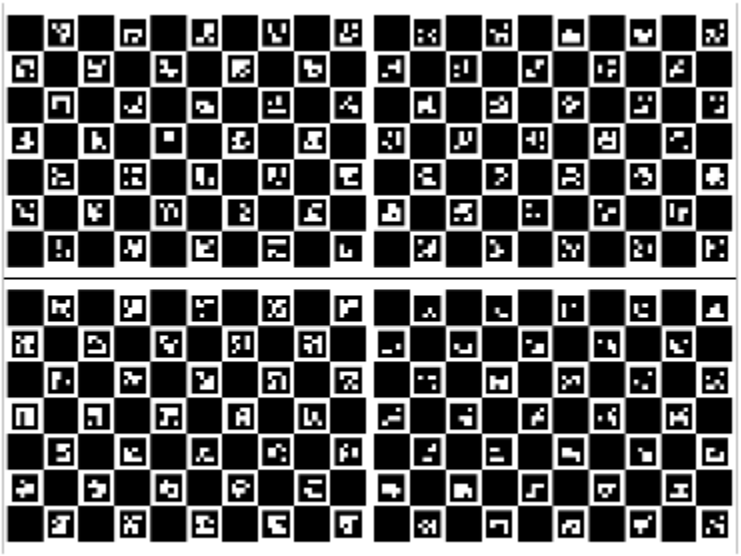
```
imwrite(I,"ChArUco_7X10_4X4_100_75.png")
```

Next Steps: Print the ChArUco board image file. Use the printed board for capturing calibration images with the camera you intend to calibrate. To capture calibration images for an effective single camera calibration, see “Prepare Camera and Capture Images for Camera Calibration”.

Generate Multiple ChArUco Boards for Multi-Camera Calibration

Generate multiple ChArUco boards that are needed to calibrate a multi-camera system.

Specify properties to generate the ChArUco board. Image, checker, and marker size are in pixels.



```
patternDims = [7 10];
family = "DICT_4X4_1000";
imageSize = [900 1200];
checkerSize = 100;
markerSize = 75;
```

Generate four ChArUco boards based on specified properties with unique ArUco markers. To ensure uniqueness of ArUco markers, separate MinMarkerID of each board by the number of markers in each board. For example, a 7-by-10 ChArUco board contains 35 ArUco markers. To generate four 7-by-10 ChArUco boards that can be used for multi-camera calibration, their `MinMarkerIDs` must be 0,35,70 and 105.

```
numMarkers = floor(prod(patternDims)/2);
I1 = generateCharucoBoard(imageSize,patternDims,family,checkerSize,markerSize,MinMarkerID=0);
I2 = generateCharucoBoard(imageSize,patternDims,family,checkerSize,markerSize,MinMarkerID=numMark
I3 = generateCharucoBoard(imageSize,patternDims,family,checkerSize,markerSize,MinMarkerID=2*numMa
I4 = generateCharucoBoard(imageSize,patternDims,family,checkerSize,markerSize,MinMarkerID=3*numMa
```

Display the generated ChArUco boards.

```
montage({I1,I2,I3,I4},BorderSize=[1 1])
```

Write the ChArUco board images to files.

```
imwrite(I1,"ChArUco_7X10_4X4_100_75_1.png")
imwrite(I2,"ChArUco_7X10_4X4_100_75_2.png")
imwrite(I3,"ChArUco_7X10_4X4_100_75_3.png")
imwrite(I4,"ChArUco_7X10_4X4_100_75_4.png")
```

Next Steps: Print the ChArUco board image files. Use the printed patterns for capturing calibration images with the cameras you intend to calibrate. To capture calibration images for an effective multi-camera calibration, see “Prepare Cameras and Capture Images for Multi-Camera Calibration”.

Input Arguments

`imageSize` — ChArUco board size

2-element vector (default)

ChArUco board size in pixels, specified as a 2-element vector of the form [*height*,*width*].

`patternDims` — Pattern dimensions

two-element vector

Pattern dimensions, specified as a two-element vector that represents the number of checker boxes in the *dim1* and *dim2* dimensions of the ChArUco board image, respectively. For more details on ChArUco board patterns, see “Calibration Patterns”.

`markerFamily` — ArUco marker family name

character vector | string scalar | vector of strings | cell array of character vectors

ArUco marker family name used in CharUco board, specified as a character vector, string scalar, vector of strings, or cell array of character vectors. Each element must be one of the valid ArUco marker families listed in the table. Select a marker family suitable for your application based on the total number of markers needed, the marker length, and the Hamming distance between the marker code words. The minimum Hamming distance between markers in the same family, determine the ability to detect them and correct errors. Marker families with less number of markers can be more robust against errors than a family with a large number of markers, which can increase marker detection difficulty due to a greater number of bits to extract. These general rules apply:

- The less number of bits to detect, the longer the range in distance a marker can be detected.
- For correct identification and decoding, ArUco markers require a white border, also known as the quiet zone.

Family	Marker Size (bits)	Number of Markers in Family	Minimum Hamming Distance Between Markers (bits)
`"DICT_ARUCO_ORIGINAL"`	5-by-5	1024	3
`"DICT_4X4_50"`	4-by-4	50	4
`"DICT_4X4_100"`		100	3
`"DICT_4X4_250"`		250	2
`"DICT_4X4_1000"`		1000	2
`"DICT_5X5_50"`	5-by-5	50	8
`"DICT_5X5_100"`		100	7
`"DICT_5X5_250"`		250	6
`"DICT_5X5_1000"`		1000	5
`"DICT_6X6_50"`	6-by-6	50	13
`"DICT_6X6_100"`		100	12
`"DICT_6X6_250"`		250	11
`"DICT_6X6_1000"`		1000	9
`"DICT_7X7_50"`	7-by-7	50	19
`"DICT_7X7_100"`		250	18
`"DICT_7X7_250"`		250	17
`"DICT_7X7_1000"`		1000	14

Data Types: `char` | `string` | `cell`

`checkerSize` — ChArUco board checker box side length
scalar

ChArUco board checker box side length, specified as a scalar in world units, such as millimeters or inches. The `checkerSize` and `markerSize` must be specified in the same world units and `checkerSize` must be a larger value than `markerSize`.

`markerSize` — ArUco marker side length
scalar

ArUco marker side length, specified as a scalar in world units, such as millimeters or inches. The `checkerSize` and `markerSize` must be specified in the same world units and `checkerSize` must be a larger value than `markerSize`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `generateCharucoBoard(____,MinMarkerID=3)` sets the lowest marker ID in the board to 3.

`MarginSize` — Number of white pixels to pad margin
`10` (default) | scalar

Number of white pixels to pad margin of output image, specified as a scalar.

`MinMarkerID` — Lowest value marker ID in pattern
`0` (default) | non-negative integer

Lowest value marker ID in the pattern, specified as a non-negative integer. The markers in the pattern must correspond to sequential IDs, each incremented by `1`.

`OriginCheckerColor` — Color of the checker box located in the top-left corner of board
`"black"` (default) | `"white"`

Color of the checker box located in the top-left corner of ChArUco board, specified as `"black"` or `"white"`. The top-left corner value represents the origin of the board. This value must not be set to `"white"` when the board contains an odd number of boxes in the *x* dimension, specified in `patternDims(1)`.

Output Arguments

`I` — ChArUco image
grayscale

ChArUco image, returned as a grayscale image.

Data Types: `uint8`

“Calibration Patterns”

patternWorldPoints

Generate world point locations of a camera calibration pattern

Syntax

```
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize)
worldPoints = patternWorldPoints("circle-grid-symmetric",patternDims,
centerDistance)
worldPoints = patternWorldPoints("circle-grid-asymmetric",patternDims,
centerDistance)
worldPoints = patternWorldPoints("charuco-board",patternDims,checkerSize)
worldPoints = patternWorldPoints("aprilgrid",patternDims,tagSize,tagSpacing)
worldPoints = patternWorldPoints(patternName, ___ )
```

Description

`worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize)` generates keypoints for a checkerboard camera calibration pattern with dimensions specified by `patternDims` and `squareSize`.

`worldPoints = patternWorldPoints("circle-grid-symmetric",patternDims, centerDistance)` generates keypoints for a symmetric circle grid camera calibration pattern with dimensions specified by `patternDims` and `centerDistance`.

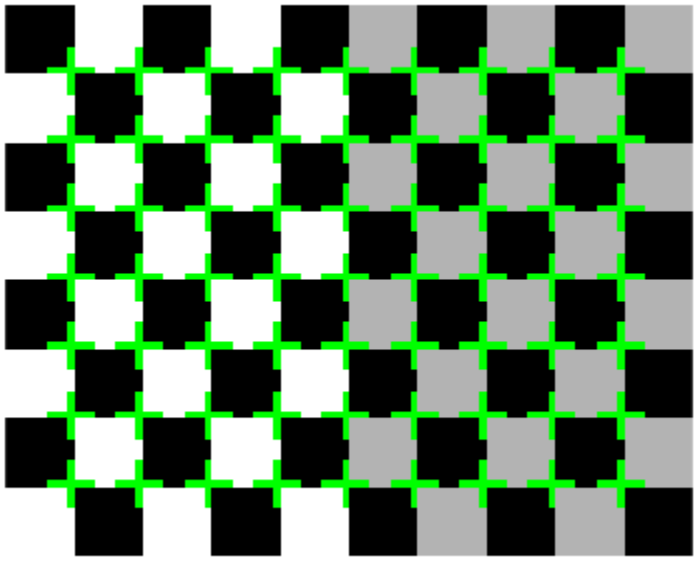
`worldPoints = patternWorldPoints("circle-grid-asymmetric",patternDims, centerDistance)` generates keypoints for an asymmetric circle grid camera calibration pattern with dimensions specified by `patternDims` and `centerDistance`.

`worldPoints = patternWorldPoints("charuco-board",patternDims,checkerSize)` generates keypoints for a ChArUco board camera calibration pattern with dimensions specified by `patternDims` and `checkerSize`.

`worldPoints = patternWorldPoints("aprilgrid",patternDims,tagSize,tagSpacing)` generates keypoints for an AprilGrid camera calibration pattern with dimensions specified by `patternDims`, `tagSize`, and `tagSpacing`.

`worldPoints = patternWorldPoints(patternName, ___ )` generates keypoints for the calibration pattern specified by `patternName`.

Examples



Generate and Plot Corners of an 8-by-10 Checkerboard

Generate the checkerboard and obtain world coordinates.

```
squareSize = 10;
patternDims = [8 10];
I = checkerboard(squareSize,patternDims(1)/2,patternDims(2)/2);
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Offset the points by placing the first point at the lower-right corner of the first square.

```
imshow(insertMarker(I,worldPoints + squareSize));
```

Generate Point Locations for AprilGrid

To generate the world point locations of keypoints in an AprilGrid, define the grid pattern dimensions (number of AprilTags along width and height), the size of each AprilTag, and the spacing between consecutive AprilTags. The tag size and spacing is specified in millimeters.

```
patternDims = [6,6];
tagSize = 25; % millimeters
tagSpacing = 10; % millimeters
worldPoints = patternWorldPoints("aprilgrid",patternDims,tagSize,tagSpacing);
```

Generate Point Locations for Asymmetric Circle Grid

Specify the center-to-center distance in millimeters (mm) between adjacent circles in the asymmetric circle grid pattern.

```
patternDims = [4,11];
centerDistance = 9; % millimeters
worldPoints = patternWorldPoints("circle-grid-asymmetric",patternDims,centerDistance);
```

Generate Point Locations for ChArUco board

Define the dimensions of the ChArUco board pattern and the size of each checker square to generate the world point locations of its keypoints. The checker square size is in millimeters.

```
patternDims = [7,10];
checkerSize = 27; % millimeters
worldPoints = patternWorldPoints("charuco-board",patternDims,checkerSize);
```

Generate Point Locations for Symmetric Circle Grid

Specify the center-to-center distance in millimeters (mm) between adjacent circles for the symmetric circle grid pattern.

```
patternDims = [8,11];
centerDistance = 19;  % millimeters
worldPoints = patternWorldPoints("circle-grid-symmetric",patternDims,centerDistance);
```

Input Arguments

`patternDims` — Pattern dimensions

two-element vector

Pattern dimensions, specified as a two-element vector. The first and second element represent the number of checker boxes or circles in the *x*- and *y*- dimensions, respectively. For a ChArUco board pattern, ensure that the board is oriented with the origin located at the top-left corner.

The pattern boards have these origin locations:

- Checkerboard — Lower-right corner of the top-left square of the board.
- Symmetric and asymmetric circle grids — Center of the top-left circle.
- ChArUco marker — Lower-right ChArUco corner, which corresponds to the minimum ArUco marker ID.
- AprilGrid pattern — Bottom-left corner, which corresponds to the minimum ID AprilTag.

For more details on calibration patterns, see “Calibration Patterns”.

`squareSize` — Side length of square

scalar

Side length of the square, specified as a scalar in world units such as millimeters or inches.

`centerDistance` — Center-to-center distance between two circles

scalar

Center-to-center distance between two circles, specified in world units such as millimeters or inches.

`checkerSize` — Side length of ChArUco checker board square

scalar

Side length of a ChArUco checker board square, specified in world units such as millimeters or inches.

`tagSize` — Size of AprilTag
scalar

Size of the AprilTag, specified as a scalar in world units, such as millimeters or inches.

`tagSpacing` — Space between two consecutive AprilTags
positive scalar

Space between two consecutive AprilTags, specified as a positive scalar.

`patternName` — Camera calibration pattern name
`"checkerboard"` | `"circle-grid-symmetric"` | `"circle-grid-asymmetric"` | `"charuco-board"` | `"aprilgrid"`

Camera calibration pattern name, specified as one of these options:

- `"checkerboard"`
- `"circle-grid-symmetric"`
- `"circle-grid-asymmetric"`
- `"charuco-board"`
- `"aprilgrid"`

Output Arguments

`worldPoints` — Keypoint locations
M-by-2 matrix

Keypoint locations, returned as an *M*-by-2 matrix in world coordinates. The matrix contains *M* points with coordinates in the form [*x y*]. The number of points the function returns is calculated based on the type of pattern:

- Checkerboard and ChArUco board — `(patternDims(1)-1)*(patternDims(2)-1)`
- Symmetric and asymmetric circle grid — `patternDims(1)*patternDims(2)`
- AprilGrid pattern — `patternDims(1)*patternDims(2)*4`

detectCharucoBoardPoints

Detect ChArUco board pattern in images

Syntax

```
imagePoints = detectCharucoBoardPoints(I,patternDims,markerFamily,
checkerSize,markerSize)
imagePoints = detectCharucoBoardPoints( ___ ,intrinsics)
[imagePoints,imagesUsed] = detectCharucoBoardPoints(imageFileNames, ___ )
[ ___ ] = detectCharucoBoardPoints(images, ___ )

[imagePoints] = detectCharucoBoardPoints(I1,I2,patternDims,markerFamily,
checkerSize,markerSize)
[imagePoints] = detectCharucoBoardPoints(I1,I2,patternDims,markerFamily,
checkerSize,markerSize,intrinsics)
[imagePoints,pairsUsed] = detectCharucoBoardPoints(imageFileNames1,
imageFileNames2,patternDims,markerFamily,checkerSize,markerSize)
[ ___ ] = detectCharucoBoardPoints(I1,I2,intrinsics)

[ ___ ] = detectCharucoBoardPoints( ___ ,Name=Value)
```

Description

Single Image ChArUco Board Detection

`imagePoints = detectCharucoBoardPoints(I,patternDims,markerFamily, checkerSize,markerSize)` detects a ChArUco board in a 2-D truecolor or grayscale image. The function uses local homography to detect ChArUco corners.

`imagePoints = detectCharucoBoardPoints( ___ ,intrinsics)` detects ChArUco corners using approximated pose estimation. The approximation is based on the estimated extrinsic properties, given the camera `intrinsics`.

`[imagePoints,imagesUsed] = detectCharucoBoardPoints(imageFileNames, ___ )` detects a ChArUco board in the image files specified by `imageFileNames`, and additionally returns the list of images in which the board is detected `imagesUsed`.

`[ ___ ] = detectCharucoBoardPoints(images, ___ )` detects a ChArUco board in the specified images `images`.

Stereo Pair ChArUco Board Detection

`[imagePoints] = detectCharucoBoardPoints(I1,I2,patternDims,markerFamily, checkerSize,markerSize)` detects a ChArUco board in a set of 2-D truecolor or grayscale image.

`[imagePoints] = detectCharucoBoardPoints(I1,I2,patternDims,markerFamily, checkerSize,markerSize,intrinsics)` detects ChArUco corners in a set of 2-D truecolor or grayscale using approximated pose estimation. The approximation is based on the estimated extrinsic properties, given the camera `intrinsics`.

`[imagePoints,pairsUsed] = detectCharucoBoardPoints(imageFileNames1, imageFileNames2,patternDims,markerFamily,checkerSize,markerSize)` detects an

ChArUco pattern in the stereo pairs of image files specified by `imageFileNames1` and `imageFileNames2`. The function additionally returns a list of the pairs in which the board is detected `pairsUsed`.

`[ ___ ] = detectCharucoBoardPoints(I1,I2,intrinsics)` detects an ChArUco pattern in the stereo pairs of image files specified by `images1` and `images2`.

Optional Arguments

`[ ___ ] = detectCharucoBoardPoints( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `NumBorderBits=2` sets the number of border bits to detect a marker to 2.

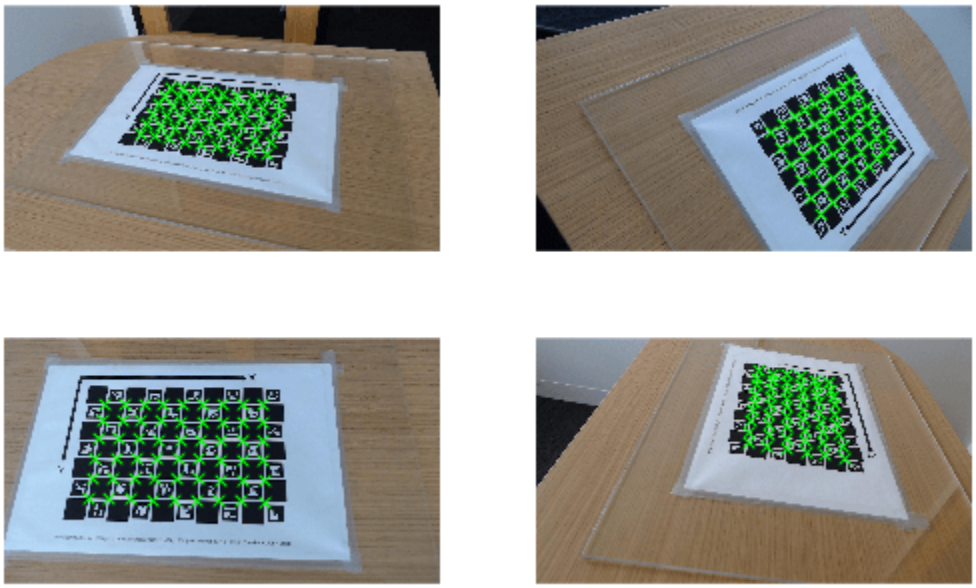
Examples

Detect ChArUco Board in Images

Specify your calibration images.

```
imds = imageDatastore("charuco");
images = imds.Files;
```

Define the ChArUco board properties. Checker size and marker size are in millimeters.



```
markerFamily = "DICT_4X4_1000";
patternDims = [7 10];
checkerSize = 29;
markerSize = 21;
```

Detect the board in the image.

```
imagePoints = detectCharucoBoardPoints(images,patternDims,markerFamily,checkerSize,markerSize);
```

Display the points from the first four images.

```
tiledlayout(2,2,TileSpacing="compact",Padding="compact");
for i = 1:4
  nexttile
  imshow(images{i})
  hold on
  plot(imagePoints(:,1,i,1),imagePoints(:,2,i,1),"gx");
end
```

Detect ChArUco Board in Stereo Image Pair

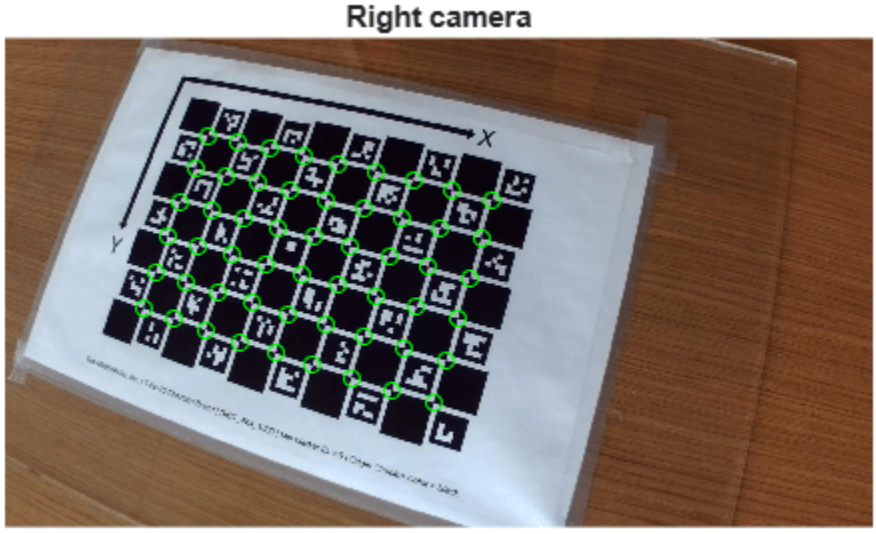
Load a stereo image pair containing a ChArUco board into the workspace.

```
I1 = imread("leftChArUco.jpg");
I2 = imread("rightChArUco.jpg");
```

Define the ChArUco board properties. The checker board and marker size are specified in millimeters.

```
markerFamily = "DICT_4X4_1000";
patternDims = [7 10];
checkerSize = 29;
markerSize = 21;
```

Detect the ChArUco board in the images.

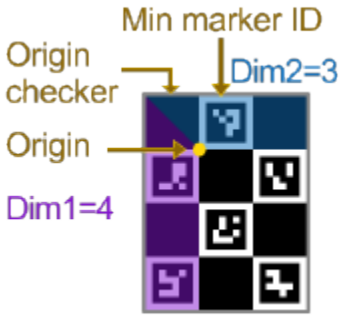


```
imagePoints = detectCharucoBoardPoints(I1,I2,patternDims,markerFamily,checkerSize,markerSize);
```

Display the detected points in the left and right images.

```
figure(1)
imshow(I1)
hold on
plot(imagePoints(:,1,1,1),imagePoints(:,2,1,1),"go");
title("Left camera")
```

```
figure(2)
imshow(I2)
hold on
plot(imagePoints(:,1,1,2),imagePoints(:,2,1,2),"go");
title("Right camera")
```



Input Arguments

`patternDims` — Pattern dimensions

two-element vector

Pattern dimensions, specified as a two-element vector that represents the number of checkers in the *dim1* and *dim2* dimensions of the ChArUco board, respectively.

For more details on ChArUco board patterns, see “Calibration Patterns”.

`markerFamily` — ArUco marker family used in ChArUco board

`"DICT_ARUCO_ORIGINAL"` | `"DICT_4X4_1000"` | `"DICT_5X5_1000"` | `"DICT_6X6_1000"` | `"DICT_7X7_1000"`

ArUco marker family used in ChArUco board, specified as `"DICT_ARUCO_ORIGINAL"`, `"DICT_4X4_1000"`, or `"DICT_5X5_1000"`, `"DICT_6X6_1000"`, or `"DICT_7X7_1000"`.

`checkerSize` — ChArUco board checker side length

scalar

ChArUco board checker side length, specified as a scalar in world units, such as millimeters or inches. The `checkerSize` and `markerSize` must be specified in the same world units and `checkerSize` must be a larger value than `markerSize`.

`markerSize` — ArUco marker side length

scalar

ArUco marker side length, specified as a scalar in world units, such as millimeters or inches. The `checkerSize` and `markerSize` must be specified in the same world units and `checkerSize` must be a larger value than `markerSize`.

`intrinsics` — Camera intrinsics

scalar `cameraIntrinsics` object | two-element vector

Camera intrinsics, specified as a scalar `cameraIntrinsics` object for a single camera, a two-element vector for a stereo camera, `cameraParameters` object, or a `stereoParameters` object.

To specify a `fisheyeIntrinsics` object, first undistort the image using the `undistortFisheyeImage` function. Use the undistorted image for the `detectChArUcoBoardPoints` image input and the `cameraIntrinsics` object that the `undistortFisheyeImage` function returns for the `intrinsics` argument.

`I` — Image
2-D truecolor image | grayscale image

Image, specified as a 2-D truecolor image or grayscale image.

Data Types: `uint8` | `int16` | `uint16` | `single` | `double`

`images` — Images
H-by-*W*-by-*numColorChannels*-by-*numImages* array

Images, specified as an *H*-by-*W*-by-*numColorChannels*-by-*numImages* array, where *H* and *W* describe the height and width of each image, respectively. *numColorChannels* is the number of color channels in each image, and *numImages* is the number of images.

Data Types: `uint8` | `int16` | `uint16` | `single` | `double`

`I1` — Stereo pair images from camera one
H-by-*W*-by-*numColorChannels*-by-*numImages* array

Stereo pair images from camera one, specified as an *H*-by-*W*-by-*numColorChannels*-by-*numImages* array, where *H* and *W* describe the height and width of each image, respectively. *numColorChannels* is the number of color channels in each image, and *numImages* is the number of images.

Data Types: `uint8` | `int16` | `uint16` | `single` | `double`

`I2` — Stereo pair images from camera two
H-by-*W*-by-*numColorChannels*-by-*numImages* array

Stereo pair images from camera two, specified as an *H*-by-*W*-by-*numColorChannels*-by-*numImages* array, where *H* and *W* describe the height and width of each image, respectively. *numColorChannels* is the number of color channels in each image, and *numImages* is the number of images.

Data Types: `uint8` | `int16` | `uint16` | `single` | `double`

`imageFileNames` — Image file names
cell array of character vectors | array of strings

Image file names, specified as a cell array of character vectors or an array of strings.

`imageFileNames1` — Stereo image file names for camera one
cell array of character vectors | array of strings

Stereo image file names for camera one, specified as a cell array of character vectors or an array of strings.

`imageFileNames2` — Stereo image file names for camera two
cell array of character vectors | array of strings

Stereo image file names for camera two, specified as a cell array of character vectors or an array of strings.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `detectCharucoBoardPoints(___,NumBorderBits=2)` sets the number of marker border bits to detect a marker to 2.

Descriptive Properties

`MinMarkerID` — Lowest value marker ID in pattern

`0` (default) | non-negative integer

Lowest value marker ID in the pattern, specified as a non-negative integer. The markers in the pattern must correspond to sequential IDs, each incremented by `1`.

`OriginCheckerColor` — Color of the checker located in the top-left corner of board origin

`"black"` (default) | `"white"`

Color of the checker located in the top-left corner of ChArUco board origin, specified as `"black"` or `"white"`. The board origin is the keypoint closest to the ArUco marker with the lowest ID. This value must not be set to `"white"` when the board contains an odd number of boxes in the *x* dimension, specified in `patternDims(1)`.

Adaptive Thresholding Arguments

`WindowSizeRange` — Window size range

`[3 23]` (default) | two-element vector

Window size range, in pixels, specified as a two-element vector of the form `[`*`min max`*`]`. The elements set the minimum and maximum size, respectively, for the windows used for adaptive thresholding. Each value *n* in the range represents an *n*-by-*n* square window. Each element of this argument must be a positive integer greater than or equal to `3`. The function determines the local window threshold by calculating the average pixel value obtained from the sum of its surrounding pixels. Increase the *max* value when using ArUco markers that are larger than 400-by-400 pixels.

`WindowSizeStep` — Window step size

`10` (default) | positive integer

Window step size, in pixels, specified as a positive integer. The function uses the window step size for adaptive thresholding, but stays within the range set by the `WindowSizeRange` argument. The function starts at the minimum size of the range, and then increments the window size by the value of `WindowSizeStep`, until it reaches the maximum range value. If the window size is too small and a marker is large, the function might not detect that marker. This can occur when the window overlaps with the marker border. If the window size is large and a marker is small, the function might detect the marker, but the difference in size can negatively impact processing speed.

Contour Filtering Arguments

`MarkerSizeRange` — Range for marker boundary perimeter length

`[0.0075 1]` (default) | two-element vector

Range for marker boundary perimeter length, specified as a two-element vector of the form [*min max*]. The elements set the minimum and maximum size for the perimeter length of detected markers. Specify each element as a value normalized to the maximum dimension of the image. Reduce the range if a rejected marker completely encloses a valid marker.

`SquarenessTolerance` — Maximum polygonal approximation error

`0.03` (default) | positive scalar

Maximum polygonal approximation error, specified as a positive scalar. The function utilizes the Douglas-Peucker algorithm to apply a polygonal approximation to each marker candidate, accepting only those that closely resemble a square shape. The value of the `SquarenessTolerance` is relative to the candidate marker length (in pixels). Decrease this value to filter false corner detections in occluded markers. Increase this value to detect marker candidates in highly distorted images.

Bit Extraction Arguments

`NumBorderBits` — Number of border bits in marker
`1` (default) | positive integer

Number of border bits in the marker, specified as a positive integer. By default, the marker boundary contains one bit. If the function does not detect a marker candidate, first ensure that you have correctly set the `markerFamily`, then check the ChArUco manufacturer manual to get the correct value for the number of border bits to use.

`ResolutionPerBit` — Resolution of the decoder
`4` (default) | positive integer

Resolution of the decoder to use in the bit extraction step, in pixels, specified as a positive integer. This value sets the number of pixels, per bit, to use in the obtained image after correcting perspective distortion. Increase this value to improve the accuracy with which the function reads marker IDs at the expense of runtime speed.

Subpixel Corner Refinement Arguments

`RefineCorners` — Subpixel refinement process
`false` or `0` (default) | `true` or `1`

Subpixel refinement process, specified as a logical `1`(`true`) or `0`(`false`). Set this value to `true` to enable the subpixel refinement process for the detected marker corner locations. This step is computationally expensive. Enable this process only if the corner locations must be accurate for pose estimation or for camera calibration applications.

`RefinementWindowSize` — Window size of subpixel refinement process
`5` (default) | positive integer

Window size of the subpixel refinement process, in pixels, specified as a positive integer. Increasing this value can cause the window area to include a corner of the image. As a result of this proximity, marker corners might move to an incorrect locations.

`RefinementMaxIterations` — Maximum number of iterations for subpixel refinement process
`30` (default) | positive integer

Maximum number of iterations the subpixel refinement process, specified as a positive integer. The process stops after the specified number of iterations even if it has not achieved the termination tolerance `RefinementTolerance`.

`RefinementTolerance` — Termination tolerance
`0.1` (default) | positive scalar

Termination tolerance, specified as a positive scalar.

Output Arguments

`imagePoints` — Corner coordinates of detected ChArUco board

M-by-2 matrix | *M*-by-2-by- *numImages* | *M*-by-2-by- *numPairs*-by-2 array

Corner coordinates of detected ChArUco board, returned as an *M*-by-2 matrix, *M*-by-2-by- *numImages* array, or an *M*-by-2-by-*numPairs*-by-2 array. *M* is the number of ChArUco boards detected. Each row of the matrix or array specifies the *x*-*y* coordinates of the corner of a ChArUco pattern.

- For single images — This argument is an *M*-by-2 matrix or an *M*-by-2-by- *numImages* array, when detecting ChArUco board pattern in single images. *numImages* is the number of images.
- For stereo pairs — This argument is an *M*-by-2-by-*numPairs*-by-2 array when detecting ChArUco board patterns in stereo pairs of images. *numPairs* is the number of image pairs in which an ChArUco board patterns is detected. `imagePoints(:,:,:,1)` returns the points from the first set of images, and `imagePoints(:,:,:,2)` are the points from the second set.

When no ArUco marker was detected in the board image, the function returns `imagePoints` with `NaN` for its surrounding ChArUco corner locations.

`imagesUsed` — ChArco board pattern detection flag

logical vector

ChArUco board pattern detection flag, returned as a logical vector. A value of `true` in the `imagesUsed` vector indicates that the pattern has been detected in the corresponding image.

`pairsUsed` — Stereo pair ChArUco board pattern detection flag

logical vector

Stereo pair ChArUco board pattern detection flag, returned as a logical vector. A value of `true` in the `pairsUsed` vector indicates that the ChArUco board pattern has been detected in the corresponding image pair.

Tips

- When no ArUco marker was detected in the board image, the function returns `imagePoints` with `NaN` for its surrounding ChArUco corner locations.
- To debug any missed detections of ArUco markers, you can use the `readArucoMarker` function.
- To specify a `fisheyeIntrinsics` object, first undistort the image using the `undistortFisheyeImage` function. Use the undistorted image for the `detectChArUcoBoardPoints` image input and the `cameraIntrinsics` object that the `undistortFisheyeImage` function returns for the `intrinsics` argument.
- To detect multiple ChArUco boards in the same image, use this function with a unique for `MinMarkerID`, for each board.
- To use this function, the markers in the pattern must correspond to sequential IDs, each incremented by `1`.

Version History

Introduced in R2024b

R2025a: Generate C/C++ code using MATLAB Coder

The `detectCharucoBoardPoints` function now supports the generation of C/C++ code (requires MATLAB Coder).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Generates code only on host platforms.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

Thread-Based Environment

Run code in the background using MATLAB® `backgroundPool` or accelerate code with Parallel Computing Toolbox™ `ThreadPool`.

The `detectCharucoBoardPoints` function fully supports thread-based environments. For more information, see “Run MATLAB Functions in Thread-Based Environment”.

detectAprilGridPoints

Detect keypoints of AprilGrid pattern in images

Syntax

```
imagePoints = detectAprilGridPoints(I,patternDims,tagFamily)
[imagePoints,imagesUsed] = detectAprilGridPoints(imageFileNames, ___ )
[ ___ ] = detectAprilGridPoints(images, ___ )

imagePoints = detectAprilGridPoints(images1,images2,patternDims,tagFamily)
[imagePoints,pairsUsed] = detectAprilGridPoints(imageFileNames1,
imageFileNames2, ___ )
[ ___ ] = detectAprilGridPoints(images1,images2, ___ )

[ ___ ] = detectAprilGridPoints( ___ ,Name=Value)
```

Description

Single Image AprilGrid Detection

`imagePoints = detectAprilGridPoints(I,patternDims,tagFamily)` detects keypoints of an AprilGrid pattern in a 2-D truecolor or grayscale image `I`. `patternDims` specifies the number of tags in the pattern, and `tagFamily` specifies the AprilTag family.

`[imagePoints,imagesUsed] = detectAprilGridPoints(imageFileNames, ___ )` detects an AprilGrid pattern in the image files specified by name in `imageFileNames`, and additionally returns the list of images in which the pattern is detected `imagesUsed`.

`[ ___ ] = detectAprilGridPoints(images, ___ )` detects an AprilGrid in the specified images `images`.

Stereo Pair AprilGrid Detection

`imagePoints = detectAprilGridPoints(images1,images2,patternDims,tagFamily)` detects keypoints of an AprilGrid pattern in a 2-D truecolor or grayscale images `images1` and `images2`. `patternDims` specifies the number of tags in the pattern, and `tagFamily` specifies the AprilTag family.

`[imagePoints,pairsUsed] = detectAprilGridPoints(imageFileNames1, imageFileNames2, ___ )` detects an AprilGrid pattern in the stereo pairs of image files specified by the image file names in `imageFileNames1` and `imageFileNames2`. The function additionally returns a list of the pairs in which the pattern is detected `pairsUsed`.

`[ ___ ] = detectAprilGridPoints(images1,images2, ___ )` detects an AprilGrid pattern in the stereo pairs of images specified by `images1` and `images2`.

Optional Arguments

`[ ___ ] = detectAprilGridPoints( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `NumBorderBits=1` sets the number of tag border bits to generate an AprilTag to `1`.

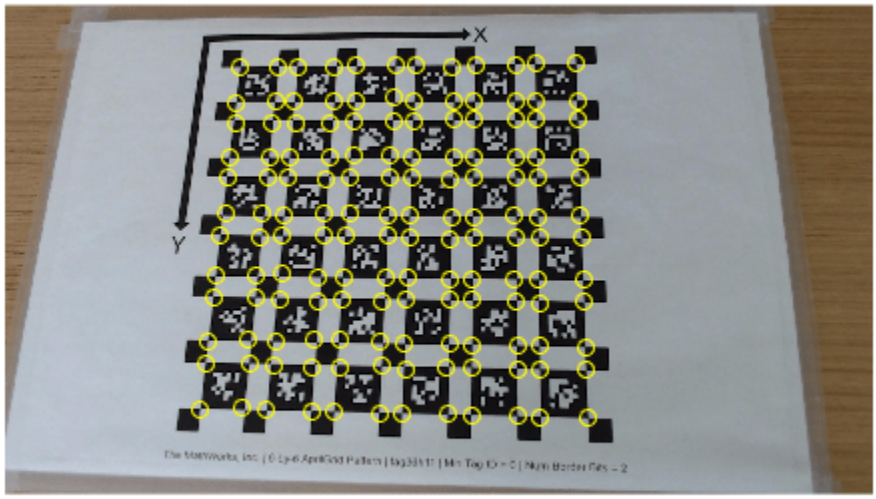
Examples

Detect AprilGrid in Image

Load the calibration image containing an AprilGrid into the workspace.

```
I = imread("aprilgrid.jpg");
```

Define the AprilGrid properties.



```
tagFamily = "tag36h11";
patternDims = [6 6];
```

Detect AprilGrid in the image.

```
imagePoints = detectAprilGridPoints(I,patternDims,tagFamily);
```

Display the detected keypoints of AprilGrid in the image.

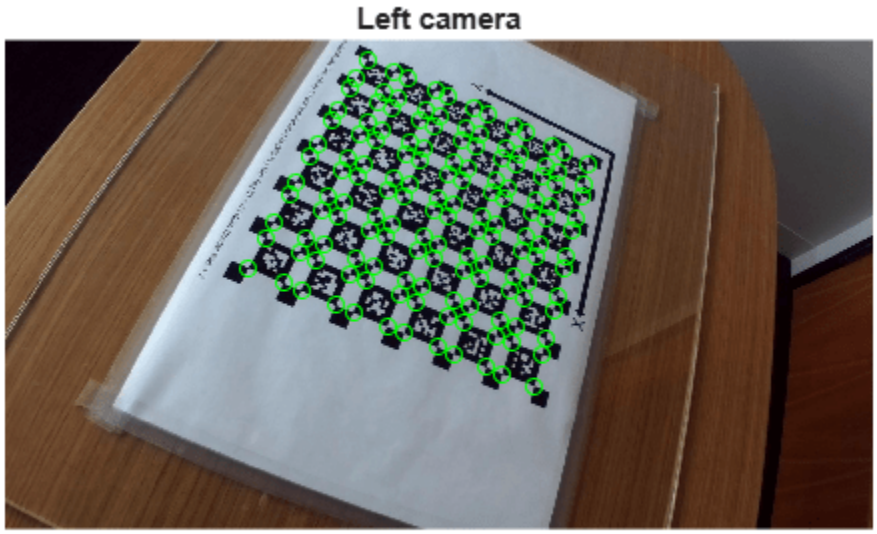
```
imshow(I);
hold on;
plot(imagePoints(:,1),imagePoints(:,2),"yo");
```

Detect AprilGrid in Stereo Image Pair

Load a stereo image pair containing an AprilGrid pattern into the workspace.

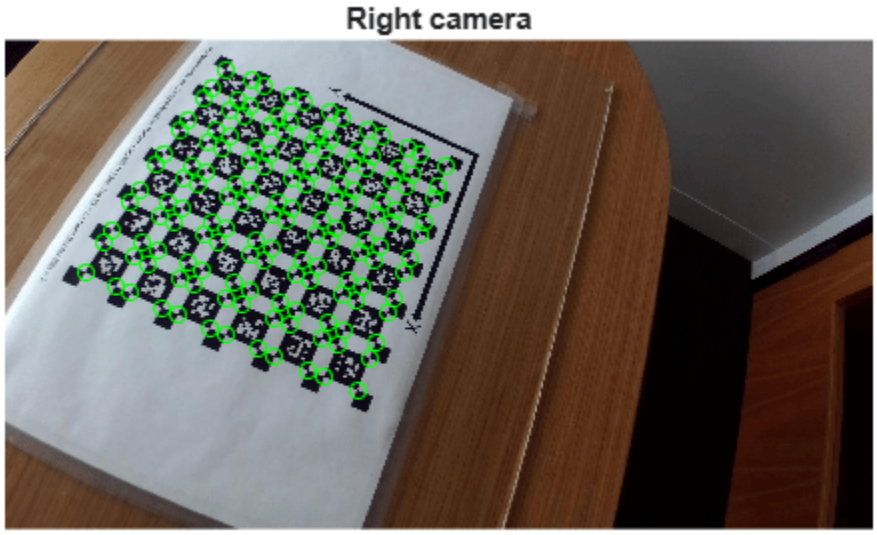
```
I1 = imread("leftAprilGrid.jpg");
I2 = imread("rightAprilGrid.jpg");
```

Define the AprilGrid properties.



```
tagFamily = "tag36h11";
patternDims = [6 6];
```

Detect the AprilGrid keypoints.

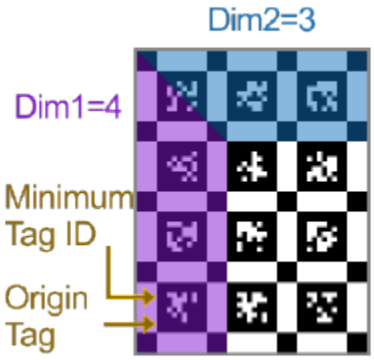


```
imagePoints = detectAprilGridPoints(I1,I2,patternDims,tagFamily);
```

Display the detected points on the image.

```
figure(1)
imshow(I1)
hold on
plot(imagePoints(:,1,1,1),imagePoints(:,2,1,1),"go");
title("Left camera")
```

```
figure(2)
imshow(I2)
hold on
plot(imagePoints(:,1,1,2),imagePoints(:,2,1,2),"go");
title("Right camera")
```



Input Arguments

`patternDims` — Pattern dimensions

two-element vector

Pattern dimensions, specified as a two-element vector that represents the number of enclosed squares in the vertical and horizontal dimensions of the AprilGrid image, respectively.

For more details on AprilTag patterns, see “Calibration Patterns”.

`tagFamily` — AprilTag marker family used in AprilGrid pattern

`"tag36h11"` | `"tag25h9"` | `"tag16h5"`

AprilTag marker family used in the AprilGrid pattern, specified as `"tag36h11"`, `"tag25h9"`, or `"tag16h5"`.

`I` — Image
2-D truecolor image | grayscale image

Image, specified as a 2-D truecolor image or grayscale image.

Data Types: `uint8` | `int16` | `uint16` | `single` | `double`

`images` — Images
H-by-*W*-by-*numColorChannels*-by-*numImages* array

Images, specified as an *H*-by-*W*-by-*numColorChannels*-by-*numImages* array, where *H* and *W* describe the height and width of each image, respectively. *numColorChannels* is the number of color channels in each image, and *numImages* is the number of images.

Data Types: `uint8` | `int16` | `uint16` | `single` | `double`

`images1` — Stereo pair images from camera one
H-by-*W*-by-*numColorChannels*-by-*numImages* array

Stereo pair images from camera one, specified as an *H*-by-*W*-by-*numColorChannels*-by-*numImages* array, where *H* and *W* describe the height and width of each image, respectively. *numColorChannels* is the number of color channels in each image, and *numImages* is the number of images.

Data Types: `uint8` | `int16` | `uint16` | `single` | `double`

`images2` — Stereo pair images from camera two
H-by-*W*-by-*numColorChannels*-by-*numImages* array

Stereo pair images from camera two, specified as an *H*-by-*W*-by-*numColorChannels*-by-*numImages* array, where *H* and *W* describe the height and width of each image, respectively. *numColorChannels* is the number of color channels in each image, and *numImages* is the number of images.

Data Types: `uint8` | `int16` | `uint16` | `single` | `double`

`imageFileNames` — Image filenames
cell array of character vectors | array of strings

Image filenames, specified as a cell array of character vectors or an array of strings.

`imageFileNames1` — Stereo image filenames for camera one
cell array of character vectors | array of strings

Stereo image filenames for camera one, specified as a cell array of character vectors or an array of strings.

`imageFileNames2` — Stereo image filenames for camera two
cell array of character vectors | array of strings

Stereo image filenames for camera two, specified as a cell array of character vectors or an array of strings.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `detectAprilGridPoints(I,patternDims,NumBorderBits=1)` sets the number of tag border bits to generate an AprilTag to `1`.

`NumBorderBits` — Number of tag border bits
`2` (default) | `1`

Number of tag border bits, specified as `1` or `2`. The tag border bits are used to generate the AprilTags. The border bits relate to each generated tag image, but not to a tag family. Refer to the manufacturer manual for your AprilTag pattern, to set this value.

If the function does not detect a fully visible tag, check that the `tagFamily` is correct. Otherwise, the specified `NumborderBits` might be incorrect.

`MinTagID` — Lowest value tag ID in pattern
`0` (default) | nonnegative integer

Lowest value tag ID in the AprilGrid pattern, specified as a nonnegative integer. The tags in the pattern must have sequential IDs with an increment of `1`.

`GaussianSigma` — Standard deviation for 2-D Gaussian smoothing kernel
`0` (default) | nonnegative scalar

Standard deviation for 2-D Gaussian smoothing kernel, specified as a nonnegative scalar. The Gaussian kernel smooths the input image to decrease white Gaussian noise. Increase this value to increase the processing speed, but at the cost of reduced precision.

`DecimationFactor` — Decimation factor
`1` (default) | positive integer

Decimation factor, specified as a positive integer. The decimation factor controls the scale of the downsampling. Increase this value to increase the detection rate, while decreasing detection distance.

Output Arguments

`imagePoints` — Corner coordinates of detected AprilGrid pattern
M-by-2 matrix | *M*-by-2-by- *numImages* array | *M*-by-2-by-*numPairs*-by-2 array

Corner coordinates of the detected AprilGrid pattern, returned as an *M*-by-2 matrix, *M*-by-2-by-*numImages* array, or an *M*-by-2-by-*numPairs*-by-2 array. *M* is the number of AprilGrid patterns detected, calculated as the product of the number of Aprilgrid patterns detected in each dimension. Each row of the matrix or array specifies the *xy*- coordinates of the center an AprilGrid.

- For single image — This argument is an *M*-by-2 matrix.
- For mutliple images — This argument is an *M*-by-2-*numImages* array.
- For stereo pairs — This argument is an *M*-by-2-by-*numPairs*-by-2 array, where *numPairs* is the number of image pairs in which the function detects an AprilGrid. `imagePoints(:,:,:,1)` returns the points from the first set of images, and `imagePoints(:,:,:,2)` returns the points from the second set.

`imagesUsed` — Pattern detection flag
logical vector

Pattern detection flag, returned as a logical vector. A value of `true` in the `imagesUsed` vector indicates that the pattern has been detected in the corresponding image.

`pairsUsed` — Stereo pair pattern detection flag
logical vector

Stereo pair pattern detection flag, returned as a logical vector. A value of `true` in the `pairsUsed` vector indicates that the pattern has been detected in the corresponding image pair.

Version History

Introduced in R2024b

Extended Capabilities

Thread-Based Environment

Run code in the background using MATLAB® `backgroundPool` or accelerate code with Parallel Computing Toolbox™ `ThreadPool`.

The `detectAprilGridPoints` function fully supports thread-based environments. For more information, see “Run MATLAB Functions in Thread-Based Environment”.

readArucoMarker

Detect and estimate pose for ArUco marker in image

Syntax

```
[id,loc] = readArucoMarker(I)
[id,loc] = readArucoMarker(I,markerFamily)
[id,loc,pose] = readArucoMarker( ___ ,intrinsics,markerSize)
[ ___ ,detectedFamily,rejections] = readArucoMarker( ___ )
[ ___ ] = readArucoMarker( ___ ,Name=Value)
```

Description

`[id,loc] = readArucoMarker(I)` detects ArUco markers in the input image `I`, and returns the locations and IDs associated with the markers.

`[id,loc] = readArucoMarker(I,markerFamily)` detects ArUco markers of only the specified families, `markerFamily`.

`[id,loc,pose] = readArucoMarker( ___ ,intrinsics,markerSize)` returns the poses of the markers with respect to the specified camera intrinsic parameters, `intrinsics`, and size of the markers, `markerSize`, in addition to any combination of input arguments from previous syntaxes.

`[ ___ ,detectedFamily,rejections] = readArucoMarker( ___ )` returns the recognized ArUco marker families, `detectedFamily`, and the *xy*-locations of rejected ArUco marker candidates, `rejections`, in addition to any combination of arguments from previous syntaxes.

`[ ___ ] = readArucoMarker( ___ ,Name=Value)` specifies options using one or more name-value arguments. For example, `WindowSizeStep=12` sets the number of pixels by which to increment the window size during adaptive thresholding to 12.

Examples

Read ArUco Markers in Image

Read an image into the workspace.

```
I = imread("ArUcoMarkersMulti.jpg");
```

Read the ArUco markers in the image to get their IDs, pixel locations, and marker families.

```
[ids,locs,detectedFamily] = readArucoMarker(I);
```

Overlay the marker edges, corners, and IDs on the image for visualization.

```
numMarkers = length(ids);
for i = 1:numMarkers
  loc = locs(:,:,i);

  % Display the marker ID and family
```

```
  disp("Detected marker ID, Family: " + ids(i) + ", " + detectedFamily(i))

  % Insert marker edges
  I = insertShape(I,"polygon",{loc},Opacity=1,ShapeColor="green",LineWidth=4);

  % Insert marker corners
  markerRadius = 6;
  numCorners = size(loc,1);
  markerPosition = [loc,repmat(markerRadius,numCorners,1)];
  I = insertShape(I,"FilledCircle",markerPosition,ShapeColor="red",Opacity=1);

  % Insert marker IDs
  center = mean(loc);
  I = insertText(I,center,ids(i),FontSize=30,BoxOpacity=1);
end
```

```
Detected marker ID, Family: 3, DICT_4X4_1000
Detected marker ID, Family: 34, DICT_5X5_1000
Detected marker ID, Family: 84, DICT_6X6_1000
Detected marker ID, Family: 264, DICT_7X7_1000
Detected marker ID, Family: 879, DICT_ARUCO_ORIGINAL
```

Display the results.

```
imshow(I)
```

Estimate ArUco Poses in Image

Read an image that contains ArUco markers into the workspace.

```
I = imread("ArUcoBoard.jpg");
```

Load intrinsics of the camera that captured the image.

```
data = load("camIntrinsicsArucoBoard.mat");
intrinsics = data.intrinsics;
```

Undistort the image and display it.

```
[I,camIntrinsics] = undistortFisheyeImage(I,intrinsics);
imshow(I)
```

Measure the marker size in millimeters.

```
markerSize = 25.4; % millimeters
```

Specify the marker family for faster performance of `readArucoMarker` function.

```
markerFamily = "DICT_6X6_250";
```

Estimate marker poses.

```
[ids,locs,poses] = readArucoMarker(I,markerFamily,camIntrinsics,markerSize);
```

Overlay estimated poses on the image for visualization.

```
% Origin and axes vectors for the object coordinate system
worldPoints = [0 0 0; markerSize/2 0 0; 0 markerSize/2 0; 0 0 markerSize/2];

for i = 1:length(poses)
  % Get image coordinates for axes
  imagePoints = world2img(worldPoints,poses(i),camIntrinsics);

  axesPoints = [imagePoints(1,:) imagePoints(2,:);
                imagePoints(1,:) imagePoints(3,:);
                imagePoints(1,:) imagePoints(4,:)];
```

```
  % Draw colored axes
  I = insertShape(I, "Line", axesPoints, ...
      Color = ["red","green","blue"], LineWidth=10);
end
```

Display the results.

```
imshow(I)
```

Input Arguments

`I` — Input image

M-by-*N*-by-3 truecolor image | *M*-by-*N* grayscale image

Input image, specified as an *M*-by-*N*-by-3 truecolor image or an *M*-by-*N* grayscale image. The input image must be undistorted.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16`

`markerFamily` — ArUco marker families

character vector | string scalar | vector of strings | cell array of character vectors

ArUco marker families, specified as a character vector, string scalar, vector of strings, or cell array of character vectors. Each element must be one of the valid ArUco marker families listed in the table. Specifying a family can reduce the run time of the function by restricting its search. Use this argument to improve the execution time when you know the marker family in the image. Be default, the function searches for:

`[ "DICT_ARUCO_ORIGINAL","DICT_4X4_1000","DICT_5X5_1000","DICT_6X6_1000", "DICT_7X7_1000"]`.

Family	Marker Size (bits)	Number of Markers in Family	Minimum Hamming Distance Between Markers (bits)
"DICT_ARUCO_ORIGINAL"	5-by-5	1024	3
"DICT_4X4_50"	4-by-4	50	4
"DICT_4X4_100"		100	3
"DICT_4X4_250"		250	2
"DICT_4X4_1000"		1000	2
"DICT_5X5_50"	5-by-5	50	8
"DICT_5X5_100"		100	7
"DICT_5X5_250"		250	6
"DICT_5X5_1000"		1000	5
"DICT_6X6_50"	6-by-6	50	13
"DICT_6X6_100"		100	12
"DICT_6X6_250"		250	11
"DICT_6X6_1000"		1000	9
"DICT_7X7_50"	7-by-7	50	19
"DICT_7X7_100"		250	18
"DICT_7X7_250"		250	17
"DICT_7X7_1000"		1000	14

Data Types: `char` | `string` | `cell`

`intrinsics` — Camera intrinsic parameters
`cameraIntrinsics` object

Camera intrinsic parameters, specified as a `cameraIntrinsics` object.

`markerSize` — Size of marker
positive scalar

Size of the marker in world units (such as millimeters), specified as a positive scalar. The function defines the size of the markers as the length of one side of the square marker.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `readArucoMarker(I,WindowSizeStep=12)` sets the number of pixels by which to increment the window size during adaptive thresholding to `12`.

Adaptive Thresholding Arguments

`WindowSizeRange` — Window size range

`[3 23]` (default) | two-element vector

Window size range, in pixels, specified as a two-element vector of the form `[min max]`. The elements set the minimum and maximum size, respectively, for the windows used for adaptive thresholding. Each value *n* in the range represents an *n*-by-*n* square window. Each element of this argument must be a positive integer greater than or equal to `3`. The function determines the local window threshold by calculating the average pixel value obtained from the sum of its surrounding pixels. Increase the *max* value when using ArUco markers that are larger than 400-by-400 pixels.

`WindowSizeStep` — Window step size

`10` (default) | positive integer

Window step size, in pixels, specified as a positive integer. The function uses the window step size for adaptive thresholding, but stays within the range set by the `WindowSizeRange` argument. The function starts at the minimum size of the range, and then increments the window size by the value of `WindowSizeStep`, until it reaches the maximum range value. If the window size is too small and a marker is large, the function might not detect that marker. This can occur when the window overlaps with the marker border. If the window size is large and a marker is small, the function might detect the marker, but the difference in size can negatively impact processing speed.

Contour Filtering Arguments

`MarkerSizeRange` — Range for marker boundary perimeter length

`[0.0075 1]` (default) | two-element vector

Range for marker boundary perimeter length, specified as a two-element vector of the form [*min max*]. The elements set the minimum and maximum size for the perimeter length of detected markers. Specify each element as a value normalized to the maximum dimension of the image. Reduce the range if a rejected marker completely encloses a valid marker.

`SquarenessTolerance` — Maximum polygonal approximation error

`0.03` (default) | positive scalar

Maximum polygonal approximation error, specified as a positive scalar. The function utilizes the Douglas-Peucker algorithm to apply a polygonal approximation to each marker candidate, accepting only those that closely resemble a square shape. The value of the `SquarenessTolerance` is relative to the candidate marker length (in pixels). Decrease this value to filter false corner detections in occluded markers. Increase this value to detect marker candidates in highly distorted images.

Bit Extraction Arguments

`NumBorderBits` — Number of border bits in marker

`1` (default) | positive integer

Number of border bits in the marker, specified as a positive integer. By default, the marker boundary contains one bit. If the function does not detect a marker candidate, first ensure that you have correctly set the `markerFamily`, then follow one of these two steps:

- If you used the `generateArucoMarker` function to generate the marker image, then ensure this name-value argument value is set to the same value as `NumBorderBits` of the `generateArucoMarker` function.

- If you did not use the `generateArucoMarker` function, then check the ArUco marker manufacturer manual to get the correct value for the number of border bits to use.

`ResolutionPerBit` — Resolution of the decoder
`4` (default) | positive integer

Resolution of the decoder to use in the bit extraction step, in pixels, specified as a positive integer. This value sets the number of pixels, per bit, to use in the obtained image after correcting perspective distortion. Increase this value to improve the accuracy with which the function reads marker IDs at the expense of runtime speed. The maximum value for argument is `1000`.

Subpixel Corner Refinement Arguments

`RefineCorners` — Subpixel refinement process
`false` or `0` (default) | `true` or `1`

Subpixel refinement process, specified as a logical `1`(`true`) or `0`(`false`). Set this value to `true` to enable the subpixel refinement process for the detected marker corner locations. This step is computationally expensive. Enable this process only if the corner locations must be accurate for pose estimation or for camera calibration applications.

`RefinementWindowSize` — Window size of subpixel refinement process
`5` (default) | positive integer

Window size of the subpixel refinement process, in pixels, specified as a positive integer. Increasing this value can cause the window area to include a corner of the image. As a result of this proximity, marker corners might move to an incorrect locations.

`RefinementMaxIterations` — Maximum number of iterations for subpixel refinement process
`30` (default) | positive integer

Maximum number of iterations the subpixel refinement process, specified as a positive integer. The process stops after the specified number of iterations even if it has not achieved the termination tolerance `RefinementTolerance`.

`RefinementTolerance` — Termination tolerance
`0.1` (default) | positive scalar

Termination tolerance, specified as a positive scalar.

Output Arguments

`id` — Marker IDs
N-element vector

Marker IDs, returned as an *N*-element vector of positive integers.

`loc` — Locations of detected markers in image
4-by-2-by-*N* array

Locations of the detected markers in the image, returned as a 4-by-2-by-*N* array. The array contains the *xy*-locations of the four corners for each detected marker. *N* is the number of detected markers.

`pose` — Poses of markers
array of `rigidtform3d` objects

Poses of markers with respect to the camera, returned as an array of `rigidtform3d` objects. Each object encapsulates the 3-D rigid transformation of a marker in the same world units as the `markerSize` input argument. The origin of each marker frame is located at the center of the corresponding marker. The planar surface on which the ArUco marker sits defines the *XY*-plane of the marker frame with the *Z*-axis pointing out of the marker.

`detectedFamily` — Detected ArUco marker families
vector of strings

Detected ArUco marker families, returned as a vector of strings.

`rejections` — Locations of rejected ArUco marker candidates
4-by-2-by-*P* array

Locations of the rejected ArUco marker candidates, returned as a 4-by-2-by-*P* array. The array contains the *xy*-locations for the four corners of each rejected marker candidate. *P* is the number of rejected marker candidates.

Tips

- This function does not account for lens distortion during pose estimation. To estimate poses, the input image must be undistorted. To estimate poses with a camera that has been calibrated using the Scaramuzza model, you can use the virtual pinhole model returned by the `undistortFisheyeImage` function.
- Consider the number of markers your application requires, marker length, and Hamming distance when choosing a marker family. The minimum Hamming distance between markers in the same family determines how capable the function is of detecting them and correcting errors. Smaller marker families, in terms of the number of markers in the family, and marker families with more bits have a larger minimum Hamming distance, but the additional bits to extract can make marker detection more difficult. For example, if your application only requires 10 markers, you can use a family of 10 markers for increased error robustness over a family of 1000 markers. In summary:
  - The fewer bits used to encode the ID in the ArUco marker, the greater the distance from the camera that you can detect the marker. The marker family name specifies the number of bits (for example, `DICT_4X4_50` has a marker size of 4-by-4, totaling 16 bits).
  - Refer to the full list of ArUco family markers, specified in the `markerFamily` argument description.
- Use one or more of these debugging tips:
  - Include a white border (also called a quiet zone) around ArUco markers for proper identification and decoding.
  - The function does not detect markers if the images have been flipped vertically or horizontally.
  - The function does not detect markers if their square shape has been altered as a result of lens distortion. You can undistort images to improve marker detection.
  - If the function does not detect a marker image, and does not return it as a rejected marker candidate, you might need to modify the adaptive thresholding steps. You can do this by adjusting the `WindowSizeRange` and `WindowSizeStep` values.

- If the function does not detect a marker image, but returns it as a rejected candidate, verify or adjust the `markerFamily` and `NumBorderBits` values. Also, verify that the image has not been flipped vertically or horizontally.
- If a detected or rejected marker incorrectly encompasses any surrounding black borders, adjust the `MarkerSizeRange` value.
- If the function returns an incorrect marker ID, or if it detects the same marker using two different marker families, increase the `ResolutionPerBit` value.

Algorithms

When the detection process starts, the function binarizes the input image using adaptive thresholding at different neighborhood window sizes. The function extracts marker rejections on each of the binarized images.

The marker detection algorithm uses these steps:

1. Perform adaptive thresholding to binarize the image.
2. Extract and filter contours to detect square-shaped marker candidates.
3. Remove perspective distortion and extract marker bits to analyze the inner codification of the marker bits.
4. Perform error correction to identify valid markers.
5. Optionally, perform subpixel refinement of corner positions.

Version History

Introduced in R2024a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Generates portable C code using a C++ compiler that links to OpenCV (Version 4.7.0) libraries. See “Portable C Code Generation for Functions That Use OpenCV Library”.
- During code generation, `detectedFamily` output argument is returned as cell array unlike vector of strings in simulation.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

During code generation, `detectedFamily` output argument is returned as cell array unlike vector of strings in simulation.

Functions

`generateArucoMarker` | `undistortImage`

Topics
“Calibration Patterns”

generateArucoMarker

Generate ArUco marker images

Syntax

```
imgs = generateArucoMarker(markerFamily,ids,markerSize)
imgs = generateArucoMarker( ___ ,NumBorderBits=numBits)
```

Description

`imgs = generateArucoMarker(markerFamily,ids,markerSize)` generates ArUco marker images `imgs` of the specified family `markerFamily` and size `markerSize` with the corresponding identifiers `ids`.

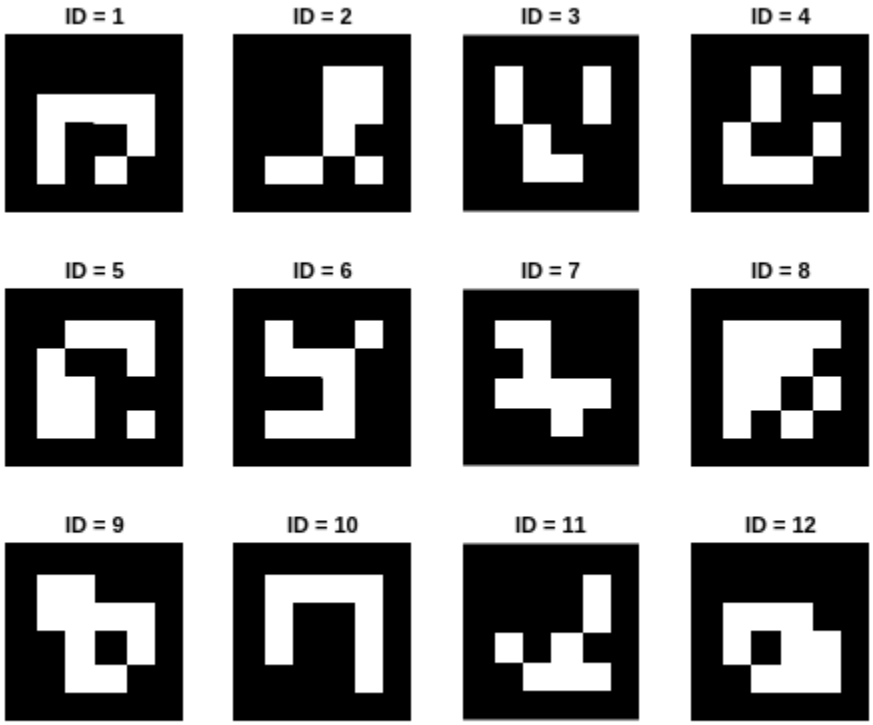
`imgs = generateArucoMarker( ___ ,NumBorderBits=numBits)` sets the number of marker border bits to add when generating the marker, in addition to all input arguments from the previous syntax. Specify `numBits` as a positive integer value. The default value is set to `1`.

Examples

Generate ArUco Marker Images

Generate 12 ArUco marker images, display them, and write them to PNG files.

Specify the number, size, family, and IDs of the markers to generate.



```
numMarkers = 12;
markerSize = 50; % in pixels
markerFamily = "DICT_4X4_250";
ids = 1:numMarkers;
```

Generate the ArUco markers.

```
imgs = generateArucoMarker(markerFamily,ids,markerSize);
```

Display the markers.

```
tiledlayout(3,4,TileSpacing="compact")
for i = 1:numMarkers
    nexttile
    imshow(imgs(:,:,i))
    title("ID = " + ids(i))
end
```

Write each marker image to a PNG file.

```
for i = 1:numMarkers
    filename = markerFamily + "_ID" + ids(i) + ".png";
    imwrite(imgs(:,:,i), filename)
end
```

Input Arguments

`markerFamily` — ArUco marker family name

character vector | string scalar | vector of strings | cell array of character vectors

ArUco marker families, specified as a character vector, string scalar, vector of strings, or cell array of character vectors. Each element must be one of the valid ArUco marker families listed in the table. Select a marker family suitable for your application based on the total number of markers needed, the marker length, and the Hamming distance between the marker code words. The minimum Hamming distance between markers in the same family, determine the ability to detect them and correct errors. Marker families with less number of markers can be more robust against errors than a family with a large number of markers, which can increase marker detection difficulty due to a greater number of bits to extract. These general rules apply:

- The less number of bits to detect, the longer the range in distance a marker can be detected.
- For correct identification and decoding, ArUco markers require a white border, also known as the quiet zone.

Family	Marker Size (bits)	Number of Markers in Family	Minimum Hamming Distance Between Markers (bits)
"DICT_ARUCO_ORIGINAL"	5-by-5	1024	3
"DICT_4X4_50"	4-by-4	50	4
"DICT_4X4_100"		100	3
"DICT_4X4_250"		250	2
"DICT_4X4_1000"		1000	2
"DICT_5X5_50"	5-by-5	50	8
"DICT_5X5_100"		100	7
"DICT_5X5_250"		250	6
"DICT_5X5_1000"		1000	5
"DICT_6X6_50"	6-by-6	50	13
"DICT_6X6_100"		100	12
"DICT_6X6_250"		250	11
"DICT_6X6_1000"		1000	9
"DICT_7X7_50"	7-by-7	50	19
"DICT_7X7_100"		250	18
"DICT_7X7_250"		250	17
"DICT_7X7_1000"		1000	14

Data Types: `char` | `string` | `cell`

`ids` — Marker IDs
N-element vector

Marker IDs, specified as an *N*-element vector of positive integers. Each element must be nonnegative and less than the family size, which is the total number of markers available in the marker family. For example, the family size of `"DICT_7X7_250"` is 250.

`markerSize` — Size of each marker
positive integer

Size of each marker, in pixels, specified as a positive integer. This value sets the length of one side of a square ArUco marker. The marker size must be large enough to store the number of bits required for the specified marker family. For example, you cannot generate an image of 5-by-5 pixels for a marker from the `"DICT_6X6_100"` family, which requires a 6-by-6 pixel size. For more information, see the table in the `markerFamily` input description.

Output Arguments

`imgs` — Marker images
M-by-*M*-by-*N* array

Marker images, returned as an *M*-by-*M*-by-*N* array.

Data Types: `uint8`

Version History

Introduced in R2024a

Functions

`readArucoMarker`

groundTruthToOpenLabel

Convert ground truth object to OpenLabel JSON file

Syntax

```
groundTruthToOpenLabel(gTruth,jsonFilename)
groundTruthToOpenLabel( ___ ,PrettyPrint=false)
```

Description

`groundTruthToOpenLabel(gTruth,jsonFilename)` converts ground truth data `gTruth`, to the ASAM OpenLABEL® format and writes the result to a JavaScript Object Notation (JSON), `jsonFilename`.

`groundTruthToOpenLabel( ___ ,PrettyPrint=false)` adds indentations to the output file. A value of `true` adds the indentation and a value of `false` will not add it. The default value is set to `false`, which produces a smaller size file.

Examples

Convert Ground Truth Object to ASAM OpenLABEL JSON File

Add the folder that contains images to the MATLAB® path.

```
imageDir = fullfile(matlabroot,"toolbox","vision","visiondata","vehicles");
addpath(imageDir);
```

Load ground truth object data related to vehicles from a previously saved MAT file.

```
data = load("vehicleTrainingGroundTruth.mat");
gTruth = data.vehicleTrainingGroundTruth;
```

Convert the ground truth object data to a JSON file in the ASAM OpenLABEL® format. Set `PrettyPrint` to `true` to insert indentations in the output file.

```
groundTruthToOpenLabel(gTruth,"vehicleGtruthOpenLABEL",PrettyPrint=true);
```

Inspect the output JSON file by using the `edit` command:

```
edit vehicleGtruthOpenLABEL.json
```

Input Arguments

`gTruth` — Ground truth object

`groundTruth` object (default)

Ground truth object, specified by a `groundTruth`. Only objects generated by the Image Labeler and Video Labeler apps that include labels can be converted using this function.

`jsonFilename` — JSON filename
character string (default)

JSON filename for the returned file, specified by a character string. For details regarding the JSON format, see ASAM OpenLABEL specification. Not all aspects of the ground truth object data can be represented in the OpenLABEL format. To compensate for the differences and ambiguities between the data that could not be represented and the ASAM specifications, the function makes these customizations to the JSON file:

- For an image collection used with the `Image Labeler`, each object in the JSON file's OpenLABEL *object_data* section, contains a *text* field that references the location of the images within the file system.
- Pixel label images are not embedded into the *image* OpenLABEL object. Instead, they are referenced in the *image* object using the *text* field in the *object_data_pointer* section of the JSON file.
- Projected cuboids from `groundTruth` objects are stored as eight points in an OpenLABEL `poly2d` object modified to accommodate it. These modified `poly2d` objects are tagged with the boolean field `matlab_projected_cuboid` set to `true`.
- Information stored in the `gTruth.LabelDefinitions` object such as, `Group`, `Description`, and `LabelColor` is placed in the *matlab_label_definitions* field of the custom *metadata* section in the OpenLABEL JSON file
- Pixel label values to class name correspondences are stored in the custom *matlab_label_definitions* field of the JSON file.
- Closed polygons contain a *hierarchy* field with the top-most layered polygon listed first, with a zero index. In the case of overlapping polygons, the top-layered polygons are marked with lower index numbers than the polygons they cover (below them).

groundTruthFromOpenLabel

Convert OpenLabel JSON file to ground truth object

Syntax

```
groundTruthFromOpenLabel(gTruth,jsonFile)
```

Description

`groundTruthFromOpenLabel(gTruth,jsonFile)` converts ASAM OpenLABEL® format JavaScript Object Notation (JSON) data `jsonFilename` to ground truth `gTruth`.

You can use this function with the JSON file produced by the `groundTruthToOpenLabel` function. However, using this function with any third-party tools might produce an invalid ground truth object. If you encounter this issue, you can contact the MathWorks® "Contact Technical Support" help system for assistance.

Examples

Convert ASAM OpenLABEL JSON file to Ground Truth Object

Add the folder that contains images, to the MATLAB® path. These data files must be available prior to converting the ASAM OpenLABEL JSON file.

```
imageDir = fullfile(matlabroot,"toolbox","vision","visiondata","vehicles");
addpath(imageDir);

data = load("vehicleTrainingGroundTruth.mat");
gTruthOriginal = data.vehicleTrainingGroundTruth;
```

Convert the ground truth object to JSON file in ASAM OpenLABEL format.

```
groundTruthToOpenLabel(gTruthOriginal,"vehicleGtruthOpenLABEL");
```

Convert JSON format file to a `groundTruth` object.

```
gTruth = groundTruthFromOpenLabel("vehicleGtruthOpenLABEL.json");
```

Inspect the data in the ground truth object.

```
imageLabeler(gTruth);
```

Input Arguments

`jsonFile` — JSON file

character string (default)

JSON file, specified by a character string. The file must contain ground truth stored in the ASAM OpenLabel format. For details regarding the JSON format, see ASAM OpenLABEL specification.

Output Arguments

`gTruth` — Ground truth object
`groundTruth` object (default)

Ground truth object, returned as a `groundTruth`.

Version History

Introduced in R2024b

folders2labels

Get list of labels from folder names

Syntax

```
lbls = folders2labels(loc)
lbls = folders2labels(loc,Name,Value)

lbls = folders2labels(ds)

[lbls,files] = folders2labels( ___ )
```

Description

Use this function when you are working on a machine or deep learning classification problem and your labeled data is stored in folders that have the corresponding label names.

`lbls = folders2labels(loc)` creates a list of labels based on the folder names specified by the location `loc`.

`lbls = folders2labels(loc,Name,Value)` specifies additional input arguments using name-value pairs. For example, `'FileExtensions','.mat'` includes only .mat files in the scan for labels.

`lbls = folders2labels(ds)` creates a list of labels based on the files contained in `ds`. `ds` can be a datastore, a `matlab.io.datastore.FileSet` object, or a `matlab.io.datastore.BlockedFileSet` object.

`[lbls,files] = folders2labels( ___ )` additionally returns a list of files. The `i`th element of `lbls` corresponds to the label of the `i`th file in `files`.

Examples

Labels from Folder Names

Create a folder called `Files` in the current folder containing three subfolders, `Files_1`, `Files_2`, and `Files_3`. Add to each subfolder a random number of files, each containing a random signal of random size.

```
mkdir Files

for kj = 1:3
    fname = "Files_" + kj;
    mkdir(fname)
    for jk = 1:randi(4)
        sname = "sig_" + kj + "_" + jk;
        sgn = randn(randi([30 50]),randi(2));
        save(sname,"sgn")
        movefile(sname + ".mat",fname)
    end
```

```
    movefile(fname,"Files")
end
```

List the contents of the folders.

```
dir("*/*/*")
```

```
Files Found in: Files\Files_1

.            ..           sig_1_1.mat  sig_1_2.mat  sig_1_3.mat  sig_1_4.mat

Files Found in: Files\Files_2

.            ..           sig_2_1.mat  sig_2_2.mat

Files Found in: Files\Files_3

.            ..           sig_3_1.mat  sig_3_2.mat  sig_3_3.mat
```

Create a list of labels based on the folder names.

```
lbls = folders2labels("Files")
```

```
lbls = 9×1 categorical
     Files_1
     Files_1
     Files_1
     Files_1
     Files_2
     Files_2
     Files_3
     Files_3
     Files_3
```

List the names of the files associated with the labels.

```
[~,files] = folders2labels("Files");
[~,fnames] = fileparts(files)
```

```
fnames = 9×1 string
    "sig_1_1"
    "sig_1_2"
    "sig_1_3"
    "sig_1_4"
    "sig_2_1"
    "sig_2_2"
    "sig_3_1"
    "sig_3_2"
    "sig_3_3"
```

Remove the `Files` directory you created at the beginning of the example.

```
rmdir Files s
```

Input Arguments

`loc` — Files or folders to scan for labels

character vector | cell array of character vectors | string scalar | string array

Files or folders to scan for labels, specified as a character vector, a cell array of character vectors, a string scalar, or a string array, containing the location of files or folders that are local or remote.

- Local files or folders — Specify `loc` as a local path to files or folders. If the files are not in the current folder, then the local path must specify full or relative paths. Files within subfolders of the specified folder are included by default. You can use the wildcard character (*) when specifying the local path. This character specifies that the file search include all matching files or all files in the matching folders.
- A remote location specified using an internationalized resource identifier (IRI).
- Remote files or folders — Specify `loc` to be the full paths of the files or folders as a uniform resource locator (URL) of the form `hdfs:///path_to_file`. For more information, see “Work with Remote Data”.

`folders2labels` looks for all file formats. To specify a custom list of file extensions to scan, use the `FileExtensions` argument.

Example: `'whale.mat'`

Example: `'../dir/data/signal.mat'`

Example: `"../dir/data/"`

Example: `{'dataFiles/Files_1/' 'dataFiles/Files_2/'}`

Example: `["dataFiles/Files_1/" "dataFiles/Files_2/"]`

Data Types: `char` | `string` | `cell`

`ds` — Data repository

datastore | `matlab.io.datastore.FileSet` object | `matlab.io.datastore.BlockedFileSet` object

Data repository, specified as a datastore, a `matlab.io.datastore.FileSet` object, or a `matlab.io.datastore.BlockedFileSet` object.

- If `ds` is a datastore, it must contain a `Files` property from which label names are parsed.
- If `ds` is a `matlab.io.datastore.FileSet` object, `folders2labels` obtains the label names from the file names listed in the `FileInfo` property of `ds`.
- If `ds` is a `matlab.io.datastore.BlockedFileSet` object, `folders2labels` obtains the label names from the file names listed in the `BlockInfo` property of `ds`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `folders2labels('C:\dir\signaldata','FileExtensions','.csv')` specifies a local path and includes only CSV files in the scan for labels.

`IncludeSubfolders` — Subfolder inclusion flag
`true` or `1` (default) | `false` or `0`

Subfolder inclusion flag, specified as `true` or `false`. Specify `true` to include all files and subfolders within each folder or `false` to include only the files within each folder.

Example: `'IncludeSubfolders',true`

Data Types: `logical` | `double`

`FileExtensions` — Signal file extensions
character vector | cell array of character vectors | string scalar | string array

Signal file extensions, specified as a string scalar, string array, character vector, or cell array of character vectors.

Example: `'FileExtensions','.csv'`

Data Types: `string` | `char` | `cell`

Output Arguments

`lbls` — List of labels
categorical vector

List of labels, returned as a categorical vector.

`files` — List of files
string vector

List of files, returned as a string vector. The `i`th element of `lbls` corresponds to a label for the `i`th file in `files`.

Version History

Introduced in R2021a

`labeledSignalSet` | `signalLabelDefinition` | `countlabels` | `filenames2labels` | `splitlabels`

splitlabels

Find indices to split labels according to specified proportions

Syntax

```
idxs = splitlabels(lblsrc,p)
idxs = splitlabels(lblsrc,p,'randomized')
idxs = splitlabels( ___ ,Name,Value)
```

Description

Use this function when you are working on a machine or deep learning classification problem and you want to split a dataset into training, testing, and validation sets that hold the same proportion of label values.

`idxs = splitlabels(lblsrc,p)` finds logical indices that split the labels in `lblsrc` based on the proportions or number of labels specified in `p`.

`idxs = splitlabels(lblsrc,p,'randomized')` randomly assigns the specified proportion of label values to each index set in `idxs`.

`idxs = splitlabels( ___ ,Name,Value)` specifies additional input arguments using name-value pairs. For example, `'UnderlyingDatastoreIndex',3` splits the labels only in the third underlying datastore of a combined datastore.

Examples

Split Vowels

Read William Shakespeare's sonnets with the `fileread` function. Extract all the vowels from the text and convert them to lowercase.

```
sonnets = fileread("sonnets.txt");
vowels = lower(sonnets(regexp(sonnets,"[AEIOUaeiou]")))';
```

Count the number of instances of each vowel.

```
cnts = countlabels(vowels)
```

```
cnts=5×3 table
    Label    Count    Percent
    _____    _____    _______

      a      4940     18.368
      e      9028     33.569
      i      4895     18.201
      o      5710     21.232
      u      2321     8.6302
```

Split the vowels into a training set containing 500 instances of each vowel, a validation set containing 300, and a testing set with the rest. All vowels are represented with equal weights in the first two sets but not in the third.

```
spltn = splitlabels(vowels,[500 300]);

for kj = 1:length(spltn)
    cntsn{kj} = countlabels(vowels(spltn{kj}));
end
cntsn{:}

```

Split Vowels and Consonants

Read William Shakespeare's sonnets with the `fileread` function. Remove all nonalphabetic characters from the text and convert to lowercase.

```
sonnets = fileread("sonnets.txt");
letters = lower(sonnets(regexp(sonnets,"[A-z]")))';
```

Classify the letters as consonants or vowels and create a table with the results. Show the first few rows of the table.

```
type = repmat("consonant",size(letters));
type(regexp(letters','[aeiou]")) = "vowel";

T = table(letters,type,'VariableNames',["Letter" "Type"]);
head(T)
```

```
    Letter       Type
    ______    __________

      t       "consonant"
      h       "consonant"
      e       "vowel"
      s       "consonant"
      o       "vowel"
      n       "consonant"
```

```
      n       "consonant"
      e       "vowel"
```

Display the number of instances of each category.

```
cnt = countlabels(T,'TableVariable',"Type")
```

```
cnt=2×3 table
      Type       Count    Percent
    _________    _____    _______

    consonant    46516    63.365
    vowel        26894    36.635
```

Split the table into two sets, one containing 60% of the consonants and vowels and the other containing 40%. Display the number of instances of each category.

```
splt = splitlabels(T,0.6,'TableVariable',"Type");

sixty = countlabels(T(splt{1},:),'TableVariable',"Type")
```

```

      s       2497     35.615
```

Split Data in Datastore

Create a dataset that consists of 100 Gaussian random numbers. Label 40 of the numbers as `A`, 30 as `B`, and 30 as `C`. Store the data in a combined datastore containing two datastores. The first datastore has the data and the second datastore contains the labels.

```
dsData = arrayDatastore(randn(100,1));
dsLabels = arrayDatastore([repmat("A",40,1); ...
            repmat("B",30,1); repmat("C",30,1)]);
dsDataset = combine(dsData,dsLabels);
cnt = countlabels(dsDataset,UnderlyingDatastoreIndex=2)
```

```
cnt=3×3 table
    Label    Count    Percent
    _____    _____    _______

      A       40        40
      B       30        30
      C       30        30
```

Split the data set into two sets, one containing 60% of the numbers and the other with the rest.

```
splitIndices = splitlabels(dsDataset,0.6,UnderlyingDatastoreIndex=2);

dsDataset1 = subset(dsDataset,splitIndices{1});
cnt1 = countlabels(dsDataset1,UnderlyingDatastoreIndex=2)
```

```
cnt1=3×3 table
    Label    Count    Percent
    _____    _____    _______

      A       24        40
      B       18        30
      C       18        30
```

```
dsDataset2 = subset(dsDataset,splitIndices{2});
cnt2 = countlabels(dsDataset2,UnderlyingDatastoreIndex=2)
```

```
cnt2=3×3 table
    Label    Count    Percent
    _____    _____    _______

      A       16        40
      B       12        30
      C       12        30
```

Input Arguments

`lblsrc` — Input label source

categorical vector | string vector | logical vector | numeric vector | cell array | table | datastore | `CombinedDatastore` object

Input label source, specified as one of these:

- A categorical vector.
- A string vector or a cell array of character vectors.
- A numeric vector or a cell array of numeric scalars.
- A logical vector or a cell array of logical scalars.
- A table with variables containing any of the previous data types.
- A datastore whose `readall` function returns any of the previous data types.
- A `CombinedDatastore` object containing an underlying datastore whose `readall` function returns any of the previous data types. In this case, you must specify the index of the underlying datastore that has the label values.

`lblsrc` must contain labels that can be converted to a vector with a discrete set of categories.

Example: `lblsrc = categorical(["B" "C" "A" "E" "B" "A" "A" "B" "C" "A"],["A" "B" "C" "D"])` creates the label source as a ten-sample categorical vector with four categories: `A`, `B`, `C`, and `D`.

Example: `lblsrc = [0 7 2 5 11 17 15 7 7 11]` creates the label source as a ten-sample numeric vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `string` | `table` | `cell` | `categorical`

`p` — Proportions or numbers of labels

integer scalar | scalar in (0, 1) | vector of integers | vector of fractions

Proportions or numbers of labels, specified as an integer scalar, a scalar in the range (0, 1), a vector of integers, or a vector of fractions.

- If `p` is a scalar, `splitlabels` finds two splitting index sets and returns a two-element cell array in `idxs`.
  - If `p` is an integer, the first element of `idxs` contains a vector of indices pointing to the first `p` values of each label category. The second element of `idxs` contains indices pointing to the remaining values of each label category.

- If `p` is a value in the range (0, 1) and `lblsrc` has K_i elements in the ith category, the first element of `idxs` contains a vector of indices pointing to the first `p` × K_i values of each label category. The second element of `idxs` contains the indices of the remaining values of each label category.

- If `p` is a vector with N elements of the form p_1, p_2, ..., p_N, `splitlabels` finds N + 1 splitting index sets and returns an (N + 1)-element cell array in `idxs`.
  - If `p` is a vector of integers, the first element of `idxs` is a vector of indices pointing to the first p_1 values of each label category, the next element of `idxs` contains the next p_2 values of each label category, and so on. The last element in `idxs` contains the remaining indices of each label category.
  - If `p` is a vector of fractions and `lblsrc` has K_i elements of the ith category, the first element of `idxs` is a vector of indices concatenating the first p_1 × K_i values of each category, the next element of `idxs` contains the next p_2 × K_i values of each label category, and so on. The last element in `idxs` contains the remaining indices of each label category.

Note

- If `p` contains fractions, then the sum of its elements must not be greater than one.
- If `p` contains numbers of label values, then the sum of its elements must not be greater than the smallest number of labels available for any of the label categories.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'TableVariable',"AreaCode",'Exclude',["617" "508"]` specifies that the function split labels based on telephone area code and exclude numbers from Boston and Natick.

`Include` — Labels to include in index sets
vector of label categories | cell array of label categories

Labels to include in the index sets, specified as a vector or cell array of label categories. The categories specified with this argument must be of the same type as the labels in `lblsrc`. Each category in the vector or cell array must match one of the label categories in `lblsrc`.

`Exclude` — Labels to exclude from index sets
vector of label categories | cell array of label categories

Labels to exclude from the index sets, specified as a vector or cell array of label categories. The categories specified with this argument must be of the same type as the labels in `lblsrc`. Each category in the vector or cell array must match one of the label categories in `lblsrc`.

`TableVariable` — Table variable to read
first table variable (default) | character vector | string scalar

Table variable to read, specified as a character vector or string scalar. If this argument is not specified, then `splitlabels` uses the first table variable.

`UnderlyingDatastoreIndex` — Underlying datastore index
integer scalar

Underlying datastore index, specified as an integer scalar. This argument applies when `lblsrc` is a `CombinedDatastore` object. `splitlabels` counts the labels in the datastore obtained using the `UnderlyingDatastores` property of `lblsrc`.

Output Arguments

`idxs` — Splitting indices
cell array

Splitting indices, returned as a cell array.

Version History

Introduced in R2021a

`countlabels` | `filenames2labels` | `folders2labels`

cuboid2img

Project cuboids from 3-D world coordinates to 2-D image coordinates

Syntax

```
projectedCuboid = cuboid2img(cuboid,projectionMatrix)
[projectedCuboid,validIndex] = cuboid2img( ___ )
[projectedCuboid,validIndex,allFaceVertices] = cuboid2img( ___ )
[ ___ ] = cuboid2img( ___ ,Name=Value)
```

Description

`projectedCuboid = cuboid2img(cuboid,projectionMatrix)` projects the 3-D cuboids into an image using the image data and camera intrinsic parameters specified by the projection matrix. The function returns the image with projected cuboids.

`[projectedCuboid,validIndex] = cuboid2img( ___ )` returns a logical array that indicates which input cuboid projections are within the field of view of the camera, using the input arguments from the first syntax.

`[projectedCuboid,validIndex,allFaceVertices] = cuboid2img( ___ )` returns the face vertices of each projected cuboid to facilitate visualization of specific projected cuboid faces. You can use the `showShape` or `insertShape` function to visualize the projected cuboid faces.

`[ ___ ] = cuboid2img( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `cuboid2img(data.cuboid,projectionMatrix,OutputFormat="rectangles")` specifies to output each cuboid as two projected cuboid faces forming axis-aligned rectangles.

Examples

Project 3-D Cuboid to Image

Load an image into the workspace and resize it.

```
imOrig = imread(fullfile(matlabroot,"toolbox","vision","visiondata", ...
        "stopSignImages","image004.jpg"));
I = imresize(imOrig,[1080 1920]);
```

Load a MAT file that contains 3-D cuboid labels and the camera projection matrix of the sensor that captured the images.

```
data  = load("cuboidData.mat");
projectionMatrix = data.projectionMatrix;
cuboid = data.cuboid;
```

Convert the 3-D cuboids into 2-D projected cuboids.

```
vertices = cuboid2img(cuboid,projectionMatrix);
```

Insert the projected cuboids into the image, and then display the result.

```
Iout = insertShape(I,"projected-cuboid",vertices);
imshow(Iout)
```

Highlight One Face of -D Cuboid

Load an image into the MATLAB® workspace, and then resize it.

```
imOrig = imread(fullfile(matlabroot,"toolbox","vision","visiondata", ...
        "stopSignImages","image004.jpg"'));
I = imresize(imOrig,[1080 1920]);
```

Load MAT file previously created 3-D cuboid labels and the camera projection matrix of the sensor used to capture the images.

```
data  = load("cuboidData.mat");
projectionMatrix = data.projectionMatrix;
cuboid = data.cuboid;
```

Convert 3-D cuboids into 2-D projected cuboids, and obtain the face vertices of the projected cuboids.

```
[projectedCuboids,validIdx,allFaceVertices] = cuboid2img(cuboid,projectionMatrix);
```

Insert the projected cuboids into the image.

```
I = insertShape(I,"projected-cuboid",projectedCuboids);
```

Select the third face of each projected cuboid.

```
whichFace = 3;
selectedFaceVertices = allFaceVertices(:,:,whichFace);
```

Highlight the selected faces using a filled polygon and display the result.

```
J = insertShape(I,"filled-polygon",selectedFaceVertices);
imshow(J)
```

Input Arguments

`cuboid` — Cuboid positions, sizes, and orientations

M-by-9 matrix

Cuboid positions, sizes, and orientations, specified as an *M*-by-9 matrix. *M* is the number of cuboids. Each row specifies the position, size, and orientation of a cuboid in the form [*xctr yctr zctr xlen ylen zlen xrot yrot zrot*]:

- Position — *xctr*, *yctr*, and *zctr* are the coordinates of the center of the 3-D cuboid.
- Size — *xlen*, *ylen*, *zlen* are the lengths of the *x*,*y*, and *z* sides of the 3-cuboid.
- Orientation — *xrot yrot zrot* are the *x*,*y*, and *z* rotation angles of the 3-D cuboid in degrees.

Data Types: `single` | `double`

`projectionMatrix` — Camera projection matrix

3-by-4 matrix

Camera projection matrix, specified as a 3-by-4 matrix. The function uses the projection matrix to map the 3-D world points of each cuboid onto the 2-D image plane. You can create a projection matrix using the `cameraProjection` function.

Data Types: `single` | `double`

Name-Value Pair Arguments

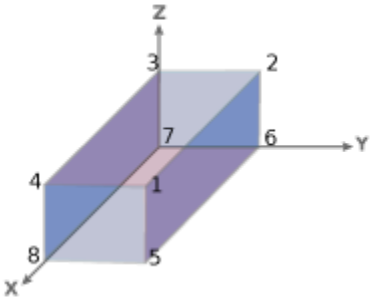
Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `cuboid2img(data.cuboid,projectionMatrix,OutputFormat="rectangles")` specifies to output each cuboid as two projected cuboid faces forming axis-aligned rectangles.

`OutputFormat` — Output format

`"vertices"` (default) | `"rectangles"`

Output format in which to represent the projected cuboids, specified as `"vertices"` or `"rectangles"`.



Output Format	Description
`"vertices"`	`projectedCuboid` is an 8-by-2-by-*P* array of vertices, where *P* is the number of projected cuboids. Each page of the array contains the [*x y*] locations for the four corners of the front face and four corners of the rear face of the projected cuboid.
`"rectangles"`	`projectedCuboid` is an *P*-by-8 matrix, where *P* is the number of rectangular projected cuboids. Each row of the matrix contains an eight-element vector of the form [*x1 y1 w1 h1 x2 y2 w2 h2*], where [*x1 y1*] and [*x2 y2*] are the upper-left coordinates of the front- and rear-facing rectangles, respectively. The function adjusts the projected cuboid vertices such that the front and rear cuboid faces form axis-aligned rectangles, and enclose all of the related projected vertices. Use the rectangular output when you need to create projected cuboid data compatible with the Image Labeler, Video Labeler, or Ground Truth Labeler app.

Output Arguments

`projectedCuboid` — Projected cuboids

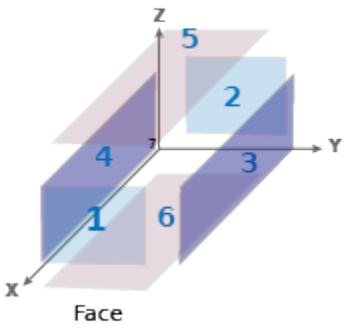
8-by-2-by-*P* array | *P*-by-8 matrix

Projected cuboids, returned as an 8-by-2-by-*P* array or a *P*-by-8 matrix. *P* is the number of projected cuboids. *P* is less than or equal to the number of input 3-D cuboids *M*. Any cuboids specified in the input `cuboid` that are outside the camera field of view are not included in the output. Each page, *P* of the output contains the [*x y*] locations for the eight vertices of a projected cuboid. The order of the vertices is `[1 2 3 4 5 6 7 8]`, where `[1 4 8 5]` and `[2 3 7 6]` define the front-facing and rear-facing rectangles, respectively, counterclockwise from the upper-right vertex.

`validIndex` — Index of projected cuboids

M-by-1 logical vector

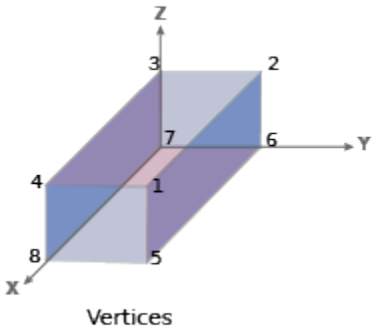
Index of projected cuboids, returned as an *M*-by-1 logical vector, where *M* is the number of input 3-D cuboids. A logical `1` value indicates a valid, corresponding projected cuboid in front of the camera, containing at least one vertex with positive coordinates. A logical `0` value indicates that the corresponding projected cuboid is invalid.



`allFaceVertices` — Face vertices

P-by-8-by-6 array

Face vertices, returned as a *P*-by-8-by-6 array, where *P* is the number of returned projected cuboids. Each page of the array contains the four vertices for the six faces of each of the returned projected cuboids. You can use this output to visualize specific faces of the cuboids. For example, to return the vertices of the fifth face of the third projected cuboid, specify:



```
allFaceVertices(3,:,5)
```

The order of the cuboid faces in the array is front-facing, rear-facing, right-facing, left-facing, top-facing, and bottom-facing.

Face

Face	Face vertices
1	[1 4 8 5]
2	[2 6 7 3]
3	[1 5 6 2]
4	[4 3 7 8]
5	[1 2 3 4]
6	[5 8 7 6]

Vertices

You can use the `allFaceVertices` output with the `showShape` or `insertShape` function to visualize the faces of the projected cuboids. For an example, see “Highlight One Face of -D Cuboid” on page 3-109.

generateCircleGridPoints

Generate circle grid point locations

Syntax

```
worldPoints = generateCircleGridPoints(patternDims,centerDistance)
worldPoints = generateCircleGridPoints( ___ ,Name=Value)
```

Description

`worldPoints = generateCircleGridPoints(patternDims,centerDistance)` generates circle grid point locations based on the specified number of circles in each dimension `patternDims` and the specified distance in world units between the centers of two adjacent circles `centerDistance`.

For more details on circle grid patterns, see “Circle Grid Patterns”.

`worldPoints = generateCircleGridPoints( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `PatternType="symmetric"` sets the pattern type to `"symmetric"`.

Examples

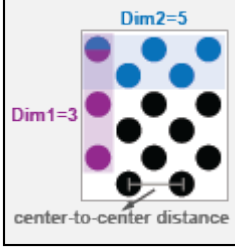
Generate Point Locations for Asymmetric Circle Grid

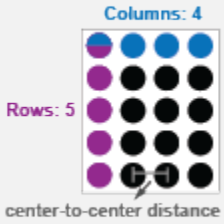
Specify the distance between the centers of adjacent circles, in millimeters (mm). By default, the function generates point locations for an asymmetric circle grid.

```
centerDistance = 9;
worldPoints = generateCircleGridPoints([4 11],centerDistance);
```

Generate Point Locations for Symmetric Circle Grid

Specify the distance between the centers, in millimeters (mm). Set the pattern type to `"symmetric"`.

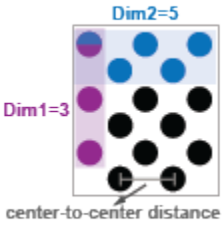




```
centerDistance = 19;
worldPoints = generateCircleGridPoints([8 11],centerDistance, ...
                                       PatternType="symmetric");
```

Input Arguments

`patternDims` — Pattern dimensions



1-by-2 vector

Pattern dimensions, specified as a 1-by-2 vector that represents the number of circles in each dimension. For the asymmetric pattern, Dimension 1 corresponds to the number of circles in each column. Dimension 2 corresponds to the total number of circles in the first two adjacent rows. For more details on circle grid patterns, see “Circle Grid Patterns”.

Asymmetric	Symmetric
	

`centerDistance` — Distance between centers of two adjacent circles
scalar

Distance between centers of two adjacent circles in the same row or column, specified as a scalar in world units, such as millimeters.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `PatternType="symmetry"` sets the pattern type to `"symmetry"`

`PatternType` — Type of circle grid pattern
`"asymmetric"` (default) | `"symmetric"`

Type of circle grid pattern for which the function generates point locations, specified as `"asymmetric"` or `"symmetric"`.

Output Arguments

`worldPoints` — Circle grid center locations
M-by-2 matrix

Circle grid center locations, returned as an *M*-by-2 matrix. Each row of the matrix specifies the *xy*-coordinates of a circle center relative to the origin. The origin (0,0) is the center of the top-left circle in the grid. *M* is the total number of circles in the grid,calculated as the product of the circle count in each dimension: `prod(patternDims)`.

pcfromdepth

Convert depth image to point cloud

Syntax

```
ptCloud = pcfromdepth(depthImage,depthScaleFactor,intrinsics)
ptCloud = pcfromdepth( ___ ,Name=Value)
```

Description

`ptCloud = pcfromdepth(depthImage,depthScaleFactor,intrinsics)` converts a depth image using camera intrinsics, into a point cloud. The output point cloud is specified in 3-D world coordinates with its origin centered at the camera. The `depthScaleFactor`, normally provided by the RGB-D camera manufacturer specifies a division factor for the depth image.

This function applies only for RGB-D cameras.

`ptCloud = pcfromdepth( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `pcfromdepth(depthImage,depthScaleFactor,intrinsics,DepthRange=[0,Inf])` sets the depth range to the 2-element vector value of `[0,Inf]`.

Examples

Create Point Cloud Representation of Image Points Using Depth Image

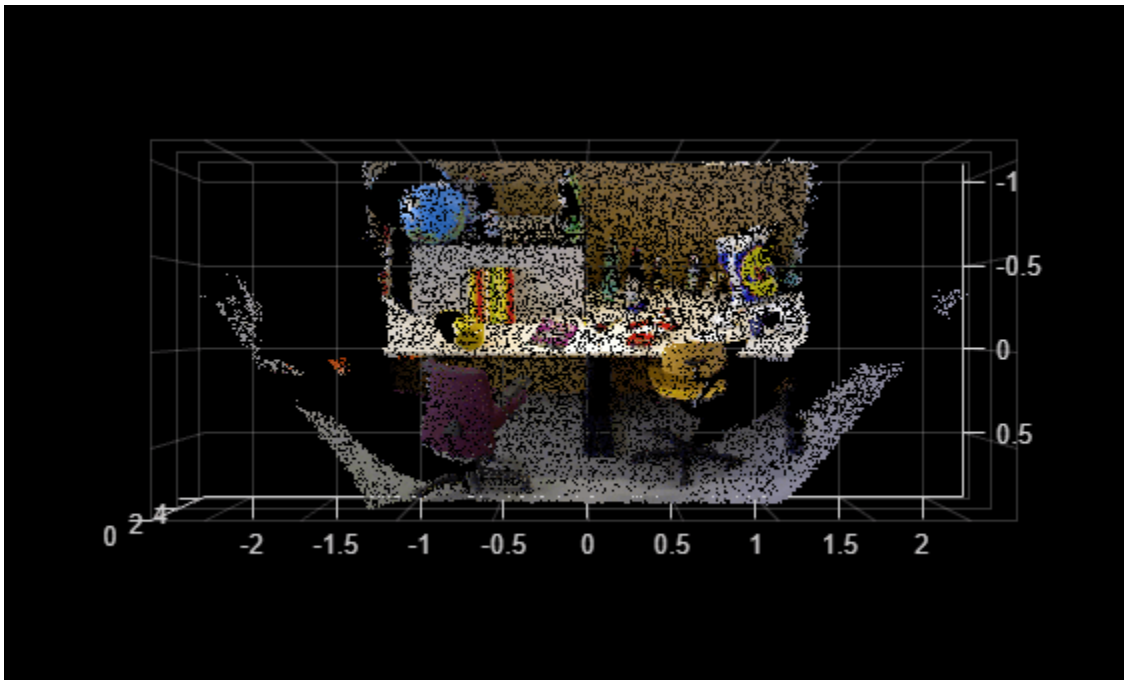
Read and display the depth image taken from an RGB-D camera.

```
depthImage = imread("sampleDepth.png");
imshow(depthImage)
```

Read and display the color image that corresponds to the depth image.

```
colorImage = imread("sampleImage.png");
imshow("sampleImage.png")
```

Create a `cameraIntrinsics` object to store the camera intrinsics parameters. The focal length, principal point, and image size are in units of pixels. The maximum camera depth is in meters.



```
focalLength      = [535.4, 539.2];
principalPoint   = [320.1, 247.6];
imageSize        = size(depthImage,[1,2]);
intrinsics       = cameraIntrinsics(focalLength,principalPoint,imageSize);
depthScaleFactor = 5e3;
maxCameraDepth   = 5;
```

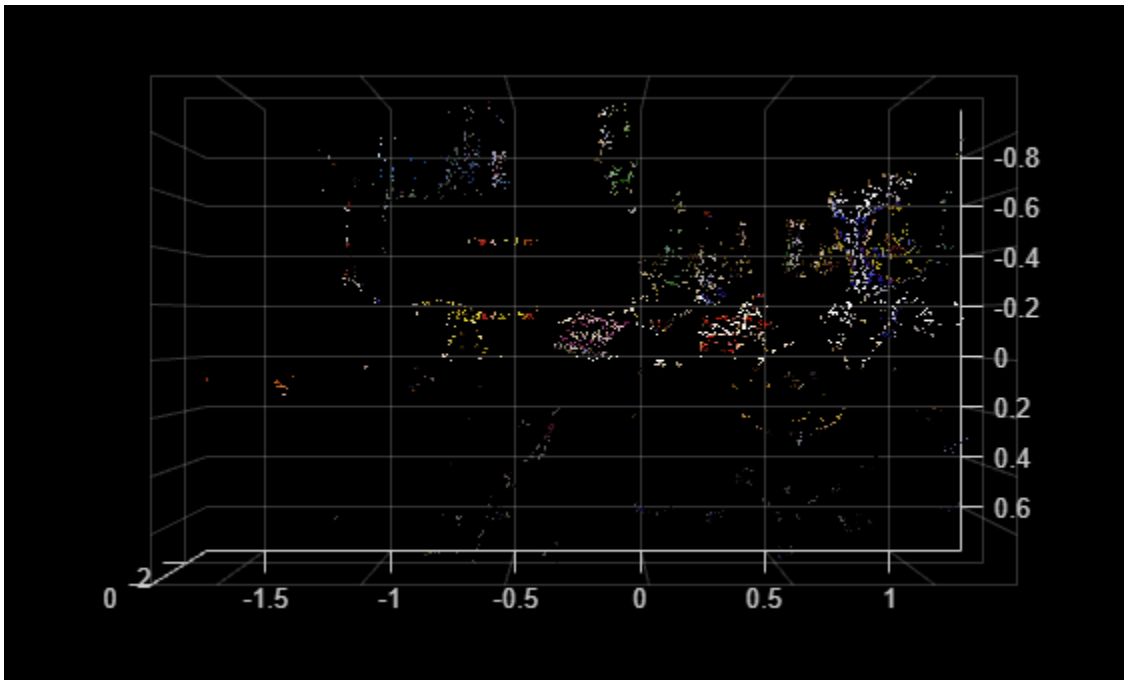
Convert depth map into world points, converting all points into point cloud.

```
ptCloud = pcfromdepth(depthImage,depthScaleFactor, intrinsics, ...
                      ColorImage=colorImage, ...
                      DepthRange=[0 maxCameraDepth]);
```

Display the resulting point cloud.

```
pcshow(ptCloud, VerticalAxis="Y", VerticalAxisDir="Up", ViewPlane="YX");
```

Detect and extract ORB features from the color image.



```
imagePoints = detectORBFeatures(im2gray(colorImage));
```

Convert depth map into world points, converting only feature points into point cloud.

```
ptCloud = pcfromdepth(depthImage,depthScaleFactor, intrinsics, ...
                      ColorImage=colorImage, ...
                      ImagePoints=imagePoints, ...
                      DepthRange=[0 maxCameraDepth]);
```

Display the resulting point cloud.

```
pcshow(ptCloud, VerticalAxis="Y", VerticalAxisDir="Up", ViewPlane="YX");
```

Input Arguments

`depthImage` — Depth image
M-by-*N* numeric matrix

Depth image, specified as an *M*-by-*N* numeric matrix. Input images must be undistorted.

`depthScaleFactor` — Depth correction factor
real scalar numeric

Depth correction factor, specified as a real scalar numeric type. This value is normally provided by the RGB-D camera manufacturer and specifies a division factor for the depth image input `depthImage`, which was taken with the camera. For example, for the world 3-D coordinates (*X*,*Y*,*Z*), where *Z* represents the depth, at any pixel coordinate (*u*,*v*), *Z* would be computed as:

```
Z = depthImage[u,v]/depthScaleFactor
```

`intrinsics` — Camera intrinsics
`cameraIntrinsics` object

Camera intrinsics, specified as a `cameraIntrinsics` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `pcfromdepth(depthImage,depthScaleFactor,intrinsics,DepthRange=[0,Inf])` sets the depth range to the 2-element vector value of `[0,Inf]`.

`ImagePoints` — Image points
`[]` (default) | *M*-by-2 matrix

Image points, specified as an *M*-by-2 matrix of [*x* *y*] coordinates, where *M* is the number of points, or by one of the feature point objects listed in “Point Feature Types”. Only points that are specified in the object are converted into a point cloud.

`ColorImage` — Color image
`[]` (default) | *M*-by-*N*-by-3 matrix

Color image, specified as an *M*-by-*N*-by-3 matrix of type numeric. The color image is associated with the depth image from the RGB-D camera.

`DepthRange` — Depth range of the RGB-D camera
`[0 inf]` (default) | 1-by-2 vector

Depth range of the RGB-D camera in world units, specified as a 1-by-2 vector. World units can be expressed as a measurement, such as meters. The range specifies the minimum and maximum depth range used to filter out invalid depth values after computing the point cloud.

`ROI` — Rectangular region of points to convert to a point cloud
`[1 1 size(depthImage,2) size(depthImage,1)]` (default) | [*x y width height*] vector

Rectangular region of points to convert to a point cloud, specified as [*x y width height*]. [*x y*] specifies the upper-left corner of the rectangular region of interest.

Output Arguments

`ptCloud` — Point cloud
`pointCloud` object

Point cloud created from depth image, returned as a `pointCloud` object. When you specify the `ImagePoints` name-value argument as an input, the function returns an unorganized point cloud. Otherwise, the function returns an organized point cloud.

detectCircleGridPoints

Detect circle grid pattern in images

Syntax

```
imagePoints = detectCircleGridPoints(I,patternDims)
[imagePoints,imagesUsed] = detectCircleGridPoints(imageFileNames,patternDims)
[___] = detectCircleGridPoints(images,patternDims)

[imagePoints,pairsUsed] = detectCircleGridPoints(imageFileNames1,
imageFileNames2,patternDims)
[___] = detectCircleGridPoints(images1,images2,patternDims)

[___] = detectCircleGridPoints(___,Name=Value)
```

Description

Single Image Circle Grid Detection

`imagePoints = detectCircleGridPoints(I,patternDims)` detects a circle grid in a 2-D truecolor or grayscale image, `I`. For more details on circle grid patterns, see “Circle Grid Patterns”.

`[imagePoints,imagesUsed] = detectCircleGridPoints(imageFileNames,patternDims)` detects a circle grid in the image files specified by `imageFileNames`, and additionally returns the list of images in which the circle grid is detected `imagesUsed`.

`[___] = detectCircleGridPoints(images,patternDims)` detects a circle grid in the specified images `images`.

Stereo Pair Circle Grid Detection

`[imagePoints,pairsUsed] = detectCircleGridPoints(imageFileNames1, imageFileNames2,patternDims)` detects a circle grid in the stereo pairs of image files specified by `imageFileNames1` and `imageFileNames2`. The function additionally returns a list of the pairs in which the pattern is detected `pairsUsed`.

`[___] = detectCircleGridPoints(images1,images2,patternDims)` detects a circle grid in the stereo pairs of image files specified by `images1` and `images2`.

Optional Arguments

`[___] = detectCircleGridPoints(___,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `detectCircleGridPoints(I,patternDims,PatternType="symmetric")` detects a symmetric circle grid in the specified workspace.

Examples

Detect Symmetric Circle Grid in Image

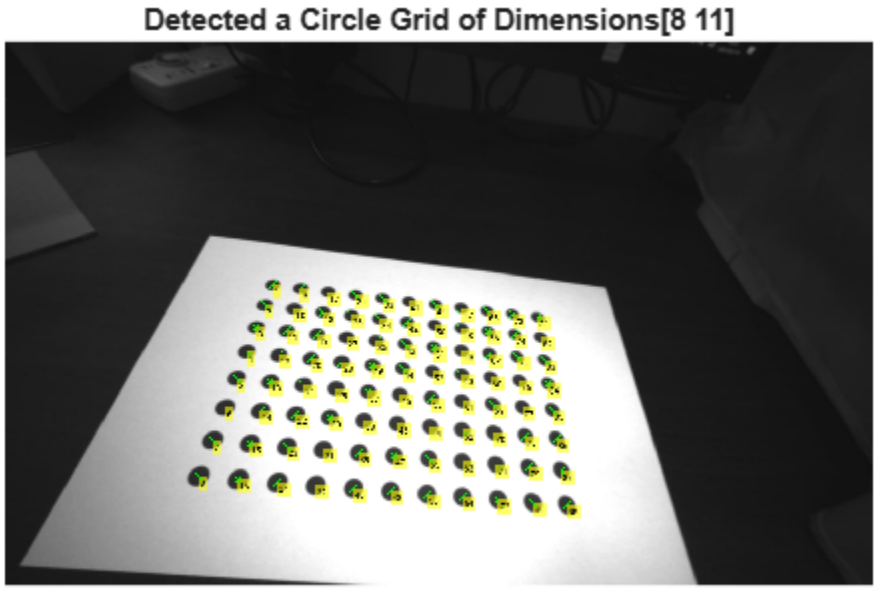
Load an image containing a circle grid pattern into the workspace.

```
imageFileName = fullfile(toolboxdir("vision"),"visiondata", ...
                "calibration","circleGrid","mono","image08.jpg");
I = imread(imageFileName);
```

Define the dimensions for the circle grid pattern.

```
patternDims = [8 11];
```

Detect the circle grid points.



```
imagePoints = detectCircleGridPoints(I,patternDims,PatternType="symmetric")
```

```
imagePoints = 88×2

  404.2823  461.8252
  391.4709  500.9889
  377.3850  543.9532
  361.7202  591.7051
      ⋮
```

Display the detected points on the image.

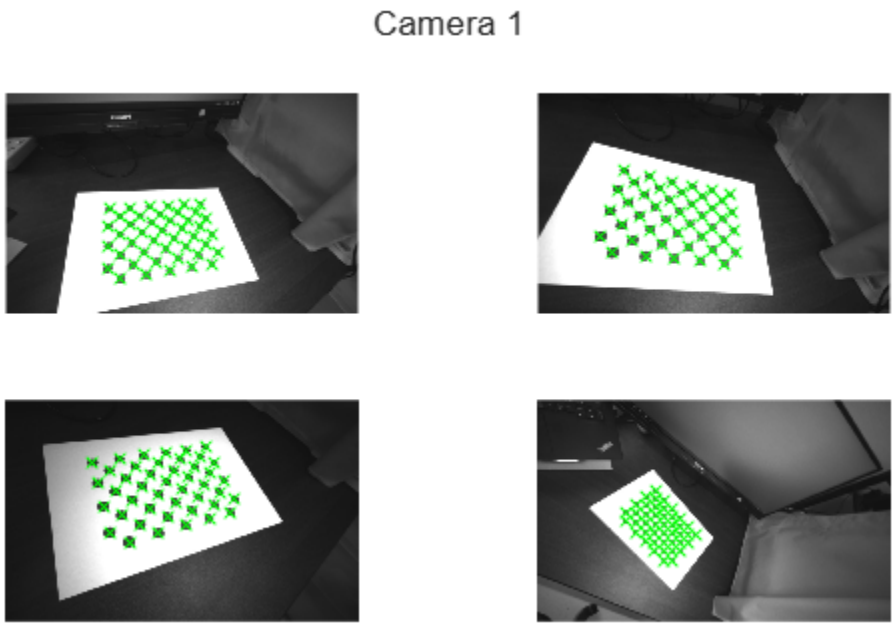
```
J = insertText(I,imagePoints,1:size(imagePoints,1));
J = insertMarker(J,imagePoints,"x",MarkerColor="green",Size=5);
imshow(J)
title("Detected a Circle Grid of Dimensions" + mat2str(patternDims))
```

Detect Asymmetric Circle Grid in Stereo Images

Specify your calibration images.

```
imageDir = fullfile(toolboxdir("vision"),"visiondata", ...
                            "calibration","circleGrid","stereo");
leftImages = imageDatastore(fullfile(imageDir,"left"));
rightImages = imageDatastore(fullfile(imageDir,"right"));
images1 = leftImages.Files;
images2 = rightImages.Files;
```

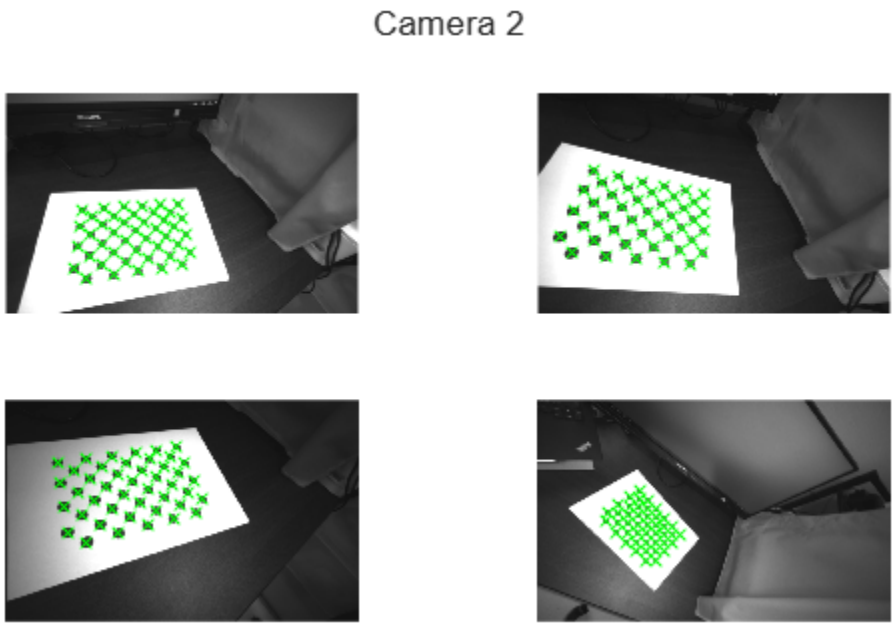
Define the dimensions for the circle grid pattern.



```
patternDims = [4 11];
```

Detect the circle grid points in the images.

```
[imagePoints,pairsUsed] = detectCircleGridPoints(images1,images2,patternDims);
```

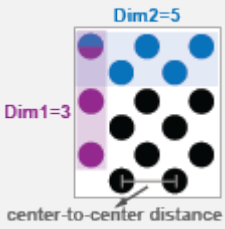


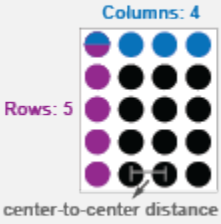
Display the points from the first four images of camera one.

```
figure
t1 = tiledlayout(2,2,TileSpacing="compact",Padding="compact");
for i = 1:4
  nexttile
  imshow(images1{i})
  hold on
  plot(imagePoints(:,1,i,1),imagePoints(:,2,i,1),"gx");
end
title(t1,"Camera 1")
```

Display points from the first four images from camera two.

```
images2 = images2(pairsUsed);
figure
t2 = tiledlayout(2,2,TileSpacing="compact",Padding="compact");
for i = 1:4
  nexttile
  imshow(images2{i})
  hold on
  plot(imagePoints(:,1,i,2),imagePoints(:,2,i,2),"gx");
end
title(t2,"Camera 2")
```





Input Arguments

`patternDims` — Pattern dimensions

two-element vector

Pattern dimensions, specified as a two-element vector [*nx ny*], where *nx* is the number of circles along the *x*-axis and *ny* is the number along the *y*-axis in the image.

Asymmetric	Symmetric
	

`I` — Image

2-D truecolor image | grayscale image

Image, specified as a 2-D truecolor image or grayscale image.

Data Types: `uint8` | `int16` | `uint16` | `single` | `double`

`images` — Images

H-by-*W*-by-*numColorChannels*-by-*numImages* array

Images, specified as an *H*-by-*W*-by-*numColorChannels*-by-*numImages* array, where *H* and *W* describe the height and width of each image, respectively. *numColorChannels* is the number of color channels in each image, and *numImages* is the number of images.

Data Types: `uint8` | `int16` | `uint16` | `single` | `double`

`images1` — Stereo pair images from camera one
H-by-*W*-by-*numColorChannels*-by-*numImages* array

Stereo pair images from camera one, specified as an *H*-by-*W*-by-*numColorChannels*-by-*numImages* array, where *H* and *W* describe the height and width of each image, respectively. *numColorChannels* is the number of color channels in each image, and *numImages* is the number of images

Data Types: `uint8` | `int16` | `uint16` | `single` | `double`

`images2` — Stereo pair images from camera two
H-by-*W*-by-*numColorChannels*-by-*numImages* array

Stereo pair images from camera two, specified as an *H*-by-*W*-by-*numColorChannels*-by-*numImages* array, where *H* and *W* describe the height and width of each image, respectively. *numColorChannels* is the number of color channels in each image, and *numImages* is the number of images

Data Types: `uint8` | `int16` | `uint16` | `single` | `double`

`imageFileNames` — Image file names
cell array of character vectors | array of strings

Image file names, specified as a cell array of character vectors or an array of strings.

`imageFileNames1` — Stereo image file names for camera one
cell array of character vectors | array of strings

Stereo image file names for camera one, specified as a cell array of character vectors or an array of strings.

`imageFileNames2` — Stereo image file names for camera two
cell array of character vectors | array of strings

Stereo image file names for camera two, specified as a cell array of character vectors or an array of strings.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `detectCircleGridPoints(I,patternDims,PatternType="symmetric")` detects a symmetric circle grid in the specified workspace.

`PatternType` — Circle grid pattern type
`"asymmetric"` (default) | `"symmetric"`

Circle grid pattern type, specified as `"asymmetric"` or `"symmetric"`.

`circleColor` — Circle color
`"black"` (default) | `"white"`

Circle color, specified as `"black"` or `"white"`. Choose the color for the circle that has the strongest contrast with the background.

Output Arguments

`imagePoints` — Center coordinates of detected circle grid

M-by-2 matrix | *M*-by-2-by- *numPairs*-by-2 array

Center coordinates of detected circle grid, returned as an *M*-by-2 matrix or an *M*-by-2-by-*numPairs*-by-2 array. *M* is the number of circle grids detected, calculated as the product of the number of circle grids detected in each dimension. Each row of the matrix or array specifies the *x*-*y* coordinates of the center of a circle grid.

- For single images — This argument is an *M*-by-2 matrix when detecting circle grids in single images.
- For stereo pairs — This argument is an *M*-by-2-by-*numPairs*-by-2 array when detecting circle grids in stereo pairs of images. *numPairs* is the number of image pairs in which a circle grid is detected. `imagePoints(:,:,:,1)` returns the points from the first set of images, and `imagePoints(:,:,:,2)` are the points from the second set.

`imagesUsed` — Pattern detection flag

logical vector

Pattern detection flag, returned as a logical vector. A value of `true` in the `imagesUsed` vector indicates that the pattern has been detected in the corresponding image.

`pairsUsed` — Stereo pair pattern detection flag

logical vector

Stereo pair pattern detection flag, returned as a logical vector. A value of `true` in the `pairsUsed` vector indicates that the pattern has been detected in the corresponding image pair.

Algorithms

For a circle grid pattern to be detected, the pattern must:

- Contain at least 16 circles
- Be fully visible in the image of a single camera or in both images of a pair of stereo cameras
- Each circle in the pattern must have a minimum diameter of 50 pixels for successful detection.

For additional details on circle grid patterns, see “Circle Grid Patterns”.

Version History

Introduced in R2021b

Extended Capabilities

Thread-Based Environment

Run code in the background using MATLAB® `backgroundPool` or accelerate code with Parallel Computing Toolbox™ `ThreadPool`.

The `detectCircleGridPoints` function fully supports thread-based environments. For more information, see “Run MATLAB Functions in Thread-Based Environment”.

writeVideoScenes

Write video sequence to video file

Syntax

```
filenames = writeVideoScenes(gTruth,timeRanges,folderNames)
filenames = writeVideoScenes(gTruth,timeRanges,rootFolder,folderNames)
filenames = writeVideoScenes( ___ ,Name=Value)
```

Description

`filenames = writeVideoScenes(gTruth,timeRanges,folderNames)` writes sequences of ground truth data to separate files, `filenames`, that correspond to time ranges, `timeRanges`. Video files are written to the folders specified by the `folderNames` input.

The function writes video scenes using the image data and corresponding timestamp data contained in the specified `groundTruth` objects. All nonimage data, such as lidar, is ignored.

`filenames = writeVideoScenes(gTruth,timeRanges,rootFolder,folderNames)` also specifies the root folder name to prepend to each of the folder names.

`filenames = writeVideoScenes( ___ ,Name=Value)` specifies options using name-value arguments, in addition to any combination of input arguments from previous syntaxes. For example, `writeVideoScenes(gTruth,timeRanges,folderNames,Verbose=true)` displays progress information while writing video scenes to files.

Examples

Gather Scene Label Information and Write Video Scenes to Files

Load ground truth scene label definitions and label data into the workspace.

```
data = load("groundTruthSceneLabels.mat");
labelDefinitions = data.labelDefinitions;
labelData = data.labelData;
```

Create a ground truth data source using a video file.

```
gSource = groundTruthDataSource("viptrain.avi");
```

Create a ground truth object using the ground truth data source.

```
gTruth = groundTruth(gSource,labelDefinitions,labelData);
```

Gather all the scene time ranges and the scene labels.

```
[timeRanges,sceneLabels] = sceneTimeRanges(gTruth);
```

Select a folder in the temp directory to write the video scenes to.

```
rootFolder = fullfile(tempdir,"videoScenes");
```

Use the scene label names as folder names.

```
folderNames = sceneLabels;
```

Write the video scenes to the "`videoScenes`" folder. Specify the subfolder names for each duration as the scene label names.

```
filenames = writeVideoScenes(gTruth,timeRanges,rootFolder,folderNames);
```

```
[==================================================] 100%
Elapsed time: 00:00:02
Estimated time remaining: 00:00:00
```

Input Arguments

`gTruth` — Ground truth

vector of `groundTruth` objects | vector of `groundTruthMultisignal` objects

Ground truth, specified as a vector of `groundTruth` objects or `groundTruthMultisignal` objects.

`timeRanges` — Time ranges of ground truth source data

M-by-1 cell array | *M*-by-*N* cell array

Time ranges of ground truth source data, specified as an *M*-by-1 cell array for a `groundTruth` object or an *M*-by-*N* cell array for a `groundTruthMultisignal` object. *M* is the number of elements in `gTruth` and *N* represents the number of signals per element. Each cell of the array contains a *T*-by-2 duration matrix, where *T* is the number of time ranges in the corresponding element of `gTruth`. Each row of the matrix corresponds to a time range in the ground truth data for which a scene label has been applied, specified in the form [*rangeStart rangeEnd*].

`folderNames` — Folder names

M-1 cell array | *M*-by-*N* cell array

Folder names for the video scenes, specified as an *M*-by-1 cell array for a `groundTruth` object or an *M*-by-*N* cell array for a `groundTruthMultisignal` object. Each cell in the cell array corresponds to an element of `gTruth`, and contains a *T*-by-1 vector of strings or categorical vector that specifies the paths to the folders for the corresponding time ranges.

You must specify each folder name must be specified as a full path or as a relative path from the current folder. When you specify a folder name that does not exist, the function creates a new folder with the specified name. When writing video scene files, the function overwrites files with the same name that already exists in the specified folder. For example, if you call the `writeVideoScenes` function twice with the same input arguments, the files output by the second function call overwrite those from the first.

To select and write specific signals in a `groundTruthMultisignal` object to a specified location, use the `selectLabelsBySignalName` function before calling the `writeVideoScene` function.

`rootFolder` — Root folder name

character vector | string scalar

Root folder name to prepend to each of the folder names, specified as a character vector or a string scalar.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `writeVideoScenes(gTruth,timeRanges,folderNames,Verbose=true)` displays progress information while writing video scenes to files.

`NamePrefix` — File name prefix

array of strings | cell array of character vectors

File name prefix, specified as an array of strings or a cell array of character vectors. Default values depend on the `gTruth` input type:

- `groundTruth` object — The function uses the file names (without their extension) in the `DataSource` property of the `groundTruth` object.
- `groundTruthMultisignal` object — The function uses the input signal names.

`VideoProfile` — Video profile

`"Motion JPEG AVI"` (default) | `"Archival"` | `"Motion JPEG 2000"` | `"MPEG-4"` | `"Uncompressed AVI"` | `"Indexed AVI"` | `"Grayscale AVI"`

Video profile for writing video scenes, specified as one of the video profiles listed in the table. The `VideoProfile` argument usage is the same as the `profile` argument of the `VideoWriter` object.

Value of `VideoProfile`	Description
`"Archival"`	Motion JPEG 2000 file with lossless compression
`"Motion JPEG AVI"`	AVI file using Motion JPEG encoding
`"Motion JPEG 2000"`	Motion JPEG 2000 file
`'MPEG-4'`	MPEG-4 file with H.264 encoding (systems with Windows 7 or later, or macOS 10.7 and later)
`'Uncompressed AVI'`	Uncompressed AVI file with `RGB24` video
`'Indexed AVI'`	Uncompressed AVI file with indexed video
`'Grayscale AVI'`	Uncompressed AVI file with grayscale video

`Verbose` — Display progress on screen

`true` or `1` (default) | `false` or `0`

Display progress on screen, specified as a logical `1`(`true`) or `0`(`false`).

Output Arguments

`filenames` — Full path file names

M-by-1 cell array

Full path file names to the saved video scenes, returned as an *M*-by-1 cell array of *T*-by-1 vector of strings. *M* is the number of elements in the `gTruth` input argument. *T* is the number of time ranges in the corresponding element of `gTruth`. Each element of the vector of strings specifies the full path to the saved video scene for the corresponding time range.

The function sets the output file names as `NamePrefix_`*UID*`.`*EXT*, where *UID* is a unique integer index for each written scene and *EXT* is the video file extension determined by the `VideoProfile` argument.

Version History

Introduced in R2021b

Objects

`groundTruthMultisignal` | `groundTruthDataSource` | `groundTruth`

Functions

`selectLabelsBySignalName` | `gatherLabelData` | `objectDetectorTrainingData` | `pixelLabelTrainingData` | `sceneTimeRanges`

sceneTimeRanges

Time ranges of scene labels from ground truth data

Syntax

```
timeRanges = sceneTimeRanges(gTruth)
[timeRanges,sceneLabels] = sceneTimeRanges(gTruth)
```

Description

`timeRanges = sceneTimeRanges(gTruth)` returns the time ranges that define the start and end times for the scene labels applied to the ground truth data sources in `gTruth`.

`[timeRanges,sceneLabels] = sceneTimeRanges(gTruth)` also returns the scene labels that correspond to the time ranges.

Examples

Gather Scene Time Ranges and Scene Labels

Load ground truth scene label definitions and label data into the workspace.

```
data = load("groundTruthSceneLabels.mat");
labelDefinitions = data.labelDefinitions;
labelData = data.labelData;
```

Create a ground truth data source using a video file.

```
gSource = groundTruthDataSource("viptrain.avi");
```

Create a ground truth object using the ground truth data source.

```
gTruth = groundTruth(gSource,labelDefinitions,labelData);
```

Gather all the scene time ranges and the scene labels.

```
[timeRanges,sceneLabels] = sceneTimeRanges(gTruth);
```

Display the scene time ranges for the ground truth data.

```
timeRanges{1}
```

```
ans = 3×2 duration
        0 sec   8.0333 sec
      8.3 sec   10.033 sec
       12 sec   16.333 sec
```

Display the corresponding scene labels for the ground truth data.

```
sceneLabels{1}
```

```
ans = 3×1 categorical
     walking
     sitting
     trainMoving
```

Input Arguments

`gTruth` — Ground truth

vector of `groundTruth` objects | vector of `groundTruthMultisignal` objects

Ground truth, specified as a vector of `groundTruth` objects or `groundTruthMultisignal` objects.

Output Arguments

`timeRanges` — Time ranges of ground truth source data

M-by-1 cell array

Time ranges of the ground truth source data, returned as an *M*-by-1 cell array. *M* is the number of elements in `gTruth`. Each of the cell array contains a *T*-by-2 duration matrix. *T* is the number of time ranges in the corresponding element of `gTruth`. Each row of the matrices corresponds to a time range in the ground truth data for which a scene label has been applied, specified in the form [*rangeStart rangeEnd*].

To select and obtain scene time ranges for specific signals in a `groundTruthMultisignal` object, use the `selectLabelsBySignalName` function before calling the `sceneTimeRanges` function.

`sceneLabels` — Scene labels for each time range

M-by-1 cell array of categorical vectors

Scene labels for each time range, returned as an *M*-by-1 cell array of *T*-by-2 categorical vectors. *M* is the number of elements in `gTruth`. *T* is the number of time ranges in each corresponding ground truth data source.

Functions

`selectLabelsBySignalName` | `gatherLabelData` | `objectDetectorTrainingData` | `pixelLabelTrainingData` | `writeVideoScenes`

stereoParametersFromOpenCV

Convert stereo camera parameters from OpenCV to MATLAB

Syntax

```
stereoParams = stereoParametersFromOpenCV(intrinsicMatrix1,
distortionCoefficients1,intrinsicMatrix2,distortionCoefficients2,
rotationOfCamera2,translationOfCamera2,imageSize)
stereoParams = stereoParametersFromOpenCV( ___ ,WorldUnits=worldUnits)
```

Description

`stereoParams = stereoParametersFromOpenCV(intrinsicMatrix1, distortionCoefficients1,intrinsicMatrix2,distortionCoefficients2, rotationOfCamera2,translationOfCamera2,imageSize)` converts the OpenCV stereo parameters, specified by the input arguments, into a MATLAB `stereoParameters` object `stereoParams`.

The OpenCV spatial coordinate system specifies the upper-left pixel center at (`0,0`), whereas the MATLAB spatial coordinate system specifies the pixel center at (`1,1`). The `stereoParametersFromOpenCV` function compensates for this difference by adding 1 to both of the *x* and *y*-values for the converted principal point.

OpenCV stereo parameters cannot be converted to a MATLAB `stereoParameters` object when an OpenCV fisheye model is used. In this case, you can recalibrate the stereo camera using the Stereo Camera Calibrator app.

`stereoParams = stereoParametersFromOpenCV( ___ ,WorldUnits=worldUnits)` specifies a string `worldUnits`, that describes the units of the world points in addition to the input arguments from the previous syntax. Specify worldUnits as a character vector or string scalar. For example, `stereoParametersFromOpenCV( ___ ,WorldUnits="mm")` describes all parameters in terms of the world units "mm".

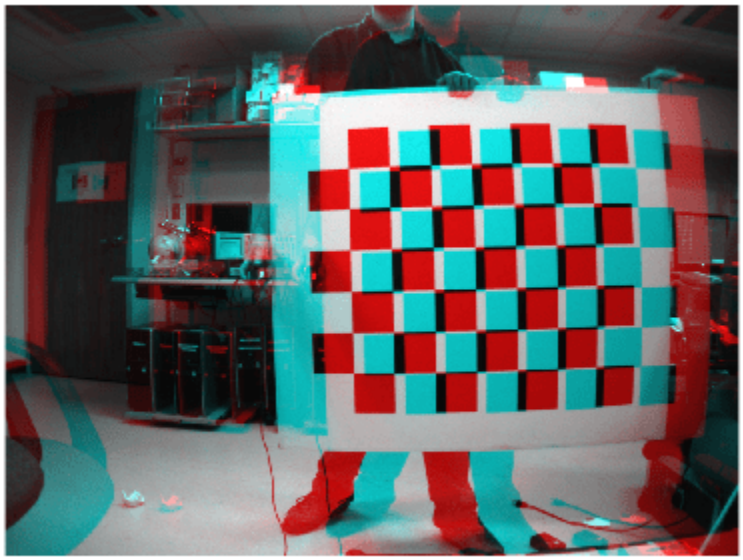
Examples

Rectify Stereo Images in MATLAB Using Stereo Parameters from OpenCV

Load OpenCV stereo parameters from a MAT file into the workspace.

```
load openCVStereoParameters.mat
```

Convert the loaded stereo parameters from OpenCV to MATLAB format.



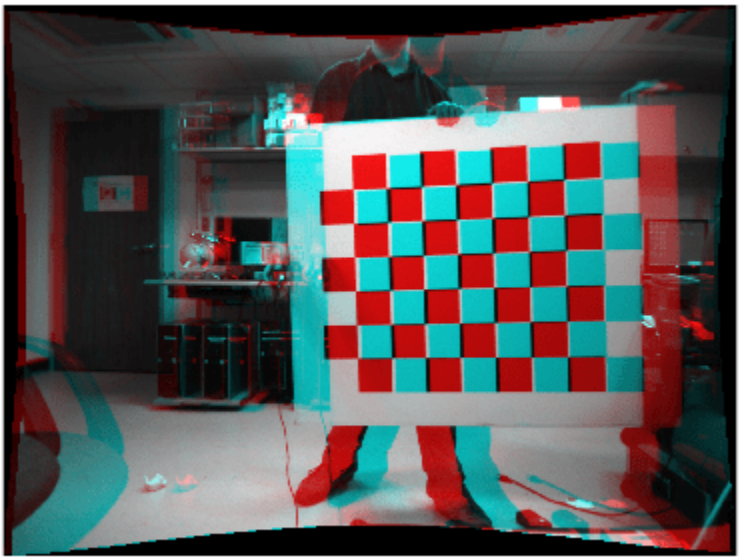
```
stereoParams = stereoParametersFromOpenCV(intrinsicMatrix1, ...
    distortionCoefficients1,intrinsicMatrix2,distortionCoefficients2, ...
    rotationOfCamera2,translationOfCamera2,imageSize);
```

Load the images to rectify.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata','calibration','stereo');
I1 = imread(fullfile(imageDir,'left','left01.png'));
I2 = imread(fullfile(imageDir,'right','right01.png'));
```

Display the unrectified images.

```
imshow(stereoAnaglyph(I1,I2));
```



Rectify the images using the full output view.

```
[J1,J2] = rectifyStereoImages(I1,I2,stereoParams,OutputView='full');
```

Display the resulting rectified images.

```
imshow(stereoAnaglyph(J1,J2));
```

Import Stereo Camera Parameters from ROS

The ROS camera calibration package estimates stereo camera parameters using the OpenCV camera calibration tools [1]. After calibrating a stereo camera in ROS, you can export its camera parameters to an INI file using the camera calibration parser. To use the calibrated stereo camera with Computer Vision Toolbox™ functions, such as `rectifyStereoImages`, you must read the camera parameters from the INI file and convert them into a `stereoParameters` object using `stereoParametersFromOpenCV`.

Note: The `stereoParametersFromOpenCV` function supports importing stereo camera parameters for only those pinhole camera models that use the `ROS plumb-bob` distortion model.

Read Stereo Camera Parameters from ROS INI File

Read the stereo camera parameters stored in stereo`Params.ini` using the helper function `helperReadINI`.

```
stereoParamsINI = helperReadINI("stereoParams.ini");
```

Compute Baseline Parameters of Stereo Camera

The baseline parameters of a stereo camera describe the relative translation and rotation of the two cameras in the stereo camera pair. The relative rotation and translation of camera 2 with respect to camera 1 is required to create the `stereoParameters` object using `stereoParametersFromOpenCV`. You can compute these from the rectification and projection matrices read from the ROS INI file [2].

Extract the two camera parameters from the `stereoParams` structure.

```
cameraParams1 = stereoParamsINI.narrow_stereo_left;
cameraParams2 = stereoParamsINI.narrow_stereo_right;
```

Extract the translation of camera 2 relative to camera 1 from the last column of the projection matrix.

```
translationOfCamera2 = cameraParams2.projection(:,end);
```

The rotation of camera 2 relative to camera 1, R_{21}, is derived from the rectification matrices of the stereo pair R_1 and R_2. The rectification matrices are the rotation matrices that align the camera coordinate system to the ideal stereo image plane such that epipolar lines in both stereo images are parallel. Compute the rotation of camera 2 relative to camera 1 as $R_{21} = R_2 * R_1^T$.

```
rotationOfCamera2 = cameraParams2.rectification*cameraParams1.rectification';
```

Create `stereoParameters` Object Using `stereoParametersFromOpenCV`

Extract the intrinsic matrices and distortion coefficients of the two cameras from the `stereoParams` structure.

```
intrinsicMatrix1 = cameraParams1.camera_matrix;
intrinsicMatrix2 = cameraParams2.camera_matrix;

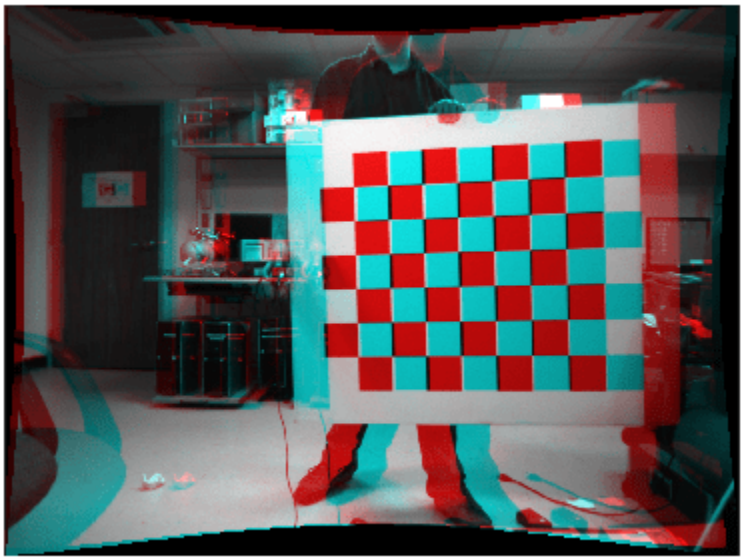
distortionCoefficients1 = cameraParams1.distortion;
distortionCoefficients2 = cameraParams2.distortion;
```

Obtain the image size from the `image` field of the `stereoParams` structure.

```
imageSize = [stereoParamsINI.image.height stereoParamsINI.image.width];
```

Use `stereoParametersFromOpenCV` to create a `stereoParameters` object from the ROS stereo camera parameters.

```
stereoParametersObj = stereoParametersFromOpenCV(intrinsicMatrix1, ...
    distortionCoefficients1,intrinsicMatrix2,distortionCoefficients2, ...
    rotationOfCamera2,translationOfCamera2,imageSize);
```



Rectify Pair of Stereo Images

Use the imported stereo parameters with `rectifyStereoImages` to rectify an image pair captured using the calibrated stereo camera.

```
% Load the image pair.
imageDir = fullfile(toolboxdir("vision"),"visiondata","calibration","stereo");
leftImages = imageDatastore(fullfile(imageDir,"left"));
rightImages = imageDatastore(fullfile(imageDir,"right"));
I1 = readimage(leftImages,1);
I2 = readimage(rightImages,1);

% Rectify the image pair.
[J1,J2] = rectifyStereoImages(I1,I2,stereoParametersObj,OutputView="full");

% Display the results.
figure
J = stereoAnaglyph(J1,J2);
imshow(J)
```

Supporting Functions

helperReadINI

The `helperReadINI` function reads the camera parameters from its input INI file that has been exported from ROS.

```
function cameraParams = helperReadINI(filename)
% helperReadINI reads a ROS INI file, filename, and returns a structure with
% these fields: image, <camera_name1>, <camera_name2>. image is a
% structure describing the height and width of the image captured by the
% cameras of the stereo pair. The fields <camera_name1> and <camera_name2>
% are structures named after the camera names present in the INI file, and they contain
% these fields: camera_matrix, distortion, rectification_matrix,
% and projection_matrix. These fields are stored in the INI file with their
% values placed in a new line followed by their name.

    f = fopen(filename,"r");
    sectionName = '';

    while ~feof(f)
        % Read line from file.
        line = fgetl(f);

        % Trim leading and trailing whitespaces.
        line = strtrim(line);

        if isempty(line) || line(1)=='#'
            % Skip empty line and comments.
            continue
        elseif line(1) == '[' && line(end) == ']'
            % Identify section names and continue reading.
            sectionName = line(2:end-1);
```

```
            sectionName = strrep(sectionName,'/','_');
            continue
        end

        % Replace blankspaces with underscores to create valid MATLAB variable
        % name.
        name = line;
        name(name == ' ') = '_';

        % Read the value data in upcoming lines.
        value = [];
        while ~feof(f)
            line = fgetl(f);
            line = strtrim(line);

            if isempty(line)
                % A empty line indicates end of value data.
                break
            elseif line(1)=='#'
                % Skip comment lines.
                continue
            end
            line = str2num(line); %#ok
            value = [value; line]; %#ok
        end

        % Store post-processed value.
        if isempty(sectionName)
            cameraParams.(name) = value;
        else
            cameraParams.(sectionName).(name) = value;
        end
    end

    fclose(f);
end
```

Input Arguments

`intrinsicMatrix1` — Intrinsics matrix of camera 1

3-by-3 matrix

Intrinsics matrix of camera 1 from OpenCV, specified as a 3-by-3 matrix of the form:

$$\begin{bmatrix} fx & 0 & cx \\ 0 & fy & cy \\ 0 & 0 & 1 \end{bmatrix}$$

where *fx* and *fy* are the focal lengths in the *x* and *y*-directions, and *cx*,*cy*) is the principal point in specified in OpenCV.

`intrinsicMatrix2` — Intrinsics matrix of camera 2
3-by-3 matrix

Intrinsics matrix of camera 2 from OpenCV, specified as a 3-by-3 matrix of the form:

$$\begin{bmatrix} fx & 0 & cx \\ 0 & fy & cy \\ 0 & 0 & 1 \end{bmatrix}$$

where *fx* and *fy* are the focal lengths in the *x* and *y*-directions, and *cx*,*cy* is the principal point in specified in OpenCV.

`distortionCoefficients1` — Camera 1 radial and tangential distortion coefficients
5-element vector | 8-element vector

Camera 1 radial and tangential distortion coefficients, returned as a 5- or 8-element vector.

- 5-element vector — Of the form [*k1 k2 p1 p2 k3*]
- 8-element vector — Of the form [*k1 k2 p1 p2 k3 k4 k5 k6*].

  The values of *k1*, *k2*, ..., *k6* describe the radial distortion and *p1* and *p2* describe the tangential distortion, specified in OpenCV.

`distortionCoefficients2` — Camera 2 radial and tangential distortion coefficients
5-element vector | 8-element vector

Camera 2 radial and tangential distortion coefficients, returned as a 5- or 8-element vector.

- 5-element vector — Of the form [*k1 k2 p1 p2 k3*]
- 8-element vector — Of the form [*k1 k2 p1 p2 k3 k4 k5 k6*].

  The values of *k1*, *k2*, ..., *k6* describe the radial distortion and *p1* and *p2* describe the tangential distortion, specified in OpenCV.

`rotationOfCamera2` — Rotation of camera 2 relative to camera 1
3-by-3 matrix

Rotation of camera 2 relative to camera 1 from OpenCV, specified as a 3-by-3 matrix.

`translationOfCamera2` — Translation of camera 2 relative to camera 1
three-element vector

Translation of camera 2 relative to camera 1 from OpenCV, specified as a three-element vector.

`imageSize` — Image size
two-element vector

Image size, specified as a two-element vector in the form [*mrows*,*ncols*].

Output Arguments

`stereoParams` — Stereo parameters
`stereoParameters` object

Stereo parameters, returned as a `stereoParameters` object. The object contains OpenCV intrinsics for a pinhole camera model. In cases where the OpenCV pinhole model uses more than eight distortion coefficients, which cannot be converted to a `cameraIntrinsics` object, you can recalibrate your camera using the Stereo Camera Calibrator app as an alternative solution.

Version History

Introduced in R2021b

R2024b: Import OpenCV pinhole camera model with six radial distortion coefficients

The `stereoParametersFromOpenCV` has been updated to support OpenCV pinhole camera model with 6 radial distortion coefficients.

Apps
Stereo Camera Calibrator | Camera Calibrator

Objects
`cameraParameters` | `stereoParameters`

Functions
`undistortImage` | `stereoAnaglyph` | `stereoParametersToOpenCV` | `cameraIntrinsicsFromOpenCV` | `cameraIntrinsicsToOpenCV`

stereoParametersToOpenCV

Convert stereo camera parameters from MATLAB to OpenCV

Syntax

```
[intrinsicMatrix1,distortionCoefficients1,intrinsicMatrix2,
distortionCoefficients2,rotationOfCamera2,translationOfCamera2,imageSize] =
stereoParametersToOpenCV(stereoParams)
```

Description

`[intrinsicMatrix1,distortionCoefficients1,intrinsicMatrix2,
distortionCoefficients2,rotationOfCamera2,translationOfCamera2,imageSize] =
stereoParametersToOpenCV(stereoParams)` converts a MATLAB `stereoParameters` object `stereoParams` to OpenCV stereo parameters.

The OpenCV spatial coordinate system specifies the upper-left pixel center at `(0,0)`, whereas the MATLAB spatial coordinate system specifies the pixel center at `(1,1)`. The `stereoParametersToOpenCV` function compensates for this difference by subtracting 1 to both of the *x* and *y*-values for the converted principal point.

OpenCV stereo parameters do not include the skew of a pinhole camera model. Therefore, only the intrinsics estimated without the skew can be exported to OpenCV.

Examples

Calibrate Stereo Camera and Convert Parameters to OpenCV Format

Specify the calibration images.

```
leftImages = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
   "calibration","stereo","left"));
rightImages = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
   "calibration","stereo","right"));
```

Detect the checkerboards in the image pairs.

```
[imagePoints,patternDims] = detectCheckerboardPoints(leftImages.Files,rightImages.Files);
```

Specify the world coordinates of the checkerboard keypoints in millimeters.

```
squareSize = 108; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Calibrate the stereo camera system. Both cameras have the same resolution.

```
I = readimage(leftImages,1);
imageSize = size(I,1:2);
stereoParams = estimateCameraParameters(imagePoints,worldPoints, ...
   ImageSize=imageSize);
```

Convert the MATLAB® stereo parameters object to the OpenCV format.

```
[intrinsicMatrix1,distortionCoefficients1,intrinsicMatrix2, ...
   distortionCoefficients2,rotationOfCamera2,translationOfCamera2] =...
   stereoParametersToOpenCV(stereoParams);
```

Input Arguments

`stereoParams` — Stereo parameters

`stereoParameters` object

Stereo parameters, specified as a `stereoParameters` object.

Output Arguments

`intrinsicMatrix1` — Intrinsics matrix of camera 1

3-by-3 matrix

Intrinsics matrix of camera 1 formatted for OpenCV, returned as a 3-by-3 matrix of the form:

$$\begin{bmatrix} fx & 0 & cx \\ 0 & fy & cy \\ 0 & 0 & 1 \end{bmatrix}$$

where *fx* and *fy* are the focal lengths in the *x* and *y*-directions, and (*cx*,*cy*) is the principal point in specified in the OpenCV input.

`intrinsicMatrix2` — Intrinsics matrix of camera 2

3-by-3 matrix

Intrinsics matrix of camera 2 formatted for OpenCV, returned as a 3-by-3 matrix of the form:

$$\begin{bmatrix} fx & 0 & cx \\ 0 & fy & cy \\ 0 & 0 & 1 \end{bmatrix}$$

where *fx* and *fy* are the focal lengths in the *x* and *y*-directions, and (*cx*,*cy*) is the principal point in specified in the OpenCV input.

`distortionCoefficients1` — Camera 1 radial and tangential distortion coefficients

five-element vector

Camera 1 radial and tangential distortion coefficients, returned as a five-element vector in the form [*k1 k2 p1 p2 k3*]. The values of *k1*, *k2*, and *k3* describe the radial distortion and *p1* and *p2* describe the tangential distortion, specified in OpenCV.

`distortionCoefficients2` — Camera 2 radial and tangential distortion coefficients

five-element vector

Camera 2 radial and tangential distortion coefficients, returned as a five-element vector in the form [*k1 k2 p1 p2 k3*]. The values of *k1*, *k2*, and *k3* describe the radial distortion and *p1* and *p2* describe the tangential distortion, specified in OpenCV.

`rotationOfCamera2` — Rotation of camera 2 relative to camera 1
3-by-3 matrix

Rotation of camera 2 relative to camera 1 from OpenCV, specified as a 3-by-3 matrix.

`translationOfCamera2` — Translation of camera 2 relative to camera 1
three-element vector

Translation of camera 2 relative to camera 1 from OpenCV, specified as a three-element vector.

`imageSize` — Image size
two-element vector

Image size, specified as a two-element vector in the form [*mrows*,*ncols*].

cameraIntrinsicsFromOpenCV

Convert camera intrinsic parameters from OpenCV to MATLAB

Syntax

```
intrinsics = cameraIntrinsicsFromOpenCV(intrinsicMatrix,
distortionCoefficients,imageSize)
```

Description

`intrinsics = cameraIntrinsicsFromOpenCV(intrinsicMatrix, distortionCoefficients,imageSize)` converts the OpenCV intrinsics, specified by the input arguments, into a MATLAB object `intrinsics`, which can be `cameraIntrinsics` or `cameraIntrinsicsKB`.

The OpenCV spatial coordinate system specifies the upper-left pixel center at (`0,0`), whereas the MATLAB spatial coordinate system specifies the pixel center at (`1,1`). The `cameraIntrinsicsFromOpenCV` function compensates for this difference by adding 1 to both of the *x* and *y*-values for the converted principal point.

Examples

Undistort Image in MATLAB Using Camera Intrinsics from OpenCV

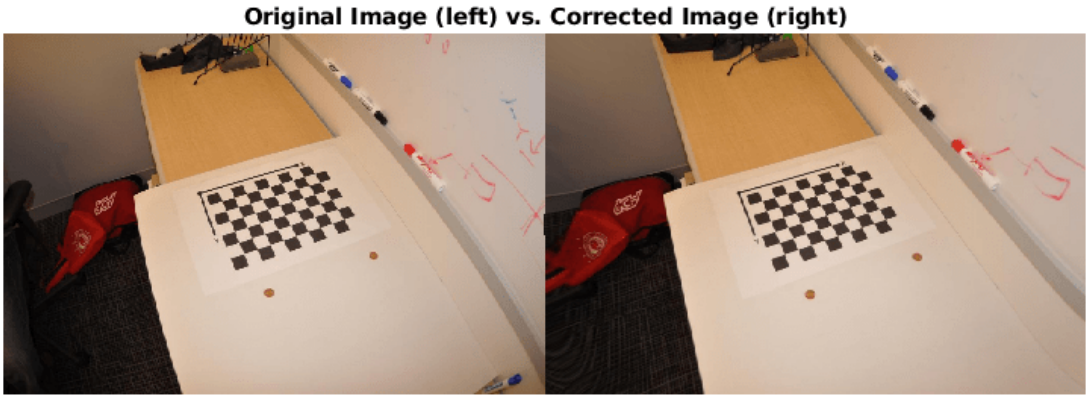
Define OpenCV camera intrinsic parameters in the workspace.

```
intrinsicMatrix = [729.4644    0       570.6455;
                   0       728.8196  346.0108;
                   0         0         1  ];
distortionCoefficients = [-0.4262  0.5460  0.0038  -0.0051  -0.6176];
```

Define the image size returned by the camera.

```
imageSize = [712 1072];
```

Convert the intrinsic parameters from OpenCV to MATLAB format.



```
intrinsics = cameraIntrinsicsFromOpenCV(intrinsicMatrix, ...
                                        distortionCoefficients,imageSize);
```

Load the image to undistort.

```
filename = fullfile(toolboxdir("vision"),"visiondata","calibration", ...
                    "mono","image01.jpg");
I = imread(filename);
```

Undistort the image and display the results.

```
J = undistortImage(I,intrinsics);
imshowpair(I,J,"montage");
title("Original Image (left) vs. Corrected Image (right)");
```

Undistort Image Using Fisheye Camera Parameters from OpenCV

Define OpenCV fisheye parameters in the workspace.

```
intrinsicMatrix = [875.88  0.00   1005.62; ...
                   0.00    874.76 741.52; ...
                   0.00,   0.00,  1.00];
distortionCoeffs = [0.08, -0.16, 0.35, -0.26];
```

Define the image size returned by the camera.

```
imageSize =[1500 2000];
```

Import the intrinsic camera parameters for a fisheye lens from OpenCV.

```
intrinsicsKB = cameraIntrinsicsFromOpenCV(intrinsicMatrix,distortionCoeffs,imageSize)
```

```
intrinsicsKB =
  cameraIntrinsicsKB with properties:

              FocalLength: [875.8800 874.7600]
            PrincipalPoint: [1.0066e+03 742.5200]
                 ImageSize: [1500 2000]
    DistortionCoefficients: [0.0800 -0.1600 0.3500 -0.2600]
                         K: [3×3 double]
```

Load an image to undistort.

```
filename = fullfile(toolboxdir("vision"),"visiondata", ...
    "calibration","gopro","gopro01.jpg");
I = imread(filename);
```

Undistort the image and display the results.

```
J = undistortImage(I,intrinsicsKB);
imshowpair(I,J,"montage");
title("Original Image (left) vs. Corrected Image (right)");
```

Import Camera Intrinsic Parameters from ROS

The ROS camera calibration package estimates camera intrinsic parameters using the OpenCV camera calibration tools [1]. After calibrating a camera in ROS, you can import its intrinsic parameters to a YAML file using the camera calibration parser in ROS. To use the calibrated camera with Computer Vision Toolbox™ functions, such as `undistortImage`, you must read the camera parameters from the YAML file and then convert them into a `cameraIntrinsics` object using `cameraIntrinsicsFromOpenCV`.

Note: The `cameraIntrinsicsFromOpenCV` function supports importing camera intrinsic parameters for only those pinhole camera models that use the `ROS plumb-bob` distortion model.

Read Camera Intrinsic Parameters from a ROS YAML File

Read the camera parameters stored in `cameraParams.yaml` using the helper function `helperReadYAML`.

```
intrinsicsParams = helperReadYAML("cameraParams.yaml");
```

Create `cameraIntrinsics` Object Using `cameraIntrinsicsFromOpenCV`

Use the `cameraIntrinsicsFromOpenCV` function to create a `cameraIntrinsics` object from the camera matrix and the distortion coefficients.

```
imageSize = [intrinsicsParams.image_height intrinsicsParams.image_width];
intrinsicMatrix = intrinsicsParams.camera_matrix;
distortionCoefficients = intrinsicsParams.distortion_coefficients;

intrinsicsObj = cameraIntrinsicsFromOpenCV(intrinsicMatrix,distortionCoefficients,imageSize);
```

Undistort Image

Use the imported camera intrinsics with `undistortImage` to undistort an image captured using the calibrated camera.

```
% Load the captured image.
imageName = fullfile(toolboxdir("vision"),"visiondata","calibration","stereo","left","left01.png
I = imread(imageName);

% Undistort the image.
J = undistortImage(I,intrinsicsObj,OutputView="full");

% Display the result.
figure
montage({I,J})
```

Supporting Functions

helperReadYAML

The `helperReadYAML` function reads the monocular camera parameters from the input YAML file that was exported from ROS.

```
function cameraParams = helperReadYAML(filename)
% helperReadYAML reads a ROS YAML file, filename, and returns a structure
% with these fields: image_width, image_height, camera_name,
% camera_matrix, distortion_model, distortion_coefficients,
% rectification_matrix, and projection_matrix. These fields are stored
% in the YAML file colon separated from their values in different lines.

    f = fopen(filename,'r');
    stringFields = {'camera_name','distortion_model'};
```

```
    while ~feof(f)

        [name,value,isEmptyLine] = helperReadYAMLLine(f);
        if isEmptyLine
            continue
        end

        if ~isempty(value)
            % Convert all values to numbers except for known string
            % fields.
            if ~any(contains(name, stringFields))
                value = str2num(value); %#ok
            end
        else
            % An empty value in ROS YAML files indicates a matrix in
            % upcoming lines. Read the matrix from the upcoming lines.
            value = helperReadYAMLMatrix(f);
        end

        % Store post-processed value.
        cameraParams.(name) = value;
    end

    fclose(f);
end
```

helperReadYAMLMatrix

The `helperReadYAMLMatrix` function reads the rows, columns and data fields of a matrix in the ROS YAML file.

```
function matrix = helperReadYAMLMatrix(f)
%   helperReadYAMLMatrix reads a matrix from the ROS YAML file. A matrix in
%   a ROS YAML file has three fields: rows, columns and data. rows and col
%   describe the matrix size. data is a contiguous array of the matrix
%   elements in row-major order. This helper function assumes the presence
%   of all three fields of a matrix to return the correct matrix.

    numRows = 0;
    numCols = 0;
    data = [];

    % Read numRows, numCols and matrix data.
    while ~feof(f)
        [name,value,isEmptyLine] = helperReadYAMLLine(f);

        if isEmptyLine
            continue
        end

        switch name
            case 'rows'
                numRows = str2num(value); %#ok
            case 'cols'
                numCols = str2num(value); %#ok
            case 'data'
                data    = str2num(value); %#ok
```

```
                % Terminate the while loop as data is the last
                % field of a matrix in the ROS YAML file.
                break
            otherwise
                % Terminate the while loop if any other field is
                % encountered.
                break
        end
    end

    if numel(data) == numRows*numCols
        % Reshape the matrix using row-major order.
        matrix = reshape(data,[numCols numRows])';
    end
end
```

helperReadYAMLLine

The `helperReadYAMLLine` function reads a line of a ROS YAML file.

```
function [name,value,isEmptyLine] = helperReadYAMLLine(f)

    % Read line from file.
    line = fgetl(f);

    % Trim leading and trailing white spaces.
    line = strtrim(line);

    if isempty(line) || line(1)=='#'
        % Empty line or comment.
        name = '';
        value = '';
        isEmptyLine = true;
    else
        % Split the line to get name and value.
        c = strsplit(line,':');
        assert(length(c)==2,'Unexpected file format')

        name = c{1};
        value = strtrim(c{2}); % Trim leading white space.
        isEmptyLine = false;
    end
end
```

References

[1] ROS.org Camera Calibration

Input Arguments

`intrinsicMatrix` — Camera intrinsic matrix

3-by-3 matrix

Camera intrinsic matrix from OpenCV, specified as a 3-by-3 matrix of the form:

$$\begin{bmatrix} fx & 0 & cx \\ 0 & fy & cy \\ 0 & 0 & 1 \end{bmatrix}$$

where *fx* and *fy* are the focal lengths in the *x* and *y*-directions, and (*cx*,*cy*) is the principal point in OpenCV.

`distortionCoefficients` — Camera distortion coefficients
4-element vector | 5-element vector | 8-element vector

Camera distortion coefficients from OpenCV, specified as a 4-, 5-, or 8-element vector. The function returns a `cameraIntrinsics` object when using extended pinhole model distortion coefficients and a `cameraIntrinsicsKB` object for fisheye distortion coefficients.

- Extended pinhole model — 5-element vector of the form [*k1 k2 p1 p2 k3*] or an 8-element vector of the form [*k1 k2 p1 p2 k3 k4 k5 k6*].

  In the Robot Operating System (ROS), the 5-element vector is referred to as the plumb_bob model, while the 8-element vector is known as the rational_polynomial model.

  The values of *k1*, *k2*, ..., *k6* describe the radial distortion and *p1* and *p2* describe the tangential distortion, specified in OpenCV.
- Kannala-Brandt model [1] — 4-element vector of the form [*k1 k2 k3 k4*]. These values are the distortion coefficients from the OpenCV fisheye camera model.

`imageSize` — Image size
2-element vector

Image size, specified as a 2-element vector in the form [*mrows*,*ncols*].

Output Arguments

`intrinsics` — Camera intrinsic parameters
`cameraIntrinsics` object | `cameraIntrinsicsKB` object

Camera intrinsic parameters, returned as a `cameraIntrinsics` or `cameraIntrinsicsKB` object. The function returns a `cameraIntrinsics` object when using extended pinhole model distortion coefficients and a `cameraIntrinsicsKB` object for fisheye distortion coefficients.

- `cameraIntrinsics` object — Contains OpenCV intrinsics for a pinhole camera model. In cases where the OpenCV pinhole model uses more than eight distortion coefficients, which cannot be converted to a `cameraIntrinsics` object, you can recalibrate your camera using the Camera Calibrator app as an alternative solution.
- `cameraIntrinsicsKB` object — Contains camera intrinsic calibration parameters for a fisheye lens, using the Kannala-Brandt model.

Version History

Introduced in R2021b

R2024b: Import OpenCV pinhole camera model with six radial distortion coefficients

The `cameraIntrinsicsFromOpenCV` has been updated to support OpenCV pinhole camera model with 6 radial distortion coefficients.

cameraIntrinsicsToOpenCV

Convert camera intrinsic parameters from MATLAB to OpenCV

Syntax

```
[intrinsicMatrix,distortionCoefficients] = cameraIntrinsicsToOpenCV(
intrinsics)
```

Description

`[intrinsicMatrix,distortionCoefficients] = cameraIntrinsicsToOpenCV(intrinsics)` converts a MATLAB `cameraIntrinsics` or `cameraParameters` object, specified by `intrinsics`, to OpenCV camera intrinsic parameters.

The OpenCV spatial coordinate system specifies the upper-left pixel center at (`0,0`), whereas the MATLAB spatial coordinate system specifies the pixel center at (`1,1`). The `cameraIntrinsicsToOpenCV` function compensates for this difference by subtracting 1 from both the *x* and *y*-values for the converted principal point.

OpenCV camera intrinsic parameters do not include the skew of a pinhole camera model. Therefore, only the intrinsics that were estimated without the skew can be exported to OpenCV.

Examples

Calibrate Camera in MATLAB and Convert Intrinsic Parameters to OpenCV

Create a set of calibration images.

```
images = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
                        "calibration","mono"));
imageFileNames = images.Files;
```

Detect the checkerboard calibration pattern in the images.

```
[imagePoints,patternDims] = detectCheckerboardPoints(imageFileNames);
```

Generate the world coordinates of the corners of the squares. Square size is in millimeters.

```
squareSize = 29; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Calibrate the camera.

```
I = readimage(images,1);
imageSize = size(I,1:2);
params = estimateCameraParameters(imagePoints,worldPoints,ImageSize=imageSize);
```

Convert the intrinsic parameters to OpenCV format

```
[intrinsicMatrix,distortionCoefficients] = cameraIntrinsicsToOpenCV(params);
```

Input Arguments

`intrinsics` — Camera intrinsic parameters

`cameraIntrinsics` object | `cameraParameters` object

Camera intrinsic parameters, specified as a `cameraIntrinsics` or a `cameraParameters` object.

Output Arguments

`intrinsicMatrix` — Camera intrinsic matrix

3-by-3 matrix

Camera intrinsics matrix formatted for OpenCV, returned as a 3-by-3 matrix of the form:

$$\begin{bmatrix} fx & 0 & cx \\ 0 & fy & cy \\ 0 & 0 & 1 \end{bmatrix}$$

where *fx* and *fy* are the focal lengths in the *x* and *y*-directions, and (*cx*,*cy*) is the principal point in OpenCV.

`distortionCoefficients` — Camera radial and tangential distortion coefficients

five-element vector

Camera radial and tangential distortion coefficients, returned as a five-element vector in the form [*k1 k2 p1 p2 k3*]. The values of *k1*, *k2*, and *k3* describe the radial distortion and *p1* and *p2* describe the tangential distortion, specified in OpenCV.

In the Robot Operating System (ROS), the 5-element vector is referred to as the plumb_bob model.

detectSIFTFeatures

Detect scale invariant feature transform (SIFT) features

Syntax

```
points = detectSIFTFeatures(I)
points = detectSIFTFeatures(I,Name=Value)
```

Description

`points = detectSIFTFeatures(I)` detects SIFT features in the 2-D grayscale or binary input image `I` and returns a `SIFTPoints` object. The `detectSIFTFeatures` function implements the Scale-Invariant Feature Transform (SIFT) algorithm to find local features in an image.

`points = detectSIFTFeatures(I,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `detectSIFTFeatures(I,ContrastThreshold=0.0133)` detects SIFT features with a contrast of less than `0.0133`.

Examples

Detect Interest Points and Mark Locations

Load an image.

```
I = imread('cameraman.tif');
```

Detect SIFT features in the image.

```
points = detectSIFTFeatures(I);
```

Display the results.

```
imshow(I);
hold on;
plot(points.selectStrongest(10))
```

Input Arguments

`I` — Input image

M-by-*N* grayscale or binary image

Input image, specified as an *M*-by-*N* 2-D grayscale or binary image. The input image must be a real, nonsparse value.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `detectSIFTFeatures(I,ContrastThreshold=0.0133)` detects SIFT features with a contrast of less than `0.0133`.

`ContrastThreshold` — Contrast threshold

`0.0133` (default) | non-negative scalar in range `[0,1]`

Contrast threshold for selecting the strongest features, specified as a non-negative scalar in the range `[0,1]`. The threshold is used to filter out weak features in low-contrast regions of the image. Increase the contrast threshold to decrease the number of returned features.

`EdgeThreshold` — Edge threshold

`10.0` (default) | non-negative scalar

Edge threshold, specified as a non-negative scalar greater than or equal to `1`. The threshold is used to filter out unstable edge-like features in the image that are susceptible to noise. Increase the edge threshold to decrease the number of features removed by filtering.

`NumLayersInOctave` — Number of layers in each octave
`3` (default) | integer scalar

Number of layers in each octave, specified as an integer scalar greater than or equal to `1`. The number of octaves is computed automatically from the image resolution. Increase the number of layers in each octave to detect larger features in the image.

`Sigma` — Sigma of the Gaussian
`1.6` (default) | scalar

Sigma of the Gaussian, specified as a scalar. The sigma of the Gaussian is applied to the input image at the initial octave. Sigma values are typically in the range `[1,2]`. Lower the sigma value if the image is blurry.

`ROI` — Region of interest
`[1 1 M N]` (default) | four-element vector

Region of interest for keypoint detection, specified as the comma-separated pair consisting of `'ROI'` and a vector of the format [*x y width height*]. The first two elements represent the location of the upper left corner of the region of interest. The last two elements represent the width and the height of the region of interest. The width and height of the region of interest must each be a value greater than or equal to 63.

Output Arguments

`points` — SIFT features
`SIFTPoints` object

SIFT features, returned as a `SIFTPoints` object. This object contains information about SIFT features detected in the 2-D grayscale or binary image.

Version History

Introduced in R2021b

normalRotation

Compute transform for rotation of normal to plane

Syntax

```
tform = normalRotation(model,referenceVector)
```

Description

`tform = normalRotation(model,referenceVector)` returns the geometric transformation object for a normal vector of a plane to the reference vector, `referenceVector`. `model` is a `planeModel`.

Examples

Transform Point Cloud

Construct a velodyneFileReader object.

```
veloReader = velodyneFileReader('lidarData_ConstructionRoad.pcap','HDL32E');
```

Read the first frame of lidar data.

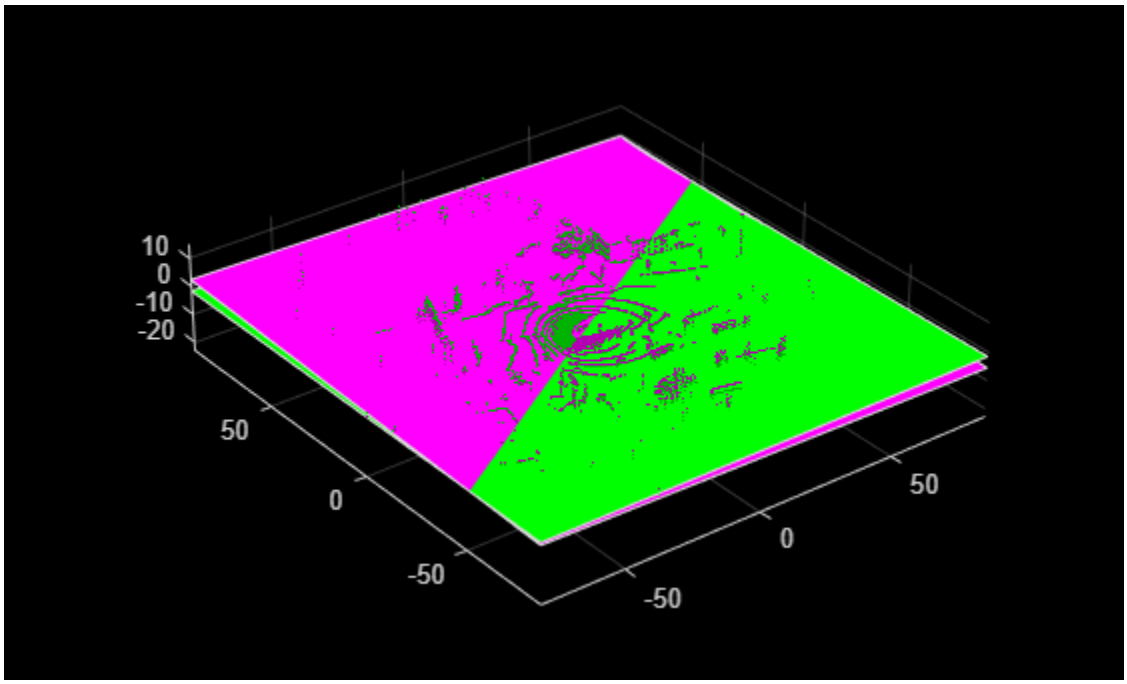
```
frameNumber = 1;
ptCloud  = readFrame(veloReader,frameNumber);
```

Find the ground plane.

```
maxDistance = 0.4;
referenceVector = [0 0 1];

groundPlane = pcfitplane(ptCloud,maxDistance,referenceVector);
```

Transform the ground plane such that it is parallel to the X-Y plane.



```
tform = normalRotation(groundPlane,referenceVector);
```

Transform the point cloud.

```
ptCloudOut = pctransform(ptCloud,tform);
```

Display the original and transformed point cloud.

```
planeParams = groundPlane.Parameters * tform.T;
transformedPlane = planeModel(planeParams);
figure;
pcshowpair(ptCloudOut,ptCloud);
hold on;
plot(groundPlane, 'Color', 'magenta');
plot(transformedPlane, 'Color', 'green');
```

Input Arguments

`model` — Parametric plane model
plane model

Parametric plane model returned by `planeModel`.

`referenceVector` — Reference vector
1-by-3 vector

Reference vector, specified as a 1-by-3 vector.

Output Arguments

`tform` — Geometric transformation
`rigidtform3d` object

Geometric transformation, returned as a `rigidtform3d` object. The `rigidtform3d` object describes the rigid 3-D transformation that aligns the normal vector of a plane to `referenceVector`.

Version History

Introduced in R2020b

R2022b: Returns `rigidtform3d` object
Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, the `normalRotation` function now

returns `tform` as a `rigidtform3d` object, which uses the premultiply convention. Before, the function returned `tform` as a `rigid3d` object, which uses the postmultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

showShape

Display shapes on image, video, or point cloud

Syntax

```
showShape(shape,position)
showShape( ___ ,Name=Value)
```

Description

`showShape(shape,position)` displays one or more instances of a shape `shape` in the current axes at the specified locations `position`.

`showShape( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to the input arguments from the previous syntax. For example, `Color="yellow"` sets the color for the shapes to yellow.

Examples

Display Detected Objects in Image

Read an image into the workspace.

```
I = imread("visionteam1.jpg");
```

Create an aggregate channel features (ACF) people detector.

```
detector = peopleDetectorACF
```

```
detector =
  acfObjectDetector with properties:

             ModelName: 'inria-100x41'
    ObjectTrainingSize: [100 41]
       NumWeakLearners: 2048
```

Detect people in the image.

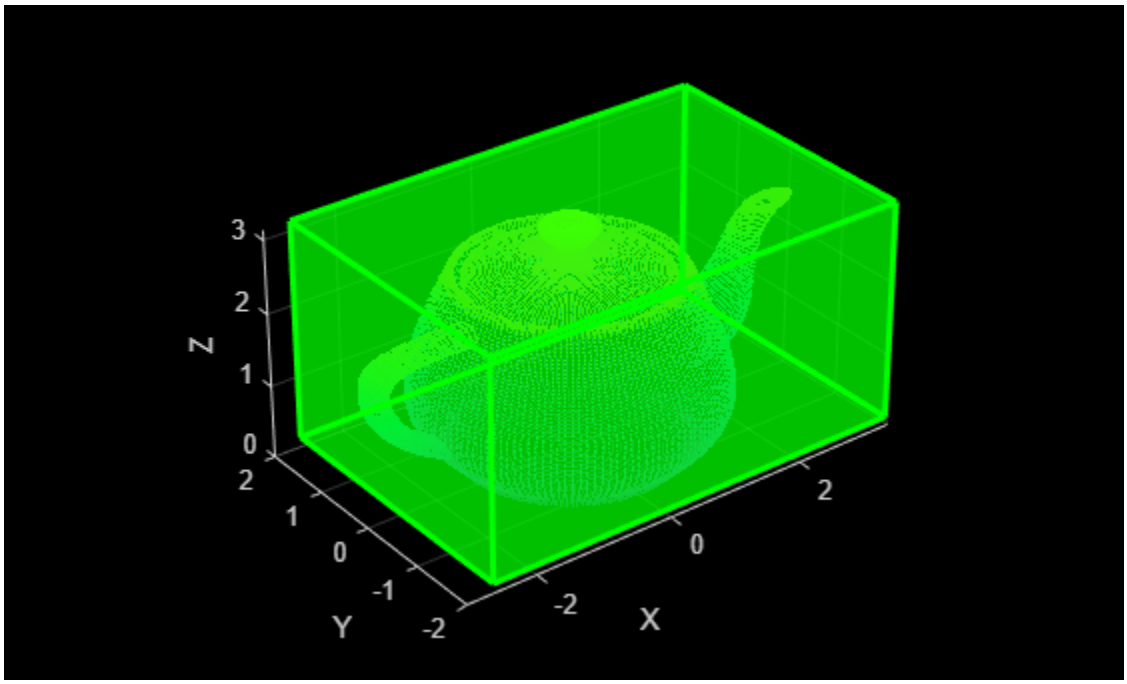
```
[bboxes,scores] = detect(detector,I);
```

Display the image with a labeled rectangle around each detected person. Display the associated detection score around each detected person.

```
figure
imshow(I)
labels = "person:" + scores;
showShape("rectangle",bboxes,Label=labels)
```

Display Bounding Box Around Object in Point Cloud

Read point cloud data into the workspace.



```
ptCloud = pcread("teapot.ply");
```

Display the point cloud data.

```
figure
pcshow(ptCloud)
xlabel("X")
ylabel("Y")
zlabel("Z")
```

Define a cuboid and display it in green with an opacity of `0.5`.

```
pos = [0.3753 0 1.65 6 4 3 0 0 0];
showShape("cuboid",pos,Color="green",Opacity=0.5)
```

Visualize Cuboid Around Moving Object in Point Cloud Stream

Read point cloud data into the workspace.

```
ptCloud = pcread("teapot.ply");
```

Define a rotation matrix and 3-D transform to rotate the point cloud, and an associated cuboid, by 5 degrees.

```
rot = 5;
R = [ cosd(rot) sind(rot) 0 0; ...
     -sind(rot) cosd(rot) 0 0; ...
      0       0           1 0; ...
      0       0           0 1];

tform = affine3d(R);
```

Compute the *x* and *y* rendered limits of the point cloud, to ensure that you do not clip the point cloud during rotation.

```
pcLimits = abs([ptCloud.XLimits ptCloud.YLimits]);
maxLimit = max(pcLimits);
```

Add a margin to the plot to prevent the rotation from clipping the cuboid.

```
margin = 1;
maxLimit = maxLimit + margin;

xlimits = [-maxLimit maxLimit];
ylimits = [-maxLimit maxLimit];
zlimits = ptCloud.ZLimits;
```

Create a player for visualizing the point cloud.

```
player = pcplayer(xlimits,ylimits,zlimits);
```

Customize the player axes labels.

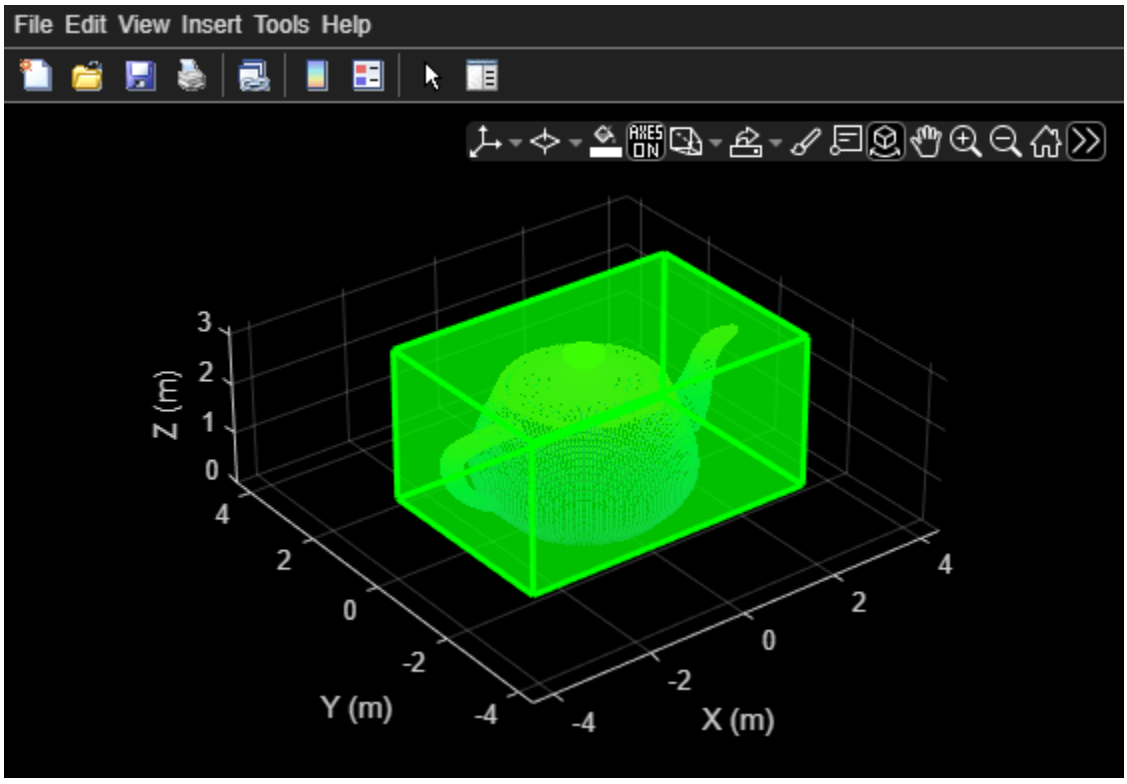
```
xlabel(player.Axes,"X (m)");
ylabel(player.Axes,"Y (m)");
zlabel(player.Axes,"Z (m)");
```

Define a cuboid around the point cloud.

```
cuboidPosition = [0.3753 0 1.65 6 4 3 0 0 0];
```

Define the output view for a cuboid rotation. Use the same limits as the player so that the view does not clip the cuboid. Then, display the rotated point cloud and cuboid.

```
gridSize = [1 1 1];
ref = imref3d(gridSize,xlimits,ylimits,zlimits);



for i = 1:round((360/rot))
    % Rotate the point cloud.
    ptCloud = pctransform(ptCloud,tform);

    % Rotate the cuboid.
    cuboidPosition = bboxwarp(cuboidPosition,tform,ref);

    % Show the rotated point cloud data.
    view(player,ptCloud)

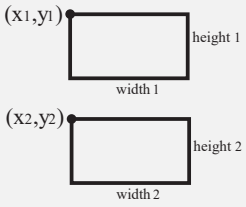
    % Show the rotated cuboid.
    showShape("cuboid",cuboidPosition, ...
        Parent=player.Axes, ...
        Color="green", ...
        Opacity=0.5)

    % Use drawnow to synchronize the point cloud and shape visualizations.
    drawnow
end
```

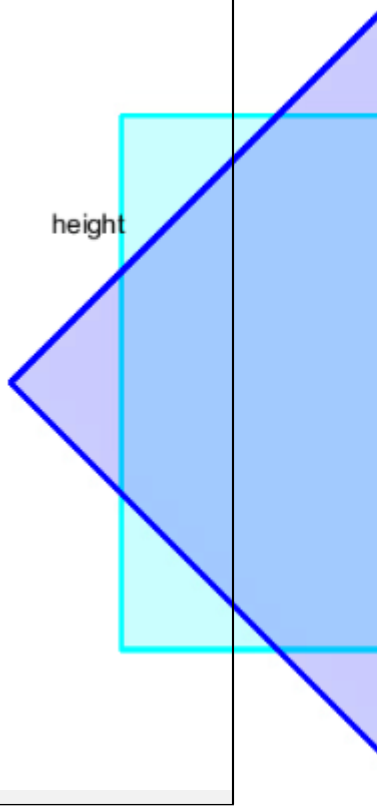
Input Arguments

`shape` — Type of shape

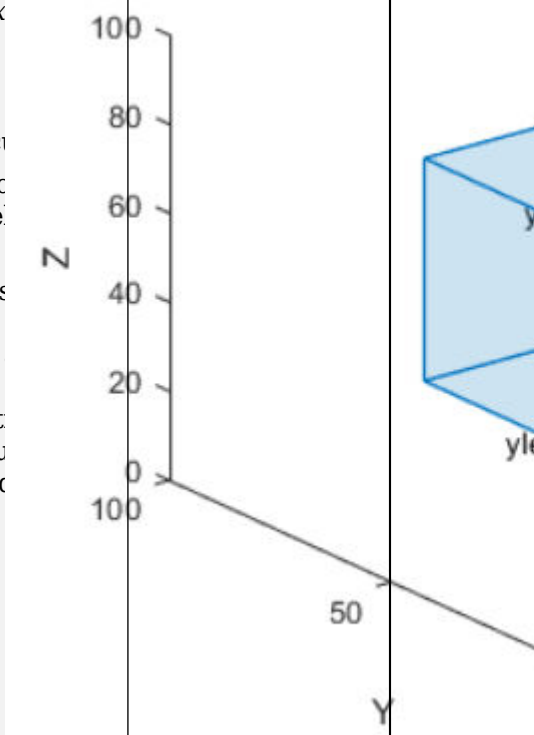
`"rectangle"` | `"line"` | `"polygon"` | `"circle"` | `"cuboid"` | `"projected-cuboid"` | `"ellipse"`



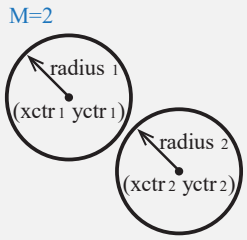
Type of shape, specified as `"rectangle"`, `"line"`, `"polygon"`, `"circle"`, `"cuboid"`, `"projected-cuboid"`, or `"ellipse"`.



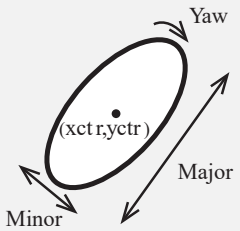
Data Types: `char`



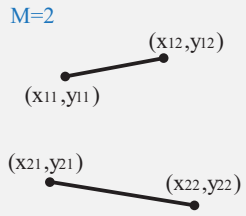
`position` — Positions and sizes of shapes



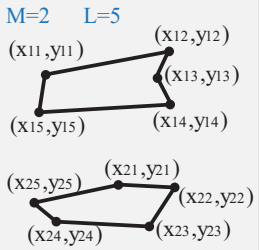
matrix | vector | cell array



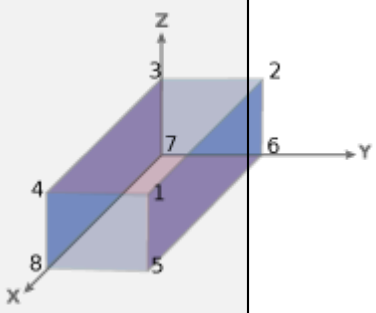
Position of shape, specified according to the type of shape, as described in the table.



Shape	Position	Definition
`rectangle`	For one or more axis-aligned rectangles, specify as an M-by-4 numeric matrix, where each row specifies a rectangle of the form $[x\ y\ width\ height]$. • M is the number of axis-aligned rectangles. • x and y specify the upper-left corner of the rectangle. • w specifies the width of the rectangle, which is its length along the x-axis. • h specifies the height of the rectangle, which is its length along the y-axis. $\begin{bmatrix} x_1 & y_1 & width_1 & height_1 \\ x_2 & y_2 & width_2 & height_2 \\ \vdots & \vdots & \vdots & \vdots \\ x_M & y_M & width_M & height_M \end{bmatrix}$	M=2 



Shape	Position	Definition
	For one or more rotated rectangles, specify in spatial coordinates as an *M*-by-5 numeric matrix, where each row specifies a rotated rectangle of the form [*xctr yctr w h yaw*]. • *M* is the number of rotated rectangles. • *xctr* and *yctr* specify the center of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis before rotation. • *h* specifies the height of the rectangle, which is its length along the *y*-axis before rotation. • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the rectangle.	



Shape	Position	Definition
`cuboid`	For one or more cuboids, specify in spatial coord an *M*-by-9 numeric matrix where each row speci cuboid of the form [*xctr yctr zctr xlen ylen zlen x* *zrot*], where • *M* is the number of cuboids. • *xctr*, *yctr*, and *zctr* specify the center of the c • *xlen*, *ylen*, and *zlen* specify the length of the c along the *x*-axis, *y*-axis, and *z*-axis, respective rotation. • *xrot*, *yrot*, and *zrot* specify the rotation angles cuboid around the *x*-axis, *y*-axis, and *z*-axis, respectively. The *xrot*, *yrot*, and *zrot* rotation are in degrees about the cuboid center. Each is clockwise-positive with respect to the posit direction of the associated spatial axis. The fu computes rotation matrices assuming ZYX orc angles [*xrot yrot zrot*].	

Shape	Position	Definition
`circle`	For one or more circles, specify spatial coordinates as an *M*-by-3 numeric matrix, where each row specifies a circle of the form [*xctr yctr radius*]. • *M* is the number of circles. • *xctr* and *yctr* specify the center of the circle. • *radius* specifies the radius of the circle. $\begin{bmatrix} xctr_1 & yctr_1 & radius_1 \\ xctr_2 & yctr_2 & radius_2 \\ \vdots & \vdots & \vdots \\ xctr_M & yctr_M & radius_M \end{bmatrix}$	

Shape	Position	Definition
`ellipse`	For one or more ellipses, specify in spatial coordinates as an *M*-by-5 matrix, where each row specifies an ellipse of the form [*xctr yctr major minor yaw*] • *M* is the number of ellipses. • *xctr* and *yctr* specify the center of the ellipse. • *major* and *minor* are the lengths of the major and minor ellipse axes, respectively. • *yaw* is the angle of rotation in degrees. The angle of rotation is clockwise positive around the center of the ellipse.	

Shape	Position	Definition
`line`	For one or more lines, specify spatial coordinates using one of these formats to specify a single line with connected endpoints, multiple lines with the same number of endpoints, or multiple lines with different numbers of endpoints. • Single lines with connected endpoints — Specify as a *P*-by-2 matrix, where each row specifies an endpoint in the form [*x y*], and the endpoint in one row connects directly to the endpoint in the next. *P* is the number of endpoints in the line. • Multiple lines with the same number of endpoints — Specify as an *M*-by-2*P* matrix, where each row specifies the consecutive endpoints of a single line in the form [*x1 y1 x2 y2 ... xp yp*]. Each [*x y*] pair is the coordinates of a single endpoint. *M* is the number of specified lines, and *P* is the number of endpoints per line. • Multiple lines with different numbers of endpoints — Specify as an *M*-by-1 cell array, where each cell contains the endpoints for a single line as a *P*-by-2 matrix or a 1-by-2*P* vector]. *M* is the number of specified lines, and *P* is the number of endpoints for each line	

Shape	Position	Definition
`polygon`	For one or more polygons, specify in spatial coordinates as an *M*-by-1 cell array, where each cell contains an *L*-by-2 matrix of [*x y*] vertex locations or a 1-by-2*L* vector of consecutive vertex locations of the form [x_1, y_1, x_2,y_2, … x_L,y_L]. • *M* is the number of polygons. • Each [*x y*] pair describes a vertex location or endpoint. • *L* is the number of vertices in a polygon or endpoints in a line. Each polygon or line can have a different number of vertices or endpoints.	

Shape	Position	Definition
`projected-cuboid`	For one or more projected cuboids, specify in spatial coordinates as an 8-by-2-by-*M* array or an *M*-by-8 matrix, where *M* is the number of projected cuboids. When specified as an 8-by-2-by-*M* array, each row must contain the [*x y*] location of a projected cuboid vertex. The vertices connect to form a cuboid with six faces. The order of the input vertices must match the order shown in the diagram. When specified as an *M*-by-8 matrix, each row specifies the dimensions of the front-facing and rear-facing sides of a projected cuboid in the form, [*x1 y1 w1 h1 x2 y2 w2 h2*], where [*x1 y1*] and [*x2 y2*] specify the upper-left coordinates of the front-facing and rear-facing sides, respectively, and [*w1 h1*] and [*w2 h2*] specify the corresponding widths and heights.	

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `showShape("rectangle",bboxes,Color="yellow")` sets the color for the shapes to yellow.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `showShape("rectangle",bboxes,"Color","yellow")` sets the color for the shapes to yellow.

`Label` — Shape label

`[]` (default) | scalar | *M*-element vector | *M*-element cell array of character vectors

Shape label, specified as a scalar, *M*-element vector, or an *M*-element cell array of character vectors, where *M* is the number of shapes.

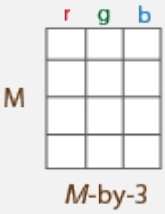
If the input is a scalar value, then the function applies the label to each shape. If the input is an *M*-element vector or cell array, then the function applies the unique label to the corresponding shape, using the order in which you specify the shapes to the function.

`Color` — Shape color

`"green"` (default) | short color name | color name | vector of color names | three-column matrix of RGB triplets

Shape color, specified as a short color name, color name, vector of color names, three-column matrix of RGB triplets.

The supported colors table lists RGB intensities in the range [0, 1], but you must specify RGB triplets in the range of your selected data type. For example, if specifying this argument as a matrix of `uint8` values, you must convert each intensity value to the range [0, 255]. To convert the listed intensity



values to a `uint8` data type, use the code `uint8(255*intensity)`, where intensity is an RGB triplet value listed in the table.

You can specify a different color for each shape or one color for all shapes. To specify one color for all markers, specify `Color` as a color name or an [*R G B*] vector.

Specification	Format	Example

Specify one color for all shapes (or markers)	Short color name or color name	`"r"`
		
		`"red"`

	RGB triplet	 `[1 0 0]`
Specify a color for each shape (or marker)	Vector of color names	`["red","yellow","blue"]`

	Three-column matrix of RGB triplets	`[1 0 0`
		` 0 1 1`
		` 1 0 1`
		` 1 1 1]`
		

This table lists the supported shape colors.

Color Name	Short Name	RGB Triplet	Appearance
`"red"`	`"r"`	`[1 0 0]`	
`"green"`	`"g"`	`[0 1 0]`	
`"blue"`	`"b"`	`[0 0 1]`	
`"cyan"`	`"c"`	`[0 1 1]`	
`"magenta"`	`"m"`	`[1 0 1]`	
`"yellow"`	`"y"`	`[1 1 0]`	
`"black"`	`"k"`	`[0 0 0]`	
`"white"`	`"w"`	`[1 1 1]`	

Data Types: `logical` | `uint8` | `uint16` | `int16` | `double` | `single` | `cell`

`Opacity` — Opacity of shape fill
`0` (default) | scalar in range [0 1] | *M*-element vector of values in range [0 1]

Opacity of the shape fill, specified as a scalar or *M*-element vector of numeric values in the range [0 1], where *M* is the number of shapes. To use the same opacity for all shapes, specify a scalar opacity value. For a fully opaque shape fill, specify `Opacity` as `1`.

`Parent` — Output axes
`gca` (default) | `Axes` graphics object

Output axes, specified as an `Axes` graphics object. For more information on Axes object properties, see Axes Properties.

`LineColor` — Shape border line color
`"auto"` (default) | one or more RGB triplets | one or more color names or short color names

Shape border line color, specified as a short color name, color name, vector of color names, three-column matrix of RGB triplets.

The supported colors table lists RGB intensities in the range [0, 1], but you must specify RGB triplets in the range of your selected data type. For example, if specifying this argument as a matrix of `uint8` values, you must convert each intensity value to the range [0, 255]. To convert the listed intensity values to a `uint8` data type, use the code `uint8(255*intensity)`, where intensity is an RGB triplet value listed in the table.

You can specify a different color for each shape or one color for all shapes. To specify one color for all markers, specify `LineColor` as a color name or an [*R G B*] vector.

`LineStripeColor` — Striped line color
`"none"` (default) | one or more RGB triplets | one or more color names or short color names

Striped line color, specified as a short color name, color name, vector of color names, three-column matrix of RGB triplets. The striped line color alternates between the colors specified by `LineColor` and `LineStripeColor`.

The supported colors table lists RGB intensities in the range [0, 1], but you must specify RGB triplets in the range of your selected data type. For example, if specifying this argument as a matrix of `uint8` values, you must convert each intensity value to the range [0, 255]. To convert the listed intensity values to a `uint8` data type, use the code `uint8(255*intensity)`, where intensity is an RGB triplet value listed in the table.

You can specify a different color for each striped line or one color for all lines. To specify one color for all the lines, specify `LineStripeColor` as a color name or an [*R G B*] vector.

`LineWidth` — Border line width
`"auto"` (default) | positive scalar integer | *M*-element vector of positive integers

Border line width in pixels, specified as a positive integer or an *M*-element vector of positive integers, where *M* is the number of shapes. To use the same line width for all shapes, specify a scalar positive integer. Otherwise, specify an *M*-element vector of positive integers.

`LineOpacity` — Border line opacity of shape
`0` (default) | *M*-element vector of values in the range [0 1]

Border line opacity of shape, specified as a scalar or *M*-element vector of numeric values in the range [0 1], where *M* is the number of shapes. To use the same opacity for all shapes, specify a scalar opacity value. For a fully opaque shape fill, specify `Opacity` as `1`.

`LabelTextColor` — Label text color
`"black"` (default) | one or more RGB triplets | one or more color names or short color names

Label text color, specified as a short color name, color name, vector of color names, three-column matrix of RGB triplets.

The supported colors table lists RGB intensities in the range [0, 1], but you must specify RGB triplets in the range of your selected data type. For example, if specifying this argument as a matrix of `uint8` values, you must convert each intensity value to the range [0, 255]. To convert the listed intensity values to a `uint8` data type, use the code `uint8(255*intensity)`, where intensity is an RGB triplet value listed in the table.

You can specify a different color for each label or one color for all labels. To specify one color for all markers, specify `LabelTextColor` as a color name or an [*R G B*] vector.

`LabelOpacity` — Label opacity
`0` (default) | *M*-element vector of values in the range [0 1]

Label opacity of shape, specified as a scalar or *M*-element vector of numeric values in the range [0 1], where *M* is the number of shapes. To use the same opacity for all labels, specify a scalar opacity value. For a fully opaque shape fill, specify `Opacity` as `1`.

`LabelFont` — Label font
`"Helvetica"` (default) | `"FixedWidth"` | supported font

Label font, specified as `"FixedWidth"` or a font that your system supports. To display and print text properly, you must select a font that your system supports. If you select an unsupported font, the function returns an error. If you specify `"FixedWidth"`, the function uses the font specified by the `FixedWidthFont` property of the Root Properties object. The fixed-width font relies on the value of `get(0,"FixedWidthFontName")`.

`LabelFontSize` — Label font size
`12` (default) | positive scalar

Label font size in points, specified as a positive scalar.

`ShowOrientation` — Original orientation indicator
`false` or `0` (default) | `true` or `1`

Original orientation indicator, specified as a numeric or logical `1` (`true`) or `0` (`false`). A value of `1` (`true`) displays the original orientation of the rotated rectangle by using an arrow annotation on the bounding box. The original orientation is defined as a zero rotation angle. A value of `0` (`false`) does not show the arrow annotation.

This argument applies only when `Shape` describes a rotated rectangle or an ellipse.

Data Types: `logical` | `integer`

Version History

Introduced in R2020b

R2026a: Added `LineStripeColor` name-value argument

Added the `LineStripeColor` name-value argument to specify a color for a striped line.

R2024b: Support for ellipse shape

Added support for `"ellipse"` to visualize one or more ellipses on top of an image or on video data.

R2024b: Default value for orientation indicator changed from `true` to `false`
Behavior changed in R2024b

Starting in R2024b, the default value for the `ShowOrientation` name-value argument will be `false`.

R2022a: Bounding Box Coordinates: Data augmentation for object detection using spatial coordinates
Behavior changed in R2022a

The `bboxresize`, `bboxcrop`, `bboxwarp`, and `showShape` functions assume the input bounding box coordinates for axis-aligned rectangles are specified in spatial coordinates and return the transformed bounding boxes in spatial coordinates.

R2022b: Visualize projected cuboids

Added support to visualize projected cuboids.

R2023b: Rotated rectangle support for bounding box

You can specify a rotated rectangle bounding box using the form [*xctr yctr width height yaw*].

pcregistercorr

Register two point clouds using phase correlation

Syntax

```
tform = pcregistercorr(moving,fixed,gridSize,gridStep)
[tform,rmse] = pcregistercorr( ___ )
[tform,rmse,peak] = pcregistercorr( ___ )
[ ___ ] = pcregistercorr( ___ ,Name=Value)
```

Description

`tform = pcregistercorr(moving,fixed,gridSize,gridStep)` computes the rigid transformation that registers the moving point cloud `moving`, to the fixed point cloud `fixed`, using an image-based phase correlation algorithm.

The function performs registration by first converting both point clouds to a 2-D occupancy grid in the *X*-*Y* plane with center at the origin (0,0,0). The occupancy of each grid cell is determined using the *Z*-coordinate values of points within the grid.

`[tform,rmse] = pcregistercorr( ___ )` additionally returns the root mean square error of the Euclidean distance between the aligned point clouds.

`[tform,rmse,peak] = pcregistercorr( ___ )` additionally returns the peak correlation value of the phase difference between the two occupancy grids.

`[ ___ ] = pcregistercorr( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `Window=false` sets the `Window` name-value argument to `false` to suppress using windowing.

Examples

Register Lidar Moving Point Cloud to Fixed Point Cloud

Read data from a Velodyne® packet capture (PCAP) file into the workspace.

```
veloReader = velodyneFileReader('lidarData_ConstructionRoad.pcap','HDL32E');
```

Read a fixed and a moving point cloud from frames of the lidar data.

```
frameNumber = 1;
skipFrame   = 5;
fixed  = readFrame(veloReader,frameNumber);
moving = readFrame(veloReader,frameNumber + skipFrame);
```

Find the ground planes for both the moving and the fixed point clouds. Set the maximum distance in meters.

```
maxDistance = 0.4;
referenceVector = [0 0 1];
```

```
groundMoving = pcfitplane(moving,maxDistance,referenceVector);
groundFixed = pcfitplane(fixed,maxDistance,referenceVector);
```

Transform the point clouds so that their ground planes are parallel to the *X*-*Y* plane.

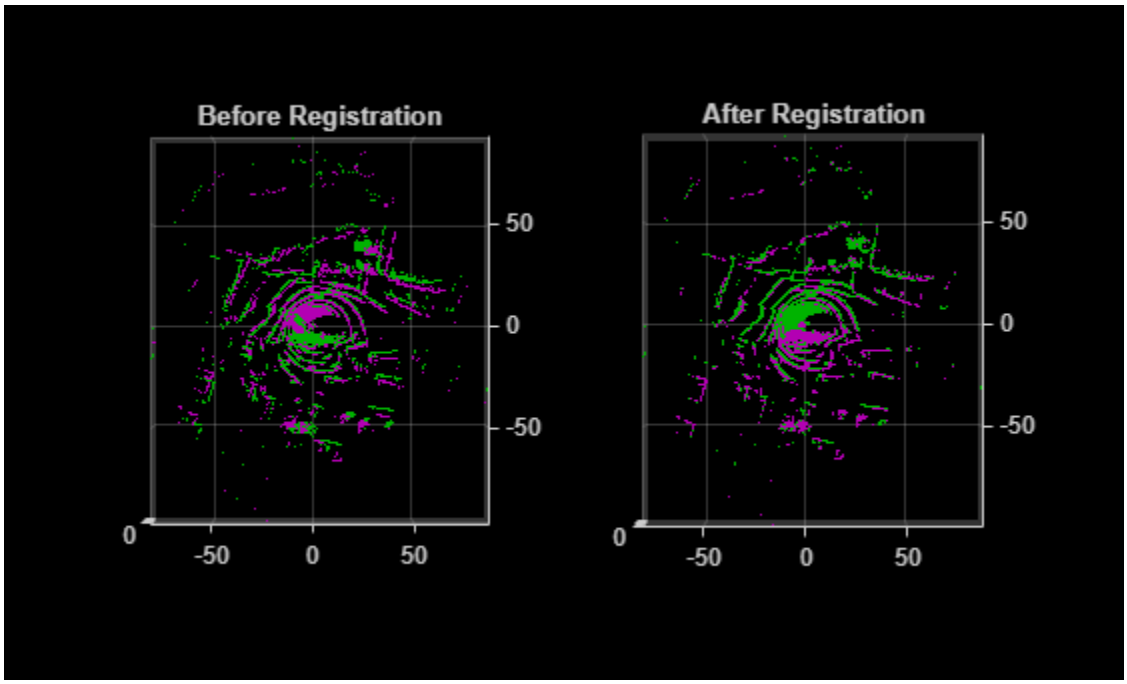
```
tformMoving = normalRotation(groundMoving,referenceVector);
tformFixed = normalRotation(groundFixed,referenceVector);

movingCorrected = pctransform(moving,tformMoving);
fixedCorrected = pctransform(fixed,tformFixed);
```

Register the moving point cloud against the fixed point cloud. Set the occupancy grid size to 100-by-100 meters and the size of each grid cell to 0.5-by-0.5 meters.

```
gridSize = 100;
gridStep = 0.5;

tform = pcregistercorr(movingCorrected,fixedCorrected,gridSize,gridStep);
```



Transform the moving point cloud using the estimated rigid transformation.

```
combinedTform = rigidtform3d(tformFixed.A * tformMoving.A * tform.A);
movingReg = pctransform(moving,combinedTform);
```

Visualize the registration.

```
figure
subplot(121)
pcshowpair(moving,fixed)
title('Before Registration')
view(2)

subplot(122)
pcshowpair(movingReg,fixed)
title('After Registration')
view(2)
```

Input Arguments

`moving` — Moving point cloud
`pointCloud` object

Moving point cloud, specified as a `pointCloud` object.

`fixed` — Fixed point cloud
`pointCloud` object

Fixed point cloud, specified as a `pointCloud` object.

`gridSize` — Size of square occupancy grid
scalar

Size of square occupancy grid, specified as a scalar value in world units. The occupancy grid has both width and height equal to this value. The occupancy grid is centered at the origin (0, 0, 0) and the spatial extent of the occupancy grid is [-`gridSize`/2, `gridSize`/2].

`gridStep` — Size of each grid cell
scalar

Size of each grid cell, specified as a scalar value in world units.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `Zlimit=[0 3]` sets the *Z*-axis lower limit to `0` and the upper limit to `3`.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

`Zlimit` — *Z*-axis limits
`[0 3]` (default) | vector of form [*zmin zmax*]

Z-axis limits to compute the occupancy of a grid cell, specified as a vector of the form [*zmin zmax*], where *zmin* and *zmax* are numeric scalars. The function scales points with a *Z*-axis value from *zmin* to *zmax* to probabilities in the range [0, 1]. Values less than *zmin* are assigned an occupancy value of `0`. Values greater than *zmax* are assigned an occupancy value of `1`.

`Window` — Logical to use windowing
`1` (`true`) (default) | `0` (`false`)

Logical to use windowing to suppress spectral leakage effects in the frequency domain, specified as a numeric or logical `0` (`false`) or `1` (`true`). When you set `Window` to `true`, the function uses a Blackman window to increase the stability of registration results. If the common features that will be aligned in the occupancy grids are oriented along the edges, then setting `Window` to `false` could provide superior registration results.

Output Arguments

`tform` — Rigid transformation
`rigidtform3d` object

Rigid transformation, returned as a `rigidtform3d` object. The `rigidtform3d` object describes the rigid 3-D transformation that registers the moving point cloud to the fixed point cloud.

`rmse` — Root mean square error
positive scalar

Root mean square error, returned as a positive numeric scalar that represents the Euclidean distance between the aligned points. The aligned points is a result of the moving point cloud transformed by the `tform` output and the fixed point cloud. For each point in the fixed point cloud, the algorithm finds the closest point in the transformed moving point cloud, then computes the Euclidean distance between the points, and then computes the `rmse`. A low `rmse` value indicates a more accurate registration. The `rmse` calculation is:

```
rmse = sqrt(sum(distance.^2,'all')/numel(distance));
```

peak — Peak correlation value
scalar value

Peak correlation value of the phase difference between the two occupancy grids, returned as a scalar value. A peak value less than `0.03` indicates a poor registration result.

Tips

- The phase correlation method is best used to register point clouds when the transformation can be described by a translation in the *X*-*Y* plane and a rotation around the *Z*-axis. For example, a ground vehicle with a horizontally mounted lidar moving on a flat surface.
- The phase correlation algorithm expects motion to be exclusively along the *X*-*Y* plane, as with the ground plane. If motion is not exactly in the *X*-*Y* plane, you can use the `normalRotation` function

to transform the point clouds. For example, in vehicular motion, you can reduce the effects of vehicle suspension or surface features such as potholes and speed bumps by using the `normalRotation` function.

- Increasing the size of the occupancy grid increases the computational demands of this function. You can control the size of the occupancy grid by modifying the `gridSize` and `gridStep` arguments.
- If you obtain poor registration results and the `peak` correlation value is less than `0.03`, try setting the `Window` argument to `false`.

Version History

Introduced in R2020b

R2022b: Returns `rigidtform3d` object

Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, the `pcregistercorr` function now returns `tform` as a `rigidtform3d` object, which uses the premultiply convention. Before, the function returned `tform` as a `rigid3d` object, which uses the postmultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

R2023b: `pcregistercorr` supports GPU code generation

The `pcregistercorr` function supports CUDA code generation for NVIDIA GPUs. You must have MATLAB Coder and GPU Coder to generate CUDA code.

scanContextDistance

Distance between scan context descriptors

Syntax

```
dist = scanContextDistance(descriptor1,descriptor2)
```

Description

`dist = scanContextDistance(descriptor1,descriptor2)` computes the normalized distance between scan context descriptors. Determine loop closure candidates using the computed distance.

A scan context descriptor is a 2-D global feature descriptor for a point cloud that can be used to detect loop closures. To extract a scan context descriptor from a point cloud, use the `scanContextDescriptor` function.

Examples

Extract and Compare Scan Context Descriptors of Point Clouds

Create a Velodyne® packet capture (PCAP) file reader.

```
veloReader = velodyneFileReader('lidarData_ConstructionRoad.pcap','HDL32E');
```

Read the 1st, 2nd, and 30th scan into the workspace.

```
ptCloud1 = readFrame(veloReader,1);
ptCloud2 = readFrame(veloReader,2);
ptCloud30 = readFrame(veloReader,30);
```

Extract scan context descriptors from each of the point clouds.

```
descriptor1 = scanContextDescriptor(ptCloud1);
descriptor2 = scanContextDescriptor(ptCloud2);
descriptor30 = scanContextDescriptor(ptCloud30);
```

Compute the descriptor distance between the 1st and 2nd scan context descriptors, and between the 1st and 30th scan context descriptors.

```
dist1to2 = scanContextDistance(descriptor1,descriptor2);
dist1to30 = scanContextDistance(descriptor1,descriptor30);
```

Display the scan context descriptor distances.

```
disp("Descriptor distance from frame 1 to 2:  " + num2str(dist1to2))
```

```
Descriptor distance from frame 1 to 2:  0.087647
```

```
disp("Descriptor distance from frame 1 to 30: " + num2str(dist1to30))
```

```
Descriptor distance from frame 1 to 30: 0.31551
```

Input Arguments

`descriptor1` — Scan context descriptor of point cloud

M-by-*N* matrix

Scan context descriptor of point cloud, specified as an *M*-by-*N* matrix. To ensure an accurate distance measurement, use the same radial range when extracting this descriptor as for `descriptor2`.

Data Types: `single` | `double`

`descriptor2` — Scan context descriptor of point cloud

M-by-*N* matrix

Scan context descriptor of point cloud, specified as an *M*-by-*N* matrix. To ensure an accurate distance measurement, use the same radial range when extracting this descriptor as for `descriptor1`.

Data Types: `single` | `double`

Output Arguments

`dist` — Distance between scan context descriptors

scalar in the range [0,1)

Distance between the scan context descriptors, returned as a scalar in the range [0,1). A small value indicates that the scan contexts are likely to belong to the same location, and are loop closure candidates. The function returns `dist` as a `single` data type when either `descriptor1` or `descriptor2` inputs is of `single` data type. Otherwise, the function returns `dist` as a `double` data type.

Data Types: `single` | `double`

Algorithms

- The function computes the distance between scan context descriptors using a modified cosine distance and normalizes it to the range [`0` to `1`).

scanContextDescriptor

Extract scan context descriptor from point cloud

Syntax

```
descriptor = scanContextDescriptor(ptCloud)
descriptor = scanContextDescriptor(ptCloud,Name,Value)
```

Description

`descriptor = scanContextDescriptor(ptCloud)` extracts a scan context descriptor from a point cloud, `ptCloud`.

A scan context descriptor is a 2-D global feature descriptor of a point cloud that can be used to detect loop closures. The function computes the descriptor by first binning points from a 3-D point cloud scan into concentric radial and azimuthal bins, and then selecting the maximum *z*-height of points in each bin.

`descriptor = scanContextDescriptor(ptCloud,Name,Value)` specifies options using one or more name-value pair arguments.

Examples

Extract and Compare Scan Context Descriptors of Point Clouds

Create a Velodyne® packet capture (PCAP) file reader.

```
veloReader = velodyneFileReader('lidarData_ConstructionRoad.pcap','HDL32E');
```

Read the 1st, 2nd, and 30th scan into the workspace.

```
ptCloud1 = readFrame(veloReader,1);
ptCloud2 = readFrame(veloReader,2);
ptCloud30 = readFrame(veloReader,30);
```

Extract scan context descriptors from each of the point clouds.

```
descriptor1 = scanContextDescriptor(ptCloud1);
descriptor2 = scanContextDescriptor(ptCloud2);
descriptor30 = scanContextDescriptor(ptCloud30);
```

Compute the descriptor distance between the 1st and 2nd scan context descriptors, and between the 1st and 30th scan context descriptors.

```
dist1to2 = scanContextDistance(descriptor1,descriptor2);
dist1to30 = scanContextDistance(descriptor1,descriptor30);
```

Display the scan context descriptor distances.

```
disp("Descriptor distance from frame 1 to 2:  " + num2str(dist1to2))
```

```
Descriptor distance from frame 1 to 2:  0.087647

disp("Descriptor distance from frame 1 to 30: " + num2str(dist1to30))

Descriptor distance from frame 1 to 30: 0.31551
```

Input Arguments

`ptCloud` — Point cloud

`pointCloud` object

Point cloud, specified as `pointCloud` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'NumBins',[20 60]` sets the number of radial bins to `20`, and the number of azimuthal bins to `60`.

`NumBins` — Number of concentric radial and angular bins

`[20 60]` (default) | vector of form [*numRadialBins numAzimuthalBins*]

Number of concentric radial and angular bins, specified as the comma-separated pair consisting of `'NumBins'` and a vector of the form [*numRadialBins numAzimuthalBins*], where *numRadialBins* is a positive integer that specifies the number of concentric radial bins and *numAzimuthalBins* specifies the number of concentric angular bins. To extract more compact descriptors, you can decrease the number of bins, but this reduces the discriminative power.

`MinPointsPerBin` — Minimum number of points for a bin to be included in descriptor

`5` (default) | scalar

Minimum number of points for a bin to be included in descriptor, specified as the comma-separated pair consisting of `'MinPointsPerBin'` and a positive integer. Bins that do not contain the minimum number of points are not included in the descriptor. For these bins, the function returns `NaN`. To reduce the chances for noise to be included as a bin, increase this value.

`SensorOrigin` — Sensor origin

`[0 0]` (default) | two-element vector

Sensor origin, specified as the comma-separated pair consisting of `'SensorOrigin'` and a two-element vector. The elements set the *x*- and *y*-axis coordinate points, respectively, of the sensor origin in world units. The function centers the bins around the origin of the scan.

`RadialRange` — Radial bounds of descriptor

full spatial extent of point cloud (default) | two-element vector

Radial bounds of the descriptor used when binning points, specified as the comma-separated pair consisting of `'RadialRange'` and a two-element vector in the form [*rmin*,*rmax*]. Use this name-value argument to restrict the spatial bounds covered by the descriptor.

Output Arguments

`descriptor` — Scan context descriptor

M-by-*N* matrix

Scan context descriptor, returned as an *M*-by-*N* matrix, where *M* and *N* are the number of concentric radial and angular bins, respectively, in the descriptor. These are specified by the `NumBins` property.

The function returns inherits the data type of the `Location` property of the input point cloud.

Data Types: `single` | `double`

Tips

- The scan context descriptor function assumes that the sensor is mounted roughly horizontally and that the input point cloud is in the sensor coordinate system.
- To determine loop closure candidates, compare the distance between two scan context descriptors using the `scanContextDistance` function.

Version History

“Implement Point Cloud SLAM in MATLAB”

pcalign

Align array of point clouds

Syntax

```
ptCloudOut = pcalign(ptClouds,tforms)
ptCloudOut = pcalign(ptClouds,tforms,gridStep)
ptCloudOut = pcalign( ___ ,GridFilter=gridFilterMethod)
```

Description

`ptCloudOut = pcalign(ptClouds,tforms)` aligns an array of point clouds, `ptClouds`, into one point cloud by using the specified transformations `tforms`.

`ptCloudOut = pcalign(ptClouds,tforms,gridStep)` applies a box grid filter with 3-D boxes of size specified as `gridStep`, to the aligned point cloud. The grid filter returns a single point per 3-D box.

`ptCloudOut = pcalign( ___ ,GridFilter=gridFilterMethod)` sets the method to downsample the aligned point cloud.

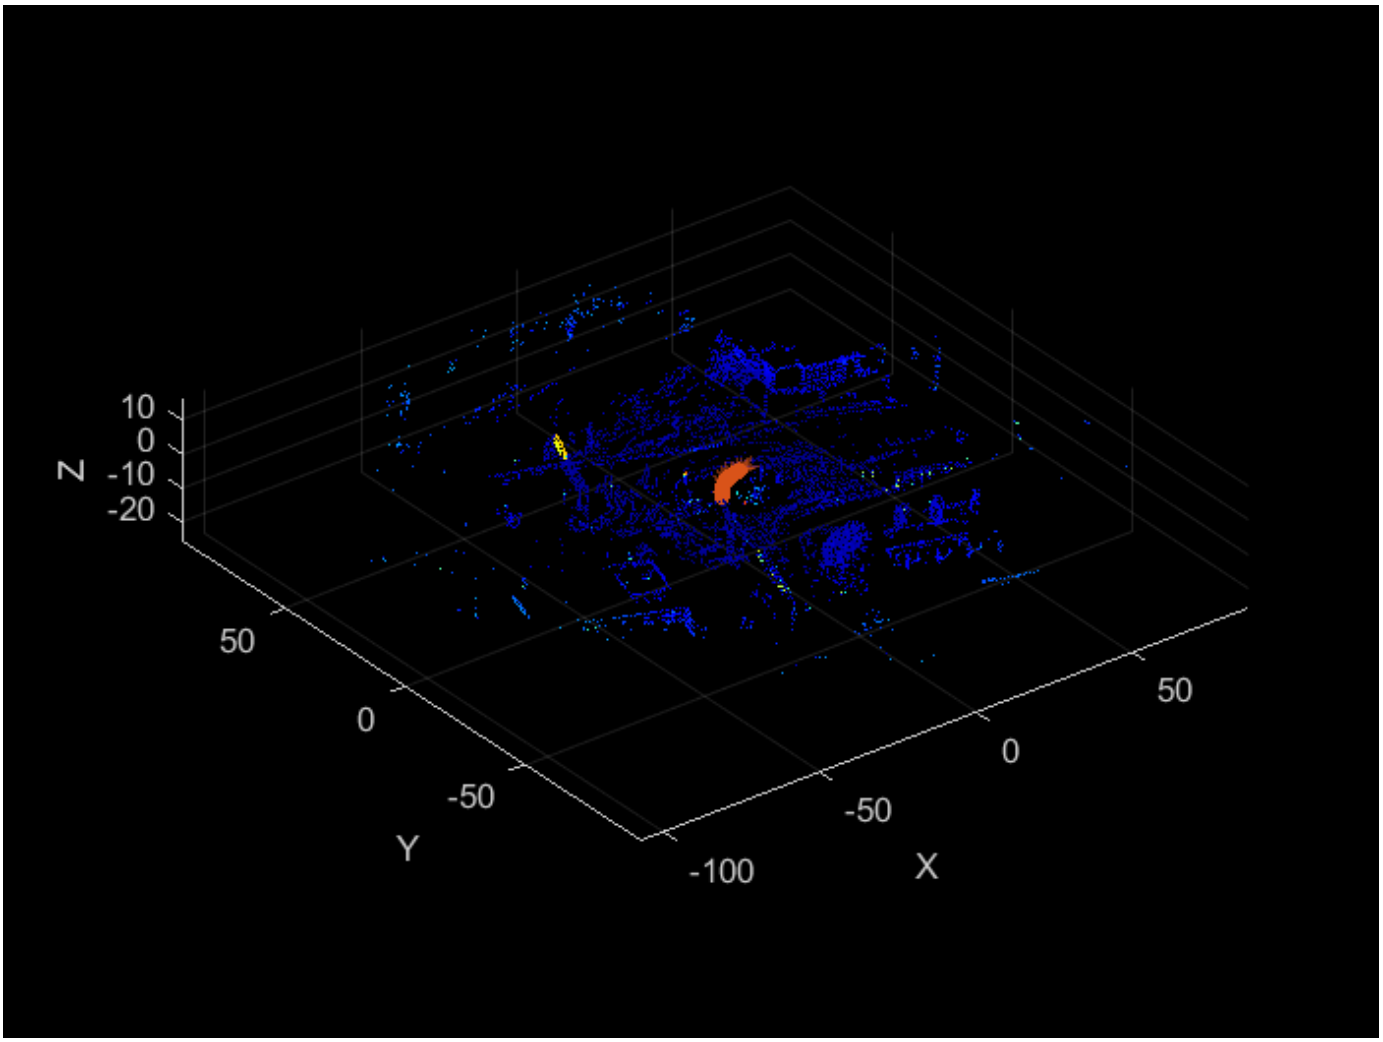
Examples

Align Point Clouds from View Set

Load a point cloud view set into the workspace.

```
data = load('vSetPointClouds.mat');
vSet = data.vSet;
```

Extract the point clouds and their absolute poses from the view set.



```
ptClouds = vSet.Views.PointCloud;
tforms   = vSet.Views.AbsolutePose;
```

Align the point clouds using their absolute poses, and apply a 3-D box filter of size 1 to the aligned point cloud.

```
gridStep = 1;
ptCloudMap = pcalign(ptClouds,tforms,gridStep);
```

Display the aligned point cloud map.

```
pcshow(ptCloudMap)
hold on
plot(vSet)
```

Input Arguments

`ptClouds` — Point clouds
`pointCloud` array

Point clouds, specified as a `pointCloud` array.

`tforms` — 3-D rigid or affine geometric transformations
M-by-1 `rigidtform3d` array | *M*-by-1 `affinetform3d` array

3-D rigid or affine geometric transformations, specified as an *M*-by-1 array of `rigidtform3d` objects or an *M*-by-1 array of `affinetform3d` objects. The `tforms` argument must contain the same number of elements as the `ptClouds` argument.

`gridStep` — Size of 3-D box for grid filter
positive scalar

Size of the 3-D box for the grid filter, specified as a positive scalar. Increasing the value of `gridStep` can reduce memory usage by merging more points, but it can also reduce the amount of detail captured. The grid filter returns a single point per 3-D box.

Data Types: `single` | `double`

`gridFilterMethod` — Method to downsample aligned point cloud
`"average"` (default) | `"nearest"`

Method to downsample the aligned point cloud, specified as one of:

- `"average"` (default) — Selects a point in the voxel by averaging the location, color, intensity, and normal of all points within the voxel.
- `"nearest"` — Selects the voxel's location, color, intensity, and normal based on the point nearest to the centroid of the voxel.

Output Arguments

`ptCloudOut` — Aligned point cloud
`pointCloud` object

Aligned point cloud, returned as a `pointCloud` object.

Tips

- If the input point clouds do not all have an assigned value for a property, the function does not assign a value for that property in the returned point cloud. For example, if some of the input point clouds have values for the `Color` property but another one does not, then the function does not return a value for the `Color` property of `ptCloudOut`.
- The function filters out points with `NaN` or `Inf` values.

Version History

Introduced in R2020b

R2022b: Supports new geometric transformation objects

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, you can now specify `tforms` as an array of `rigidtform3d` or `affinetform3d` objects, which use the premultiply convention.

Although you can still specify `tforms` as an array of `rigid3d` or `affine3d` objects, these objects are not recommended because they use the postmultiply convention. You can streamline your geometric transformation workflows by switching to the new premultiply geometric transformation objects. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

pccat

Concatenate 3-D point cloud array

Syntax

```
ptCloudOut = pccat(ptClouds)
```

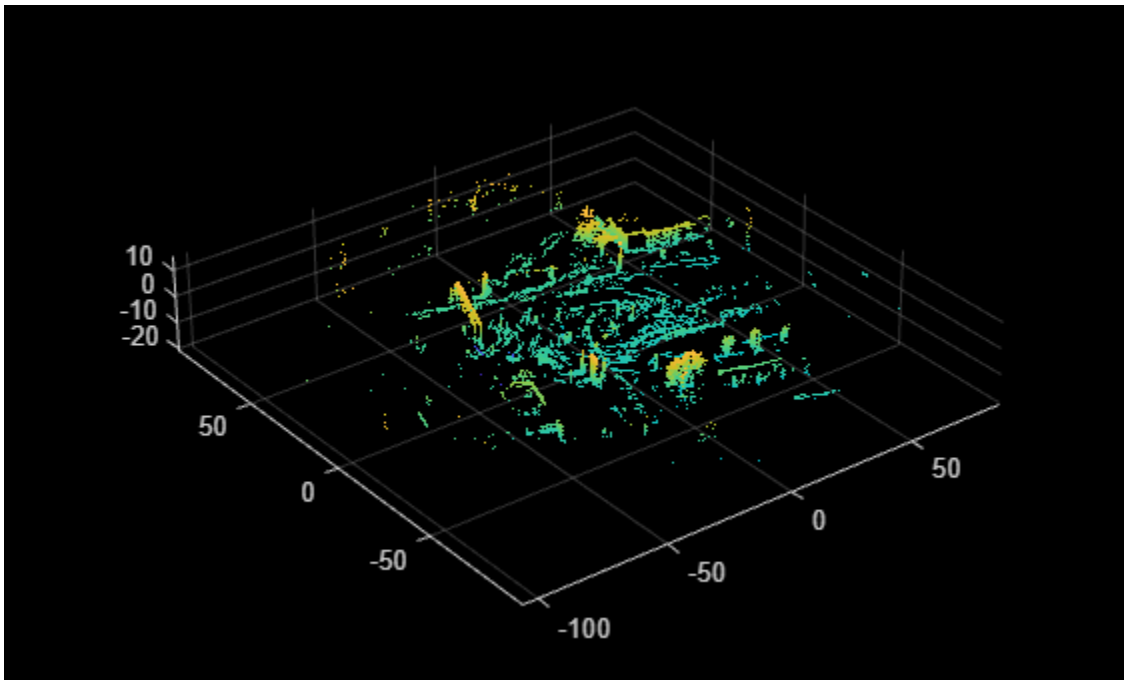
Description

`ptCloudOut = pccat(ptClouds)` concatenates a 3-D point cloud array, `ptClouds`. `ptCloudOut` contains the `Location`, `Color`, `Normal`, and `Intensity` property values of all the concatenated point clouds.

Examples

Combine Sequence of Point Clouds

Read a sequence of aligned point clouds.



```
filePath = fullfile(toolboxdir('vision'),'visiondata','pcdmapseq');
fileDS = fileDatastore(filePath,'ReadFcn',@pcread,'UniformRead',true);
ptClouds = readall(fileDS);
```

Concatenate point clouds into a single point cloud.

```
ptCloudOut = pccat(ptClouds);
```

Display concatenated point cloud.

```
pcshow(ptCloudOut)
```

Input Arguments

`ptClouds` — Point clouds

M-by-1 `pointCloud` array

Point cloud objects, specified as an *M*-by-1 `pointCloud` array.

Output Arguments

`ptCloudOut` — Concatenated point cloud

`pointCloud` object

Concatenated point cloud, returned as a `pointCloud` object. `ptCloudOut` contains the `Location`, `Color`, `Normal`, and `Intensity` property values of all the concatenated point clouds.

Tips

- If the input point clouds do not all have an assigned value for a property, the function does not assign a value for that property in the returned point cloud. For example, if some of the input point clouds have values for the `Color` property but another one does not, then the function does not return a value for the `Color` property of `ptCloudOut`.
- The function filters out points with `NaN` or `Inf` values.

Version History

Introduced in R2020b

Extended Capabilities

readAprilTag

Detect and estimate pose for AprilTag in image

Syntax

```
[id,loc] = readAprilTag(I)
[id,loc] = readAprilTag(I,tagFamily)
[___,pose] = readAprilTag(___,intrinsics,tagSize)
[___,detectedFamily] = readAprilTag(___)
[___] = readAprilTag(___,Name=Value)
```

Description

`[id,loc] = readAprilTag(I)` detects AprilTags in the input image `I` and returns the locations and IDs associated with the tags.

`[id,loc] = readAprilTag(I,tagFamily)` detects AprilTags of only the specified families, `tagFamily`.

`[___,pose] = readAprilTag(___,intrinsics,tagSize)` returns the poses of the tags with respect to the specified camera intrinsic parameters, `intrinsics` and size of the tags `tagSize` in addition to any combination of arguments in previous syntaxes.

`[___,detectedFamily] = readAprilTag(___)` returns the recognized AprilTag families, `detectedFamily`.

`[___] = readAprilTag(___,Name=Value)` specifies options using one or more name-value arguments. For example, `GaussianSigma=2`, sets the standard deviation to 2 for the 2-D Gaussian smoothing kernel.

Examples

Detect AprilTags in Image

Read an image into the workspace.

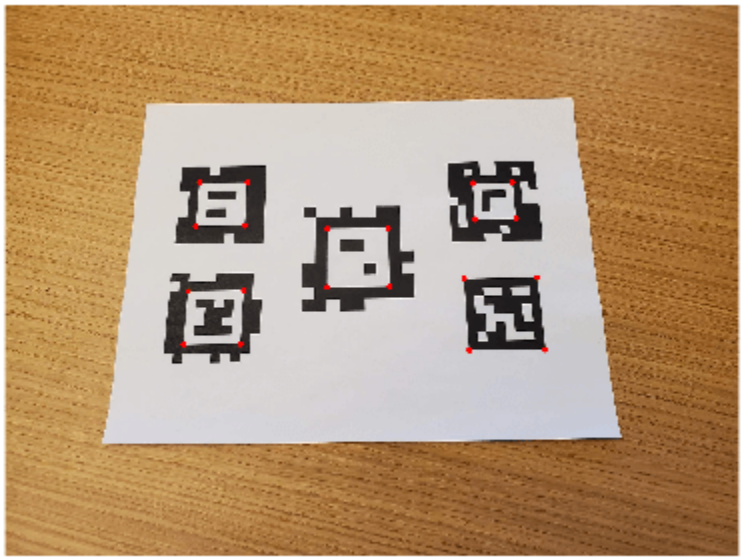
```
I = imread("aprilTagsMulti.jpg");
```

Specify the AprilTag formats to search in the image.

```
tagFamily = ["tag36h11","tagCircle21h7","tagCircle49h12","tagCustom48h12","tagStandard41h12"];
```

Detect tags and tag locations in the image, and read the tag IDs.

```
[id,loc,detectedFamily] = readAprilTag(I,tagFamily);

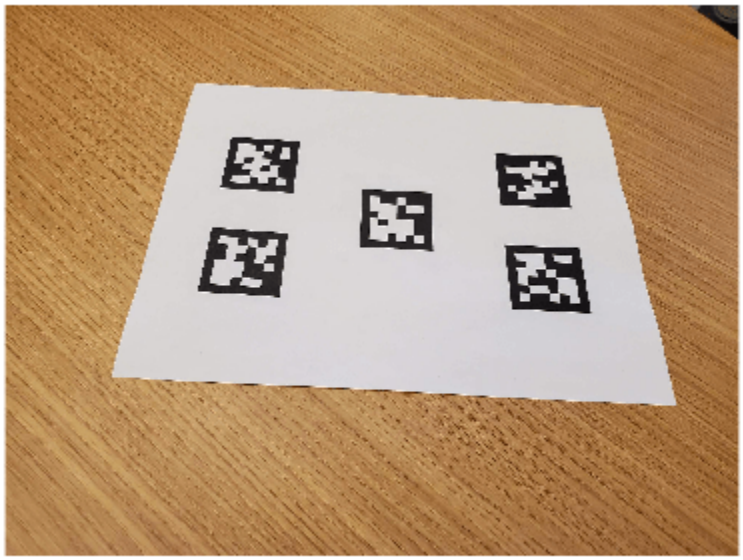


for idx = 1:length(id)
        % Display the ID and tag family
        disp("Detected Tag ID, Family: " + id(idx) + ", " ...
            + detectedFamily(idx));
```

```
        % Insert markers to indicate the locations
        markerRadius = 8;
        numCorners = size(loc,1);
        markerPosition = [loc(:,:,idx),repmat(markerRadius,numCorners,1)];
        I = insertShape(I,"FilledCircle",markerPosition,ShapeColor="red",Opacity=1);
end
```

```
Detected Tag ID, Family: 30, tag36h11
Detected Tag ID, Family: 32, tagCircle21h7
Detected Tag ID, Family: 98, tagStandard41h12
Detected Tag ID, Family: 195, tagCustom48h12
Detected Tag ID, Family: 884, tagCircle49h12
```

Display the image with markers to indicate the corner locations of the detected tags.



```
imshow(I)
```

Estimate AprilTag Poses in Image

Read an image that contains AprilTags into the workspace. Display the image.

```
I = imread("aprilTag36h11.jpg");
imshow(I)
```

Load the camera intrinsic parameters.

```
data = load("camIntrinsicsAprilTag.mat");
intrinsics = data.intrinsics;
```

Specify the tag size in meters.

```
tagSize = 0.04;
```

Undistort the input image using the camera intrinsic parameters.

```
I = undistortImage(I,intrinsics,OutputView="same");
```

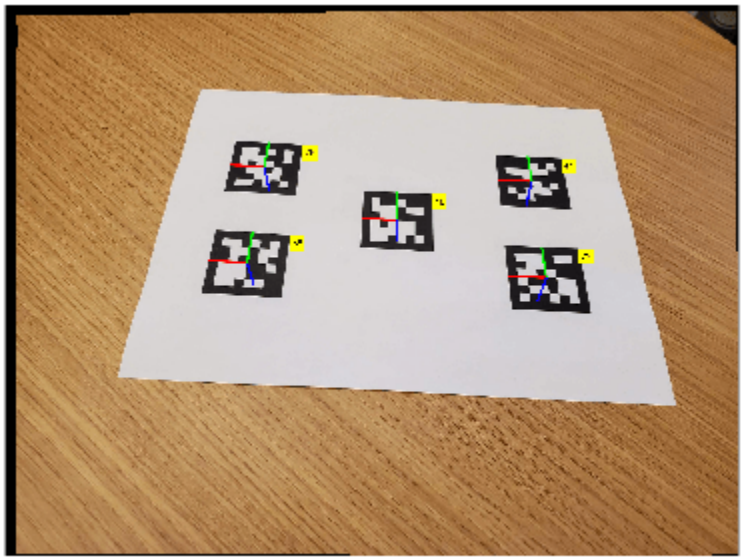
Detect a specific family of AprilTags and estimate the tag poses.

```
[id,loc,pose] = readAprilTag(I,"tag36h11",intrinsics,tagSize);
```

Set the origin for the axes vectors and for the tag frames.

```
worldPoints = [0 0 0; tagSize/2 0 0; 0 tagSize/2 0; 0 0 tagSize/2];
```

Add the tag frames and IDs to the image.



```
for i = 1:length(pose)
    % Get image coordinates for axes.
    imagePoints = world2img(worldPoints,pose(i),intrinsics);

    % Draw colored axes.
    I = insertShape(I,Line=[imagePoints(1,:) imagePoints(2,:); ...
        imagePoints(1,:) imagePoints(3,:); imagePoints(1,:) imagePoints(4,:)], ...
        ShapeColor=["red","green","blue"],LineWidth=7);

    I = insertText(I,loc(1,:,i),id(i),BoxOpacity=1,FontSize=25);
end
```

Display the annotated image.

```
imshow(I)
```

Input Arguments

`I` — Input image

M-by-*N*-by-3 truecolor image | *M*-by-*N* grayscale image

Input image, specified as an *M*-by-*N*-by-3 truecolor image or an *M*-by-*N* grayscale image.

`tagFamily` — AprilTag families

one or more valid AprilTag families

AprilTag families, specified as one or more of the valid AprilTag families listed in this table. Specifying a family can reduce the run time of the function by restricting the search.

AprilTag Family
`"tag16h5"`
`"tag25h9"`
`"tag36h11"`
`"tagCircle21h7"`
`"tagCircle49h12"`
`"tagCustom48h12"`
`"tagStandard41h12"`
`"tagStandard52h13"`

Data Types: `char` | `string` | `cell`

`intrinsics` — Camera intrinsic parameters
`cameraIntrinsics` object

Camera intrinsic parameters, specified as a `cameraIntrinsics` object.

`tagSize` — Size of tag
positive scalar

Size of the tags in world units (such as millimeters), specified as a positive scalar. The function defines the size of the tags as the length between two adjacent corner outer black edges.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `readAprilTag(I,GaussianSigma=2)` sets the standard deviation to 2 for the 2-D Gaussian smoothing kernel.

`GaussianSigma` — Standard deviation for 2-D Gaussian smoothing kernel
`0` (default) | non-negative scalar

Standard deviation for 2-D Gaussian smoothing kernel, specified as a non-negative scalar. The Gaussian kernel smooths the input image to decrease white Gaussian noise. Increase this value to increase the speed of processing, but at the cost of precision.

`DecimationFactor` — Decimation factor
2 (default) | positive integer

Decimation factor, specified as a positive integer. The decimation factor controls the scale of the downsampling. Increase this value to increase the detection rate, while decreasing detection distance.

Output Arguments

`id` — Tag IDs
vector of positive integers

Tag IDs, returned as a vector of positive integers.

`loc` — Locations of tags in image
4-by-2-by-*N* array

Locations of tags in image, returned as a 4-by-2-by-*N* array. The array contains the (*x*,*y*) locations for each of the four corners for *N* tags.

`pose` — Poses of tags
array of `rigidtform3d` objects

Poses of tags with respect to the camera, returned as an array of `rigidtform3d` objects. Each object encapsulates the 3-D rigid transformation of a tag in the same world units as the `tagSize` input

argument. The origin of each tag frame is located at the center of the corresponding tag. The *X*-*Y* plane of the tag frame is defined by the planar surface on which the AprilTag sits with the *Z*-axis pointing into the tag.

`detectedFamily` — Detected tag families
vector of strings

Detected tag families, returned as a vector of strings.

Tips

- For applications that require real-time performance, while also minimizing false-positive detections, consider using the `"tag36h11"` family tag.
- For applications that require a faster detection time as opposed to the number of supported IDs, use the `"tagStandard41h12"` family tag.
- For pregenerated tags for all supported tag families, see Pregenerated AprilTag Images on GitHub.
- The `readAprilTag` function cannot read AprilTags containing 2 border bits.

Version History

Introduced in R2020b

R2022b: Returns poses as `rigidtform3d` objects
Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, the `readAprilTag` function now returns `pose` as an array of `rigidtform3d` objects, which use the premultiply convention. Before, the function returned `pose` as an array of `rigid3d` objects, which use the postmultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

- Generates code only on host platforms.
- You must specify the input argument `tagFamily` as a character vector or an array of character vectors. String inputs are not supported.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

evaluateDetectionAOS

(To be removed) Evaluate average orientation similarity metric for object detection

Note `evaluateDetectionAOS` will be removed in a future release. Use `evaluateObjectDetection` instead.

Syntax

```
metrics = evaluateDetectionAOS(detectionResults,groundTruthData)
metrics = evaluateDetectionAOS(detectionResults,groundTruthData,threshold)
```

Description

`metrics = evaluateDetectionAOS(detectionResults,groundTruthData)` computes the average orientation similarity (AOS) metric. The metric can be used to measure the detection results `detectionResults` against ground truth data `groundTruthData`. The AOS is a metric for measuring detector performance on rotated rectangle detections.

`metrics = evaluateDetectionAOS(detectionResults,groundTruthData,threshold)` additionally specifies the overlap threshold for assigning a detection to a ground truth bounding box.

Input Arguments

`detectionResults` — Detection results

three-column table

Detection results, specified as a three-column table. The columns contain rotated rectangle bounding boxes, scores, and labels.

Bounding Box	Format	Description
Rotated rectangle	[x_{center}, y_{center}, *width*, *height*, *yaw*]	This type of bounding box is defined in spatial coordinates as an *M*-by-5 matrix representing *M* bounding boxes. The x_{center} and y_{center} coordinates represent the center of the bounding box. The *width* and *height* elements represent the length of the box along the *x* and *y* axes, respectively. The *yaw* represents the rotation angle in degrees. The amount of rotation about the center of the bounding box is measured in the clockwise direction.

`groundTruthData` — Labeled ground truth images

datastore | table

Labeled ground truth images, specified as a datastore or a table.

- If you use a datastore, your data must be set up so that calling the datastore with the `read` and `readall` functions returns a cell array or table with two or three columns. When the output contains two columns, the first column must contain bounding boxes, and the second column must contain labels, {*boxes*,*labels*}. When the output contains three columns, the second column must contain the bounding boxes, and the third column must contain the labels. In this case, the first column can contain any type of data. For example, the first column can contain images or point cloud data, such as:

data	***boxes***	***labels***
The first column must be images.	Bounding boxes	The third column must be a cell array that contains *M*-by-1 categorical vectors containing object class names. All categorical data returned by the datastore must contain the same categories.

- If you use a table, the table must have two or more columns.

data	***boxes***	***...***
The first column can contain data, such as point cloud data or images.	Each of the remaining columns must be a cell vector that contains *M*-by-5 matrices representing rotated rectangle bounding boxes. Each rotated rectangle must be of the form[x_{center}, y_{center}, *width*, *height*, *yaw*]. The vectors represent the location and size of bounding boxes for the objects in each image.	

`threshold` — Overlap threshold

nonnegative scalar

Overlap threshold, specified as a nonnegative scalar. The overlap ratio is defined as the intersection over union.

Output Arguments

`metrics` — AOS metrics

five-column table

AOS metrics, returned as a five-column table. Each row in the table contains the evaluation metrics for a class which is defined in the ground truth data contained in the `groundTruthData` input. To get the object class names:

`metrics.Properties.RowNames`

This table describes the five columns in the `metrics` table.

Column	Description
`AOS`	Average orientation similarity value
`AP`	Average precision over all the detection results, returned as a numeric scalar. Precision is a ratio of true positive instances to all positive instances of objects in the detector, based on the ground truth.
`OrientationSimilarity`	Orientation similarity values for each detection, returned as an *M*-element numeric column. *M* is one more than the number of detections assigned to a class. The first value of `OrientationSimilarity` is `1`. Orientation similarity is a normalized variant of the cosine similarity that measures the similarity between the predicted rotation angle and the ground truth rotation angle.
`Precision`	Precision values from each detection, returned as an *M*-element numeric column vector. *M* is one more than the number of detections assigned to a class. For example, if your detection results contain 4 detections with class label 'car', then `Precision` contains 5 elements. The first value of `Precision` is `1`. Precision is a ratio of true positive instances to all positive instances of objects in the detector, based on the ground truth.
`Recall`	Recall values from each detection, returned as an *M*-element numeric column vector. *M* is one more than the number of detections assigned to a class. For example, if your detection results contain 4 detections with class label 'car', then `Recall` contains 5 elements. The first value of `Recall` is `0`. Recall is a ratio of true positive instances to the sum of true positives and false negatives in the detector, based on the ground truth.

Version History

Introduced in R2020a

R2023b: `evaluateDetectionAOS` will be removed in a future release
Not recommended starting in R2023b

The `evaluateDetectionAOS` function will be removed in a future release. Use the `evaluateObjectDetection` function to evaluate object detection results with metrics such as the AOS, instead.

Objects
`boxLabelDatastore`

evaluateObjectDetection

Evaluate object detection data set against ground truth

Syntax

```
metrics = evaluateObjectDetection(detectionResults,groundTruthData)
metrics = evaluateObjectDetection(detectionResults,groundTruthData,threshold)
metrics = evaluateObjectDetection( ___ ,Name=Value)
```

Description

`metrics = evaluateObjectDetection(detectionResults,groundTruthData)` evaluates the quality of the object detection results `detectionResults` against the labeled ground truth `groundTruthData` and returns various metrics.

`metrics = evaluateObjectDetection(detectionResults,groundTruthData,threshold)` specifies the overlap threshold for assigning an output bounding box to a ground truth bounding box.

`metrics = evaluateObjectDetection( ___ ,Name=Value)` specifies one or more name-value arguments, in addition to any combination of input arguments from previous syntaxes, to configure the object detection results evaluation. For example, `AdditionalMetrics="AOS"` includes average orientation similarity metrics in the output.

Examples

Plot Precision-Recall Curve for Object Detection

Load a table containing images and ground truth bounding box labels. The first column contains the images, and the remaining columns contain the labeled bounding boxes.

```
data = load("vehicleTrainingData.mat");
trainingData = data.vehicleTrainingData;
```

Set the value of the `dataDir` variable as the location where the `vehicleTrainingData.mat` file is located. Load the test data into a local vehicle data folder.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata");
trainingData.imageFilename = fullfile(dataDir,trainingData.imageFilename);
```

Create an `imageDatastore` using the files from the table.

```
imds = imageDatastore(trainingData.imageFilename);
```

Display the first 5 rows of the training data table.

```
disp(trainingData(1:5,:))
```

imageFilename	vehicle

```
    "B:\runnable\matlab\toolbox\vision\visiondata\vehicles\image_00001.jpg"    {[126 78 20 16]}
    "B:\runnable\matlab\toolbox\vision\visiondata\vehicles\image_00002.jpg"    {[100 72 35 26]}
    "B:\runnable\matlab\toolbox\vision\visiondata\vehicles\image_00003.jpg"    {[ 62 69 26 19]}
    "B:\runnable\matlab\toolbox\vision\visiondata\vehicles\image_00004.jpg"    {[ 71 64 22 21]}
    "B:\runnable\matlab\toolbox\vision\visiondata\vehicles\image_00005.jpg"    {[147 71 25 18]}
```

Create a `boxLabelDatastore` using the label columns from the table.

```
blds = boxLabelDatastore(trainingData(:,2:end));
```

Load Pretrained Object Detector

Load a pretrained YOLO v2 object detector trained to detect vehicles into the workspace.

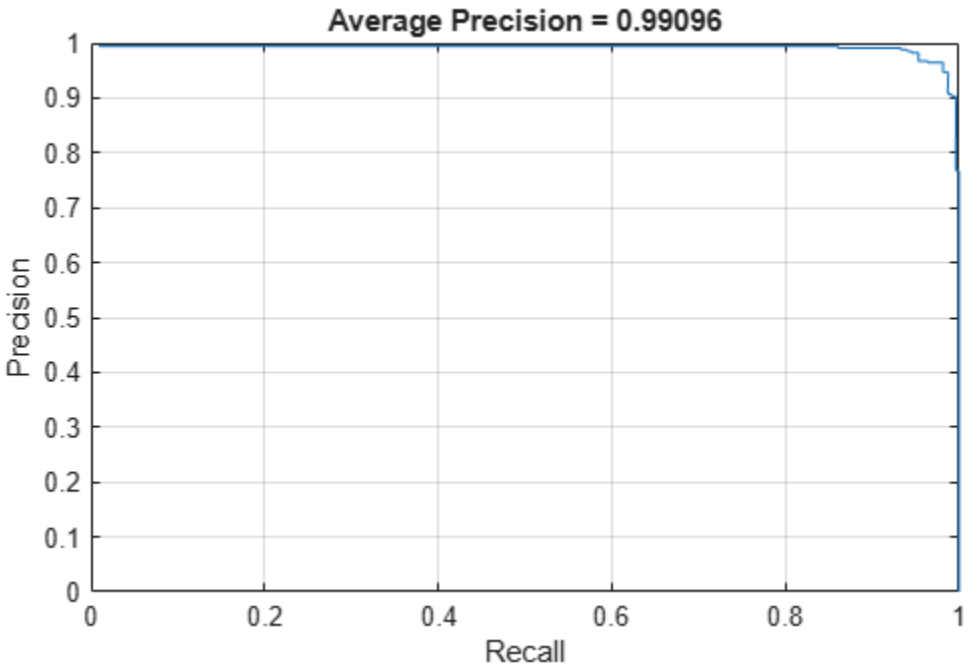
```
vehicleDetector = load("yolov2VehicleDetector.mat");
detector = vehicleDetector.detector;
```

Evaluate and Plot Object Detection Metrics

Run the detector on the test images. Set the detection threshold to a low value to detect as many objects as possible. This helps you evaluate the detector precision across the full range of recall values.

```
results = detect(detector,imds,Threshold=0.01);
```

Use `evaluateObjectDetection` to compute metrics for evaluating the performance of an object detector.



```
metrics = evaluateObjectDetection(results,blds);
```

Return the precision and recall metrics for the vehicle class using the `precisionRecall` object function.

```
[recall,precision,scores] = precisionRecall(metrics);
ap = averagePrecision(metrics);
```

Plot the precision-recall curve for the vehicle class, the only class in the data set. Compute the average precision (AP) using the `averagePrecision` object function.

```
figure
plot(recall{1},precision{1})
grid on
title("Average Precision = " + ap);
xlabel("Recall");
ylabel("Precision");
```

Compute the summary of the object detection metrics for the data set using the `summarize` object function.

```
[summaryDataset,summaryClass] = summarize(metrics);
disp(summaryDataset)
```

```
    NumObjects    mAPOverlapAvg    mAP0.5
    __________    _____________    _______

       336           0.99096       0.99096
```

Evaluate Trained ACF Object Detector on Rail Road Signs Data

This example shows how to evaluate the predictions from a trained ACF object detector on a dataset of rail road signs.

The test dataset images are stored as a zipped file attached to this example. Unzip this into the current working directory.

```
unzip("RRSignsTest.zip")
```

Load the ground truth for the railroad signs test dataset stored as a `groundTruth` object.

```
load("RRSignsGroundTruth.mat", "gTruthTest")
```

Load the pretrained ACF object detector.

```
load("RRSignsACFDetector.mat", "acfDetector")
```

Extract images and bounding boxes from the `groundTruth` object by using the `objectDetectorTrainingData` function. The function creates and stores data in the form an image datastore and a labeled bounding box datastore.

```
[imdsTest, bldsTest] = objectDetectorTrainingData(gTruthTest);
imshow(preview(imdsTest))
```

Combine the test images and ground truth labels into a single datastore.

```
testData = combine(imdsTest, bldsTest);
```

Run the detector on the test images.

```
testDetections = detect(acfDetector,testData);
```

Arrange the detector results into a format suitable for object detection evaluation. The ACF object detector does not explicitly predict the class label of an object. This label information needs to be added to the `testDetections` table.

```
numImages = height(testDetections);
labels = cell(numImages,1);
className = string(gTruthTest.LabelDefinitions.Name{1});
for i = 1:numImages
    numDetections = numel(testDetections.Scores{i});
    labels{i} = categorical(repmat(className, [numDetections 1]), className);
end

testDetections.Labels = labels;
```

Evaluate the detector results.

```
metrics = evaluateObjectDetection(testDetections, testData);
```

Display the average precision metric, which summarizes the detector's performance over the test dataset. The ACF detector performs well on this dataset with an AP of 0.8.

```
disp(summarize(metrics, MetricName="AP"))
```

```
    NumObjects    mAPOverlapAvg    mAP0.5
    __________    _____________    ______

        10             0.8           0.8
```

Display the detector performance on individual images.

```
imageSummary = imageMetrics(metrics);
disp(imageSummary)
```

```

         2                1                       1              1     0     0          1
         3                0                       1              0     0     1        NaN
         4                1                       1              1     0     0          1
         5                1                       1              1     0     0          1
         6                1                       1              1     0     0          1
         7                1                       1              1     0     0          1
         8                1                       1              1     0     0          1
         9                1                       1              1     0     0          1
        10                0                       1              0     0     1        NaN
```

The detector makes a mistake on only 2 out of 10 images in the test set, shown on rows 3 and 10.

Evaluate Miss Rate of a YOLO v2 Object Detector

This example shows how to evaluate miss rate of a pretrained YOLO v2 object detector.

Load the Vehicle Ground Truth Data

Load a table containing the vehicle training data. The first column contains the training images, the remaining columns contain the labeled bounding boxes.

```
data = load('vehicleTrainingData.mat');
trainingData = data.vehicleTrainingData(1:100,:);
```

Add fullpath to the local vehicle data folder.

```
dataDir = fullfile(toolboxdir('vision'), 'visiondata');
trainingData.imageFilename = fullfile(dataDir, trainingData.imageFilename);
```

Create an imageDatastore using the files from the table.

```
imds = imageDatastore(trainingData.imageFilename);
```

Create a boxLabelDatastore using the label columns from the table.

```
blds = boxLabelDatastore(trainingData(:,2:end));
```

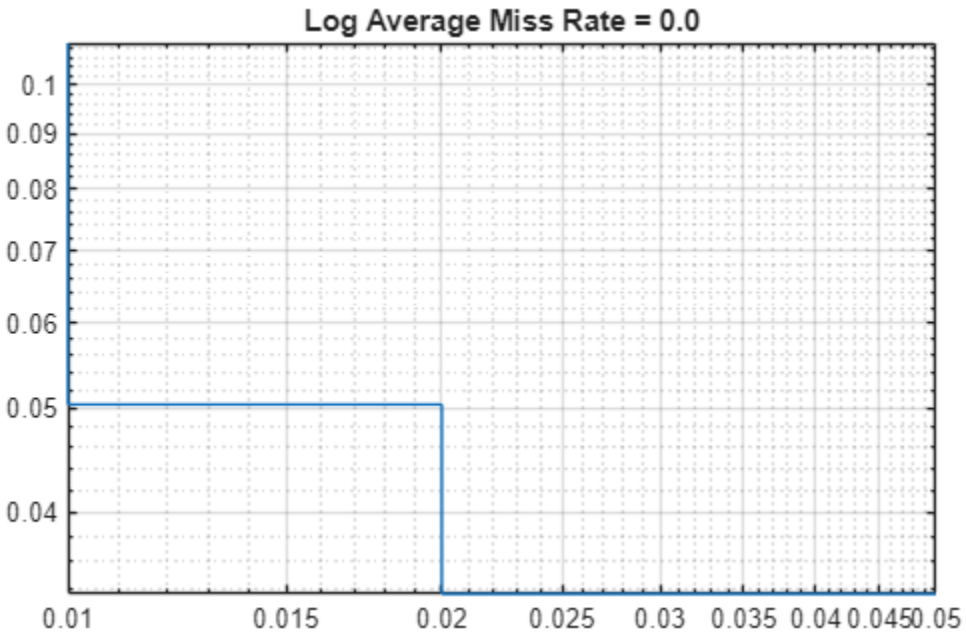
Load YOLOv2 Detector for Detection

Load the detector containing the layerGraph for trainining.

```
vehicleDetector = load('yolov2VehicleDetector.mat');
detector = vehicleDetector.detector;
```

Evaluate and Plot the Miss Rate Results

Run the detector with imageDatastore.



```
results = detect(detector,imds);
```

Evaluate the results against the ground truth data using the `evaluateObjectDetection` function. Specify the `AdditionalMetrics="LAMR"` name-value argument to include miss rate and false positives per image (FPPI) in the returned metrics.

```
metrics = evaluateObjectDetection(results,blds,AdditionalMetrics="LAMR");
```

Plot the log-miss-rate/FPPI curve.

```
figure;
loglog(metrics.ClassMetrics.FPPI{1}, metrics.ClassMetrics.MR{1});
grid on
title(sprintf('Log Average Miss Rate = %.1f', metrics.ClassMetrics.LAMR{1}))
```

Create Ground Truth and Use AOS Metric To Evaluate Rotated Rectangle Detections

Define ground truth bounding boxes in two images corresponding to a vehicle class. Each row defines a rotated bounding box of the form [*xcenter*, *ycenter*, *width*, *height*, *yaw*].

```
gtbbox_img1 = [
    2 2 10 20 45
    80 80 30 40 15
    ];

gtbbox_img2 = [
    4 4 20 40 90
```

```
    160 160 60 80 30
    ];

gtlabel = ["vehicle"
           "vehicle"
           ];
gtlabel = categorical(gtlabel);
```

Create a table to hold the ground truth data. Each row in the table shows ground truth boxes and labels for one image.

```
groundTruthData = table({gtbbox_img1;gtbbox_img2},{gtlabel;gtlabel},'VariableNames',{'Boxes','Lal
```

```
groundTruthData=2×2 table
       Boxes             Lables
    ___________    _________________

    {2×5 double}    {2×1 categorical}
    {2×5 double}    {2×1 categorical}
```

For each image, define detection results for rotated bounding boxes, scores, and labels.

```
bbox_img1 = [
    4 4 10 20 20
    50 50 30 10 30
    90 90 40 50 10 ];

bbox_img2 = [
    8 8 20 40 40
    100 100 60 20 60
    180 180 80 100 20 ];

scores = [0.9 0.7 0.8]';

labels = [
    "vehicle"
    "vehicle"
    "vehicle"
    ];
labels = categorical(labels,"vehicle");
```

Create a table to hold the detection results. Each row in the table shows detected boxes,scores and labels for one image

```
detectionResults = table({bbox_img1;bbox_img2},...
    {labels;labels},...
    {scores;scores},'VariableNames',{'Boxes','Labels','Scores'})
```

```
detectionResults=2×3 table
       Boxes             Labels              Scores
    ___________    _________________    ____________

    {3×5 double}    {3×1 categorical}    {3×1 double}
    {3×5 double}    {3×1 categorical}    {3×1 double}
```

Evaluate the results against the ground truth data using the `evaluateObjectDetection` function. Specify the `AdditionalMetrics="AOS"` name-value argument to include average orientation similarity (AOS) in the returned metrics.

```
metrics = evaluateObjectDetection(detectionResults,groundTruthData,AdditionalMetrics="AOS");
```

Display average orientation similarity (AOS) for each class averaged over all the specified overlap thresholds.

```
meanAOSOverAllOverlaps = metrics.ClassMetrics.AOSOverlapAvg
```

```
meanAOSOverAllOverlaps =
0.2600
```

Display orientation similarity vector for each class.

```
orientationSimilarity = metrics.ClassMetrics.OrientationSimilarity
```

```
orientationSimilarity = 1×1 cell array
    {[1 0.9532 0.4766 0.3177 0.2383 0.1906 0.1589]}
```

Input Arguments

`detectionResults` — Predicted object detection results

table

Predicted object detection results, specified as a three-column table with the same number of rows as the number of images in the data set. The table must contain the bounding box, predicted label, and score for each detected object in this format:

Bounding Boxes	Labels	Scores
Predicted 2-D bounding boxes for M objects, specified as an M-by-4 or M-by-5 numeric array. Each 2-D bounding box must be in the format [*x y width height*] if axis-aligned, or in the format [x_{center} y_{center} *width height yaw*] if rotated.	Predicted object labels, specified as an M-by-1 categorical vector.	Predicted scores, specified as an M-by-1 numeric vector.

The order of the elements does not matter. When the datastore returns a cell array with more than three elements, the `evaluateObjectDetection` function assumes that the first element with an M-by-4 or M-by-5 numeric array contains the bounding boxes, the first element with categorical data contains the label data, and the first element with M-by-1 numeric data contains the scores.

You can create the detection results table using the `detect` function associated with your object detector.

`groundTruthData` — Labeled ground truth

datastore | table

Labeled ground truth, specified as a datastore with two outputs or a table with two columns. If you are specifying a table, the number of rows must match the number of images in the data set with these columns:

boxes	*labels*
Ground truth 2-D bounding boxes for *M* objects, specified as an *M*-by-4 or *M*-by-5 numeric array. Each 2-D bounding box must be in the format [*x y width height*] if axis-aligned, or in the format [x_{center} y_{center} *width height yaw*] if rotated.	Ground truth object labels, specified as an *M*-by-1 categorical vector.

The order of the elements does not matter. When the datastore returns a cell array with more than three elements, the `evaluateObjectDetection` function assumes that the first element with an *M*-by-4 or *M*-by-5 numeric array contains the bounding boxes, the first element with categorical data contains the label data, and the first element with *M*-by-1 numeric data contains the scores.

`threshold` — Overlap threshold
`0.5` (default) | numeric scalar | numeric vector

Overlap threshold for assigning a detection to a ground truth box, specified as a numeric scalar in the range [0, 1] or a numeric vector. The overlap ratio is the intersection over union (IoU) ratio of two bounding boxes, or the ratio of the bounding box overlap area to the combined area of the predicted boxes and ground truth (minus the overlap).

IoU = Area of Overlap / (Ground Truth Area + Predicted Box Area – Intersection Area)

When you specify a numeric vector, the `evaluateObjectDetection` function calculates metrics for each threshold.

Tip To reduce the number of false negatives, you can lower the IoU threshold at the possible expense of increasing the number of false positives. To learn about the role of IoU in detection evaluation, see “Overlap Threshold (Intersection Over Union)” on page 3-222.

Tip To optimize model performance for your application, you can evaluate the object detection metrics across a range of overlap thresholds. To learn how to fine-tune object detector performance using multiple overlap thresholds, see “Tips” on page 3-222.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `evaluateObjectDetection(__,AdditionalMetrics=["LAMR","AOS"])` additionally returns LAMR and AOS.

`Verbose` — Evaluation progress display toggle
`true` or `1` (default) | `false` or `0`

Evaluation progress display toggle, specified as a numeric or logical `1` (`true`) or `0` (`false`). If you specify `Verbose` as `true`, the function displays progress information in the Command Window. The

displayed information includes a progress bar, elapsed time, estimated time remaining, and data set metrics.

`AdditionalMetrics` — Additional metrics
`[]` (default) | `"LAMR"` | `"AOS"` | string array

Additional metrics, specified as `"LAMR"`, `"AOS"`, or a string array. The function returns the specified metrics as additional columns in the `ClassMetrics` table of the `objectDetectionMetrics` object, as shown in this table below.

`AdditionalMetrics`	`ClassMetrics`
`"LAMR"`	**`LAMROverlapAverage`:** Log-average miss rate for each class, averaged over all specified thresholds, as a numeric scalar. **`LAMR`:** Log-average miss rate for each class, computed at each threshold, as a *numThresh*-by-1 numeric vector. **`MR`:** Miss rate vector for each class as a *numThresh*-by-*numPredictions* matrix, where *numPredictions* is the number of predicted objects. **`FPPI`:** False positives per image vector for each class as a *numThresh*-by-*numPredictions* matrix.
`"AOS"`	**`AOSOverlapAvg`:** Average orientation similarity (AOS) for each class averaged over all the specified overlap thresholds, as a numeric scalar. **`AOS`:** Average orientation (AOS) similarity for each class computed at each overlap threshold as a *numThresh*-by-1 numeric vector. **`OrientationSimilarity`:** Orientation similarity vector for each class as a *numThresh*-by-(*numPredictions*+1) matrix.

To specify `"AOS"` as an additional metric, your input data must contain rotated bounding boxes.

Output Arguments

`metrics` — Object detection metrics
`objectDetectionMetrics` object

Object detection metrics, returned as an `objectDetectionMetrics` object. The `“OverlapThreshold” on page 2-0` property of the object corresponds to the value of the `threshold` argument.

More About

Overlap Threshold (Intersection Over Union)

Use overlap (or IoU) threshold to determine whether a detection is a true positive or false positive.

A detection is a true positive (TP) when both of these conditions are met:

- The predicted class matches the class of a ground truth (indicated by the confidence score exceeding the confidence threshold).
- The predicted bounding box has an IoU greater than or equal to the specified overlap threshold.

A detection is a false positive (FP) when at least one of these conditions is met:

- The predicted class does not match the class of a ground truth.
- The predicted bounding box has an IoU less than the specified overlap threshold.

A missed detection is a false negative (FN) when one or more of these conditions is met:

- The confidence score of the detection is lower than the confidence score threshold, resulting in a missed detection.
- The detection has an IoU less than the specified threshold, resulting in the predicted bounding box does not sufficiently overlapping with the ground truth, leading to the detection being discarded.

Quantify the accuracy of an object detector on a particular dataset by evaluating the overlap between the predicted bounding boxes and the ground truth bounding boxes.

Tips

To get started with evaluating object detector performance using various metrics such as precision-recall, average precision, and confusion matrix, see “Evaluate Object Detector Performance”.

To evaluate model performance across different levels of localization accuracy and fine-tune an object detector, compute metrics at multiple overlap (IoU) thresholds. Overlap thresholds vary typically from 0.5 to 0.95 during evaluation. For example, set the overlap threshold value to 0.5 to accept moderate overlap accuracy, and set the value to 0.95 to ensure very high localization accuracy. There are many ways to use the overlap threshold to tune object detector performance.

- By evaluating common metrics, such as precision and recall, at different overlap thresholds, you can evaluate the tradeoff between detecting more objects (higher recall) and ensuring those detections are accurate (higher precision).
- By evaluating model performance at a lower overlap threshold, such as 0.5, and at higher thresholds, such as 0.95, you can determine how good the detector is at identifying objects (detection) at the expense of precise localization (bounding box accuracy).
- By computing metrics such as the mean average precision (mAP) over multiple overlap thresholds, you can produce a single performance figure that accounts for both detection and localization accuracy, enabling you to compare different detection models.

To learn how to compute metrics at a range of overlap thresholds to tune detector performance, see the "Precision and Recall for a Single Class" section of the “Multiclass Object Detection Using YOLO v2 Deep Learning” example.

Version History

Introduced in R2023b

R2026a: Evaluate per-image object detection metrics

To evaluate the per-image object detection metrics for all images or a subset of images in the data set, use the `imageMetrics` object function.

To update your code to compute per-image metrics, replace instances of the `ImageMetrics` property with the `imageMetrics` object function. For an example, see the“Multiclass Object Detection Using YOLO v2 Deep Learning” example.

R2023b: Recommended over `evaluateDetectionPrecision`, `evaluateDetectionMissRate`, `evaluateDetectionAOS`

The `evaluateObjectDetection` function enables you to simultaneously calculate the average precision, miss rate, and AOS (if applicable) to evaluate detector performance. Therefore, `evaluateObjectDetection` is recommended over `evaluateDetectionPrecision`, `evaluateDetectionMissRate`, and `evaluateDetectionAOS`, which will be removed in a future release. To update your code, ensure that your ground truth data is in the correct format. See the `groundTruthData` argument for more details.

`evaluateObjectDetection` improves on `evaluateDetectionPrecision` by enabling you to compute the object detection performance metrics for the entire data set over all classes and at specified overlap thresholds, use rotated bounding boxes, and calculate the confusion matrix. The corresponding `objectDetectionMetrics` object also enables you to evaluate object detection metrics across various object size ranges using the `metricsByArea` function.

evaluateReidentificationNetwork

Evaluate re-identification network using cumulative matching characteristic (CMC) and mean average precision (mAP) metrics

Syntax

```
[metrics,queries,gallerySets] = evaluateReidentificationNetwork(features,
labels)
[metrics,queries,gallerySets] = evaluateReidentificationNetwork( ___ ,
Name=Value)
```

Description

`[metrics,queries,gallerySets] = evaluateReidentificationNetwork(features, labels)` evaluates the performance of a re-identification (ReID) network and returns the cumulative matching characteristic (CMC) and mean average precision (mAP) metrics.

`[metrics,queries,gallerySets] = evaluateReidentificationNetwork( ___ , Name=Value)` configures the evaluation metrics using one or more name-value arguments, in addition to the input arguments from the previous syntax. For example, `DistanceMetric="euclidean-squared"` specifies `"euclidean-squared"` as the distance metrics method for measuring the distance between feature vectors.

Input Arguments

`features` — Features extracted by re-identification network

M-by-*N* matrix

Features extracted by the re-identification network using the `extractReidentificationFeatures` object function, specified as an *M*-by-*N* matrix. *N* is the number of images in the input datastore `ds`.

`labels` — Labels

1-by-*N* string array

Labels corresponding to the class name of each `features` column vector output by the `extractReidentificationFeatures` object function, specified as a 1-by-*N* string array. *N* is the number of images in the input datastore, `ds`.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `evaluateReidentificationNetwork(features,labels,DistanceMetric="euclidean-squared")` specifies `"euclidean-squared"` as the distance metrics method for measuring the distance between feature vectors.

`DistanceMetric` — Distance metrics method
`"cosine"` (default) | `"euclidean-squared"`

Distance metrics method to use in query evaluations to measure the distance between feature vectors, specified as `"cosine"` or `"euclidean-squared"`. For most cross-entropy training scenarios, use the `"euclidean-squared"` method.

`RandomizeQueries` — Order of queries
`true` or `1` (default) | `false` or `2`

Order of the queries, specified as a logical `true` or `false`. The function randomizes the order of the queries by default. If you specify `RandomizeQueries` as `false`, the function orders the queries in the same order as the columns in `features` and `labels`.

`Rank` — Ranks
`1` (default) | numeric scalar | numeric vector | `"all"`

Ranks to store in the `reidentificationMetrics` object for the CMC metric, specified as a non-repeating and increasing numeric scalar or numeric vector in the range [1, *C*], or `"all"`. *C* is the number of unique object classes in `labels`. If you specify `Rank` as `"all"`, the `reidentificationMetrics` stores all valid ranks of the CMC metric.

`Verbose` — Evaluation progress display toggle
`false` or `0` (default) | `true` or `1`

Evaluation progress display toggle, specified as a numeric or logical `1` (`true`) or `0` (`false`). If you specify `Verbose` as `true`, the function displays progress information in the Command Window. The displayed information includes a progress bar, elapsed time, estimated time remaining, and data set metrics.

Output Arguments

`metrics` — Re-identification metrics
`reidentificationMetrics` object

Re-identification metrics, returned as a `reidentificationMetrics` object.

`queries` — Queries for object retrieval
1-by-*N* vector of integers

Queries for object retrieval, returned as 1-by-*N* vector of integers. *N* is the number of columns in `features`. Each element in the vector represents the column index of the features used to query a gallery.

`gallerySets` — Gallery sets of images
C-by-*N* matrix of integers

Gallery sets of images for querying, returned as a *C*-by-*N* matrix of integers. *N* is the number of columns in `features`, and *C* is the number of unique classes in `labels`.

ssdLayers

(Removed) SSD multibox object detection network

Note `ssdLayers` function has been removed. Use the `ssdObjectDetector` function to create a SSD object detection network, instead.

Syntax

```
lgraph = ssdLayers(imageSize,numClasses,networkName)
lgraph = ssdLayers(imageSize,numClasses,network,anchorBoxes,
predictorLayerNames)
```

Description

`lgraph = ssdLayers(imageSize,numClasses,networkName)` creates a single shot detector (SSD) multibox object detection network based on the `networkName`, input image size, and the number of classes the network should be configured to classify. The network is returned as an `LayerGraph` object.

The SSD is a convolutional neural network-based object detector that predicts bounding box coordinates, classification scores, and corresponding class labels.

`lgraph = ssdLayers(imageSize,numClasses,network,anchorBoxes, predictorLayerNames)` returns an SSD that contains custom anchor boxes specified by `anchorBoxes` that are connected to the network layers at locations specified by `predictorLayerNames`. Specify these arguments in addition to the input argument from the previous syntax.

Examples

Create SSD Network Using VGG-16 Network

Specify the base network.

```
networkName = 'vgg16';
```

Specify the image size.

```
imageSize = [300 300 3];
```

Specify the classes to detect.

```
numClasses = 2;
```

Create the SSD object detection network.

```
lgraph = ssdLayers(imageSize,numClasses,networkName);
```

Visualize the network using the network analyzer.

```
analyzeNetwork(lgraph)
```

Input Arguments

`imageSize` — Size of input image

two-element vector | three-element vector

Size of input image, specified as one of these values.

- Two-element vector of the form [*H W*] for a grayscale image of size *H*-by-*W*
- Three-element vector of the form [*H W* 3] for an RGB color image of size *H*-by-*W*

When you set the `baseNetwork` input to `'vgg16'`, `'resnet50'`, or `'resnet101'`, the `imageSize` input must be of the form [*H W* 3].

`numClasses` — Number of classes for network to classify

positive scalar

Number of classes for the network to classify, specified as a positive scalar.

`network` — Pretrained convolutional neural network

`LayerGraph` object | `DAGNetwork` object | `SeriesNetwork` object

Pretrained convolutional neural network, specified as a `LayerGraph`, `DAGNetwork`, or `SeriesNetwork` object.

The pretrained convolutional neural network is used as the base for the SSD multibox object detection network. For details on pretrained networks in MATLAB, see “Pretrained Deep Neural Networks” (Deep Learning Toolbox).

`networkName` — Pretrained convolutional neural network

`'vgg16'` | `'resnet50'` | `'resnet101'`

Pretrained convolutional neural network, specified as a string or character vector for the `'vgg16'`, `'resnet50'`, or `'resnet101'` network. To specify one of these names, you must download and install the network support packages for the corresponding valid network names.

- `vgg16`
- `resnet50`
- `resnet101`

The pretrained convolutional neural network is used as the base for the SSD multibox object detection network. For details on pretrained networks in MATLAB, see “Pretrained Deep Neural Networks” (Deep Learning Toolbox).

`anchorBoxes` — Anchor boxes

1-by-*M* cell array

Anchor boxes, specified as a 1-by-*M* cell array for *M* number of predictor layers in the SSD network. Each predictor layer contains a *K*-by-2 matrix that defines *K* anchor boxes of the form [*height width*]. The number of anchor boxes in each element can vary.

The size of each anchor box is determined based on the scale and aspect ratio of different object classes present in input training data. The size of each anchor box must be smaller than or equal to

the size of the input image. You can use the clustering approach for estimating anchor boxes from the training data. For more information, see “Estimate Anchor Boxes from Training Data”.

`predictorLayerNames` — Names of layers in input
M-element vector of strings | 1-by-*M* cell array of character vectors

Names of layers in input, specified as an *M*-element vector of strings or a 1-by-*M* cell array of character vectors. The SSD detection subnetworks are attached to the predictor layers specified by this input.

Output Arguments

`lgraph` — SSD multibox object detection network
`LayerGraph` object

SSD multibox object detection network, returned as a `LayerGraph` object.

Note The default value for the `Normalization` property of the image input layer in the returned `lgraph` object is set to the `Normalization` property of the base network specified in `baseNetwork`.

Algorithms

The `ssdLayers` function creates an SSD network and returns `lgraph`, an object that represents the network architecture for an SSD object detector.

The `trainSSDObjectDetector` function trains and returns an SSD object detector, `ssdObjectDetector`. Use the `detect` object function for the `ssdObjectDetector` object to detect objects using the detector trained with the SSD network architecture.

```
bbox = detect(detector,I)
```

The `ssdLayers` function uses a pretrained neural network as the base network, to which it adds a detection subnetwork required for creating an SSD object detection network. Given a base network, `ssdLayers` removes all the layers succeeding the feature layer in the base network and adds the detection subnetwork. The detection subnetwork is comprised of groups of serially connected convolution, rectified linear unit (ReLU), and batch normalization layers. The SSD merge layer, a box regression layer, and a focal loss classification layer are added to the detection subnetwork.

Version History

Introduced in R2020a

R2024b: `ssdLayers` function has been removed
Errors starting in R2024b

The `ssdLayers` function has been removed. You can use the `ssdObjectDetector` function to create a SSD object detection network, instead.

R2023b: `ssdLayers` function will be removed
Warns starting in R2023b

The `ssdLayers` function will be removed in a future release. You can use the `ssdObjectDetector` function to create a SSD object detection network, instead.

R2022a: `ssdLayers` function is not recommended
Not recommended starting in R2022a

The `ssdLayers` function is not recommended. You can use the `ssdObjectDetector` function to create a SSD object detection network, instead.

pcbin

Spatially bin point cloud points

Syntax

```
bins = pcbin(ptCloud,numBins)
bins = pcbin(ptCloud,numBins,spatialLimits)
[bins,binLocations] = pcbin( ___ )
[ ___ ] = pcbin( ___ ,BinOutput=true)
```

Description

`bins = pcbin(ptCloud,numBins)` spatially grids points in the point cloud, `ptCloud`. The output `bins` stores spatial bin locations, which are the indices for the points. The function finds the bin locations by sampling the point cloud in each dimension by the number of bins specified by `numBins`.

`bins = pcbin(ptCloud,numBins,spatialLimits)` specifies the spatial limits to use when the function places points into bins.

`[bins,binLocations] = pcbin( ___ )` also returns `binLocations`, the spatial bounds of each bin in `bins`. `binLocations` is the same size as `bins`.

`[ ___ ] = pcbin( ___ ,BinOutput=true)` also specifies the format of the `bins` and `binLocations` output.

When you set `BinOutput` to `true`, `bins` and `binLocations` are returned as cell arrays of size [*numBinsX*,*numBinsY*,*numBinsZ*].

When you set `BinOutput` to `false` and `ptCloud` are unorganized point clouds, `bins` is returned as an *M*-by-1 numeric vector. `binLocations` is returned as an *M*-by-6 matrix.

When you set `BinOutput` to `false` and `ptCloud` are organized point clouds, `bins` is returned an *M*-by-*N* matrix. `binLocations` is returned as an *M*-by-*N*-by-6 matrix.

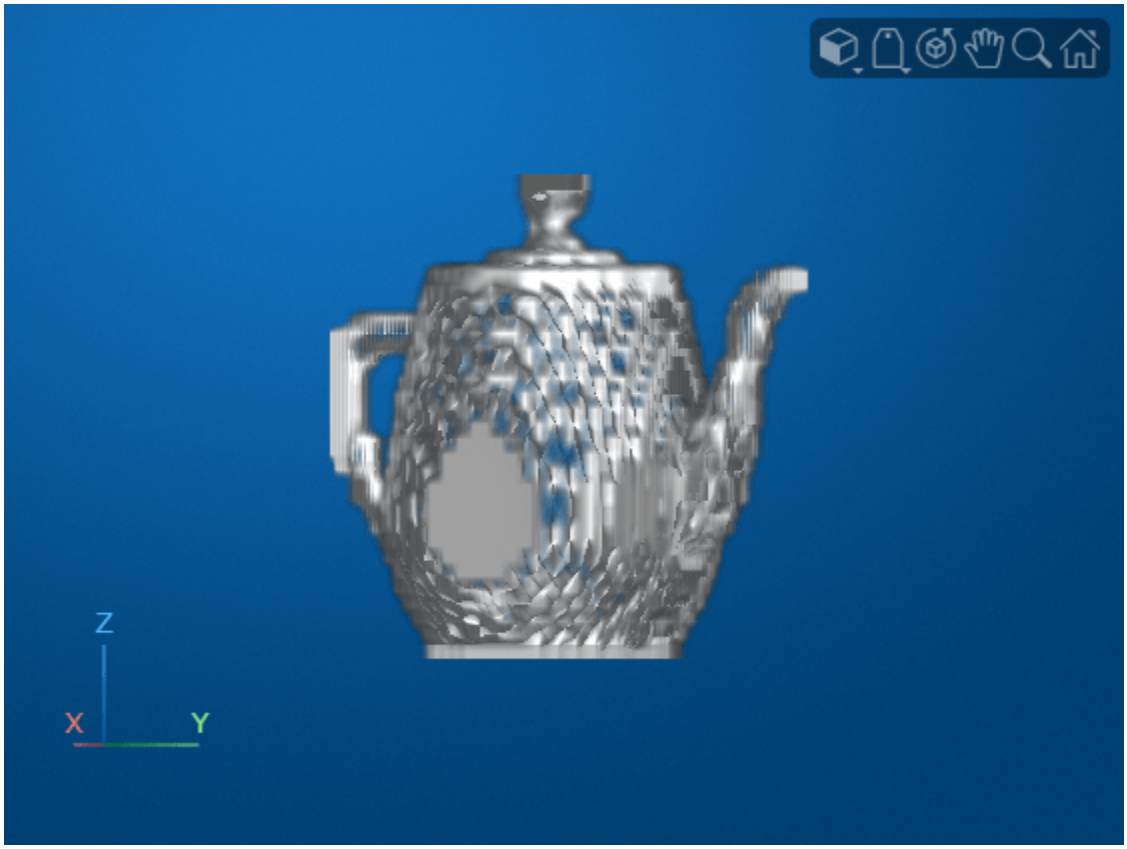
Examples

Build Occupancy Grid from Point Cloud

Read point cloud data into the workspace.

```
ptCloud = pcread("teapot.ply");
```

Spatially bin the point cloud into a 32-by-32-by-32 grid.



```
indices = pcbin(ptCloud,[32 32 32]);
```

Build an occupancy grid.

```
occupancyGrid = cellfun(@(c) ~isempty(c), indices);
```

Display the occupancy grid, and change the camera perspective for a clearer view of the grid.

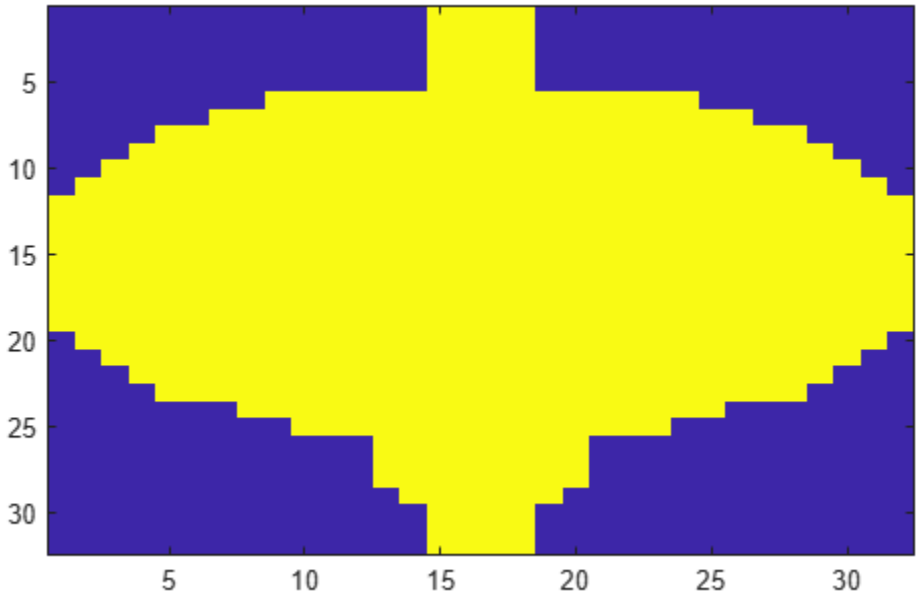
```
v = volshow(occupancyGrid);
viewer = v.Parent;
viewer.CameraPosition = [44 25 16];
viewer.CameraTarget = [16 16 16];
```

Build Bird's Eye View Density Grid from Point Cloud

Read point cloud data into the workspace.

```
ptCloud = pcread('teapot.ply');
```

Spatially bin the point cloud into a 32-by-32-by-1 grid.



```
indices = pcbin(ptCloud,[32 32 1]);
```

Build a density grid.

```
densityGrid = cellfun(@(c) ~isempty(c),indices);
```

Display the density grid.

```
figure;
imagesc(densityGrid);
```

Input Arguments

`ptCloud` — Point cloud

`pointCloud` object

Point cloud, specified as a `pointCloud` object. Points containing `Inf` or `NaN` values are invalid points and are not included in the output.

`numBins` — Number of bins

three-element numeric vector

Number of bins, specified as a three-element vector of the form [*numBinsX*,*numBinsY*, *numBinsZ*]. The vector elements indicate the number of bins to use in each dimension, respectively.

`spatialLimits` — Spatial limits

3-by-2 numeric matrix

Spatial limits, specified as a 3-by-2 numeric matrix of the form [*Xmin*, *Xmax*; *Ymin*, *Ymax*; *Zmin*, *Zmax*]. The spatial limits define the bounds used when the function bins points. Points that are outside of the specified limits are not included in the output.

Output Arguments

`bins` — Spatial bin locations

cell array | cell arrays of size [*numBinsX*,*numBinsY*,*numBinsZ*] | *M*-by-1 numeric vector | *M*-by-*N* matrix

Spatial bin locations, returned as a cell array of the same size as input `numBins`, an *M*-by-1 numeric vector, or an *M*-by-*N* matrix. The function returns a cell array when you do not use the `BinOutput`

argument. Each cell in the array contains indices to locations of points in the input point cloud that define the bins. Each bin includes the left bin edge, except for the last bin which includes both bin edges.

The table describes the size of `bins` based how you specify the `BinOutput` argument, and whether `ptCloud` is unorganized or organized.

BinOutput	**bins**
`true`	cell arrays of size [*numBinsX*,*numBinsY*,*numBinsZ*]
`false`	Unorganized point clouds *M*-by-1 numeric vector, where *M* represents the number of points.
	Organized point clouds *M*-by-*N* matrix, where *M* and *N* represents the total number of points set up as an organized point cloud.

The function processes invalid points differently, depending on how you specify the `BinOutput` argument. Invalid points are points with coordinates that contain `Inf` or `NaN`. When you set `BinOutput` to `true`, the function ignores invalid points and does not include them in the output. When you set `BinOutput` to `false`, the function returns `NaN` values for invalid points.

`binLocations` — Bin spatial bounds

cell array | cell arrays of size [*numBinsX*,*numBinsY*,*numBinsZ*] | *M*-by-6 matrix | *M*-by-*N*-by-6 matrix

Bin spatial bounds, returned as a cell array the same size as the output `bins`, cell arrays of size [*numBinsX*,*numBinsY*,*numBinsZ*], an *M*-by-6 matrix, or an *M*-by-*N*-by-6 matrix. The function returns a cell array when you do not use the `BinOutput` argument. Each cell in the array contains the spatial bounds of the bins in `bins`. The bounds for a bin are of the form [*Xmin*, *Xmax*; *Ymin*, *Ymax*; *Zmin*, *Zmax*].

The table describes the size of `binLocations` based how you specify the `BinOutput` argument, and whether `ptCloud` is unorganized or organized.

BinOutput	**binLocations**
`true`	cell arrays of size [*numBinsX*,*numBinsY*,*numBinsZ*]
`false`	Unorganized point clouds: *M*-by-6 matrix, where *M* represents the number of points located in the bin specified by the [*Xmin*, *Xmax*; *Ymin*, *Ymax*; *Zmin*, *Zmax*] spatial bound.

BinOutput	binLocations
	Organized point clouds: *M*-by-*N*-by-6 matrix, where *M* and *N* represents the number of points in an organized point cloud, with each point located in the bin specified by the [*Xmin*, *Xmax*; *Ymin*, *Ymax*; *Zmin*, *Zmax*] spatial bound.

readBarcode

Detect and decode 1-D or 2-D barcode in image

Syntax

```
msg = readBarcode(I)
msg = readBarcode(I,roi)
msg = readBarcode( ___ ,format)
[msg,detectedFormat,loc] = readBarcode( ___ )
```

Description

`msg = readBarcode(I)` detects and decodes a 1-D or 2-D barcode in the input image and returns the message associated with that barcode.

If the input image contains multiple barcodes, the `readBarcode` function decodes only the first barcode detected.

`msg = readBarcode(I,roi)` specifies a rectangular region of interest (ROI) to reduce the area in which the function searches for a barcode. The ROI must be fully contained in the input image.

`msg = readBarcode( ___ ,format)` specifies barcode formats to reduce the types of barcodes for which the function searches. Specify this argument in addition to any of the input argument combinations in previous syntaxes.

`[msg,detectedFormat,loc] = readBarcode( ___ )` additionally returns the format, `detectedFormat`, and location, `loc`, of the detected barcode.

Examples

Detect and Decode 1-D Barcode

Read an image containing a barcode into the workspace.

```
I = imread("barcode1D.jpg");
```

Detect the barcode and decode its message.

```
msg = readBarcode(I);
```

Display the decoded barcode message.

```
disp("Decoded barcode message: " + msg)
```

```
Decoded barcode message: 1234567890128
```

Search Image for 1-D Barcode

Read an image containing a barcode into the workspace.

```
I = imread("barcode1D.jpg");
```

Search the image for a 1-D barcode, returning its message, format, and location.

```
[msg,detectedFormat,loc] = readBarcode(I,'1D');
```

Display the detected barcode format.

```
disp("Barcode format: " + detectedFormat)
```

```
Barcode format: EAN-13
```

Annotate the image with the decoded barcode message.

```
xyBegin = loc(1,:);
Imsg = insertText(I,xyBegin,msg,'BoxOpacity',1,'FontSize',30);
```

Insert a line to show the scan row.

```
imSize = size(Imsg);
Imsg = insertShape(Imsg,'Line',[1 xyBegin(2) imSize(2) xyBegin(2)],'LineWidth',5);
```

Display the image.

```
imshow(Imsg)
```

Read a QR Barcode

Read an image containing a barcode.

```
I = imread("barcodeQR.jpg");
```

Define the ROI in the image that contains the barcode.

```
roi = [470, 300, 720, 620];
```

Search for a QR barcode within the ROI.

```
[msg,~,loc] = readBarcode(I,roi,"QR-CODE");
```

Annotate the image with the decoded message from the detected barcode.

```
xyText =  loc(2,:)/4;
Imsg = insertText(I,xyText,msg,"BoxOpacity",1,"FontSize",35);
```

Insert red circles onto the image to indicate the finder pattern locations.

```
Imsg = insertShape(Imsg, "FilledCircle", [loc, ...
     repmat(10, length(loc), 1)],"ShapeColor","red","Opacity",1);
```

Display the image.

```
imshow(Imsg)
```

Input Arguments

I — Input image

truecolor image | grayscale image

Input image, specified as a truecolor or grayscale image.

`roi` — Region of interest
four-element vector

Region of interest, specified as a four-element row vector of the form [*x*, *y*, *width*, *height*]. The rectangular ROI must be fully contained in the input image. [*x*,*y*] specifies the starting point for the ROI relative to the upper-left corner of the image.

If an image contains multiple barcodes, specifying an ROI can help the function detect a particular barcode. For more information, see “Read Barcodes in Image”.

`format` — Barcode format
`'1D'` | `'2D'` | one or more valid barcode formats

Barcode format, specified as one of these options. The table lists valid barcode formats.

- `'all'` — Use this option to specify all valid barcode formats. If you do not specify a format, the function uses this option.
- `'1D'` — Use this option to specify all valid 1-D barcode formats.
- `'2D'` — Use this option to specify all valid 2-D barcode formats.
- A character vector or string scalar of a valid format — Use this option to specify one barcode format.
- A cell array of character vectors or vector of strings of valid formats — Use this option to specify multiple barcode formats. The function prioritizes its search for specific barcode formats based on the order of the elements in this array.

Specifying a format can reduce the run time of the function by restricting the barcode search.

1-D Formats	2-D Formats
UPC-A	QR-CODE
UPC-E	DATA-MATRIX
EAN-8	AZTEC
EAN-13	PDF-417
CODE-39	
CODE-93	
CODE-128	
CODABAR	
ITF	
RSS-14	
RSS-EXPANDED	

Output Arguments

`msg` — Barcode message
string scalar

Barcode message, returned as a string scalar.

`detectedFormat` — Detected barcode format
string scalar

Detected barcode format, returned as a string scalar of one of the formats in this table.

1-D Formats	2-D Formats
`UPC-A`	`QR-CODE`
`UPC-E`	`DATA-MATRIX`
`EAN-8`	`AZTEC`
`EAN-13`	`PDF-417`
`CODE-39`	
`CODE-93`	
`CODE-128`	
`CODABAR`	
`ITF`	
`RSS-14`	
`RSS-EXPANDED`	

`loc` — Location of barcode
M-by-2 matrix | 2-by-2 matrix

Location of barcode, returned as an *M*-by-2 matrix for 2-D barcodes or a 2-by-2 matrix for 1-D barcodes. The matrix elements represent finder pattern locations.

Barcode	`loc` Value	Finder Pattern Locations
2-D	*M*-by-2 matrix. *M* represents the number of [*x*, *y*] locations of finder patterns.	 
1-D	2-by-2 matrix of the form [*x1*, *y1*;*x2*, *y2*], where each row represents the location of a finder pattern.	

Tips

- The function detects only clearly visible barcodes.
- Specifying a format can reduce the run time of the function by restricting the barcode search.
- For noisy images with unclear barcodes, use image preprocessing functions, such as `imsharpen`.

- The function detects only horizontally or vertically aligned barcodes. Use `imrotate` to correct poorly aligned barcodes.

Version History

Introduced in R2020a

R2024b: Generate optimized C/C++ code using Embedded Coder

Starting in R2024b, you can generate optimized C/C++ code using Embedded Coder.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Input argument `format` must be specified as a string scalar, character vector, or cell array of character vectors. String arrays are not supported.

You can also generate optimized C/C++ code using Embedded Coder.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

“Read Barcodes in Image”

balanceBoxLabels

Balance bounding box labels for object detection

Syntax

```
locationSet = balanceBoxLabels(boxLabels,blockedImages,blockSize,
numObservations)
[locationSet,bldsNew] = balanceBoxLabels(boxLabels,blockedImages,blockSize,
numObservations)
[___] = balanceBoxLabels(boxLabels,blockedImages,blockSize,numObservations,
Name=Value)
```

Description

`locationSet = balanceBoxLabels(boxLabels,blockedImages,blockSize, numObservations)` balances bounding box labels, `boxLabels`, by oversampling blocks of images containing less frequent classes, contained in the collection of blocked image objects `blockedImages`. `numObservations` is the required number of block locations, and `blockSize` specifies the block size.

`[locationSet,bldsNew] = balanceBoxLabels(boxLabels,blockedImages,blockSize, numObservations)` additionally returns bounding box label data corresponding to the balanced box labels in `locationSet`.

`[___] = balanceBoxLabels(boxLabels,blockedImages,blockSize,numObservations, Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `OverlapThreshold=0.5` specifies the overlap threshold between a bounding box and a cropping window to before boxes are clipped or discarded.

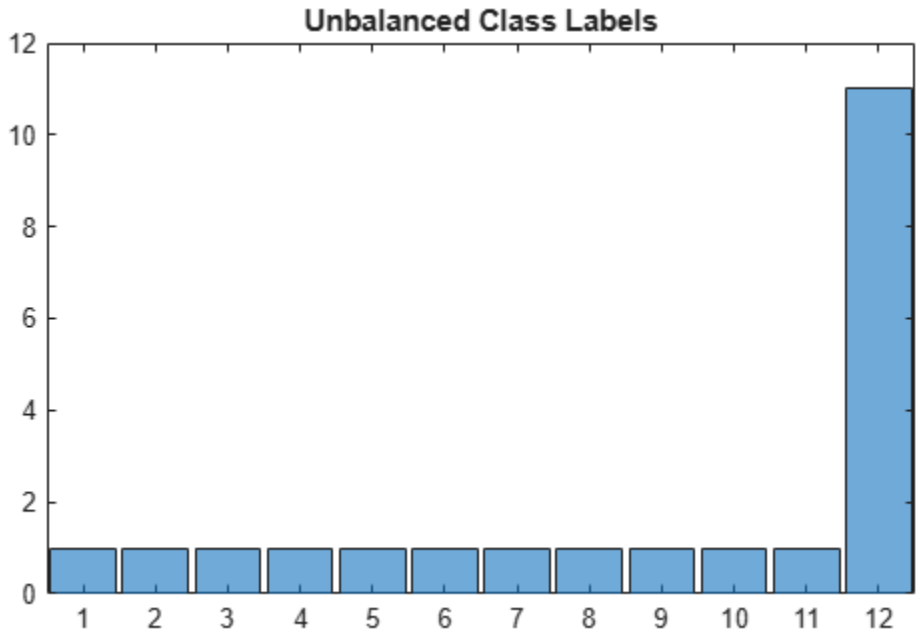
Examples

Sample Block Sets to Use in Blocked Image Object Detection

Load box labels data that contains boxes and labels for one image. The height and width of each box is 20-by-20 pixels.

```
d = load("balanceBoxLabelsData.mat");
boxLabels = d.BoxLabels;
```

Create a blocked image of size 500-by-500 pixels.



```
blockedImages = blockedImage(zeros([500 500]));
```

Choose the images size of each observation.

```
blockSize = [50 50];
```

Visualize using a histogram to identify any class imbalance in the box labels.

```
blds = boxLabelDatastore(boxLabels);
datasetCount = countEachLabel(blds);
figure
unbalancedLabels = datasetCount.Label;
unbalancedCount  = datasetCount.Count;
h1 = histogram(Categories=unbalancedLabels,BinCounts=unbalancedCount);
title("Unbalanced Class Labels")
```

Measure the distribution of box labels. If the coefficient of variation is more than 1, then there is class imbalance.

```
cvBefore = std(datasetCount.Count)/mean(datasetCount.Count)
```

```
cvBefore =
1.5746
```

Choose a heuristic value for number of observations by finding the mean of the counts of each class, multiplied by the number of classes.

```
numClasses = height(datasetCount);
numObservations = mean(datasetCount.Count) * numClasses;
```

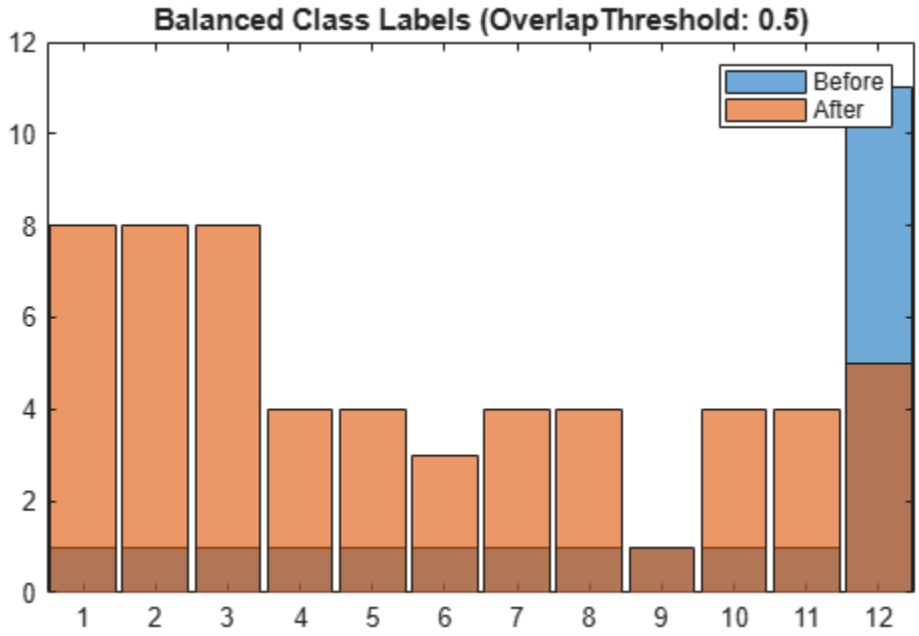
Control the amount a box can be cut using `OverlapThreshold`. Using a lower threshold value will cut objects more at the border of a block. Increase this value to reduce the amount an object can be clipped at the border, at the expense of a less balanced box labels.

```
ThresholdValue = 0.5;
```

Balance `boxLabels` using the `balanceBoxLabels` function.

```
locationSet = balanceBoxLabels(boxLabels,blockedImages,blockSize, ...
        numObservations,OverlapThreshold=ThresholdValue);
```

```
[==================================================] 100%
Elaps[==================================================] 100%
```



```
Elapsed time: 00:00:00
Estimated time remaining: 00:00:00
Balancing box labels complete.
```

Count the labels that are contained within the image blocks.

```
bldsBalanced = boxLabelDatastore(boxLabels,locationSet);
balancedDatasetCount = countEachLabel(bldsBalanced);
```

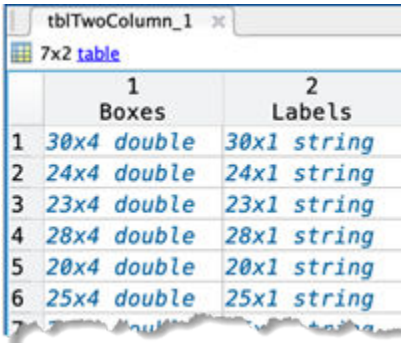
Overlay another histogram against the original label count to see if the box labels are balanced. If the labels appear to be not balanced by looking at the histograms, increase the value for `numObservations`.

```
hold on
balancedLabels = balancedDatasetCount.Label;
balancedCount  = balancedDatasetCount.Count;
h2 = histogram(Categories=balancedLabels,BinCounts=balancedCount);
title(h2.Parent,"Balanced Class Labels (OverlapThreshold: " + ThresholdValue + ")" )
legend(h2.Parent,["Before" "After"])
```

Measure the distribution of the new balanced box labels.

```
cvAfter = std(balancedCount)/mean(balancedCount)
```

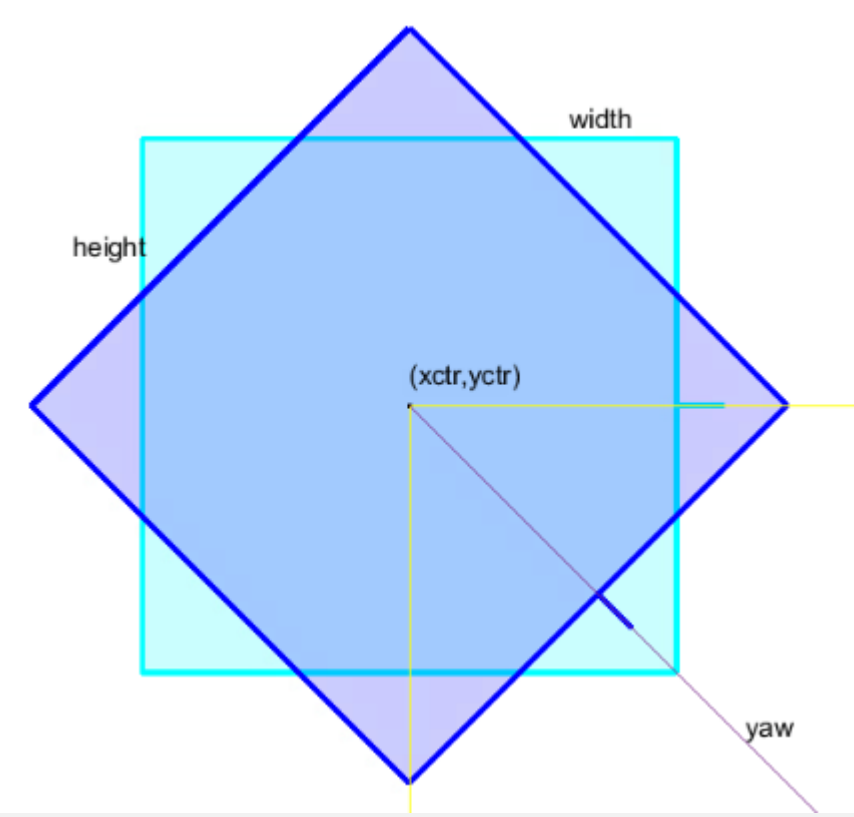
```
cvAfter =
0.4588
```



Input Arguments

`boxLabels` — Labeled bounding box data

table with two columns



Labeled bounding box data, specified as a table with two columns.

- The first column contains either all rectangle or all rotated rectangle bounding boxes.
- The second column must be a cell vector that contains the label names corresponding to each bounding box. Each element in the cell vector must be an *M*-by-1 categorical or string vector.

The table describes the format of the bounding boxes:

Bounding Box	Description
`rectangle`	Defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and `y` specify the upper-left corner of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis. • *h* specifies the height of the rectangle, which is its length along the *y*-axis.

Bounding Box	Description
`rotated-rectangle`	Defined in spatial coordinates as an *M*-by-5 numeric matrix with rows of the form [*xctr yctr w h yaw*], where: • *M* is the number of rotated rectangles. • *xctr* and *yctr* specify the center of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis before rotation. • *h* specifies the height of the rectangle, which is its length along the *y*-axis before rotation. • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the bounding box. 

To create a box label table from ground truth data,

1. Use the Image Labeler or Video Labeler app to label your ground truth. Export the labeled ground truth data to your workspace.
2. Create a bounding box label datastore using the `objectDetectorTrainingData` function.
3. You can obtain the `boxLabels` from the `LabelData` property of the box label datastore returned by `objectDetectorTrainingData`, (`blds.LabelData`).

`blockedImages` — Labeled blocked images
array of `blockedImage` objects

Labeled blocked images, specified as an array of `blockedImage` objects containing pixel label images.

`blockSize` — Block size
two-element row vector of positive integers

Block size of read data, specified as a two-element row vector of positive integers, [*numrows*,*numcols*]. The first element specifies the number of rows in the block. The second element specifies the number of columns.

`numObservations` — Number of block locations
positive integer

Number of block locations to return, specified as a positive integer.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `(OverlapThreshold=0.5)` specifies the overlap threshold between a bounding box and a cropping window to before boxes are clipped or discarded.

`Levels` — Resolution level of each image
1 (default) | positive integer scalar | *B*-by-1 vector of positive integers

Resolution level of each image in the array of `blockedImage` objects, specified as a positive integer scalar or a *B*-by-1 vector of positive integers, where *B* is the length of the array of `blockedImage` objects.

`OverlapThreshold` — Overlap threshold
1 (default) | scalar in the range [0,1]

Overlap threshold, specified as a positive scalar in the range [0,1]. When the overlap between a bounding box and a cropping window is greater than the threshold, boxes in the `boxLabels` input are clipped to the image block window border. When the overlap is less than the threshold, the boxes are discarded. When you lower the threshold, part of an object can get discarded. To reduce the amount an object can be clipped at the border, increase the threshold. Increasing the threshold can also cause less-balanced box labels.

The amount of overlap between the bounding box and a cropping window is defined as.

$$area(bboxA \cap window)/area(bboxA)$$

`Verbose` — Display progress information
`true` or `1` (default) | `false` or `0`

Display progress information, specified as a numeric or logical `1` (`true`) or `0` (`false`). Set this property to `true` to display information.

Output Arguments

`locationSet` — Balanced box labels

`blockLocationSet` object

Balanced box labels, returned as a `blockLocationSet` object. The object contains `numObservations` number of locations of balanced blocks, each of size `blockSize`.

`bldsNew` — Bounding box label data

`boxLabelDatastore` object

Bounding box label data corresponding to the balanced box labels in `locationSet`, returned as a `boxLabelDatastore` object.

Algorithms

Balancing Box Labels

To balance box labels, the function over samples classes that are less represented in the blocked image or big image. The box labels are counted across the dataset and sorted based on each class count. Each image size is split into several quadrants, based on the `blockSize` input value. The algorithm randomly picks several blocks within each quadrant with less-represented classes. The blocks without any objects are discarded. The balancing stops once the specified number of blocks are selected.

Checking for Balance

You can check the success of balancing by comparing the histograms of label count before and after balancing. You can also check the coefficient of variation value. For best results, the value should be less than the original value. For more information, see the National Institute of Standards and Technology (NIST) website, see Coefficient of Variation for more information.

Version History

Introduced in R2020a

R2025a: Option to return datastore for balanced bounding box label data

Specify the `bldsNew` output argument to return a `boxLabelDatastore` object containing bounding box label data that corresponds to the balanced box labels.

R2021a: `bigLabeledImages` argument is not recommended

Not recommended starting in R2021a

The `bigLabeledImages` argument, which supports `bigimage` objects, is not recommended. Use the `blockedImages` argument instead, which supports `blockedImage` objects. The `blockedImage` object offers several advantages including extension to N-D processing, a simpler interface, and custom support for reading and writing nonstandard image formats.

Although there are no plans to remove the `bigLabeledImages` argument at this time, switch to the `blockedImages` argument to take advantage of the additional capabilities and flexibility.

To update your code, follow these steps:

- Replace `bigimage` object input with `blockedImage` object input for the second argument of this function.
- If you want to select blocks of any of the blocked images at a resolution level other than 1, then specify the '`Levels`' name-value argument. You can omit this argument when you want to select blocks from all blocked images at resolution level 1.

The table gives an example of how to update your code.

Discouraged Usage	Recommended Replacement

This example selects blocks at resolution level 1 from a `bigimage` object.
 	
`boxLabels = load('balanceBoxLabelsData.mat').boxLabels;`
`bim = bigimage(zeros([500,500]));`
`blockSize = [50 50];`
`numObservations = 20;`
`locationSet = balanceBoxLabels(boxLabels,bim, ...`
`    blockSize,numObservations);`
	Here is equivalent code, replacing the input `bigimage` object with a `blockedImage` object.
	
	`boxLabels = load('balanceBoxLabelsData.mat').boxLabel`
	`bim = blockedImage(zeros([500,500]));`
	`blockSize = [50 50];`
	`numObservations = 20;`
	`locationSet = balanceBoxLabels(boxLabels,bim, ...`
	`    blockSize,numObservations);`

Objects

`blockLocationSet` | `blockLocationsWithROI` | `blockedImage` | `blockedImageDatastore` | `boxLabelDatastore`

blockLocationsWithROI

Select image block locations that contain bounding box ROIs

Syntax

```
[locationSet,bldsNew] = blockLocationsWithROI(blset,blds)
[locationSet,bldsNew] = blockLocationsWithROI(blset,blds,Name=Value)
```

Description

`[locationSet,bldsNew] = blockLocationsWithROI(blset,blds)` selects block locations that contain bounding box ROIs specified by `blds`. The function returns the block locations as a `blockLocationSet` object, `locationSet`, and corresponding bounding boxes as a `boxLabelDatastore` object, `bldsNew`.

`[locationSet,bldsNew] = blockLocationsWithROI(blset,blds,Name=Value)` specifies options using one or more name-value arguments. For example, `OverlapThreshold=0.5` specifies the overlap threshold between a bounding box and an image block as `0.5`.

Input Arguments

`blset` — Block locations

`blockLocationSet` object

Block locations, specified as a `blockLocationSet` object. Select blocks from blocked images using the `selectBlockLocations` function.

`blds` — Bounding box label datastore

`boxLabelDatastore` object

Bounding box label datastore of blocked images, specified as a `boxLabelDatastore` object. The `boxLabelDatastore` object must contain only axis-aligned rectangle ROIs of size *M*-by-4 or rotated rectangle ROIs of size *M*-by-4-by-5. *M* is the number of axis-aligned or rotated rectangles.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `OverlapThreshold=0.5` specifies the overlap threshold between a bounding box and an image block as `0.5`.

`Classes` — Object classes

`""` (default) | cell array of character vectors | string vector | categorical vector

Object classes, specified as a cell array of character vectors, a string vector, or a categorical vector.

`OverlapThreshold` — Overlap threshold between bounding box and image block

`1` (default) | scalar in range [0,1]

Overlap threshold between a bounding box and image block, specified as a scalar in the range [0,1]. When the overlap between a bounding box ROI and an image block is greater than or equal to this threshold, the `blockLocationsWithROI` function consider the block location, specified by the `blset` argument, to contain an object. For example, when the `OverlapThreshold` is 0.5, the `blockLocationsWithROI` function, by default, selects image blocks with at least 50% overlap with an object ROI. Meanwhile, any image block that has less than a 50% overlap with an object ROI is a background image block, and is not selected.

The amount of overlap between a bounding box ROI and an image block is defined as the area of intersection between `bboxA` and an image block, divided by the minimum area between `bboxA` and the image block.

$$\frac{area(bboxA \cap block)}{\min(area(bboxA), area(block))}$$

`SelectBackgroundImageBlocks` — Background image block selection
`false` or `0` (default) | `true` or `1`

Background image block selection, specified as a numeric or logical `1` (`true`) or `0` (`false`). Set this value to `true` or `1` to select block locations that do not contain any ROIs.

`DiscardROIsBelowThreshold` — Discard bounding box ROIs below overlap threshold
`false` or `0` (default) | `true` or `1`

Discard bounding box ROIs below the overlap threshold, specified as a numeric or logical `1` (`true`) or `0` (`false`). Set this argument as `true` or `1` to automatically remove all bounding box ROIs with an overlap threshold below the `OverlapThreshold` value from the bounding box datastore returned by the `bldsNew` argument.

Output Arguments

`locationSet` — Block locations containing object ROIs
`blockLocationSet` object

Block locations containing object ROIs, returned as a `blockLocationSet` object. By default, the `blockLocationsWithROI` function selects block locations that contain bounding box ROIs which have an overlap threshold higher than or equal to the value specified by the `OverlapThreshold` name-value argument.

Tip Specify the `SelectBackgroundImageBlocks` name-value argument as `true` to create `blockLocationSet` objects which contain only the background image blocks.

`bldsNew` — Bounding box ROIs that overlap with block locations
`boxLabelDatastore` object

Bounding box ROIs that overlap with block locations, returned as a `boxLabelDatastore` object.

Note If you specify the `SelectBackgroundImageBlocks` name-value argument as `true`, `bldsNew` returns an empty array for each background image block.

Tip To discard any bounding box ROIs with an overlap threshold below the value specified by the `OverlapThreshold` name-value argument, specify the `DiscardROIsBelowThreshold` name-value argument as `true` or `1`.

Balance pixel labels by oversampling block locations in large images

Syntax

```
blockLocations = balancePixelLabels(blockedImages,blockSize,numObservations)
blockLocations = balancePixelLabels(blockedImages,blockSize,numObservations,
Name,Value)
```

Description

`blockLocations = balancePixelLabels(blockedImages,blockSize,numObservations)` creates a list of block locations in the large labeled images, `blockedImages`, that result in a class balanced data set by oversampling image regions that contain less-common labels. `numObservations` is the required number of block locations, and `blockSize` specifies the block size.

A balanced dataset can produce better results when used for training workflows such as semantic segmentation in deep learning.

`blockLocations = balancePixelLabels(blockedImages,blockSize,numObservations, Name,Value)` specifies additional aspects of the selected blocks using name-value arguments.

Examples

Balance Pixel Labels in Unbalanced Data Set

Specify the location of a labeled image data set.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata");
labelDir = fullfile(dataDir,"buildingPixelLabels");
fileSet = matlab.io.datastore.FileSet(labelDir,FileExtensions=".png");
```

Create an array of labeled images from the data set.

```
blockedImages = blockedImage(fileSet);
```

Set the block size of the images. Assume the finest resolution level.

```
blockSize = [20 15];
```

Create a `blockedImageDatastore` from the image array.

```
blabelds = blockedImageDatastore(blockedImages,BlockSize=blockSize);
```

Count pixel label occurrences of each class. The classes in the pixel label images are not balanced.

```
pixelLabelID = [1 2 3 4];
classNames = ["sky" "grass" "building" "sidewalk"];
labelCounts = countEachLabel(blabelds, ...
    Classes=classNames,PixelLabelIDs=pixelLabelID);
```

Specify the number of block locations to sample from the data set.

```
numObservations = 2000;
```

Select the block locations from the labeled images to achieve class balancing.

```
locationSet = balancePixelLabels(blockedImages,blockSize,numObservations, ...
    Classes=classNames,PixelLabelIDs=pixelLabelID);
```

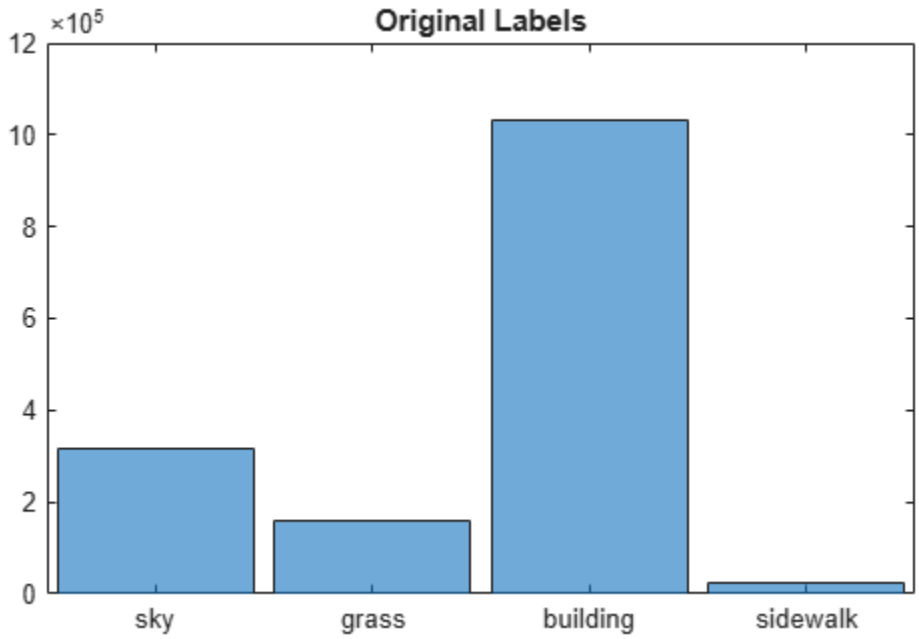
Create a `blockedImageDatastore` using the block locations after balancing.

```
blabeldsBalanced = blockedImageDatastore(blockedImages,BlockLocationSet=locationSet);
```

Recalculate the pixel label occurrences for the balanced data set.

```
labelCountsBalanced = countEachLabel(blabeldsBalanced, ...
    Classes=classNames,PixelLabelIDs=pixelLabelID);
```

Compare the original unbalanced labels and labels after label balancing.



```
figure
h1 = histogram("Categories",labelCounts.Name,...
    BinCounts=labelCounts.PixelCount)
```

```
h1 =
  Histogram with properties:

              Data: [0×0 categorical]
            Values: [314849 159787 1031235 25313]

```
title(h2.Parent,"Balanced Labels")
```

Input Arguments

`blockedImages` — Labeled blocked images

`blockedImage` object | vector of `blockedImage` objects

Labeled blocked images, specified as a `blockedImage` object or a vector of `blockedImage` objects containing pixel label images.

`blockSize` — Block size

two-element row vector of positive integers

Block size of read data, specified as a two-element row vector of positive integers, [*numrows*,*numcols*]. The first element specifies the number of rows in the block. The second element specifies the number of columns.

`numObservations` — Number of block locations

positive integer

Number of block locations to return, specified as a positive integer.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'Classes',classNames,'PixelLabelIDs',pixelLabelID`

`Levels` — Image resolution levels
`1` (default) | numeric scalar | integer-valued vector

Image resolution levels, specified as a numeric scalar or an integer-valued vector of the same length as the vector of `blockedImages`. If you specify a scalar value, then all blocked images supply blocks at the specified resolution level.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Classes` — Set of class names
`{}` (default) | `string` vector | cell array of `char` vectors

Set of class names, specified as a string vector or a cell array of character vectors.

You must specify this argument when `blockedImages` yields numeric data, such as when pixel label data is stored as an RGB image. Do not specify this argument when `blockedImages` yields categorical data.

Data Types: `char` | `string`

`PixelLabelIDs` — Numeric IDs that map labels to class names
`[]` (default) | numeric vector | *M*-by-3 numeric matrix

Numeric IDs that map labels to class names, specified as a vector of numeric IDs for each label or an *M*-by-3 matrix where *M* is the number of class names. The length of the vector must equal the number of class names. Each row is a three-element vector representing the RGB pixel value associated with each class name.

You must specify this argument when `blockedImages` yields numeric data, such as when pixel label data is stored as an RGB image. Do not specify this argument when `blockedImages` yields categorical data.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`UseParallel` — Use new or existing pool
`false` or `0` (default) | `true` or `1`

Use a new or existing parallel pool, specified as a numeric or logical `1` (`true`) or `0` (`false`). If no parallel pool is active, then a new pool is opened based on the default parallel settings. The `DataSource` property of all input `blockedImage` objects should be valid paths on each of the parallel workers.

This syntax requires the Parallel Computing Toolbox.

Data Types: `logical`

Output Arguments

`blockLocations` — Block locations
`blockLocationSet` object

Block locations, returned as a `blockLocationSet` object. The object contains `numObservations` number of locations of balanced blocks, each of size `blockSize`.

Algorithms

To balance pixel labels, the function oversamples the minority classes in the input images. The minority class is determined by calculating the overall pixel label counts for the complete dataset. The algorithm follows these steps.

1. The images in the input image array are divided into macro blocks, which is a multiple of the `blockSize` input value.
2. The function counts pixel labels for all classes in each macro block. Then, it selects the macro block with the greatest occurrences of minority classes using weighted random selection.
3. The algorithm uses a random block location within the selected macro block to perform oversampling. The origin of the block location must always be fully within the limits of the macro block.
4. The function updates the overall label counts based on the pixel label counts of the classes found for the selected macro block.
5. The function includes the new (oversampled) classes to compute new minority class.
6. This process repeats until the number of block locations processed equals the value specified by the `numObservations` input value.

Version History

Introduced in R2020a

R2021a: `bigLabeledImages` argument is not recommended

Not recommended starting in R2021a

The `bigLabeledImages` argument, which supports `bigimage` objects, is not recommended. Use the `blockedImages` argument instead, which supports `blockedImage` objects. The `blockedImage` object offers several advantages including extension to N-D processing, a simpler interface, and custom support for reading and writing nonstandard image formats.

Although there are no plans to remove the `bigLabeledImages` argument at this time, switch to the `blockedImages` argument to take advantage of the additional capabilities and flexibility.

To update your code, follow these steps:

- Replace `bigimage` object input with `blockedImage` object input for the first argument of this function.
- If you want to select blocks of any of the blocked images at a resolution level other than 1, then specify the '`Levels`' name-value argument. You can omit this argument when you want to select blocks from all blocked images at resolution level 1.
- If the blocked images yield numeric data, such as representing pixel label data as an RGB image, then specify the `'Classes'` and `'PixelLabelsIDs'` name-value arguments.

The table gives an example of how to update your code.

Discouraged Usage	Recommended Replacement

This example selects blocks at resolution level 1 from a labeled `bigimage` object.
 	
`pixelLabelIDs = [1 2 3 4];`
`classNames = ["sky" "grass" "building" "sidewalk"];`
`labelDir = fullfile(toolboxdir('vision'), ...`
`    'visiondata','buildingPixelLabels');`
`filename = fullfile(labelDir,'Label_1.png');`
`bim = bigimage(imread(filename), ...`
`    'Classes',classNames,'PixelLabelIDs',pixelLabelIDs);`
`blockSize = [20 15];`
`numObservations = 2000;`
`locationSet = balancePixelLabels(bim,1, ...`
`    blockSize,numObservations);`
	Here is equivalent code, replacing the input `bigimage` object with a `blockedImage` object.
	
	`pixelLabelIDs = [1 2 3 4];`
	`classNames = ["sky" "grass" "building" "sidewalk"];`
	`labelDir = fullfile(toolboxdir('vision'), ...`
	`    'visiondata','buildingPixelLabels');`
	`filename = fullfile(labelDir,'Label_1.png');`
	`bim = blockedImage(filename);`
	`blockSize = [20 15];`
	`numObservations = 2000;`
	`locationSet = balancePixelLabels(bim, ...`
	`    blockSize,numObservations, ...`
	`    'Classes',classNames,'PixelLabelIDs',pixelLabelIDs);`

showvipblockdatatypetable

Simulink Block Data Type Support Table

Syntax

```
showvipblockdatatypetable
```

Description

`showvipblockdatatypetable` returns a table that shows characteristics for the Simulink blocks in Computer Vision Toolbox. The table provides details regarding capabilities and limitations pertaining to code generation, variable-sizing, and supported data types for all Computer Vision Toolbox blocks. An "X" in a cell indicates a given block supports the capability indicated by the column heading. Numbered footnotes included in cells, "(#)", are described below the table.

Examples

Show Block Characteristics For Computer Vision Toolbox

You can use the `showvipblockdatatypetable` function to return a table of block characteristics for the Computer Vision Toolbox.

To return the table of block characteristics, at the MATLAB® command line type:

```
showvipblockdatatypetable
```

```
Loading Computer Vision Toolbox Library.
```

The table opens in a separate window.

Version History

Introduced in R2008b

read

Read data from label datastore

Syntax

```
C = read(ds)
[C,info] = read(ds)
```

Description

`C = read(ds)` returns data from a pixel label datastore or box label datastore. Subsequent calls to the `read` function continue reading from the endpoint of the previous call.

`[C,info] = read(ds)` also returns information about the extracted data in `info`, including metadata.

Input Arguments

ds — Input datastore

`PixelLabelDatastore` object | `boxLabelDatastore` object

Input datastore, specified as a `PixelLabelDatastore` or a `boxLabelDatastore` object.

Output Arguments

C — Output data

cell array of categorical matrices | *M*-by-2 cell array | table

Output data, returned as an *M*-by-2 cell array, cell array of categorical matrices, or a table.

Datastore	Output Description
`PixelLabelDatastore`	Table with `MiniBatchSize` number of rows. For the last batch of data in the datastore, `numObservations` must be divisible by `MiniBatchSize` or `read` returns a partial batch containing all the remaining observations in the datastore.

Datastore	Output Description
`boxLabelDatastore`	*N*-by-2 or *N*-by-3 cell matrix. *N* must be less than or equal to `ReadSize(ds)`. The first column can contain data, such as point cloud data for point cloud detectors, or images for object detectors. The second column must be a cell vector that contains *M*-by-5 matrices of bounding boxes in the format[*xcenter*,*ycenter*,*width*,*height*,*yaw*]. The third column must be a cell vector that contains the label names corresponding to each bounding box. Label names are represented as an *M*-by-1 categorical vector.

You can use the `combine` function to create a datastore to use for training.

- `combine(imds,blds)` — Combine images in an `imageDatastore` with bounding boxes and labels in a `boxLabelDatastore`.
- `combine(pxds,blds)` — Combine pixel data in a `PixelLabelDatastore` with bounding boxes and labels in a `boxLabelDatastore`.

For more information, see “Datastores for Deep Learning” (Deep Learning Toolbox).

`info` — Information about read data
structure array

Information about read data, returned as a structure array. The structure array can contain the following fields.

Datastore	Field Name	Description
`PixelLabelDatastore`	`Filename`	Fully resolved path containing the path string, name of the file, and file extension. For `PixelLabelDatastore` objects whose `ReadSize` property is greater than 1, `Filename` is a cell array of file names corresponding to each image.
	`FileSize`	Total file size, in bytes. For MAT-files, `FileSize` is the total number of key-value pairs in the file. For `PixelLabelDatastore` objects whose `ReadSize` property is greater than 1, `FileSize` is a vector of file sizes corresponding to each image.
`boxLabelDatastore`	`CurrentIndex`	Starting position of each `read` operation of the label data.

Datastore	Field Name	Description
	`ReadSize`	`ReadSize` property of the datastore.

Tips

- `read(ds)` returns an error if there is no more data in the input datastore, `ds`. Use `hasdata(ds)` with `read(ds)` to avoid the error.

Version History

Introduced in R2017b

Topics

“Datastores for Deep Learning” (Deep Learning Toolbox)

shuffle

Return shuffled version of label datastore

Syntax

```
shuffle(ds)
```

Description

`shuffle(ds)` returns a randomly shuffled version of the input datastore.

Examples

Create Randomly Shuffled Datastore

Set the location of the image and pixel label data.

```
dataDir = fullfile(toolboxdir('vision'), 'visiondata');
pxDir = fullfile(dataDir, 'buildingPixelLabels');
```

Create a pixel label datastore.

```
classNames = ["sky" "grass" "building" "sidewalk"];
pixelLabelID = [1 2 3 4];
pxds = pixelLabelDatastore(pxDir, classNames, pixelLabelID);
```

Create a new randomly shuffled datastore.

shpxds = shuffle(pxds);

Input Arguments

ds — Datastore with labeled data

`pixelLabelDatastore` | `boxLabelDatastore` object

Datastore with labeled data for training a semantic segmentation network or an object detection network, specified as a `pixelLabelDatastore` or a `boxLabelDatastore` object.

Version History

Introduced in R2020a

See Also

Functions

`objectDetectorTrainingData` | `trainnet`

Objects

preview

Read first row of data in datastore

Syntax

```
preview(ds)
```

Description

`preview(ds)` returns the first row of data in the input datastore.

Examples

Preview Data from Datastore

Load training data that contains bounding boxes with labels for a vehicles class.

```
data = load('vehicleTrainingData.mat');
trainingData = data.vehicleTrainingData;
```

Add the fullpath to the local vehicle data folder.

```
dataDir = fullfile(toolboxdir('vision'),'visiondata');
trainingData.imageFilename = fullfile(dataDir,trainingData.imageFilename);
blds = boxLabelDatastore(trainingData(:,2:end));
```

Preview the data from the box label datastore.

```
preview(blds)
```

```
ans=1×2 cell array
    {[126 78 20 16]}    {[vehicle]}
```

Input Arguments

ds — Datastore with labeled data

`boxLabelDatastore` object | `pixelLabelDatastore`

Datastore with labeled data for training a semantic segmentation network or an object detection network, specified as a `boxLabelDatastore` or a `pixelLabelDatastore` object.

Version History

Introduced in R2020a

progress

Percentage of data read from a datastore

Syntax

```
progress(ds)
```

Description

`progress(ds)` returns a fraction between 0.0 and 1.0 to indicate the percentage of data read from the datastore.

Examples

Read Datastore and Check Progress

Load training data that contains bounding boxes with labels for vehicles.

```
data = load('vehicleTrainingData.mat');
trainingData = data.vehicleTrainingData;
```

Add fullpath to the local vehicle data folder.

```
dataDir = fullfile(toolboxdir('vision'), 'visiondata');
trainingData.imageFilename = fullfile(dataDir,...
                                      trainingData.imageFilename);
blds = boxLabelDatastore(trainingData(:,2:end));
```

Read a couple of times, before looking at the progress.

```
read(blds);
read(blds);
```

See the progress made by the boxLabelDatastore.

```
preview(blds)
```

```
ans=1×2 cell array
    {[126 78 20 16]}    {[vehicle]}
```

Input Arguments

ds — Datastore with labeled data

`boxLabelDatastore` object

Datastore with labeled data for training a semantic segmentation network or an object detection network, specified as a `boxLabelDatastore` object.

Version History

Introduced in R2019b

estimateAnchorBoxes

Estimate anchor boxes for deep learning object detectors

Syntax

```
anchorBoxes = estimateAnchorBoxes(trainingData,numAnchors)
[anchorBoxes,meanIoU] = estimateAnchorBoxes(trainingData,numAnchors)
```

Description

`anchorBoxes = estimateAnchorBoxes(trainingData,numAnchors)` estimates the specified number of anchor boxes using the training data.

`[anchorBoxes,meanIoU] = estimateAnchorBoxes(trainingData,numAnchors)` additionally returns the mean intersection-over-union (IoU) value of the anchor boxes in each cluster.

Examples

Estimate Anchor Boxes for YOLO v2 Object Detection Network

This example shows how to estimate anchor boxes using a table containing the training data. The first column contains the training images and the remaining columns contain the labeled bounding boxes.

```
data = load("vehicleTrainingData.mat");
trainingData = data.vehicleTrainingData;
```

Create a `boxLabelDatastore` object using the labeled bounding boxes from the training data.

```
blds = boxLabelDatastore(trainingData(:,2:end));
```

Specify the class names using the labels from the training data.

```
classes = trainingData.Properties.VariableNames(2:end);
```

Estimate the anchor boxes using the `boxLabelDatastore` object.

```
numAnchors = 5;
anchorBoxes = estimateAnchorBoxes(blds,numAnchors);
```

Specify the image size.

```
inputImageSize = [128 228 3];
```

Use a pretrained ResNet-50 network as a base network for the YOLO v2 network.

```
baseNet = imagePretrainedNetwork("resnet50");
```

Specify the network layer to use for feature extraction. You can use the `analyzeNetwork` function to see all the layer names in a network.

```
featureLayer = "activation_49_relu";
```

Create the YOLO v2 object detection network.

```
detector = yolov2ObjectDetector(baseNet,classes,anchorBoxes, ...
    DetectionNetworkSource=featureLayer)
```

```
detector =
  yolov2ObjectDetector with properties:

                  Network: [1×1 dlnetwork]
                InputSize: [224 224 3]
        TrainingImageSize: [224 224]
              AnchorBoxes: [5×2 double]
               ClassNames: vehicle
    ReorganizeLayerSource: ''
              LossFactors: [5 1 1 1]
                ModelName: ''
```

Visualize the network using the network analyzer.

```
analyzeNetwork(detector.Network)
```

Estimate Anchor Boxes from Training Data

Anchor boxes are important parameters of deep learning object detectors such as Faster R-CNN and YOLO v2. The shape, scale, and number of anchor boxes impact the efficiency and accuracy of the detectors.

For more information, see “Anchor Boxes for Object Detection”.

Load Training Data

Load the vehicle dataset, which contains 295 images and associated box labels.

```
data = load('vehicleTrainingData.mat');
vehicleDataset = data.vehicleTrainingData;
```

Add the full path to the local vehicle data folder.

```
dataDir = fullfile(toolboxdir('vision'),'visiondata');
vehicleDataset.imageFilename = fullfile(dataDir,vehicleDataset.imageFilename);
```

Display the data set summary.

```
summary(vehicleDataset)
```

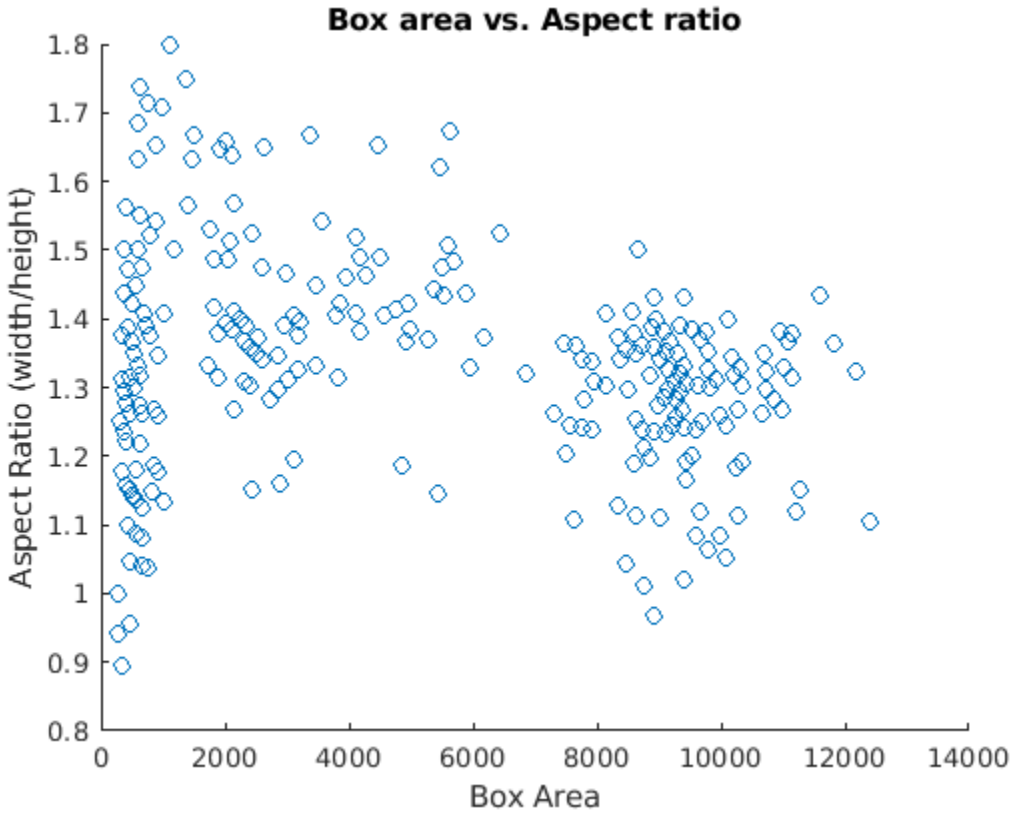
```
Variables:

    imageFilename: 295×1 cell array of character vectors

    vehicle: 295×1 cell
```

Visualize Ground Truth Box Distribution

Visualize the labeled boxes to better understand the range of object sizes present in the data set.



Combine all the ground truth boxes into one array.

```
allBoxes = vertcat(vehicleDataset.vehicle{:});
```

Plot the box area versus the box aspect ratio.

```
aspectRatio = allBoxes(:,3) ./ allBoxes(:,4);
area = prod(allBoxes(:,3:4),2);

figure
scatter(area,aspectRatio)
xlabel("Box Area")
ylabel("Aspect Ratio (width/height)");
title("Box Area vs. Aspect Ratio")
```

The plot shows a few groups of objects that are of similar size and shape, However, because the groups are spread out, manually choosing anchor boxes is difficult. A better way to estimate anchor boxes is to use a clustering algorithm that can group similar boxes together using a meaningful metric.

Estimate Anchor Boxes

Estimate anchor boxes from training data using the `estimateAnchorBoxes` function, which uses the intersection-over-union (IoU) distance metric.

A distance metric based on IoU is invariant to the size of boxes, unlike the Euclidean distance metric, which produces larger errors as the box sizes increase [1]. In addition, using an IoU distance metric

leads to boxes of similar aspect ratios and sizes being clustered together, which results in anchor box estimates that fit the data.

Create a `boxLabelDatastore` using the ground truth boxes in the vehicle data set. If the preprocessing step for training an object detector involves resizing of the images, use `transform` and `bboxresize` to resize the bounding boxes in the `boxLabelDatastore` before estimating the anchor boxes.

```
trainingData = boxLabelDatastore(vehicleDataset(:,2:end));
```

Select the number of anchors and estimate the anchor boxes using `estimateAnchorBoxes` function.

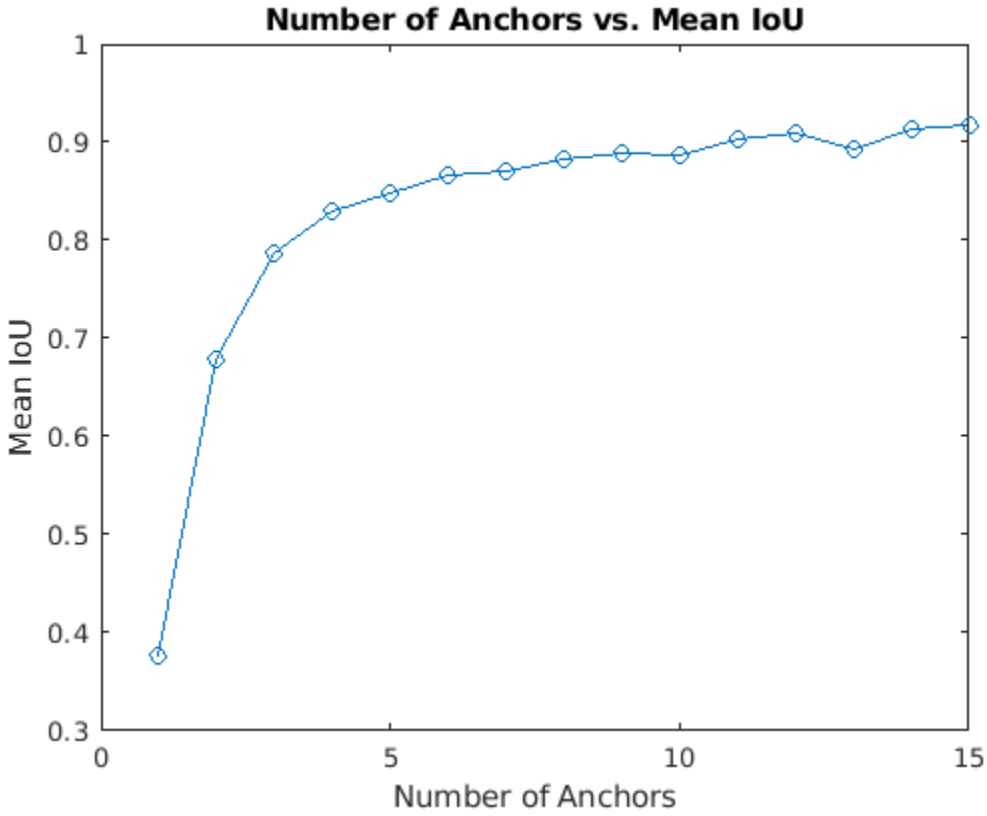
```
numAnchors = 5;
[anchorBoxes,meanIoU] = estimateAnchorBoxes(trainingData,numAnchors);
anchorBoxes
```

```
anchorBoxes = 5×2

    21    27
```

Choosing the number of anchors is another training hyperparameter that requires careful selection using empirical analysis. One quality measure for judging the estimated anchor boxes is the mean IoU of the boxes in each cluster. The `estimateAnchorBoxes` function uses a *k*-means clustering algorithm with the IoU distance metric to calculate the overlap using the equation, `1 - bboxOverlapRatio(allBoxes,boxInCluster)`.

```
meanIoU
```



```
meanIoU =
0.8411
```

The mean IoU value greater than 0.5 ensures that the anchor boxes overlap well with the boxes in the training data. Increasing the number of anchors can improve the mean IoU measure. However, using more anchor boxes in an object detector can also increase the computation cost and lead to overfitting, which results in poor detector performance.

Sweep over a range of values and plot the mean IoU versus number of anchor boxes to measure the tradeoff between number of anchors and mean IoU.

```
maxNumAnchors = 15;
meanIoU = zeros([maxNumAnchors,1]);
anchorBoxes = cell(maxNumAnchors, 1);
for k = 1:maxNumAnchors
    % Estimate anchors and mean IoU.
    [anchorBoxes{k},meanIoU(k)] = estimateAnchorBoxes(trainingData,k);
end

figure
plot(1:maxNumAnchors,meanIoU,'-o')
ylabel("Mean IoU")
xlabel("Number of Anchors")
title("Number of Anchors vs. Mean IoU")
```

Using two anchor boxes results in a mean IoU value greater than 0.65, and using more than 7 anchor boxes yields only marginal improvement in mean IoU value. Given these results, the next step is to train and evaluate multiple object detectors using values between 2 and 6. This empirical analysis helps determine the number of anchor boxes required to satisfy application performance requirements, such as detection speed, or accuracy.

Input Arguments

`trainingData` — Labeled ground truth images

datastore | table

Labeled ground truth images, specified as a datastore or a table.

- If you use a datastore, your data must be set up so that calling the datastore with the `read` and `readall` functions returns a cell array or table with two or three columns.

  When the output contains two columns, the first column must contain bounding boxes, and the second column must contain labels, {*boxes*,*labels*}.

  When the output contains three columns, the second column must contain the bounding boxes, and the third column must contain the labels, {*data*,*boxes*,*labels*}. In this case, the first column can contain any type of data. For example, the first column can contain images or point cloud data. The last column, *labels*, must be a cell array that contains *M*-by-1 categorical vectors containing object class names. All categorical data returned by the datastore must contain the same categories.

- If you use a table, the table must have two or more columns. The first column of the table must contain image file names with paths. The images must be grayscale or truecolor (RGB) and they can be in any format supported by `imread`. Each of the remaining columns must be a cell vector that specifies a single object class such as *vehicle*, *flower*, or *stop sign* in the form of an axis-aligned or a rotated rectangle bounding box. The columns must be only axis-aligned or rotated rectangle bounding boxes. For example, column 4 cannot specify axis-aligned boxes if column 3 specifies rotated rectangles. All the columns must be of the same bounding box type.

  Note When the training data is specified using a table, the `estimateAnchorBoxes` function checks these conditions

  - Axis-aligned bounding box values must be integers. Otherwise, the function automatically rounds each noninteger values to its nearest integer.
  - The bounding box must not be empty and must be within the image region. While training the network, the function ignores empty bounding boxes and bounding boxes that lie partially or fully outside the image region.

- When bounding boxes are rotated rectangles, the `estimateAnchorBoxes` function uses only the location, width, and height values of the bounding box to form similar axis-aligned anchor boxes.

The table describes the format of bounding boxes.

Bounding Box	***Description***
Axis-aligned rectangle	Defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and `y` specify the upper-left corner of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis. • *h* specifies the height of the rectangle, which is its length along the *y*-axis.

Bounding Box	*Description*
Rotated rectangle	Defined in spatial coordinates as an *M*-by-5 numeric matrix with rows of the form [*xctr yctr w h yaw*], where: • *M* is the number of rotated rectangles. • *xctr* and *yctr* specify the center of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis before rotation. • *h* specifies the height of the rectangle, which is its length along the *y*-axis before rotation. • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the bounding box. 

For more information, see “Datastores for Deep Learning” (Deep Learning Toolbox).

`numAnchors` — Number of anchor boxes
integer

Number of anchor boxes for the function to return, specified as an integer.

Output Arguments

`anchorBoxes` — Anchor boxes
N-by-2 matrix

Anchor boxes, returned as an *N*-by-2 matrix, where *N* is the number of anchor boxes and each entry has the format [*height*, *width*]. Use `numAnchors` to specify the number of anchor boxes.

`meanIoU` — Distance metric
scalar

Distance metric, returned as a scalar value. The distance metric provides the mean intersection-over-union (IoU) value of the anchor boxes in each cluster. To ensure anchor boxes overlap well with the boxes in the training data, the `meanIoU` value must be greater than 0.5. The *k*-means clustering algorithm uses the IoU distance metric to calculate the overlap using the equation `1-bboxOverlapRatio(box1,box2)`.

Version History

Introduced in R2019b

R2023b: Rotated rectangle support for bounding box

Input can be a rotated rectangle of the form [*xctr*, *yctr*, *width*, *height*, *yaw*].

caliper

Measure distance in image data using caliper tool

Syntax

```
measurementData = caliper(I,linePosition)
measurementData = caliper(I,linePosition,Name=Value)
```

Description

Add-On Required: This feature requires the Automated Visual Inspection Library for Computer Vision Toolbox add-on.

`measurementData = caliper(I,linePosition)` measures distance in a grayscale or RGB input image, `I`, using a caliper tool by positioning a profile scan line at the position `linePosition`.

Note This functionality requires the Automated Visual Inspection Library for Computer Vision Toolbox. You can install the Automated Visual Inspection Library for Computer Vision Toolbox from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

`measurementData = caliper(I,linePosition,Name=Value)` specifies options using one or more name-value arguments. For example, `Width=10` specifies the width of the profile scan as 10 pixels.

Examples

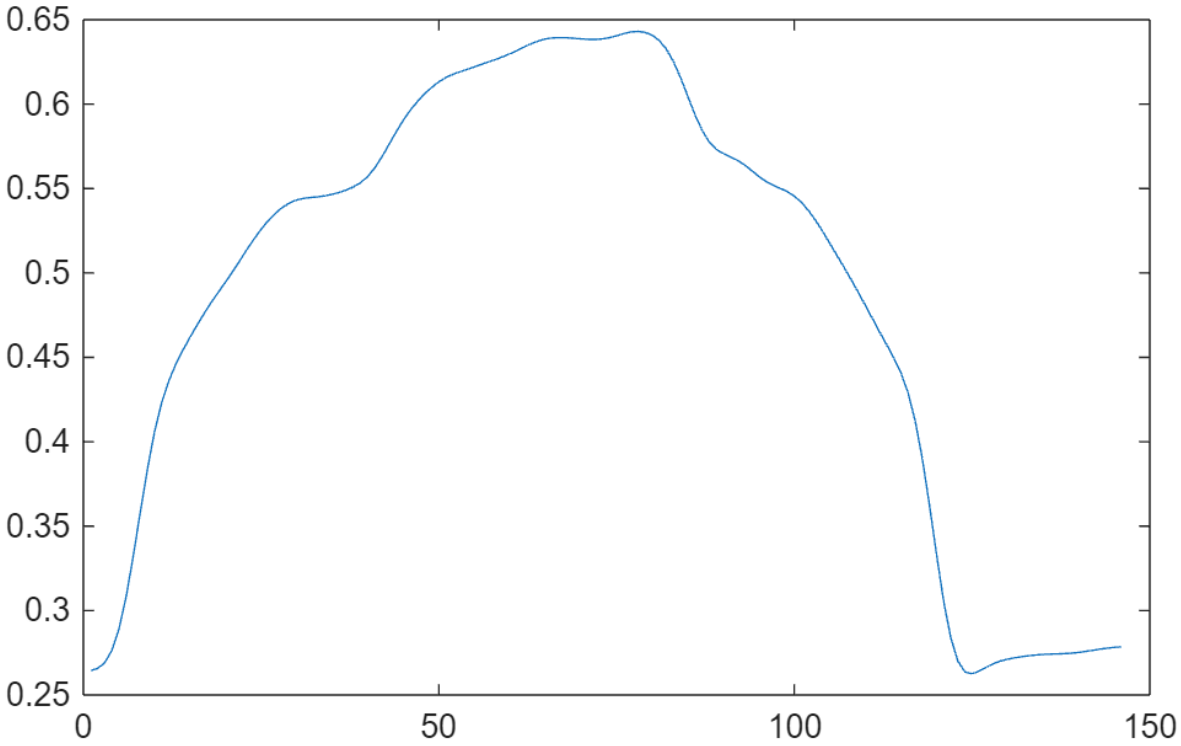
Measure Distance Between Object Edges Using Caliper

Load an image into the workspace.

```
I = imread("coins.png");
```

Display the image using the `imageshow` function.

```
imageshow(I)
```



Measure the distance between the edges of the darkest nickel coin using the `caliper` function. Specify the start and end point of the profile scan line as `[171 89; 218 131]`. To detect the coin edges, specify a gradient threshold lower than the maximum intensity gradient across the scan length using the `GradientThreshold` name-value argument. Since the coin contains two edge pairs, the function returns the distance between them, or the coin width, as `IntraEdgeDistance` value.

```
measureOut = caliper(I,[158 89; 218 131],GradientThreshold=0.04)
```

```
measureOut = struct with fields:
    InterEdgeDistance: [1×0 double]
    IntraEdgeDistance: 56.4544
        GradientValue: [0.0520 -0.0579]
             Distance: [3.4186 59.8729]
          ProfileData: [146×1 double]
```

Display the intensity gradient value along the profile scan line.

```
figure
plot(measureOut.ProfileData)
```

Input Arguments

`I` — Input image

H-by-*W* numeric matrix | *H*-by-*W*-by-3 numeric array

Input image for which to perform the caliper measurement, specified as one of these values:

Image Type	Data Format
Grayscale	*H*-by-*W* numeric matrix
RGB	*H*-by-*W*-by-3 numeric array

`linePosition` — Profile line position

2-by-2 numeric matrix

Profile line position, in pixels, specified as a 2-by-2 numeric matrix of the form $[x_1\ y_1; x_2\ y_2]$, where the $[x_1\ ,\ y_1]$ and $[x_2\ ,y_2]$ are coordinates of the start point and end point of the line, respectively.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `caliper(I,linePosition,Width=10)` specifies the width of the profile scan as 10 pixels.

`Width` — Profile scan width
`50` (default) | positive scalar

Profile scan width, specified as a positive scalar. The width is the area within which the `caliper` function computes profile scan lines measurements. The function scans in lines orthogonal to the profile centerline and using these measurements, computes a mean 1-D profile for gradient detection.

`EdgeTransition` — Edge transition type
`"both"` (default) | `"rising"` | `"falling"`

Edge transition type used in edge detection, specified as one of these options:

- `"rising"` — Detect darker-to-brighter edge transitions.
- `"falling"` — Detect brighter-to-darker edge transitions.
- `"both"` — Detect both brighter-to-darker and darker-to brighter-edge transitions.

The edge transition is relative to the direction of the scan line, from start point to end point.

`GradientThreshold` — Gradient threshold selection
`0.1` (default) | positive scalar in range `[0, 1]`

Gradient threshold for a gradient to be considered an edge, specified as a positive scalar in range `[0, 1]`. The gradient at each scan point is the normalized average gradient across the profile line width, `Width`. The `caliper` function evaluates this value at each point along the scan line. Increase the gradient threshold value to detect fewer false positive edges.

`MeasurementMode` — Measurement mode
`"edge-pair"` (default) | `"single-edge"`

Measurement mode used to compute edge data, specified as `"edge-pair"` or `"single-edge"`. This argument determines the edge type to detect, and how the `measurementData` argument outputs distance.

Value	Edge Detection Mode	`measurementData` Distance Output
`"edge-pair"`	Detect edge pairs of the type specified by the `EdgeTransition` name-value argument. When the profile scan line spans multiple edges, the caliper tool pairs each starting edge with the spatially closest ending edge to form a pair.	`measurementData` populates the `InterEdgeDistance` and `IntraEdgeDistance` fields with distance information. • `InterEdgeDistance` is the distance between the end of an edge pair and the start of the next edge pair. • `IntraEdgeDistance` is the distance between the start and end of each edge pair.

Value	Edge Detection Mode	measurementData Distance Output
"single-edge"	Detect single edges of the type specified by the EdgeTransition name-value argument.	measurementData populates the Distance field with distance information. Distance is the distance from the start point of the profile line to the position where the function detects the gradients.

Sigma — Standard deviation for Gaussian smoothing of 1-D profile data
1.0 (default) | positive scalar

Standard deviation for Gaussian smoothing of the 1-D profile data, specified as a positive scalar. Increase this value to increase the amount of Gaussian smoothing and reduce measurement noise at the possible expense of lower accuracy in detecting edge positions.

Transformation — Geometric transformation for input image data
affinetform2d object (default) | imref2d object | rigidtform2d object | simtform2d object | transltform2d object

Geometric transformation for the input image data that defines a 2-D world coordinate system, specified as an affinetform2d object, an imref2d object, a rigidtform2d object, a simtform2d object, or a transltform2d object.

Output Arguments

measurementData — Caliper measurement data
structure

Caliper measurement data, returned as a structure with these fields:

MeasurementData Field	Description
Distance	Distance between the first point of the profile line to the position of each detected edge, stored as a numeric array.
IntraEdgeDistance	Distance between the start and end of each edge pair, stored as a numeric array.
InterEdgeDistance	Distance between the end of an edge pair and the start of the next edge pair, stored as a numeric array.
ProfileData	1-D profile data that determines detected edges, stored as an *M*-element numeric vector. *M* is the integer length of the profile scan, in pixels, and each element of the vector is the mean gradient value at each scan point.

MeasurementData Field	Description
`GradientValue`	Gradient values corresponding to each edge detection, stored as a row vector or *N*-by-2 numeric matrix, depending on the value of the `measurementMode` name-value argument. • `"single-edge"` – `GradientValue` is a row vector containing gradient values associated with each detected edge. • `"edge-pair"` – `GradientValue` is an *N*-by-2 numeric matrix, where each row contains the gradient values of the start point and the end point of the corresponding edge pair. *N* is the number of detected edge pairs.

Version History

Introduced in R2025a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `EdgeTransition` and `MeasurementMode` name-value arguments must be compile-time constants. Code generation does not support cell arrays for these name-value arguments.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- The `EdgeTransition` and `MeasurementMode` name-value arguments must be compile-time constants. Code generation does not support cell arrays for these name-value arguments.

deeplabv3plusLayers

(Removed) Create DeepLab v3+ convolutional neural network for semantic image segmentation

Note `deeplabv3plusLayers` has been removed. Use the `deeplabv3plus` function instead. For more information, see “Version History”.

Syntax

```
layerGraph = deeplabv3plusLayers(imageSize,numClasses,network)
layerGraph = deeplabv3plusLayers( ___ ,"DownsamplingFactor",value)
```

Description

`layerGraph = deeplabv3plusLayers(imageSize,numClasses,network)` returns a DeepLab v3+ layer with the specified base network, number of classes, and image size.

`layerGraph = deeplabv3plusLayers( ___ ,"DownsamplingFactor",value)` additionally sets the downsampling factor (output stride) [1] to either 8 or 16. The downsampling factor sets the amount the encoder section of DeepLab v3+ downsamples the input image.

Examples

Create DeepLab v3+ Network Based on ResNet-18

Create a DeepLab v3+ network based on ResNet-18.

```
imageSize = [480 640 3];
numClasses = 5;
network = "resnet18";
lgraph = deeplabv3plusLayers(imageSize,numClasses,network, ...
             "DownsamplingFactor",16);
```

Display the network.

```
analyzeNetwork(lgraph)
```

Input Arguments

`imageSize` — Network input image size

2-element vector | 3-element vector

Network input image size, specified as a:

- 2-element vector in the format [*height*, *width*].
- 3-element vector in the format [*height*, *width*, 3]. The third element, 3, corresponds to RGB.

`numClasses` — Number of classes

integer greater than 1

Number of classes for network to classify, specified as an integer greater than 1.

`network` — Base network
`'resnet18'` | `'resnet50'` | `'mobilenetv2'` | `'xception'` | `'inceptionresnetv2'`

Base network, specified as `resnet18`, `resnet50`, `mobilenetv2`, `xception`, or `inceptionresnetv2`. You must install the corresponding network add-on.

Output Arguments

`layerGraph` — DeepLab v3+ network
`layerGraph` object

DeepLab v3+ network, returned as a `layerGraph` object for semantic image segmentation. The network uses encoder-decoder architecture, dilated convolutions, and skip connections to segment images. You must use the `trainNetwork` function (requires Deep Learning Toolbox) to train the network before you can use the network for semantic segmentation.

Algorithms

- When you use either the `xception` or `mobilenetv2` base networks to create a DeepLab v3+ network, depth separable convolutions are used in the atrous spatial pyramid pooling (ASPP) and decoder subnetworks. For all other base networks, convolution layers are used.
- This implementation of DeepLab v3+ does not include a global average pooling layer in the ASPP.

Version History

Introduced in R2019b

R2026a: Removed
Errors starting in R2026a

The `deeplabv3plusLayers` function has been removed. Use the `deeplabv3plus` function instead.

R2024b: Warns
Warns starting in R2024b

The `deeplabv3plusLayers` function issues a warning that it will be removed in a future release. Use the `deeplabv3plus` function instead. The `deeplabv3plus` function returns a `dlnetwork` object, which has these advantages over `layerGraph` objects:

- `dlnetwork` objects support a wider range of network architectures which you can then easily train using the `trainnet` function or import from external platforms.
- `dlnetwork` objects provide more flexibility. They have wider support with current and upcoming Deep Learning Toolbox functionality.
- `dlnetwork` objects provide a unified data type that supports network building, prediction, built-in training, compression, and custom training loops.
- `dlnetwork` training and prediction is typically faster than `DAGNetwork` and `SeriesNetwork` training and prediction.

To update your code, replace instances of the `deeplabv3plusLayers` with the `deeplabv3plus` function. You do not need to change the input arguments.

Discouraged Usage	Recommended Replacement

This example uses the `deeplabv3plusLayers` function to create a DeepLab v3+ network, returned as a `LayerGraph` object.
 	
`imageSize = [480 640 3];`
`numClasses = 5;`
`network = "resnet18";`
`deepLabNetwork = deeplabv3plusLayers(imageSize,numClasses,network, ...`
`    DownsamplingFactor=16);`
	Here is equivalent code that instead uses the `deeplabv3plus` function to create a DeepLab v3+ network, returned as a `dlnetwork` object.
	
	`imageSize = [480 640 3];`
	`numClasses = 5;`
	`network = "resnet18";`
	`deepLabNetwork = deeplabv3plus(imageSize,numClasses,n`
	`    DownsamplingFactor=16);`

R2024a: To be removed
Not recommended starting in R2024a

The `deeplabv3plusLayers` function will be removed in a future release.

Extended Capabilities

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

For code generation, you must first create a DeepLab v3+ network by using the `deeplabv3plusLayers` function. Then, use the `trainNetwork` function on the resulting `lgraph` object to train the network for segmentation. Once the network is trained and evaluated, you can generate code for the deep learning network object using GPU Coder.

fasterRCNNLayers

(Not recommended) Create a faster R-CNN object detection network

Note `fasterRCNNLayers` is not recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` detector For more information, see "Version History".

Syntax

```
lgraph = fasterRCNNLayers(inputImageSize,numClasses,anchorBoxes,network)
lgraph = fasterRCNNLayers(inputImageSize,numClasses,anchorBoxes,network,
featureLayer)
lgraph = fasterRCNNLayers( ___ ,Name=Value)
```

Description

`lgraph = fasterRCNNLayers(inputImageSize,numClasses,anchorBoxes,network)` returns a Faster R-CNN network as a `layerGraph` object. A Faster R-CNN network is a convolutional neural network based object detector. The detector predicts the coordinates of bounding boxes, objectness scores, and classification scores for a set of anchor boxes. To train the created network, use the `trainFasterRCNNObjectDetector` function. For more information, see "Getting Started with R-CNN, Fast R-CNN, and Faster R-CNN".

`lgraph = fasterRCNNLayers(inputImageSize,numClasses,anchorBoxes,network, featureLayer)` returns the object detection network based on the specified `featureLayer` of the network. Use this syntax when you specify the network as a `SeriesNetwork`, `DAGNetwork`, or `layerGraph`. object.

`lgraph = fasterRCNNLayers( ___ ,Name=Value)` returns the object detection network with optional input properties specified by one or more name-value arguments.

Using this function requires Deep Learning Toolbox.

Examples

Create a Faster R-CNN Object Detection Network

Specify the image size.

```
inputImageSize = [224 224 3];
```

Specify the number of objects to detect.

```
numClasses = 1;
```

Use a pretrained ResNet-50 network as the base network for the Faster R-CNN network. You must download the `resnet50` (Deep Learning Toolbox) support package.

```
network = "resnet50";
```

Specify the network layer to use for feature extraction. You can use the `analyzeNetwork` (Deep Learning Toolbox) function to see all the layer names in a network.

```
featureLayer = "activation_40_relu";
```

Specify the anchor boxes. You can also use the `estimateAnchorBoxes` function to estimate anchor boxes from your training data.

```
anchorBoxes = [64,64; 128,128; 192,192];
```

Create the Faster R-CNN object detection network.

```
lgraph = fasterRCNNLayers(inputImageSize,numClasses,anchorBoxes, ...
                          network,featureLayer)
```

```
lgraph =
  LayerGraph with properties:

     InputNames: {'input_1'}
    OutputNames: {'rcnnClassification'  'boxDeltas'  'rpnBoxDeltas'  'rpnClassification'}
         Layers: [188×1 nnet.cnn.layer.Layer]
    Connections: [205×2 table]
```

Visualize the network using the network analyzer.

```
analyzeNetwork(lgraph)
```

Input Arguments

`inputImageSize` — Network input image size

3-element vector

Network input image size, specified as a 3-element vector in the format [*height*, *width*, *depth*]. *depth* is the number of image channels. Set *depth* to `3` for RGB images, to `1` for grayscale images, or to the number of channels for multispectral and hyperspectral images.

`numClasses` — Number of classes

integer greater than 0

Number of classes for the network to classify, specified as an integer greater than 0.

`anchorBoxes` — Anchor boxes

M-by-2 matrix

Anchor boxes, specified as an *M*-by-2 matrix of *M* anchor boxes in the format [*height*, *width*]. Anchor boxes are determined based on the scale and aspect ratio of objects in the training data set. For example, if an object is localized by a square window, then you can set the size of the anchor boxes to `[64 64;128 128]`.

`network` — Pretrained classification network

`SeriesNetwork` object | `DAGNetwork` object | `LayerGraph` object | `"lexnet"` | `"vgg16"` | `"vgg19"` | `"resnet18"` | `"resnet50"` | `"resnet101"` | `"inceptionv3"` | `"googlenet"` | `"inceptionresnetv2"` | `"mobilenetv2"` | `"squeezenet"`

Pretrained classification network, specified as a `SeriesNetwork`, `DAGNetwork`, or `layerGraph`, or as on of the following:

- `'alexnet'`
- `'vgg16'`
- `'vgg19'`
- `'resnet18'`
- `'resnet50'`
- `'resnet101'`
- `'inceptionv3'`
- `'googlenet'`
- `'inceptionresnetv2'`
- `'squeezenet'`
- `'mobilenetv2'`

When you specify the network as a `SeriesNetwork` object, a `DAGNetwork` object, or by name, the function transforms the network into a Faster R-CNN network. It transforms the network by adding a region proposal network (RPN), and ROI max pooling layer, and new classification and regression layers to support object detection.

`featureLayer` — Feature extraction layer
character vector | string scalar

Feature extraction layer, specified as a character vector or a string scalar. Use one of the deeper layers in the network you specify. You can use the `analyzeNetwork` function to view the names of the layers in the input network.

Note You can specify any network layer except the fully connected layer as the feature layer.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: Set `ROIMaxPoolingLayer="auto"` to specify the function to inserts a new ROI max pooling layer after the feature extraction layer when the layer next to the feature extraction layer is not a max pooling layer.

`ROIMaxPoolingLayer` — ROI max pooling layer
`"auto"` (default) | `"insert"` | `"replace"`

ROI max pooling layer, specified as a `"auto"`, `"insert"`, or `"replace"`. You can specify whether a `roiMaxPooling2dLayer` replaces the pooling layer or follows the feature extraction layer.

If you select `"auto"`, the function:

- Inserts a new ROI max pooling layer after the feature extraction layer when the layer next to the feature extraction layer is not a max pooling layer.

- Replaces the current pooling layer after the feature extraction layer with an ROI max pooling layer.

`ROIOutputSize` — ROI max pooling layer output size
`"auto"` (default) | 2-element vector

ROI max pooling layer output size, specified as `"auto"` or a 2-element vector of positive integers. When you set the value to `"auto"`, the function determines the output size based on the `ROIMaxPoolingLayer` property. It uses the output size of the feature extraction layer or the pooling layer following the feature extraction layer.

Note If the input image dimensions specified by the `inputImageSize` argument are not in a 1-to-1 aspect ratio, you must set the value of `ROIOutputSize` using dimensions which are compatible with the feature layer output size.

Output Arguments

`lgraph` — Object detection network
`layerGraph` object

Object detection network, returned as a `layerGraph` object. The output and base network `imageInputLayer` normalization values are equal.

Version History

Introduced in R2019b

R2024b: Not Recommended
Not recommended starting in R2024b

Starting in R2024b, R-CNN object detectors are no longer recommended. Instead, use a different type of object detector, such as a `yoloxObjectDetector` or `yolov4ObjectDetector` object. These object detectors are faster than R-CNN object detectors. For more information, see “Choose an Object Detector”.

yolov2Layers

(To be removed) Create YOLO v2 object detection network

Note `yolov2Layers` will be removed in a future release. Use the `yolov2ObjectDetector` function instead. For more information, see “Version History”.

Syntax

```
lgraph = yolov2Layers(imageSize,numClasses,anchorBoxes,network,featureLayer)
lgraph = yolov2Layers(___,"ReorgLayerSource",reorgLayer)
```

Description

`lgraph = yolov2Layers(imageSize,numClasses,anchorBoxes,network,featureLayer)` creates a YOLO v2 object detection network and returns it as a `LayerGraph` object.

`lgraph = yolov2Layers(___,"ReorgLayerSource",reorgLayer)` adds a reorganization layer to the YOLO v2 network architecture following the layer `reorgLayer`,

Examples

Create YOLO v2 Network for Object Detection

Specify the size of the input image for training the network.

```
imageSize = [224 224 3];
```

Specify the number of object classes the network has to detect.

```
numClasses = 1;
```

Define the anchor boxes.

```
anchorBoxes = [1 1;4 6;5 3;9 6];
```

Specify the pretrained ResNet-50 network as the base network for YOLO v2. To use this pretrained network, you need to install the "*Deep Learning Toolbox Model for ResNet-50 Network*" support package.

```
network = resnet50;
```

Analyze the network architecture to view all the network layers.

```
analyzeNetwork(network)
```

Specify the network layer to be used for feature extraction. You can choose any layer except the fully connected layer as feature layer.

```
featureLayer = 'activation_49_relu';
```

Create the YOLO v2 object detection network. The network is returned as a `LayerGraph` object.

```
lgraph = yolov2Layers(imageSize,numClasses,anchorBoxes,network,featureLayer);
```

Analyze the YOLO v2 network architecture. The layers succeeding the feature layer are removed. A series of convolution, ReLU, and batch normalization layers along with the YOLO v2 transform and YOLO v2 output layers are added to the feature layer of the base network.

```
analyzeNetwork(lgraph)
```

Input Arguments

`imageSize` — Size of input image

two-element vector | three-element vector

Size of an input image, specified as one of these values:

- Two-element vector of form [*H W*] - For a grayscale image of size *H*-by-*W*
- Three-element vector of form [*H W* 3] - For an RGB color image of size *H*-by-*W*

`numClasses` — Number of object classes

positive integer

Number of object classes, specified as a positive integer.

`anchorBoxes` — Anchor boxes

M-by-2 matrix

Anchor boxes, specified as an *M*-by-2 matrix defining the size and the number of anchor boxes. Each row in the *M*-by-2 matrix denotes the size of the anchor box in the form of [*height width*]. *M* denotes the number of anchor boxes. This input sets the `AnchorBoxes` property of the output layer.

The size of each anchor box is determined based on the scale and aspect ratio of different object classes present in input training data. Also, the size of each anchor box must be smaller than or equal to the size of the input image. You can use the clustering approach for estimating anchor boxes from the training data. For more information, see “Estimate Anchor Boxes from Training Data”.

`network` — Pretrained convolutional neural network

`LayerGraph` object | `DAGNetwork` object | `SeriesNetwork` object

Pretrained convolutional neural network, specified as an `LayerGraph`, `DAGNetwork`, or `SeriesNetwork` object. This pretrained convolutional neural network is used as the base for the YOLO v2 object detection network. For details on pretrained networks in MATLAB, see “Pretrained Deep Neural Networks” (Deep Learning Toolbox).

`featureLayer` — Name of feature layer

character vector | string scalar

Name of feature layer, specified as a character vector or a string scalar. The name of one of the deeper layers in the `network` to be used for feature extraction. The features extracted from this layer are given as input to the YOLO v2 object detection subnetwork. You can use the `analyzeNetwork` function to view the names of the layers in the input network.

Note You can specify any network layer except the fully connected layer as the feature layer.

`reorgLayer` — Name of reorganization layer
character vector | string scalar

Name of reorganization layer, specified as a character vector or a string scalar. The name of one of the deeper layers in the `network` to be used as input to the reorganization layer. You can use the `analyzeNetwork` function to view the names of the layers in the input `network`. The reorganization layer is the pass-through layer that reorganizes the dimension of low layer features to facilitate concatenation with high layer features.

Note The input to the reorganization layer must be from any one of the network layers that lie above the feature layer.

Output Arguments

`lgraph` — YOLO v2 object detection network
`LayerGraph` object

YOLO v2 object detection network, returned as a `LayerGraph` object.

Note The default value for the `Normalization` property of the image input layer in the returned `lgraph` object is set to the `Normalization` property of the base network specified in `network`.

Algorithms

The `yolov2Layers` function creates a YOLO v2 network, which represents the network architecture for YOLO v2 object detector. Use the `trainYOLOv2ObjectDetector` function to train the YOLO v2 network for object detection. The function returns an object that generates the network architecture for YOLO v2 object detection network presented in [1] and [2].

`yolov2Layers` uses a pretrained neural network as the base network to which it adds a detection subnetwork required for creating a YOLO v2 object detection network. Given a base network, `yolov2Layers` removes all the layers succeeding the feature layer in the base network and adds the detection subnetwork. The detection subnetwork comprises of groups of serially connected convolution, ReLU, and batch normalization layers. The YOLO v2 transform layer and YOLO v2 output layer are added to the detection subnetwork. If you specify the name-value argument `"ReorgLayerSource"`, the YOLO v2 network concatenates the output of reorganization layer with the output of feature layer.

For information on creating a custom YOLO v2 network layer-by-layer, see “Create Custom YOLO v2 Object Detection Network”.

Version History

Introduced in R2019a

R2025a: `yolov2Layers` will be removed
Warns starting in R2025a

The `yolov2Layers` function will be removed in a future release. When you call the `yolov2Layers` function, it issues a warning that it will be removed. Create a YOLO v2 object detection network by using the `yolov2ObjectDetector` object instead.

R2024b: `yolov2Layers` will be removed
Not recommended starting in R2024b

The `yolov2Layers` function will be removed in a future release. Use the `yolov2ObjectDetector` function instead. The `yolov2ObjectDetector` function creates a pretrained or untrained YOLO v2 object detector, and stores the network as a `dlnetwork` object.

To update your code:

- Define your network as a `dlnetwork` object. You can load a pretrained feature extraction network by using the `imagePretrainedNetwork` function.
- Select a feature extraction layer.
- Create a `yolov2ObjectDetector` object, specifying the base network and the name of the feature extraction layer. Also, specify the names of the classes and the anchor boxes as inputs for training the network.

For more information, see “Getting Started with YOLO v2”.

Extended Capabilities

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

For code generation, you must first create a YOLO v2 network by using the `yolov2Layers` function. Then, use the `yolov2ObjectDetector` function on the resulting `lgraph` object to train the network for object detection. Once the network is trained and evaluated, you can generate code for the `yolov2ObjectDetector` object using GPU Coder.

gatherLabelData

Gather label data from ground truth

Syntax

```
labelData = gatherLabelData(gTruth,typeOfLabel)
[labelData,timestamps] = gatherLabelData( ___ )
[ ___ ] = gatherLabelData( ___ ,Name=Value)
```

Description

`labelData = gatherLabelData(gTruth,typeOfLabel)` returns label data gathered from ground truth data, `gTruth`. The function returns label data specified by `typeOfLabel`.

`[labelData,timestamps] = gatherLabelData( ___ )` additionally returns the image timestamps associated with the gathered label data, using the arguments from the previous syntax.

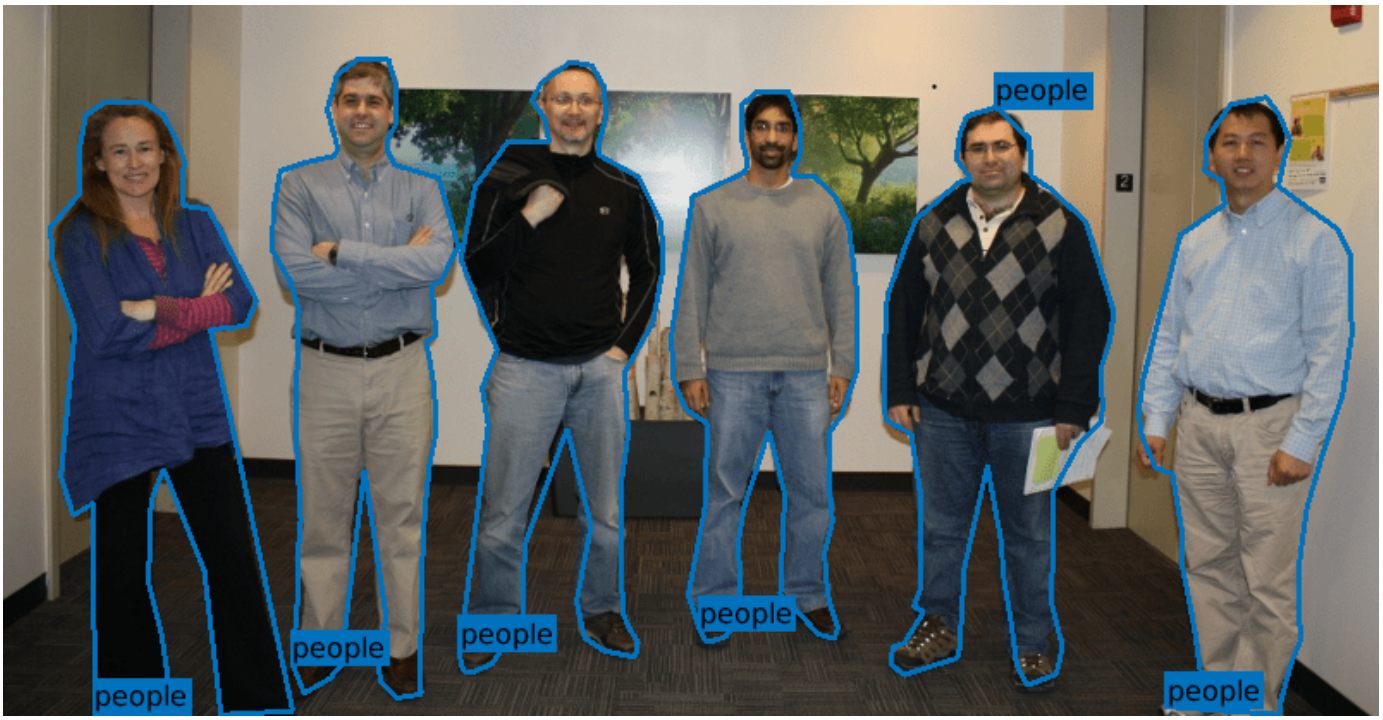
`[ ___ ] = gatherLabelData( ___ ,Name=Value)` uses name-value arguments to specify how to gather data. For example, `labelData = gatherLabelData(gTruth,typeofLabel,SampleFactor=5)` specifies to drop every 5th frame.

Examples

Gather Polygon Labels

Gather all of the polygon labels from the groundtruth image.

```
data = load('groundtruthVisionTeam.mat');
gtruth = data.groundtruthVisionTeam;
```



Gather all of the polygon objects.

```
labelData = gatherLabelData(gtruth, labelType('Polygon'), 'GroupLabelData', 'LabelType');

polygons = labelData{1}.PolygonData{1}(:,1);
polygonLabels = labelData{1}.PolygonData{1}(:,2);
```

Visualize the polygon labels.

```
im = imread('visionteam.jpg');
imshow(im);
showShape('polygon', polygons, 'Label', polygonLabels);
```

Input Arguments

`gTruth` — Ground truth data

`groundTruth` object | vector of `groundTruth` objects

Ground truth data, specified as a `groundTruth` object or vector of `groundTruth` objects.

`typeOfLabel` — Label types

vector of `labelType` objects

Label types from which to gather label data, specified as a vector of `labelType` objects. The `gatherLabelData` function gathers label data from each `groundTruth` object specified by input `gTruth` The label data is grouped in columns either by label name or by label type, specified by the `GroupLabelData` name-value argument.

Valid Enumeration Types

You can specify one or more of these enumeration types.

- `labelType.Rectangle` — Rectangle ROI labels
- `labelType.RotatedRectangle` — Rotated Rectangle ROI labels
- `labelType.Cuboid` — Cuboid ROI labels (point clouds)
- `labelType.ProjectedCuboid` — Projected cuboid ROI labels (images and video data)
- `labelType.Line` — Line ROI labels
- `labelType.PixelLabel` — Pixel ROI labels
- `labelType.Polygon` — Pixel ROI labels

- `labelType.Scene` — Scene labels

To gather label data for scenes, you must specify `labelTypes` as the `labelType.Scene` enumeration scalar. You cannot specify any other label types with `labelType.Scene`.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `labelData = gatherLabelData(gTruth,typeofLabel,SampleFactor=5)` specifies to drop every 5th frame.

`SampleFactor` — Sample factor

1 (default) | positive integer

Sample factor to subsample label data, specified as a positive integer. A sample factor of *K* includes every *K*th frame. Increase the sample factor to drop redundant frames from signals with high sample rates, such as video.

`GroupLabelData` — Group columns from label data

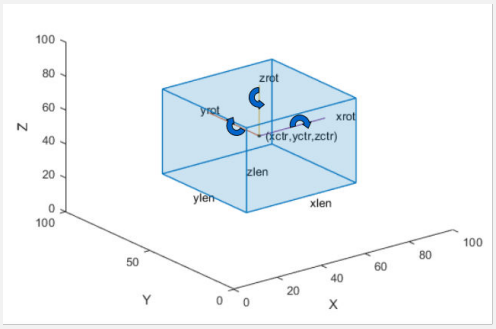
`'LabelName'` (default) | `'LabelType'`

Group columns from label data, specified as `'LabelName'` or `'LabelType'`.

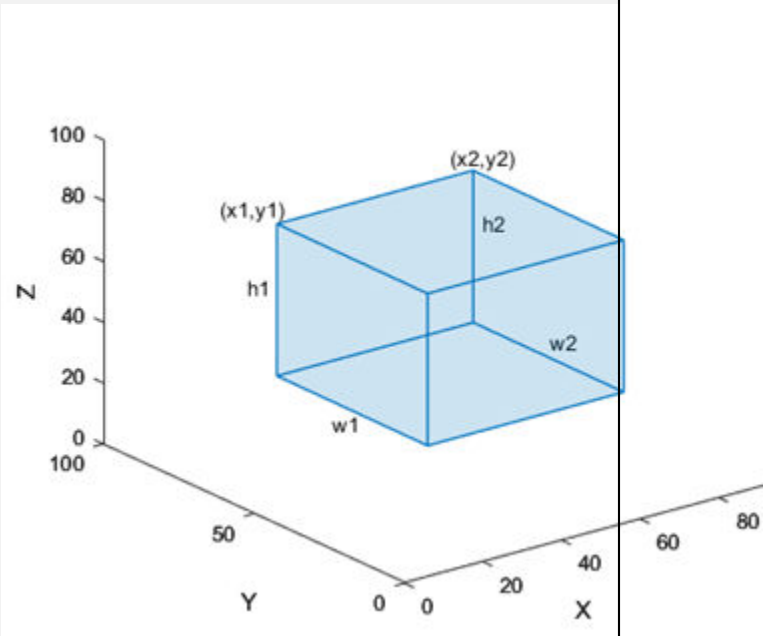
- `'LabelName'` — Groups the label data by label definitions.
- `'LabelType'` — Groups the label data by label type. Use this option to gather label data with the region-of-interest (ROI) stacking order retained by the label type.

Group label data with the scene label type (`labelType.Scene`) by label definitions only.

Output Arguments



`labelData` — Label data



cell array of tables

Label data, returned as an `M`-by-`1` cell array of tables, where `M` is the number of `groundTruth` objects in `gTruth`. The columns of the tables represent label data grouped by either label name or label type, specified by the `GroupLabelData` name-value argument.

For each cell in the table, the format of the returned label data depends on the type of label.

Label Type	Storage Format for Labels at Each Timestamp
`labelType.Rectangle`	`M`-by-4 numeric matrix of the form `[x, y, w, h]`, where: • `M` is the number of labels in the frame. • `x` and `y` specify the upper-left corner of the rectangle. • `w` specifies the width of the rectangle, which is its length along the *x*-axis. • `h` specifies the height of the rectangle, which is its length along the *y*-axis.
`labelType.RotatedRectangle`	For one or more rotated rectangles, specify in spatial coordinates as an *M*-by-5 numeric matrix, where each row specifies a rotated rectangle of the form [*xctr yctr w h yaw*]. • *M* is the number of rotated rectangles. • *xctr* and *yctr* specify the center of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis before rotation. • *h* specifies the height of the rectangle, which is its length along the *y*-axis before rotation. • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the rectangle.

Label Type	Storage Format for Labels at Each Timestamp
`labelType.Cuboid`	M-by-9 numeric matrix with rows of the form `[xctr, yctr, zctr, xlen, ylen, zlen, xrot, yrot, zrot]`, where: • `M` is the number of labels in the frame. • `xctr`, `yctr`, and `zctr` specify the center of the cuboid. • `xlen`, `ylen`, and `zlen` specify the length of the cuboid along the *x*-axis, *y*-axis, and *z*-axis, respectively, before rotation has been applied. • `xrot`, `yrot`, and `zrot` specify the rotation angles for the cuboid along the *x*-axis, *y*-axis, and *z*-axis, respectively. These angles are clockwise-positive when looking in the forward direction of their corresponding axes. The figure shows how these values determine the position of a cuboid. 

Label Type	Storage Format for Labels at Each Timestamp
`labelType.ProjectedCuboid`	M-by-8 vector of the form `[x1, y1, w1, h1, x2, y2, w2, h2]`, where: • `M` is the number of labels in the frame. • `x1, y1` specifies the *x*,*y* coordinates for the upper-left location of the front-face of the projected cuboid • `w1` specifies the width for the front-face of the projected cuboid. • `h1` specifies the height for the front-face of the projected cuboid. • `x2, y2` specifies the *x*,*y* coordinates for the upper-left location of the back-face of the projected cuboid. • `w2` specifies the width for the back-face of the projected cuboid. • `h2` specifies the height for the back-face of the projected cuboid. The figure shows how these values determine the position of a cuboid. 
`labelType.Line`	M-by-1 vector of cell arrays, where `M` is the number of labels in the frame. Each cell array contains an `N`-by-2 numeric matrix of the form `[x1 y1; x2 y2; ... ; xN yN]` for `N` points in the polyline.

Label Type	Storage Format for Labels at Each Timestamp
`labelType.PixelLabel`	Label data for all pixel label definitions is stored in a single *M*-by-1 `PixelLabelData` column for *M* images or frames. Each element contains a filename for a pixel label image. A pixel label image describes the label or labels contained in the corresponding image. The labels can be described as a 1- or 3- channel label matrix. To use `PixelLabelData` with any of the labeler apps, you must use a single-channel label matrix, where the values are of type `uint8`. You can convert a 3-channel pixel label data matrix to a single-channel label matrix programmatically to use with the labeler apps.
`labelType.Polygon`	`M`-by-1 vector of cell arrays, where `M` is the number of labels. Each cell array contains an `N`-by-2 numeric matrix of the form `[x1 y1; x2 y2; ... ; xN yN]` for `N` points in the polygon.
`labelType.Scene`	Logical `1` (`true`) if the scene label is applied, otherwise logical `0` (`false`)

`timestamps` — Timestamps
cell array of `duration` vectors

Timestamps, returned as an `M`-by-`1` cell array of `duration` vectors, where:

- `M` is the number of `groundTruth` objects in `gTruth`.
- `labelData{m}` contains the timestamps that is in the `m`th `groundTruth` object of `gTruth`.

Limitations

- The `gatherLabelData` function does not gather label data for sublabels or attributes. If a label contains sublabels or attributes, in the `labelData` output, the function returns the position of the parent label only.

Version History

Introduced in R2021a

R2022b: Project cuboids from 3-D world coordinates to 2-D image coordinates

Updated to support 3-D projected cuboid labels.

selectLabelsByGroup

Select ground truth labels by label group

Syntax

```
gtLabel = selectLabelsByGroup(gTruth,labelGroups)
```

Description

`gtLabel = selectLabelsByGroup(gTruth,labelGroups)` selects labels belonging to the groups specified by `labelGroups` from a `groundTruth` object, `gTruth`. The function returns a corresponding `groundTruth` object, `gtLabel`, that contains only the selected labels. If `gTruth` is a vector of `groundTruth` objects, then the function returns a vector of corresponding `groundTruth` objects that contain only the selected labels.

Examples

Select Ground Truth Data By Group

Load data to create a ground truth object. Add the image folder to the path.

```
data = load('stopSignsAndCars.mat');
imageFilenames = data.stopSignsAndCars.imageFilename(1:2)
```

```
imageFilenames = 2×1 cell
    {'stopSignImages/image001.jpg'}
    {'stopSignImages/image002.jpg'}
```

```
imageFilenames = fullfile(toolboxdir('vision'),'visiondata',imageFilenames);
dataSource = groundTruthDataSource(imageFilenames);
```

Define labels for identifying ground truth data.

```
names = {'stopSign';'carRear'};
types = [
    labelType('Rectangle')
    labelType('Rectangle')
    ];
groups = {'TrafficSigns';'Vehicles'};

labelDefs = table(names,types,groups,'VariableNames', {'Name','Type','Group'})
```

```
labelDefs=2×3 table
        Name          Type            Group
    ____________    _________    _______________

    {'stopSign'}    Rectangle    {'TrafficSigns'}
    {'carRear' }    Rectangle    {'Vehicles'    }
```

Initialize label data for rectangle ROIs.

```
numRows = numel(imageFilenames);
stopSignTruth = {[856   318    39    41]; [445   523  52    54]};
carRearTruth = {[398   378   315   210]; [332   633   691   287]};
```

Construct a table containing label data.

```
labelData = table(stopSignTruth,carRearTruth,'VariableNames',names)
```

```
labelData=2×2 table
        stopSign               carRear
    ___________________    ___________________

    {[856 318 39 41]}    {[398 378 315 210]}
    {[445 523 52 54]}    {[332 633 691 287]}
```

Create a `groundTruth` object.

```
gTruth = groundTruth(dataSource,labelDefs,labelData)
```

```
gTruth =
  groundTruth with properties:

          DataSource: [1×1 groundTruthDataSource]
    LabelDefinitions: [2×3 table]
           LabelData: [2×2 table]
```

Select labels by group.

```
vehicleGroundTruth = selectLabelsByGroup(gTruth, 'Vehicles')
```

```
vehicleGroundTruth =
  groundTruth with properties:

          DataSource: [1×1 groundTruthDataSource]
    LabelDefinitions: [1×3 table]
           LabelData: [2×1 table]
```

Input Arguments

`gTruth` — Ground truth

`groundTruth` object | vector of `groundTruth` objects

Ground truth, specified as a `groundTruth` object or vector of `groundTruth` objects.

`labelGroups` — Label groups

character vector | string scalar | cell array of character vectors | string vector

Label groups, specified as a character vector, string scalar, cell array of character vectors, or string vector.

To view all label groups in a `groundTruth` object, `gTruth`, enter this command at the MATLAB command prompt.

```
unique(gTruth.LabelDefinitions.Group)
```

Example: `'Vehicles'`

Example: `"Vehicles"`

Example: `{'Vehicles','Signs'}`

Example: `["Vehicles" "Signs"]`

Output Arguments

`gtLabel` — Ground truth with only selected labels
`groundTruth` object | vector of `groundTruth` objects

Ground truth with only the selected labels, returned as a `groundTruth` object or vector of `groundTruth` objects.

Each `groundTruth` object in `gtLabel` corresponds to a `groundTruth` object in the `gTruth` input. The returned objects contain only the labels belonging to the groups specified by the `labelGroups` input.

Version History

Introduced in R2019a

Objects
`groundTruth`

Functions
`selectLabelsByType` | `selectLabelsByName`

selectLabelsByType

Select ground truth labels by label type

Syntax

```
gtLabel = selectLabelsByType(gTruth,labelTypes)
```

Description

`gtLabel = selectLabelsByType(gTruth,labelTypes)` selects labels of the types specified by `labelTypes` from a `groundTruth` object, `gTruth`. The function returns a corresponding `groundTruth` object, `gtLabel`, that contains only the selected labels. If `gTruth` is a vector of `groundTruth` objects, then the function returns a vector of corresponding `groundTruth` objects that contain only the selected labels.

Examples

Select Ground Truth Data by Types

Add the image directory to the MATLAB path.

```
imageDir = fullfile(matlabroot,'toolbox','vision','visiondata','stopSignImages');
    addpath(imageDir);
```

Load the `groundTruth` object.

```
load('stopSignsAndCarsGroundTruth.mat');
```

View the label definitions.

```
stopSignsAndCarsGroundTruth.LabelDefinitions
```

```
ans=3×3 table
        Name          Type        Group
    ______________    _________    ________

    {'stopSign'}    Rectangle    {'None'}
    {'carRear' }    Rectangle    {'None'}
    {'carFront'}    Rectangle    {'None'}
```

Obtain the ground truth data for `Rectangle` `labelType`.

```
rectGroundTruth = selectLabelsByType(stopSignsAndCarsGroundTruth,labelType.Rectangle);
```

Remove the image directory from the path.

```
rmpath(imageDir);
```

Input Arguments

gTruth — Ground truth
groundTruth object | vector of groundTruth objects

Ground truth, specified as a groundTruth object or vector of groundTruth objects.

labelTypes — Label types
labelType enumeration | vector of labelType enumerations

Label types, specified as a labelType enumeration or vector of labelType enumerations.

To view all label types in a groundTruth object, gTruth, enter this command at the MATLAB command prompt.

```
unique(gTruth.LabelDefinitions.Type)
```

Example: labelType.Rectangle

Example: [labelType.Rectangle labelType.Line]

Output Arguments

gtLabel — Ground truth with only selected labels
groundTruth object | vector of groundTruth objects

Ground truth with only the selected labels, returned as a groundTruth object or vector of groundTruth objects.

Each groundTruth object in gtLabel corresponds to a groundTruth object in the gTruth input. The returned objects contain only the labels that are of the types specified by the labelTypes input.

Limitations

- Selecting sublabels by type is not supported.

Version History

Introduced in R2019a

Objects
groundTruth

Functions
selectLabelsByName | selectLabelsByGroup

selectLabelsByName

Select ground truth labels by label name

Syntax

```
gtLabel = selectLabelsByName(gTruth,labelNames)
```

Description

`gtLabel = selectLabelsByName(gTruth,labelNames)` selects labels specified by `labelNames` from a `groundTruth` object, `gTruth`. The function returns a corresponding `groundTruth` object, `gtLabel`, that contains only the selected labels. If `gTruth` is a vector of `groundTruth` objects, then the function returns a vector of corresponding `groundTruth` objects that contain only the selected labels.

Examples

Select Ground Truth Data By Name

Add the image directory to the MATLAB path.

```
imageDir = fullfile(matlabroot,'toolbox','vision','visiondata','stopSignImages');
addpath(imageDir);
```

Load the `groundTruth` object.

```
load('stopSignsAndCarsGroundTruth.mat');
```

View the label definitions.

```
stopSignsAndCarsGroundTruth.LabelDefinitions
```

```
ans=3×3 table
        Name           Type         Group
    _____________    _________    ________

    {'stopSign'}    Rectangle    {'None'}
    {'carRear' }    Rectangle    {'None'}
    {'carFront'}    Rectangle    {'None'}
```

Obtain the ground truth data for `StopSign` label name.

```
stopSignGroundTruth = selectLabelsByName(stopSignsAndCarsGroundTruth, ...
                                         'stopSign');
```

Obtain ground truth data for `carRear` and `carFront`.

```
carGroundTruth = selectLabels(stopSignsAndCarsGroundTruth, ...
                                      {'carRear','carFront'});
```

Remove the image directory from the path.

```
rmpath(imageDir);
```

Input Arguments

gTruth — Ground truth

groundTruth object | vector of groundTruth objects

Ground truth, specified as a groundTruth object or vector of groundTruth objects.

labelNames — Label names

character vector | string scalar | cell array of character vectors | string vector

Label names, specified as a character vector, string scalar, cell array of character vectors, or string vector.

To view all label names in a groundTruth object, gTruth, enter this command at the MATLAB command prompt.

```
gTruth.LabelDefinitions.Name
```

Example: 'car'

Example: "car"

Example: {'car','lane'}

Example: ["car" "lane"]

Output Arguments

gtLabel — Ground truth with only selected labels

groundTruth object | vector of groundTruth objects

Ground truth with only the selected labels, returned as a groundTruth object or vector of groundTruth objects.

Each groundTruth object in gtLabel corresponds to a groundTruth object in the gTruth input. The returned objects contain only the labels with names specified by the labelNames input.

Limitations

- Selecting pixel labels by name is not supported. However, you can select all labels of type pixel. Use the selectLabelsByType function, specifying the label type as a labelType.PixelLabel enumeration.
- Selecting sublabels by name is not supported.

Version History

Introduced in R2019a

Objects
`groundTruth`

Functions
`selectLabelsByGroup` | `selectLabelsByType`

correct

Namespace: `vision`

Correction of measurement, state, and state estimation error covariance

Syntax

```
[z_corr,x_corr,P_corr] = correct(kalmanFilter,z)
```

Description

`[z_corr,x_corr,P_corr] = correct(kalmanFilter,z)` returns the correction of measurement, state, and state estimation error covariance. The correction is based on the current measurement *z*. The object overwrites the internal state and covariance of the Kalman filter with corrected values.

Examples

Tracking Objects

Use the `predict` and `correct` functions based on detection results.

When the tracked object is detected, use the `predict` and `correct` functions with the Kalman filter object and the detection measurement. Call the functions in the following order:

```
[...] = predict(kalmanFilter);
[...] = correct(kalmanFilter,measurement);
```

When the tracked object is not detected, call the `predict` function, but not the `correct` method. When the tracked object is missing or occluded, no measurement is available. Set the functions up with the following logic:

```
[...] = predict(kalmanFilter);
If measurement exists
    [...] = correct(kalmanFilter,measurement);
end
```

If the tracked object becomes available after missing for the past *t*-1 contiguous time steps, you can call the `predict` function *t* times. This syntax is particularly useful to process asynchronous video.. For example,

```
for i = 1:k
  [...] = predict(kalmanFilter);
end
[...] = correct(kalmanFilter,measurement)
```

Input Arguments

`kalmanFilter` — Kalman filter object

object

Kalman filter object.

z — Current measurement
N-element vector

Current measurement, specified as an *N*-element vector.

Version History

Introduced in R2012b

See Also

`configureKalmanFilter` | `assignDetectionsToTracks`

distance

Namespace: `vision`

Confidence value of measurement

Syntax

```
d = distance(kalmanFilter,zmatrix)
```

Description

`d = distance(kalmanFilter,zmatrix)` computes a distance between the location of a detected object and the predicted location by the Kalman filter object. This distance computation takes into account the covariance of the predicted state and the process noise. The `distance` function can only be called after the `predict` function.

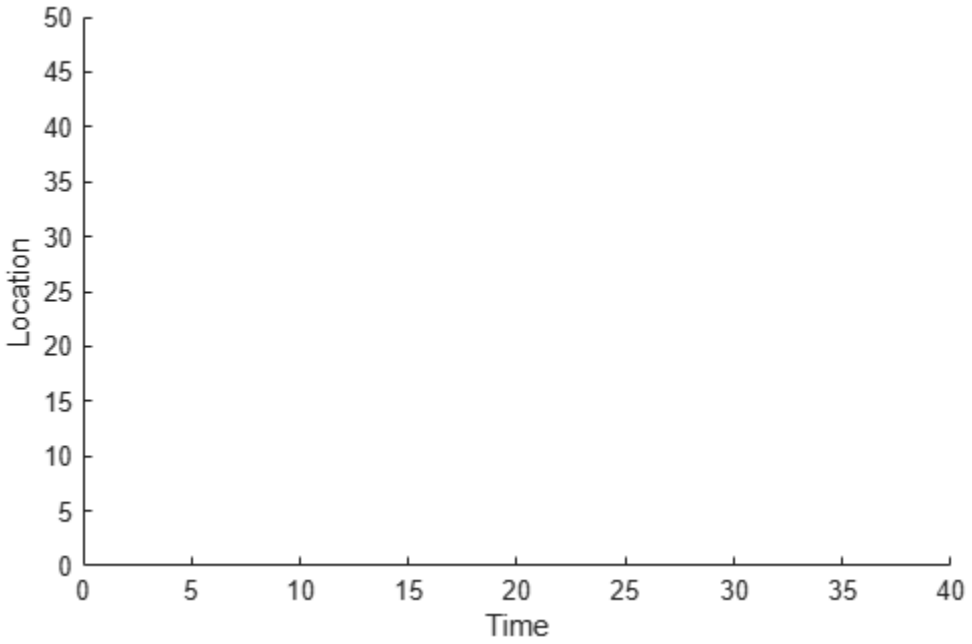
Use the `distance` function to find the best matches. The computed distance values describe how a set of measurements matches the Kalman filter. You can thus select a measurement that best fits the filter. This strategy can be used for matching object detections against object tracks in a multiobject tracking problem. This distance computation takes into account the covariance of the predicted state and the process noise.

Examples

Track Location of An Object

Track the location of a physical object moving in one direction.

Generate synthetic data which mimics the 1-D location of a physical object moving at a constant speed.

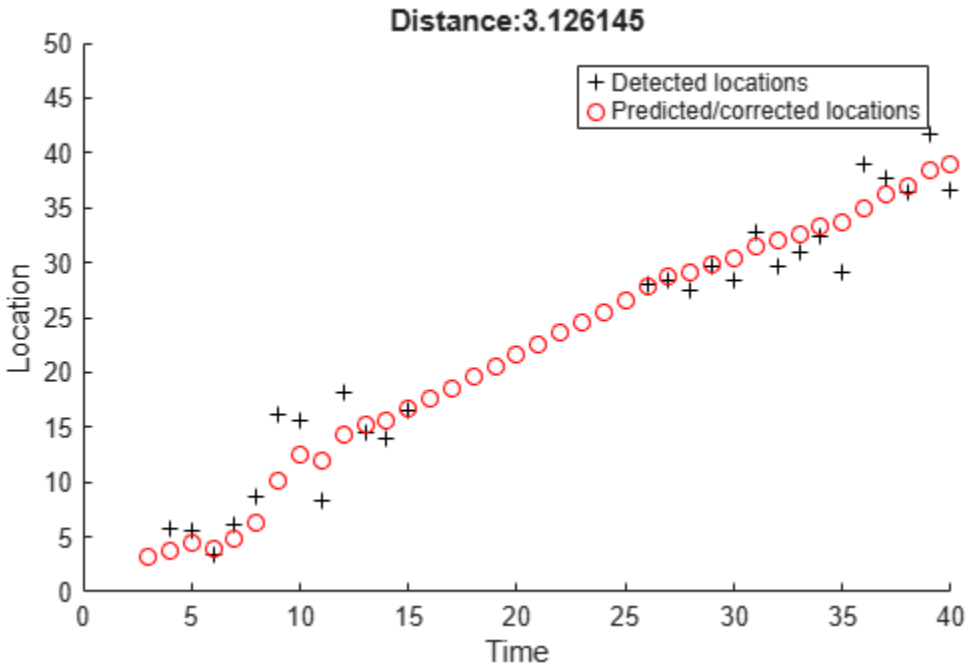


```
detectedLocations = num2cell(2*randn(1,40) + (1:40));
```

Simulate missing detections by setting some elements to empty.

```
detectedLocations{1} = [];
  for idx = 16: 25
      detectedLocations{idx} = [];
  end
```

Create a figure to show the location of detections and the results of using the Kalman filter for tracking.



```
figure;
hold on;
ylabel('Location');
ylim([0,50]);
xlabel('Time');
xlim([0,length(detectedLocations)]);
```

Create a 1-D, constant speed Kalman filter when the physical object is first detected. Predict the location of the object based on previous states. If the object is detected at the current time step, use its location to correct the states.

```
kalman = [];
for idx = 1: length(detectedLocations)
   location = detectedLocations{idx};
   if isempty(kalman)
     if ~isempty(location)

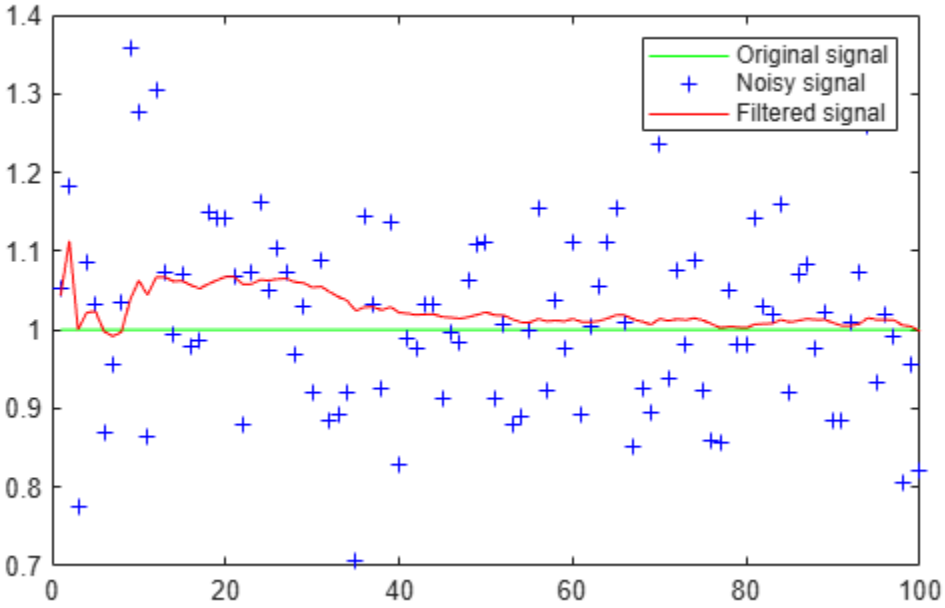
       stateModel = [1 1;0 1];
       measurementModel = [1 0];
       kalman = vision.KalmanFilter(stateModel,measurementModel,'ProcessNoise',1e-4,'MeasurementN
      kalman.State = [location, 0];
     end
   else
     trackedLocation = predict(kalman);
     if ~isempty(location)
       plot(idx, location,'k+');
      d = distance(kalman,location);
       title(sprintf('Distance:%f', d));
       trackedLocation = correct(kalman,location);
     else
       title('Missing detection');
     end
     pause(0.2);
     plot(idx,trackedLocation,'ro');
   end
 end
legend('Detected locations','Predicted/corrected locations');
```

Remove Noise from a Signal

Use Kalman filter to remove noise from a random signal corrupted by a zero-mean Gaussian noise.

Synthesize a random signal that has value of 1 and is corrupted by a zero-mean Gaussian noise with standard deviation of 0.1.

```
x = 1;
len = 100;
z = x + 0.1 * randn(1,len);
```



Remove noise from the signal by using a Kalman filter. The state is expected to be constant, and the measurement is the same as state.

```
stateTransitionModel = 1;
measurementModel = 1;
obj = vision.KalmanFilter(stateTransitionModel,measurementModel,'StateCovariance',1,'ProcessNoise

z_corr = zeros(1,len);
for idx = 1: len
 predict(obj);
 z_corr(idx) = correct(obj,z(idx));
end
```

Plot results.

```
figure, plot(x * ones(1,len),'g-');
hold on;
plot(1:len,z,'b+',1:len,z_corr,'r-');
legend('Original signal','Noisy signal','Filtered signal');
```

Input Arguments

`kalmanFilter` — Kalman filter object

object

Kalman filter object.

`zmatrix` — Location of a detected object

N-column matrix

Location of a detected object, specified as an *N*-column matrix. Each row matrix contains a measurement vector. The `distance` function returns a row vector where each distance element corresponds to the measurement input.

More About

Distance Equation

$$d(z) = (z - Hx)^T \sum^{-1} (z - Hx) + \ln\left|\sum\right|$$

Where $\Sigma = HPH^T + R$ and $|\Sigma|$ is the determinant of Σ. You can then find the best matches by examining the returned distance values.

`configureKalmanFilter` | `assignDetectionsToTracks`

predict

Namespace: `vision`

Prediction of measurement

Syntax

```
[z_pred,x_pred,P_pred] = predict(kalmanFilter)
[z_pred,x_pred,P_pred] = predict(kalmanFilter,u)
```

Description

`[z_pred,x_pred,P_pred] = predict(kalmanFilter)` returns the prediction of measurement, state, and state estimation error covariance at the next time step (e.g., the next video frame). The object overwrites the internal state and covariance of the Kalman filter with the prediction results.

`[z_pred,x_pred,P_pred] = predict(kalmanFilter,u)` additionally lets you specify the control input, *u*. This syntax applies when you set the control model, *B*.

Examples

Tracking Objects

Use the `predict` and `correct` functions based on detection results.

When the tracked object is detected, use the `predict` and `correct` functions with the Kalman filter object and the detection measurement. Call the functions in the following order:

```
[...] = predict(kalmanFilter);
[...] = correct(kalmanFilter,measurement);
```

When the tracked object is not detected, call the `predict` function, but not the `correct` method. When the tracked object is missing or occluded, no measurement is available. Set the functions up with the following logic:

```
[...] = predict(kalmanFilter);
If measurement exists
    [...] = correct(kalmanFilter,measurement);
end
```

If the tracked object becomes available after missing for the past *t*-1 contiguous time steps, you can call the `predict` function *t* times. This syntax is particularly useful to process asynchronous video.. For example,

```
for i = 1:k
  [...] = predict(kalmanFilter);
```

```
end
[...] = correct(kalmanFilter,measurement)
```

Input Arguments

`kalmanFilter` — Kalman filter object

object

Kalman filter object.

`u` — Control input

L-element vector

Control input, specified as an *L*-element vector.

Version History

Introduced in R2012b

`configureKalmanFilter` | `assignDetectionsToTracks`

pcregistercpd

Register two point clouds using CPD algorithm

Syntax

```
tform = pcregistercpd(moving,fixed)
[tform,movingReg] = pcregistercpd( ___ )
[tform,movingReg,rmse] = pcregistercpd( ___ )
[ ___ ] = pcregistercpd( ___ ,Name=Value)
```

Description

`tform = pcregistercpd(moving,fixed)` returns a transformation that registers a moving point cloud with a fixed point cloud using the CPD algorithm. The coherent point drift (CPD) algorithm [1] supports non-rigid transformations.

Note The CPD algorithm is robust to noise, outlier and missing points, at the expense of speed. Consider downsampling point clouds using `pcdownsample` before using `pcregistercpd` to improve the efficiency of registration.

Alternatively, you can speed up the algorithm by using the `extractFPFHFeatures` function to extract features before performing registration. For more details, see the “Improve CPD Performance Using FPFH Descriptors” example.

`[tform,movingReg] = pcregistercpd( ___ )` also returns the transformed point cloud that aligns with the fixed point cloud.

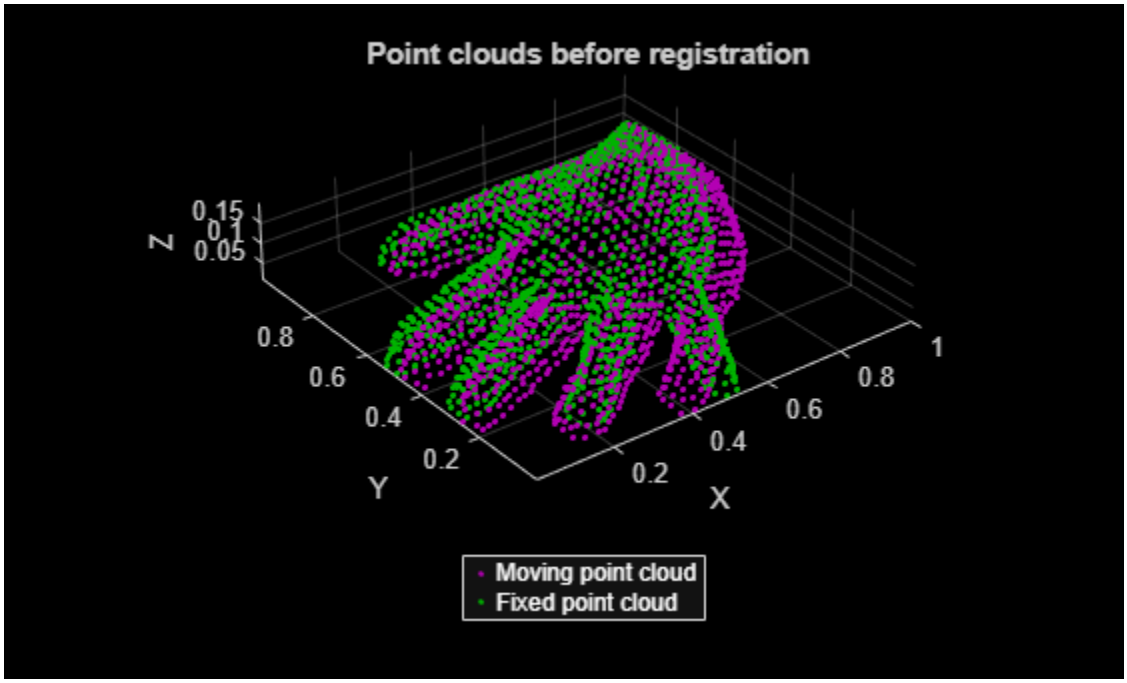
`[tform,movingReg,rmse] = pcregistercpd( ___ )` also returns the root mean square error of the Euclidean distance between the aligned point clouds.

`[ ___ ] = pcregistercpd( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `MaxIterations=20` stops the CPD algorithm after 20 iterations.

Examples

Align Two Point Clouds Using CPD Algorithm

Load point cloud data into the workspace. Extract the moving and the fixed point clouds from the point cloud data in workspace.



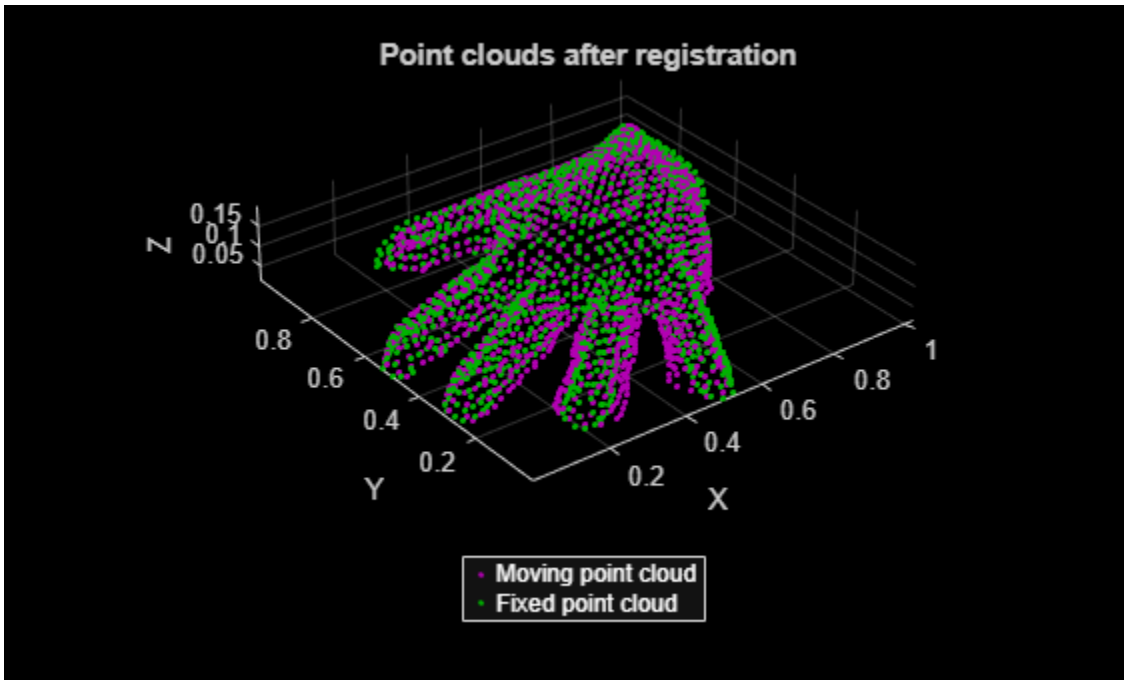
```
handData = load('hand3d.mat');
moving = handData.moving;
fixed = handData.fixed;
```

To improve the efficiency and accuracy of the CPD registration algorithm, downsample the moving and the fixed point clouds.

```
movingDownsampled = pcdownsample(moving,'gridAverage',0.03);
fixedDownsampled = pcdownsample(fixed,'gridAverage',0.03);
```

Display the downsampled point clouds before registration.

```
figure
pcshowpair(movingDownsampled,fixedDownsampled,'MarkerSize',50)
xlabel('X')
ylabel('Y')
zlabel('Z')
title('Point clouds before registration')
legend({'Moving point cloud','Fixed point cloud'},'TextColor','w')
legend('Location','southoutside')
```



Perform non-rigid registration using the CPD algorithm.

```
[tform,movingReg] = pcregistercpd(movingDownsampled,fixedDownsampled);
```

Display the downsampled point clouds after registration.

```
figure
pcshowpair(movingReg,fixedDownsampled,'MarkerSize',50)
xlabel('X')
ylabel('Y')
zlabel('Z')
title('Point clouds after registration')
legend({'Moving point cloud','Fixed point cloud'},'TextColor','w')
legend('Location','southoutside')
```

Input Arguments

`moving` — Moving point cloud
`pointCloud` object

Moving point cloud, specified as a `pointCloud` object.

`fixed` — Fixed point cloud
`pointCloud` object

Fixed point cloud, specified as a `pointCloud` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `MaxIteration=20` stops the CPD algorithm after 20 iterations.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

`Transform` — Type of transformation
`"Nonrigid"` (default) | `"Rigid"` | `"Affine"`

Type of transformation, specified as `"Nonrigid"`, `"Rigid"`, or `"Affine"`.

Data Types: `char` | `string`

`OutlierRatio` — Expected percentage of outliers
`0.1` (default) | scalar in the range [0, 1)

Expected percentage of outliers with respect to a normal distribution, specified as a scalar in the range [0, 1). Increasing this value reduces the influence of outliers and noise.

Data Types: `single` | `double`

`MaxIterations` — Maximum number of iterations
`20` (default) | positive integer

Maximum number of iterations before CPD stops, specified as a positive integer.

`MaxIterations` and `Tolerance` are both stopping conditions for the CPD algorithm. The algorithm stops when it satisfies either of the stopping conditions.

Data Types: `single` | `double`

`Tolerance` — Tolerance between consecutive CPD iterations
`1e-5` (default) | scalar

Tolerance between consecutive CPD iterations, specified as a scalar. The algorithm stops when the absolute percentage change in the values of the log likelihood function measured between consecutive iterations reaches or falls below the specified tolerance value. Decreasing this value increases the likelihood of a better alignment.

`MaxIterations` and `Tolerance` are both stopping conditions for the CPD algorithm. The algorithm stops when it satisfies either of the stopping conditions.

Data Types: `single` | `double`

`InteractionSigma` — Interaction between points
`2.0` (default) | positive scalar

Interaction between points, specified as positive scalar that represents standard deviation of a Gaussian filter. Typical values are in the range [1.5, 3]. Increasing this value increases interaction between the points in point cloud. As a result, you can observe coherent motion in the point cloud and every point undergoes the same displacement. Alternatively, decreasing this value reduces interaction between the points in point cloud. As a result, you can observe localized displacement of points and the output displacement field exhibits localized deformation.

Note To use this name-value argument, `Transform` must be `"Nonrigid"`.

Data Types: `single` | `double`

`SmoothingWeight` — Motion smoothing weight
`3.0` (default) | positive scalar

Motion smoothing weight, specified as a positive scalar. Typical values are in the range [0.1,10]. Increase this value to produce a more coherent motion in the output displacement field.

Note To use this name-value argument, `Transform` must be `"Nonrigid"`.

Data Types: `single` | `double`

`Verbose` — Display progress information

`false` (default) | `true`

Display progress information, specified as a numeric or logical `0` (`false`) or `1` (`true`). To display the progress information, set `Verbose` to `true`.

Output Arguments

`tform` — Transformation

`rigidtform3d` object | `affinetform3d` object | displacement field

Transformation, returned as a `rigidtform3d` object, an `affinetform3d` object, or a displacement field. `tform` is a 3-D transformation that registers the moving point cloud, `moving` to the fixed point cloud, `fixed`. The output type depends on the value of the `Transform` argument.

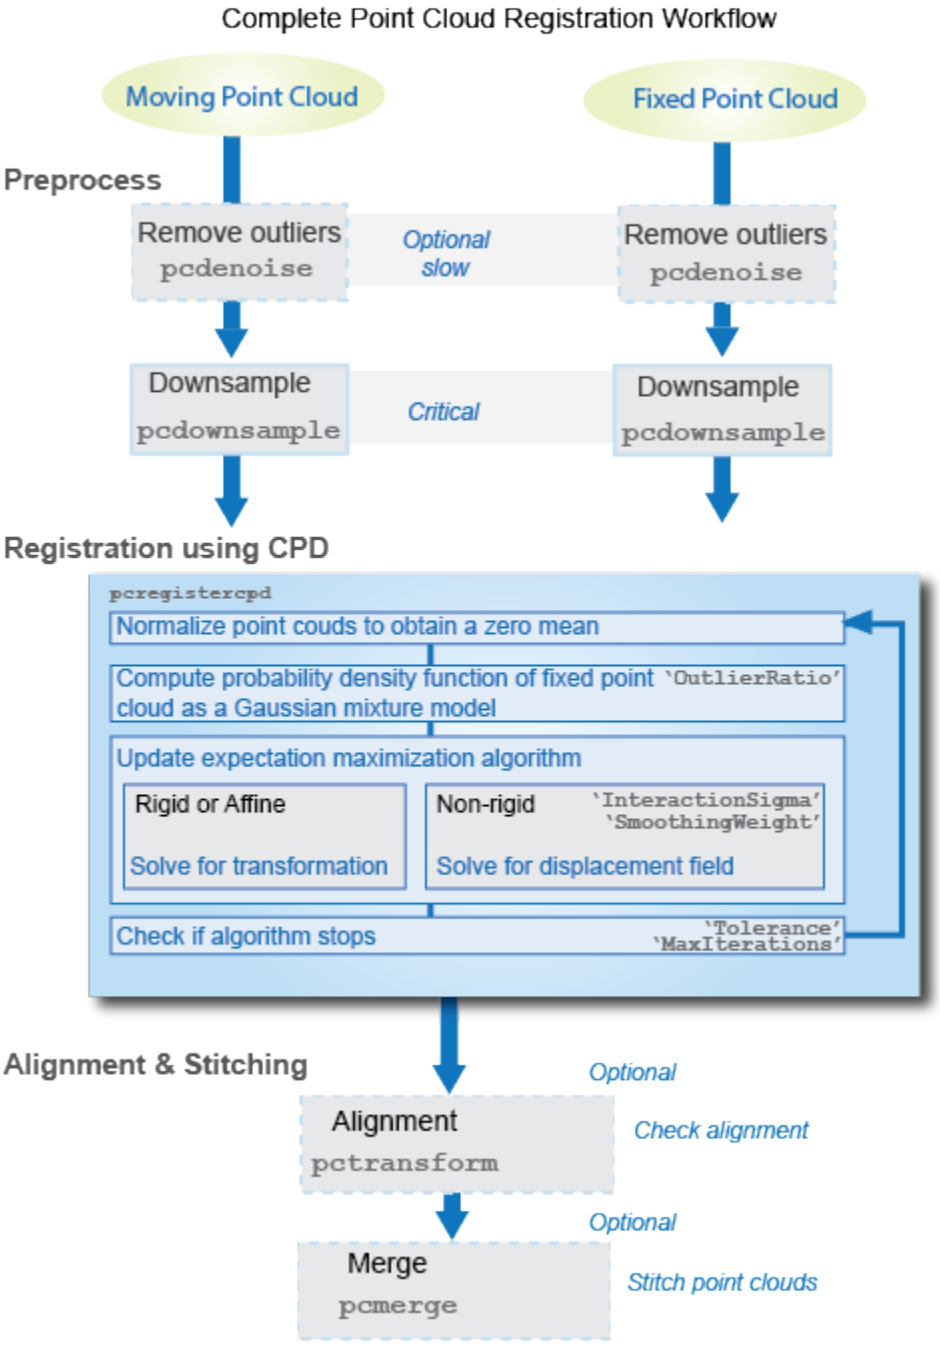
`Transform` Value	`tform`
`"Rigid"`	`rigidtform3d` object
`"Affine"`	`affinetform3d` object
`"Nonrigid"`	Displacement field, a numeric matrix of same size and datatype as the `Location` property of the moving point cloud object, `moving`.

`movingReg` — Transformed point cloud

`pointCloud` object

Transformed point cloud, returned as a `pointCloud` object. The transformed point cloud is aligned with the fixed point cloud, `fixed`.

`rmse` — Root mean square error



positive real number

Root mean square error, returned as a positive numeric scalar that represents the Euclidean distance between the aligned points. The aligned points is a result of the moving point cloud transformed by the `tform` output and the fixed point cloud. For each point in the fixed point cloud, the algorithm finds the closest point in the transformed point cloud, `movingReg`, then computes the Euclidean distance between the points, and then computes the `rmse`. A low `rmse` value indicates a more accurate registration. The `rmse` calculation is:

```
rmse = sqrt(sum(distance.^2,'all')/numel(distance));
```

Data Types: `double`

Algorithms

Both `MaxIterations` and `Tolerance` are used as stopping criteria. The algorithm stops when it satisfies either of the stopping conditions, i.e., when the number of iteration reaches `MaxIterations` or the absolute percentage change in log likelihood function is less than or equal to `Tolerance`.

Version History

Introduced in R2018b

R2022b: Returns new geometric transformation objects

Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, for rigid and affine transformation types, the `pcregistercpd` function now returns `tform` as a `rigidtform3d` or `affinetform3d` object, which use the premultiply convention. Before, the function returned `tform` as a `rigid3d` or `affine3d` object, which use the postmultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

initializeObject

Set object to track

Syntax

```
initializeObject(hbtracker,I,R)
initializeObject(hbtracker,I,R,N)
```

Description

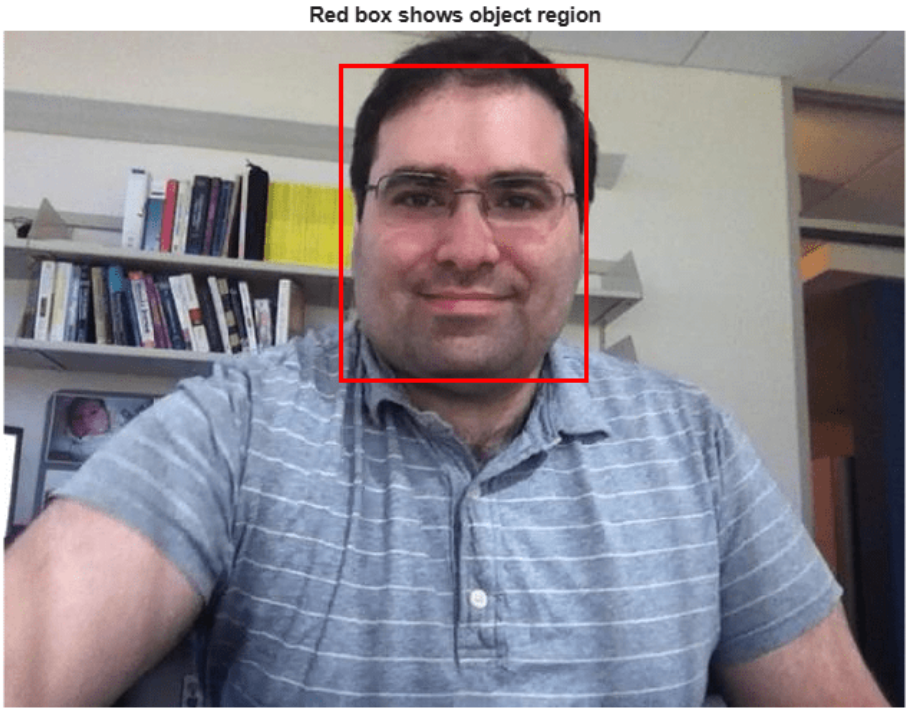
`initializeObject(hbtracker,I,R)` sets the object to track by extracting it from the [x y width height] region `R` located in the 2-D input image, `I`. The input image, `I`, can be any 2-D feature map that distinguishes the object from the background. For example, the image can be a hue channel of the HSV color space. Typically, `I` will be the first frame in which the object appears. The region, `R`, is also used for the initial search window, in the next call to the object. For best results, the object must occupy the majority of the region, `R`.

`initializeObject(hbtracker,I,R,N)` additionally, lets you specify `N`, the number of histogram bins.

Examples

Track a Face

Track and display a face in each frame of an input video.



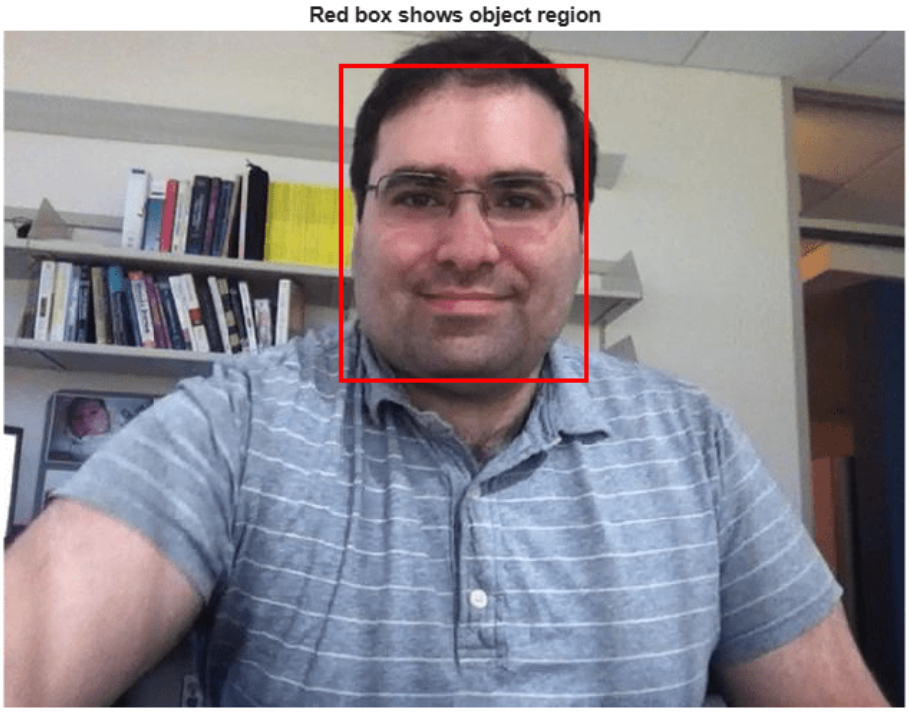
Load in the input video and create a System object displaying video.

```
videoReader = VideoReader("tilted_face.avi");
videoPlayer = vision.VideoPlayer();
```

Read the first video frame, which contains the object. Convert the image to HSV color space. Then define and display the object region.

```
objectFrame = im2single(readFrame(videoReader));
objectHSV = rgb2hsv(objectFrame);
objectRegion = [240, 25, 175, 225];
objectImage = insertShape(objectFrame,"rectangle",objectRegion,LineWidth=3,Color="red");

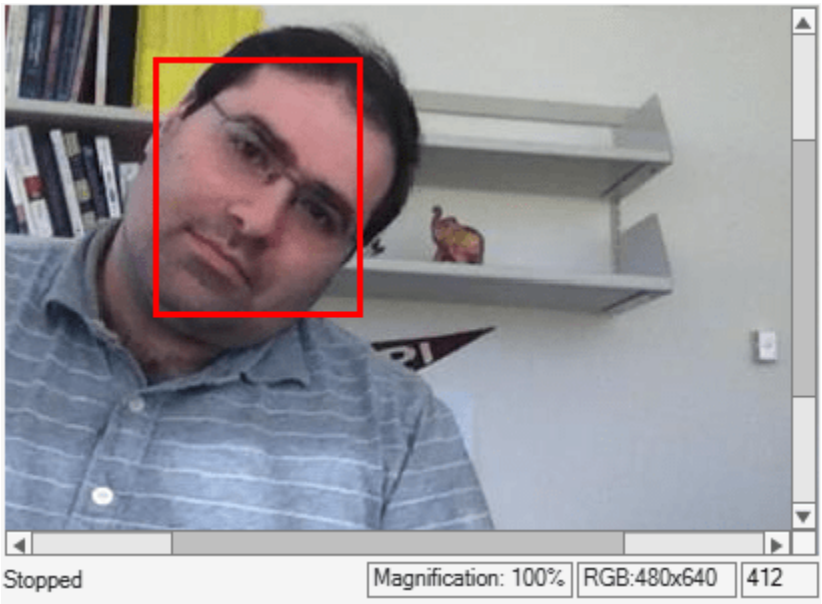
figure;
imshow(objectImage);
title("Red box shows object region")
```



Set the object, based on the hue channel of the first video frame.

```
tracker = vision.HistogramBasedTracker;
initializeObject(tracker, objectHSV(:,:,1),objectRegion);
```

Track and display the object in each video frame. The while loop reads each image frame, converts the image to HSV color space, then tracks the object in the hue channel where it is distinct from the background. Finally, the example draws a box around the object and displays the results.



```
while hasFrame(videoReader)
  frame = im2single(readFrame(videoReader));
  hsvFrame = rgb2hsv(frame);
  bbox = tracker(hsvFrame(:,:,1));
  out = insertShape(frame,"rectangle",bbox,LineWidth=3,Color="red");
  videoPlayer(out);
end
```

Release the video player.

```
release(videoPlayer);
```

Copyright 2012-2025 The MathWorks, Inc.

Input Arguments

`hbtracker` — Histogram based tracker

`vision.HistogramBasedTracker` object

Histogram based tracker, specified as a `vision.HistogramBasedTracker` object.

`I` — Video frame

grayscale | truecolor (RGB)

Video frame, specified as grayscale or truecolor (RGB).

`R` — Initial search window

[*x y width height*]

Initial search window, specified in the format [*x y width height*].

`N` — Number of histogram bins

16 (default) | integer

Number of histogram bins, specified as an integer. Increasing the number of bins enhances the ability of the tracker to discriminate the object. However, this approach also narrows the range of changes to the object's visual characteristics that the tracker can accommodate. Consequently, this narrow range increases the likelihood of losing track.

hide

Namespace:

Hide player figure

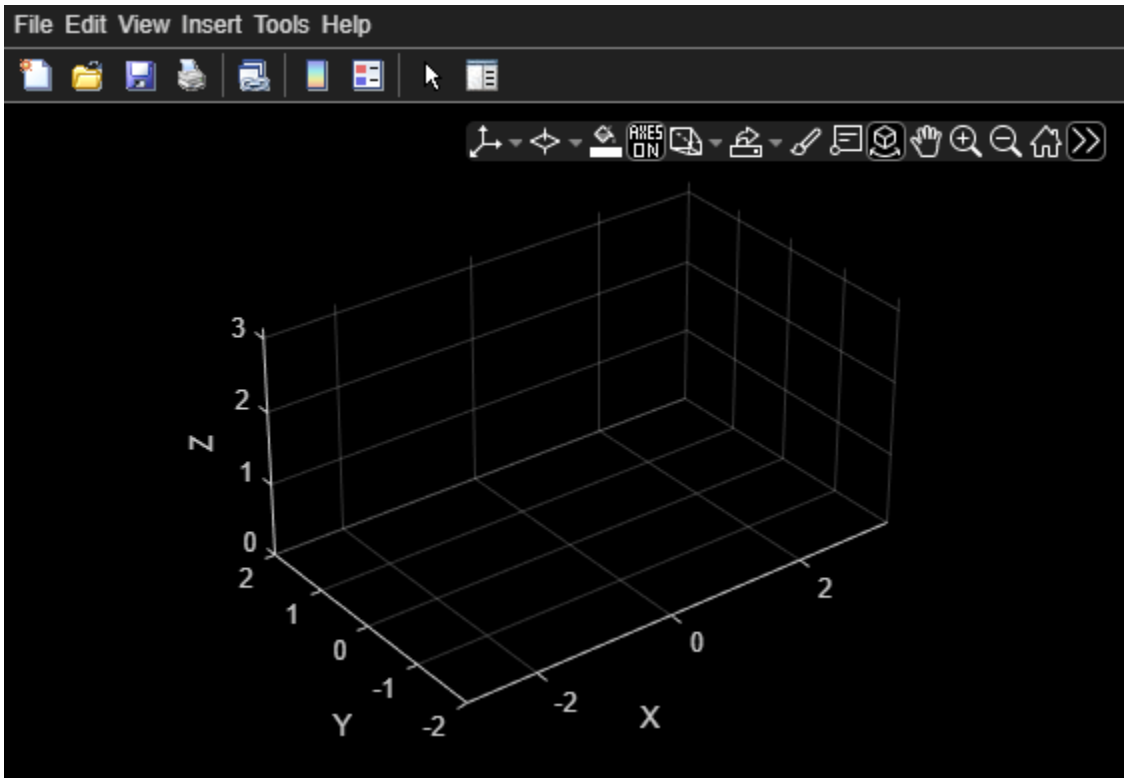
Syntax

```
hide(player)
```

Description

`hide(player)` hides the figure. To redisplay the player, use show on page 3-335(`player`).

Examples



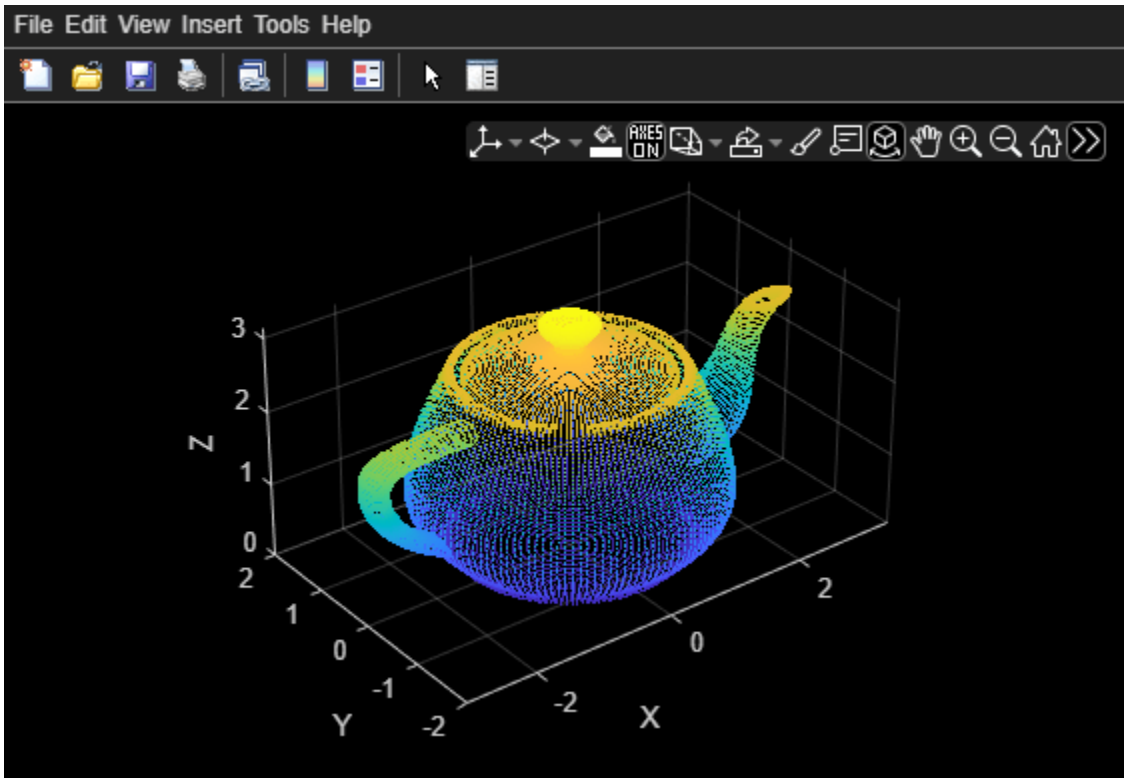
Hide and Show 3-D Point Cloud Figure

Load point cloud.

```
ptCloud = pcread('teapot.ply');
```

Create the player and customize player axis labels.

```
player = pcplayer(ptCloud.XLimits,ptCloud.YLimits,ptCloud.ZLimits);
```



Hide figure.

```
hide(player)
```

Show figure.

```
show(player)
view(player,ptCloud);
```

Input Arguments

`player` — Player
player object

Player for data, specified as a `pcplayer` or `vision.VideoPlayer` object.

Version History

Introduced in R2015b

show

Namespace:

Show player

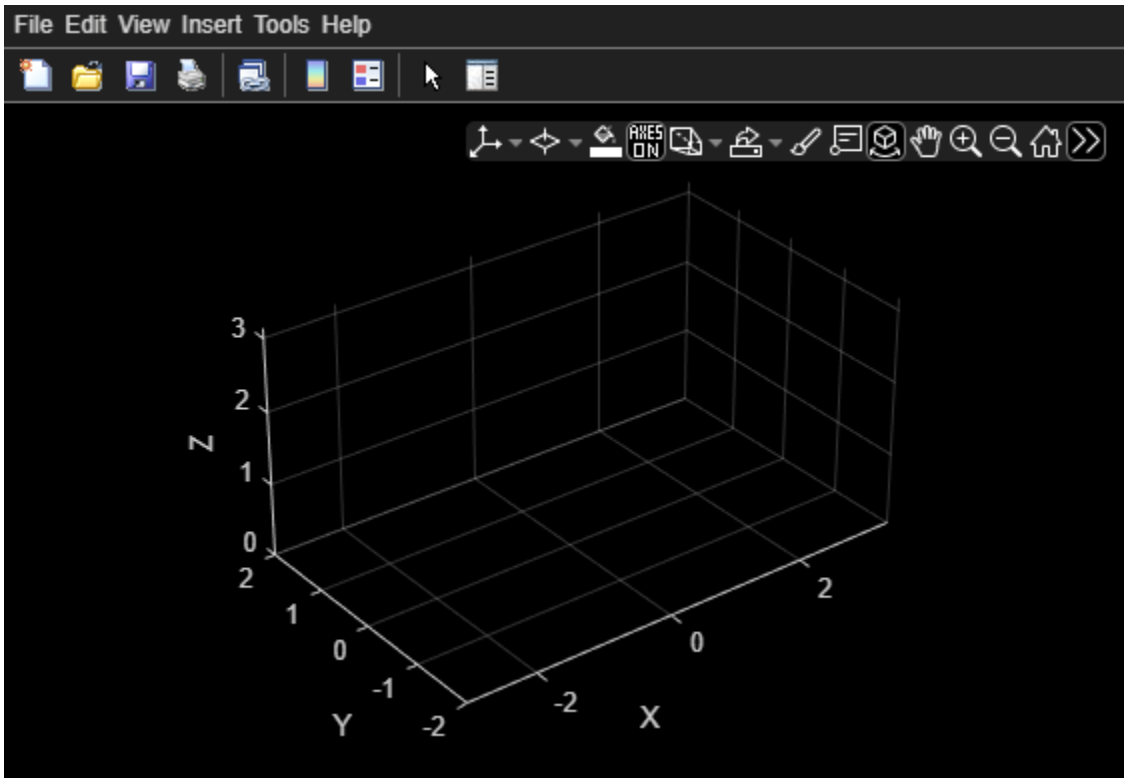
Syntax

```
show(player)
```

Description

`show(player)` makes the player figure visible again after closing or hiding it.

Examples



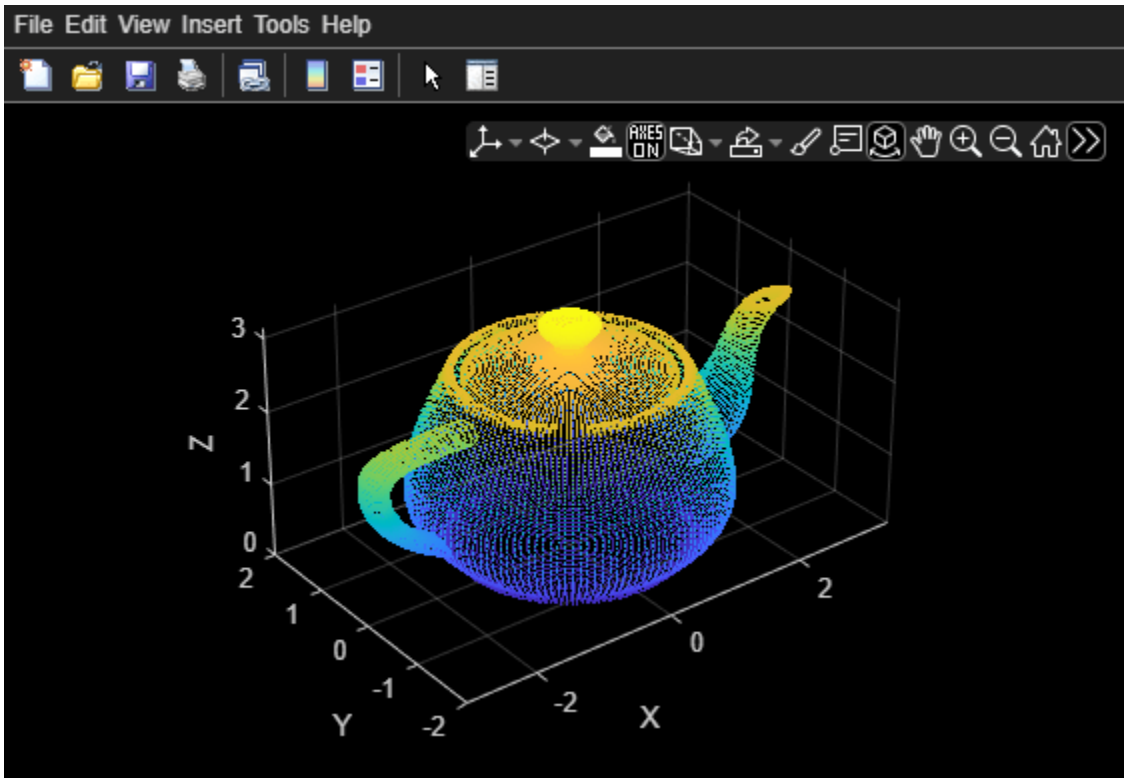
Hide and Show 3-D Point Cloud Figure

Load point cloud.

```
ptCloud = pcread('teapot.ply');
```

Create the player and customize player axis labels.

```
player = pcplayer(ptCloud.XLimits,ptCloud.YLimits,ptCloud.ZLimits);
```



Hide figure.

```
hide(player)
```

Show figure.

```
show(player)
view(player,ptCloud);
```

Input Arguments

`player` — Player

object

Player for visualizing data streams, specified as a `pcplayer` or a `vision.VideoPlayer` object. Use this method to view the figure after you have removed it from display. For example, after you x-out of a figure and you want to view it again. This is particularly useful to use after a while loop that contains display code ends.

Version History

Introduced in R2015b

initializeSearchWindow

Set initial search window

Syntax

```
initializeSearchWindow(hbtracker,R)
```

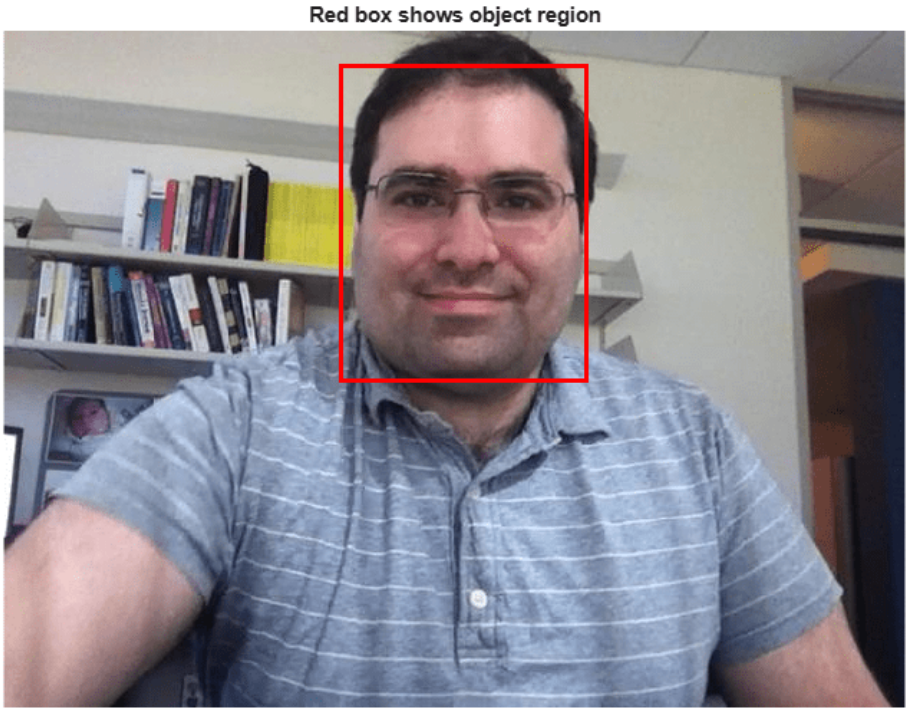
Description

`initializeSearchWindow(hbtracker,R)` sets the initial search window region,R. The tracker uses this region as the initial window to search for the object. You can also use this function when the tracker loses track of the object. Use the function to reinitialize an object's initial location and size.

Examples

Track a Face

Track and display a face in each frame of an input video.



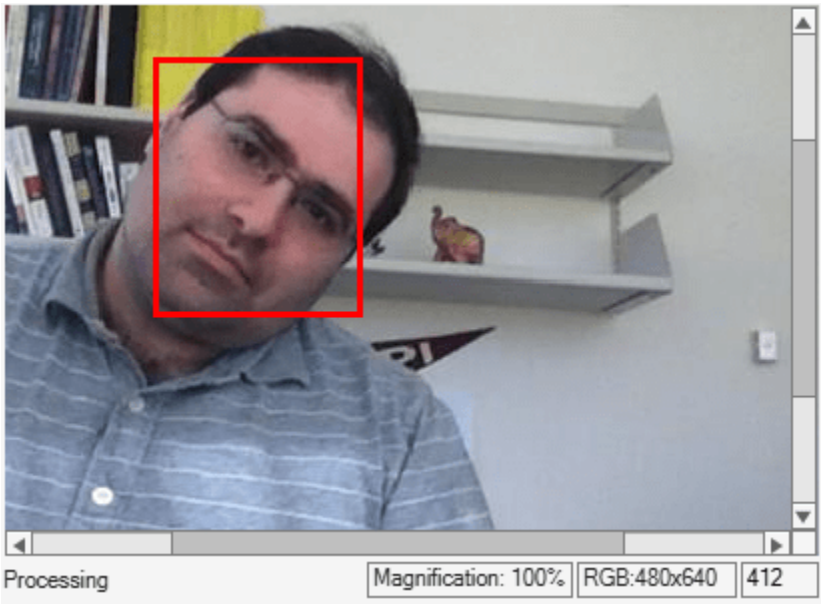
Load in the input video and create a System object displaying video.

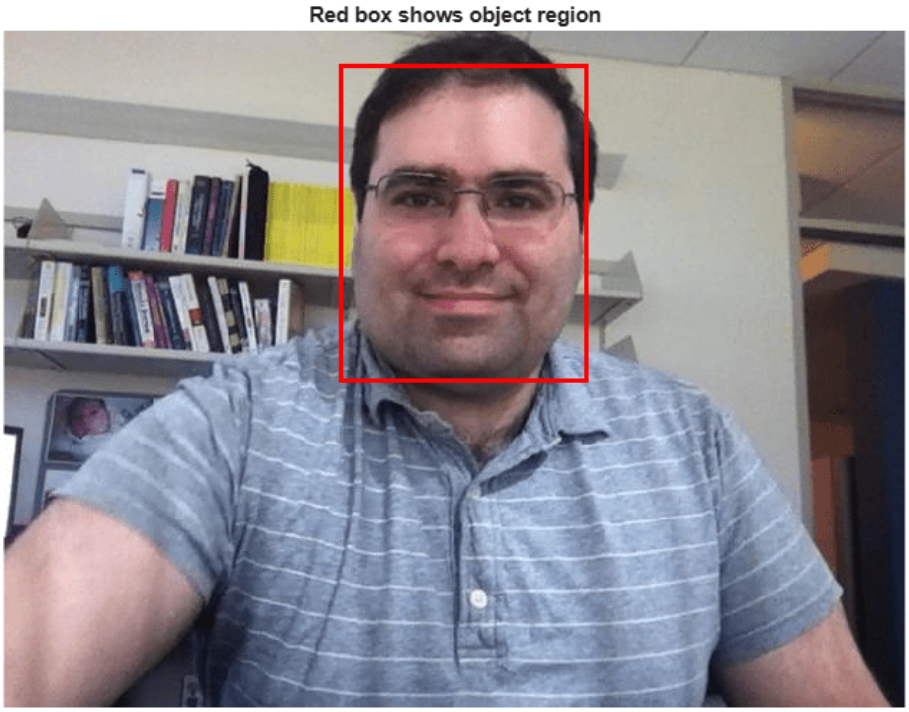
```
videoReader = VideoReader("tilted_face.avi");
videoPlayer = vision.VideoPlayer();
```

Read the first video frame, which contains the object. Convert the image to HSV color space. Then define and display the object region.

```
objectFrame = im2single(readFrame(videoReader));
objectHSV = rgb2hsv(objectFrame);
objectRegion = [240, 25, 175, 225];
objectImage = insertShape(objectFrame,"rectangle",objectRegion,LineWidth=3,Color="red");

figure;
imshow(objectImage);
title("Red box shows object region")
```

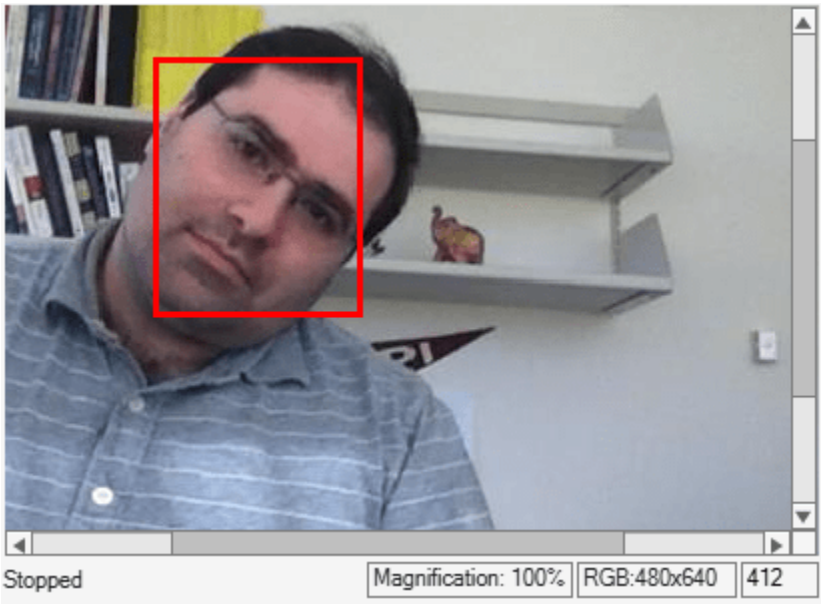




Set the object, based on the hue channel of the first video frame.

```
tracker = vision.HistogramBasedTracker;
initializeObject(tracker, objectHSV(:,:,1),objectRegion);
```

Track and display the object in each video frame. The while loop reads each image frame, converts the image to HSV color space, then tracks the object in the hue channel where it is distinct from the background. Finally, the example draws a box around the object and displays the results.



```
while hasFrame(videoReader)
  frame = im2single(readFrame(videoReader));
  hsvFrame = rgb2hsv(frame);
  bbox = tracker(hsvFrame(:,:,1));
  out = insertShape(frame,"rectangle",bbox,LineWidth=3,Color="red");
  videoPlayer(out);
end
```

Release the video player.

```
release(videoPlayer);
```

Copyright 2012-2025 The MathWorks, Inc.

Input Arguments

`hbtracker` — Histogram based tracker
`vision.HistogramBasedTracker` object

Histogram based tracker, specified as a `vision.HistogramBasedTracker` object.

R — Initial search window
[*x y width height*]

Initial search window, specified in the format [*x y width height*].

Version History

Introduced in R2012a

initialize

Initialize video frame and points to track

Syntax

```
initialize(pointTracker,points,I)
```

Description

`initialize(pointTracker,points,I)` initializes points to track and sets the initial video frame. The function sets the *M*-by-2 `points` array of [x y] coordinates with the points to track, and sets the initial video frame, `I`.

If you want to use the point tracker as a persistent variable, you must call `initialize` only during creation. If you call `initialize` in a loop, the previous state is lost and therefore, the tracker cannot maintain tracking.

Examples

Track a Face in Scene

Create System objects for reading and displaying video and for drawing a bounding box of the object.

```
videoReader = VideoReader('visionface.avi');
videoPlayer = vision.VideoPlayer('Position',[100,100,680,520]);
```

Read the first video frame, which contains the object, define the region.

```
objectFrame = readFrame(videoReader);
objectRegion = [264,122,93,93];
```

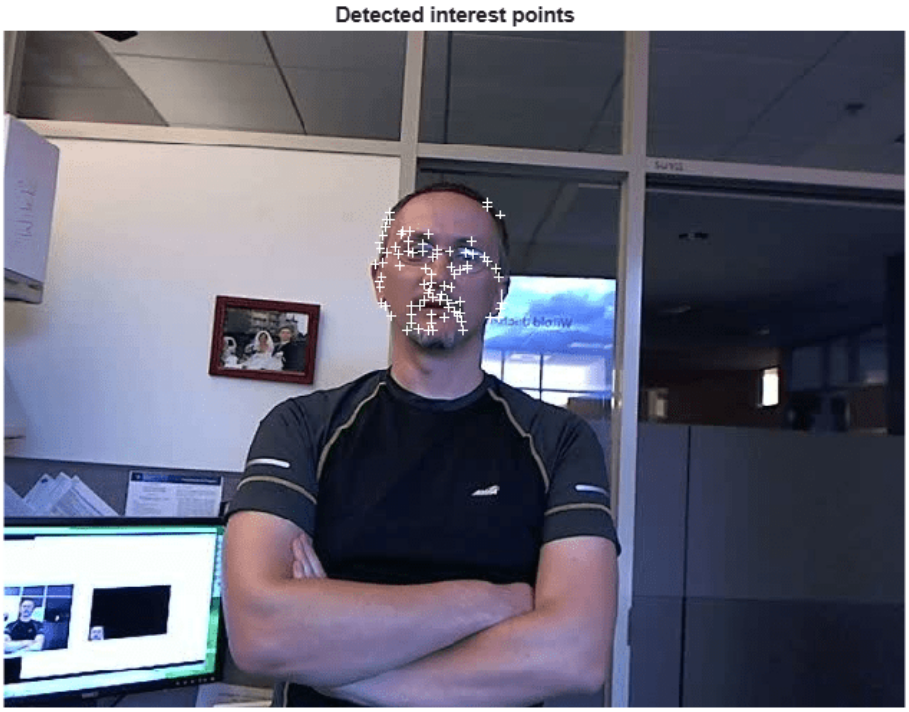
As an alternative, you can use the following commands to select the object region using a mouse. The object must occupy the majority of the region:

figure; imshow(objectFrame);

objectRegion=round(getPosition(imrect))

Show initial frame with a red bounding box.

```
objectImage = insertShape(objectFrame,'rectangle',objectRegion,'ShapeColor','red');
figure;
imshow(objectImage);
title('Red box shows object region');
```



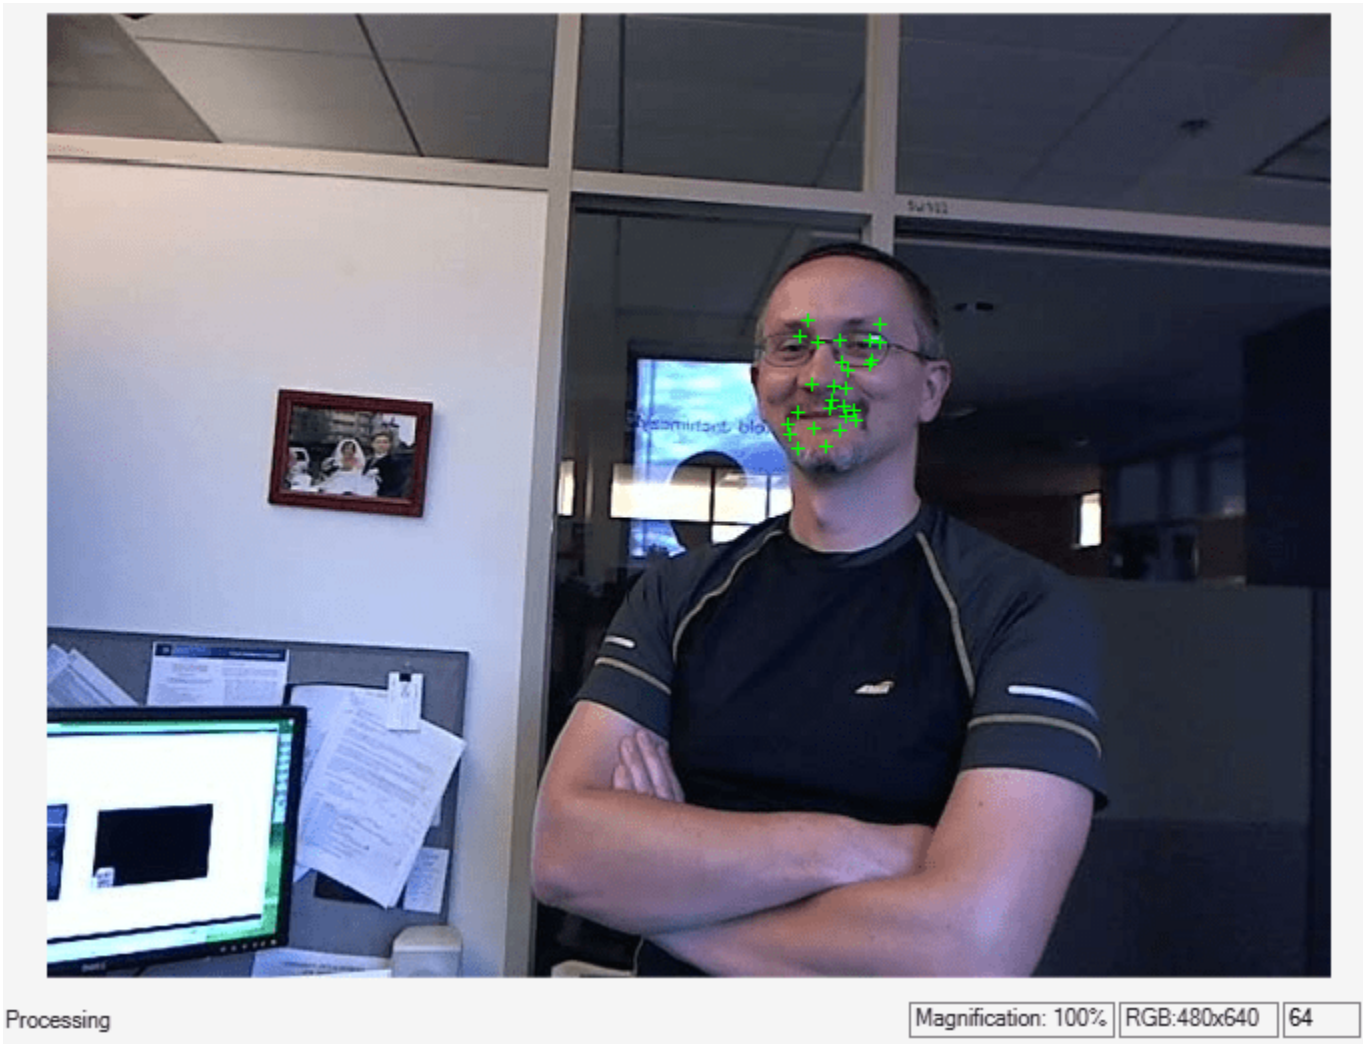
Detect interest points in the object region.

```
points = detectMinEigenFeatures(im2gray(objectFrame),'ROI',objectRegion);
```

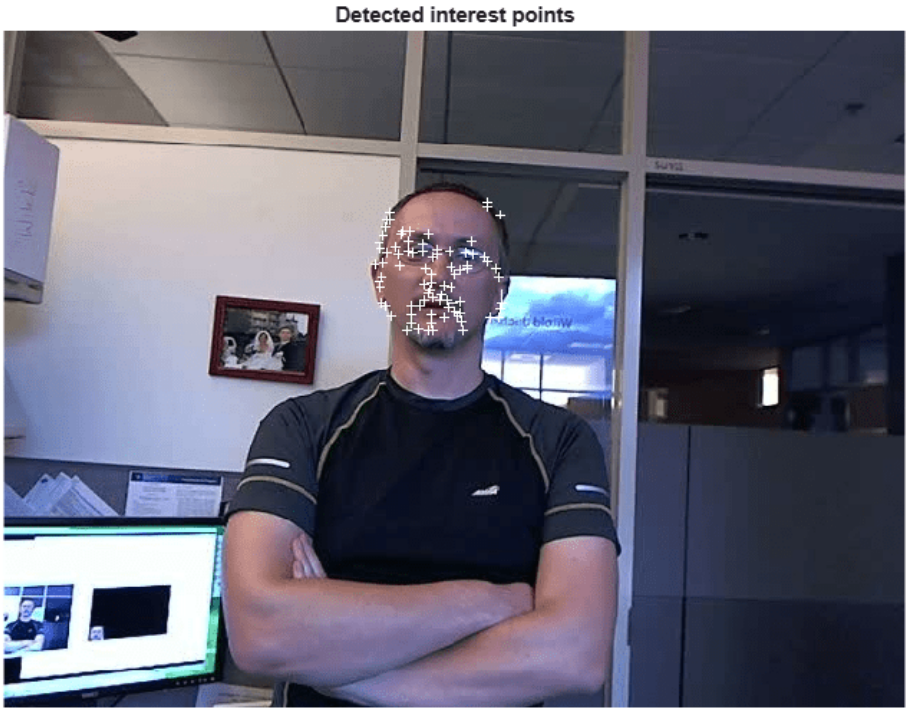
Display the detected points.

```
pointImage = insertMarker(objectFrame,points.Location,'+','MarkerColor','white');
figure;
imshow(pointImage);
title('Detected interest points');
```

Create a tracker object.



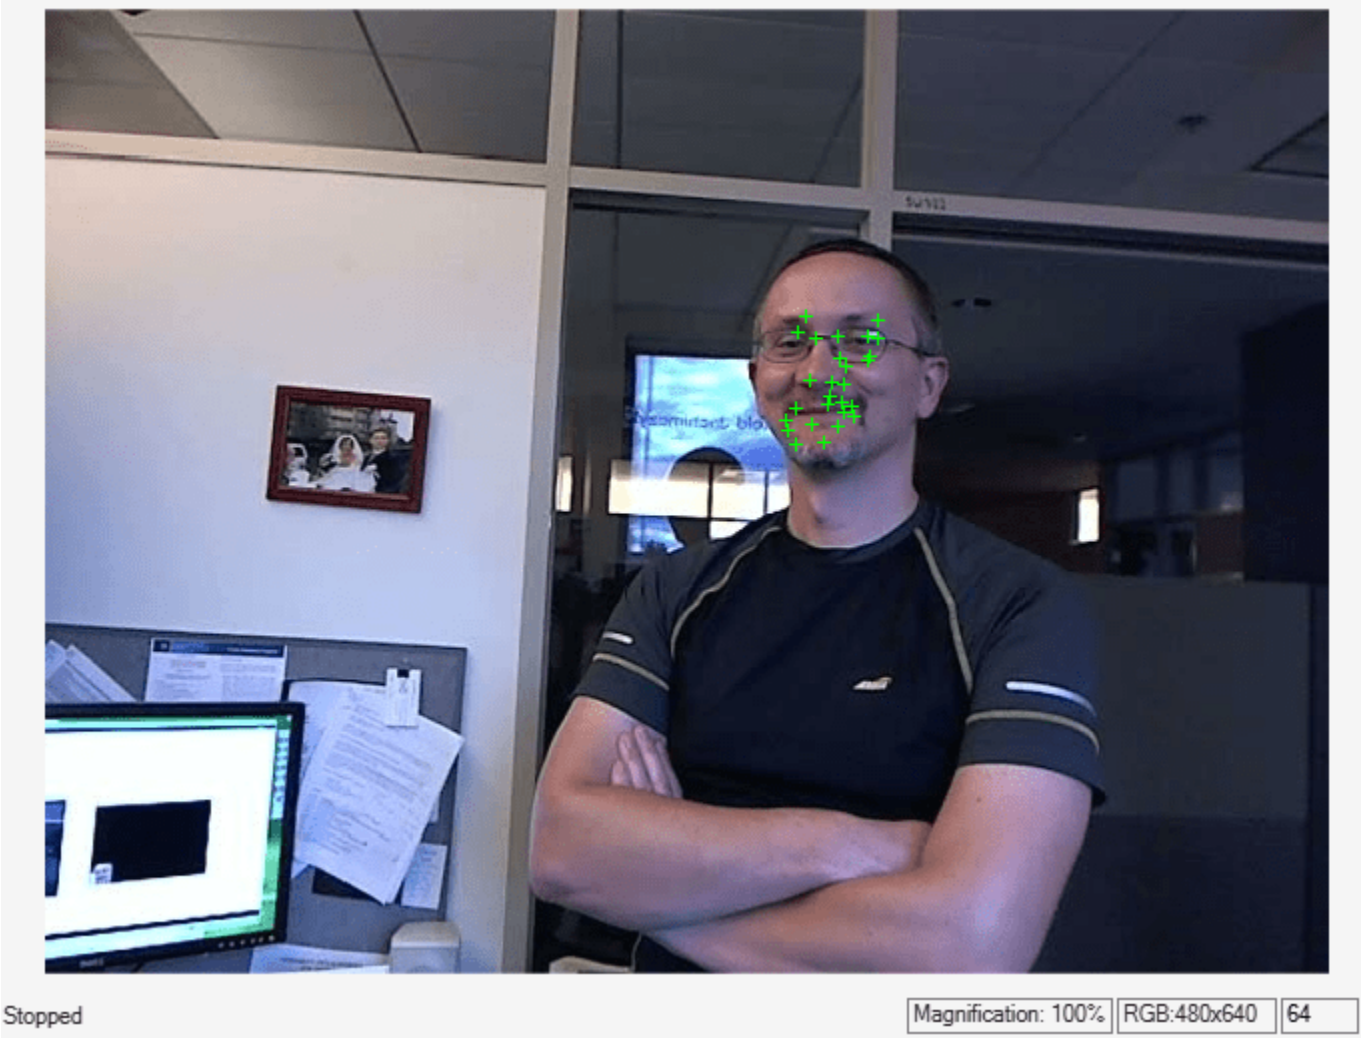
```
tracker = vision.PointTracker('MaxBidirectionalError',1);
```



Initialize the tracker.

```
initialize(tracker,points.Location,objectFrame);
```

Read, track, display points, and results in each video frame.



```
while hasFrame(videoReader)
      frame = readFrame(videoReader);
      [points,validity] = tracker(frame);
      out = insertMarker(frame,points(validity, :),'+');
      videoPlayer(out);
end
```

Processing
Magnification: 100%
RGB:480x640
64

Release the video player.

```
release(videoPlayer);
```

Input Arguments

`pointTracker` — Point tracker
`PointTracker` object

Point tracker, specified as a `vision.PointTracker` object.

`points` — Points
M-by-2 array

Points, specified as an *M*-by-2 array of [x y] coordinates that correspond to the locations of the points in the input frame, `I`.

`I` — Video frame
grayscale | truecolor (RGB)

Video frame, specified as grayscale or truecolor (RGB) and must be the same size as the images read into the tracker.

Version History

Introduced in R2012b

unet

Create U-Net convolutional neural network for semantic segmentation

Syntax

```
unetNetwork = unet(imageSize,numClasses)
[unetNetwork,outputSize] = unet(imageSize,numClasses)
___ = unet(imageSize,numClasses,Name=Value)
```

Description

`unetNetwork = unet(imageSize,numClasses)` returns a U-Net network.

Use `unet` to create the U-Net network architecture. You must train the network using the Deep Learning Toolbox function `trainnet`.

`[unetNetwork,outputSize] = unet(imageSize,numClasses)` also returns the size of the output size from the U-Net network.

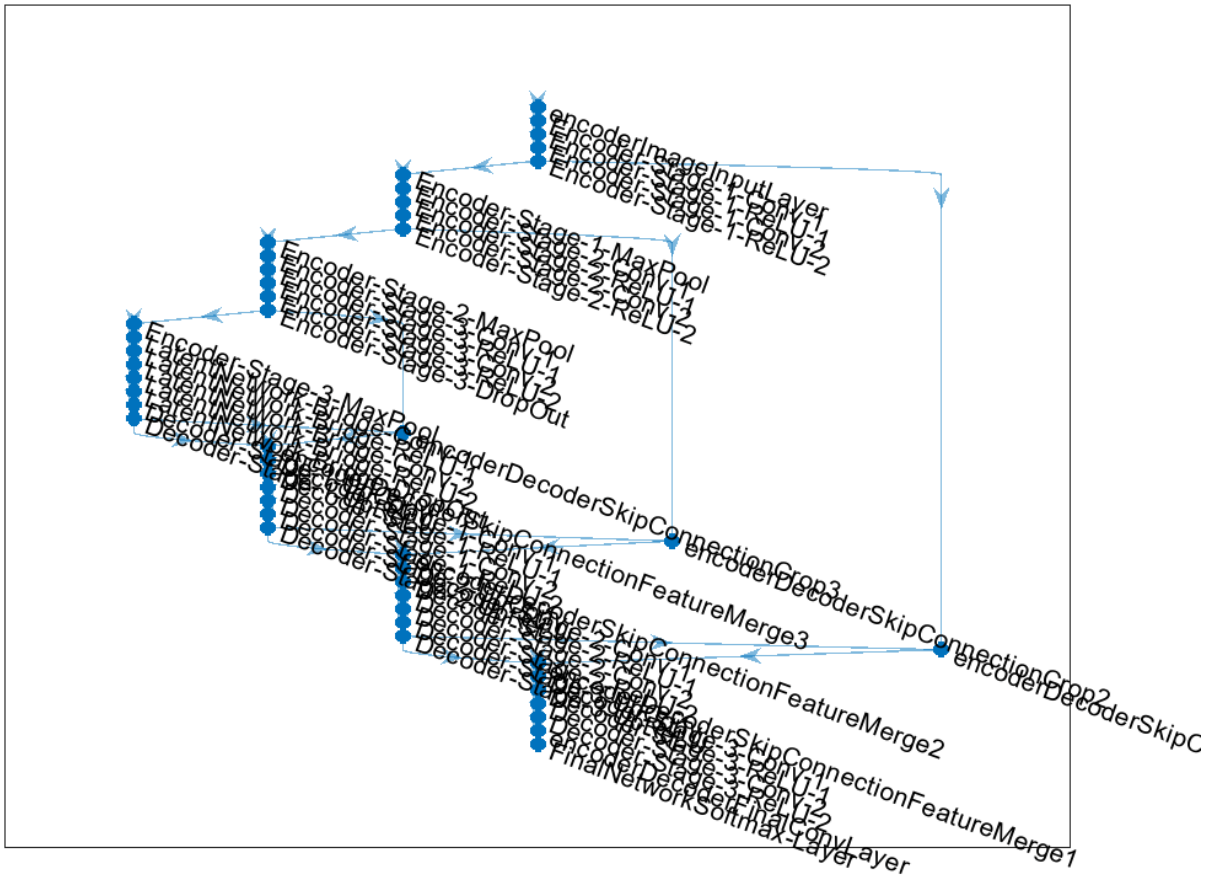
`___ = unet(imageSize,numClasses,Name=Value)` specifies options using one or more name-value arguments. For example, `unet(imageSize,numClasses,NumFirstEncoderFilters=64)` specifies the number of output channels as `64` for the first encoder stage.

Examples

Create U-Net Network with Custom Encoder-Decoder Depth

Create a U-Net network with an encoder-decoder depth of 3.

```
imageSize = [480 640 3];
numClasses = 5;
encoderDepth = 3;
unetNetwork = unet(imageSize,numClasses,EncoderDepth=encoderDepth)
```



```
unetNetwork =
  dlnetwork with properties:

         Layers: [48×1 nnet.cnn.layer.Layer]
    Connections: [53×2 table]
     Learnables: [36×3 table]

```

Display the network.

```
plot(unetNetwork)
```

Train U-Net Network for Semantic Segmentation

Load training images and pixel labels into the workspace.

```
dataSetDir = fullfile(toolboxdir("vision"),"visiondata","triangleImages");
imageDir = fullfile(dataSetDir,"trainingImages");
labelDir = fullfile(dataSetDir,"trainingLabels");
```

Create an `imageDatastore` object to store the training images.

```
imds = imageDatastore(imageDir);
```

Define the class names and their associated label IDs.

```
classNames = ["triangle","background"];
labelIDs   = [255 0];
```

Create a `pixelLabelDatastore` object to store the ground truth pixel labels for the training images.

```
pxds = pixelLabelDatastore(labelDir,classNames,labelIDs);
```

Create the U-Net network.

```
imageSize = [32 32];
numClasses = 2;
unetNetwork = unet(imageSize, numClasses)
```

```
unetNetwork =
  dlnetwork with properties:

         Layers: [61×1 nnet.cnn.layer.Layer]
    Connections: [68×2 table]
     Learnables: [46×3 table]
          State: [0×3 table]
     InputNames: {'encoderImageInputLayer'}
    OutputNames: {'FinalNetworkSoftmax-Layer'}
    Initialized: 1

  View summary with summary.
```

Create a datastore for training the network.

```
ds = combine(imds,pxds);
```

Set training options.

```
options = trainingOptions("sgdm", ...
    InitialLearnRate=1e-3, ...
    MaxEpochs=20, ...
    VerboseFrequency=10);
```

Train the network.

```
net = trainnet(ds,unetNetwork,"crossentropy",options)
```

     InputNames: {'encoderImageInputLayer'}
    OutputNames: {'FinalNetworkSoftmax-Layer'}
    Initialized: 1

  View summary with summary.
```

Input Arguments

`imageSize` — Network input image size

2-element vector | 3-element vector

Network input image size, specified as a:

- 2-element vector in the form [*height*, *width*].
- 3-element vector in the form [*height*, *width*, *depth*]. *depth* is the number of image channels. Set *depth* to 3 for RGB images, to 1 for grayscale images, or to the number of channels for multispectral and hyperspectral images.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`numClasses` — Number of classes

integer greater than 1

Number of classes in the semantic segmentation, specified as an integer greater than 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `EncoderDepth=3` specifies the encoder depth as 3.

`EncoderNetwork` — Encoder network

`dlnetwork` object

Encoder network that `unet` uses as the encoder, specified as a `dlnetwork` object. You can specify a pretrained or custom encoder network. To use a pretrained encoder network, create the network using the `pretrainedEncoderNetwork` function.

Note If you specify `EncoderNetwork`, the `unet` function does not use these name-value arguments to configure the network:

- `NumFirstEncoderFilters`
- `FilterSize`
- `ConvolutionPadding`

`EncoderDepth` — Encoder depth

4 (default) | positive integer

Encoder depth, specified as a positive integer. U-Net is composed of an encoder subnetwork and a corresponding decoder subnetwork. The depth of these networks determines the number of times the input image is downsampled or upsampled during processing. The encoder network downsamples the input image by a factor of 2^D, where D is the value of `EncoderDepth`. The decoder network upsamples the encoder network output by a factor of 2^D.

Note If you also specify `EncoderNetwork`, specify the value of `EncoderDepth` using the depth of the `EncoderNetwork` input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`NumFirstEncoderFilters` — Number of output channels for first encoder
64 (default) | positive integer

Number of output channels for the first encoder stage, specified as a positive integer or vector of positive integers. In each subsequent encoder stage, the number of output channels doubles. The `unet` function sets the number of output channels in each decoder stage to match the number in the corresponding encoder stage.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`FilterSize` — Convolutional layer filter size
3 (default) | positive odd integer | 2-element row vector of positive odd integers

Convolutional layer filter size, specified as a positive odd integer or a 2-element row vector of positive odd integers. Typical values are in the range [3, 7].

`FilterSize`	Description
scalar	The filter is square.
2-element row vector	The filter has the size [*height width*].

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ConvolutionPadding` — Type of padding
`"same"` (default) | `"valid"`

Type of padding, specified as `"same"` or `"valid"`. The type of padding specifies the padding style for the `convolution2dLayer` in the encoder and the decoder subnetworks. The spatial size of the output feature map depends on the type of padding. If you specify type of padding as:

- `"same"` — Zero padding is applied to the inputs to convolution layers such that the output and input feature maps are the same size.
- `"valid"` — Zero padding is not applied to the inputs to convolution layers. The convolution layer returns only values of the convolution that are computed without zero padding. The output feature map is smaller than the input feature map.

Note To ensure that the *height* and *width* of the inputs to max-pooling layers are even, choose the network input image size to confirm to any one of these criteria:

- If you specify `ConvolutionPadding` as `"same"`, then the *height* and *width* of the input image must be a multiple of 2^D.
- If you specify `ConvolutionPadding` as `"valid"`, then the *height* and *width* of the input image must be chosen such that $\frac{1}{2^D}\left(height - \sum_{i=1}^{D} 2^i(f_h - 1)\right)$ and $\frac{1}{2^D}\left(width - \sum_{i=1}^{D} 2^i(f_w - 1)\right)$ are multiples of 2^D.

where f_h and f_w are the height and width of the two-dimensional convolution kernel, respectively. D is the encoder depth.

Data Types: `char` | `string`

Output Arguments

`unetNetwork` — Layers

`dlnetwork` object

Layers that represent the U-Net network architecture, returned as a `dlnetwork` object.

`outputSize` — Network output image size

three-element vector

Network output image size, returned as a three-element vector of the form [*height*, *width*, *channels*]. *channels* is the number of output channels and it is equal to the number of classes specified at the input. The *height* and *width* of the output image from the network depend on the type of padding convolution.

- If you specify `ConvolutionPadding` as `"same"`, then the *height* and *width* of the network output image are the same as that of the network input image.
- If you specify `ConvolutionPadding` as `"valid"`, then the *height* and *width* of the network output image are less than that of the network input image.

Data Types: `double`

More About

U-Net Architecture

- The U-Net architecture consists of an encoder subnetwork and decoder subnetwork that are connected by a bridge section.
- The encoder and decoder subnetworks in the U-Net architecture consists of multiple stages. `EncoderDepth`, which specifies the depth of the encoder and decoder subnetworks, sets the number of stages.
- The stages within the U-Net encoder subnetwork consist of two sets of convolutional and ReLU layers, followed by a 2-by-2 max pooling layer. The decoder subnetwork consists of a transposed convolution layer for upsampling, followed by two sets of convolutional and ReLU layers.
- The bridge section consists of two sets of convolution and ReLU layers.
- The bias term of all convolutional layers is initialized to zero.
- Convolution layer weights in the encoder and decoder subnetworks are initialized using the `'He'` weight initialization method [2].

Tips

- Use `'same'` padding in convolution layers to maintain the same data size from input to output and enable the use of a broad set of input image sizes.

- Use patch-based approaches for seamless segmentation of large images. You can extract image patches by using the `randomPatchExtractionDatastore` function.
- Use `'valid'` padding to prevent border artifacts while you use patch-based approaches for segmentation.
- You can use the network created using `unet` function for GPU code generation after training with `trainnet`. For details and examples, see “Generate Code and Deploy Deep Neural Networks” (Deep Learning Toolbox).

unet3d

Create 3-D U-Net convolutional neural network for semantic segmentation of volumetric images

Syntax

```
unet3dNetwork = unet3d(inputSize,numClasses)
[unet3dNetwork,outputSize] = unet3d(inputSize,numClasses)
[___] = unet3d(inputSize,numClasses,Name=Value)
```

Description

`unet3dNetwork = unet3d(inputSize,numClasses)` returns a 3-D U-Net network. `unet3d` includes a pixel classification layer in the network to predict the categorical label for each pixel in an input volumetric image.

Use `unet3d` to create the network architecture for 3-D U-Net. Train the network using the Deep Learning Toolbox function `trainnet`.

`[unet3dNetwork,outputSize] = unet3d(inputSize,numClasses)` also returns the size of an output volumetric image from the 3-D U-Net network.

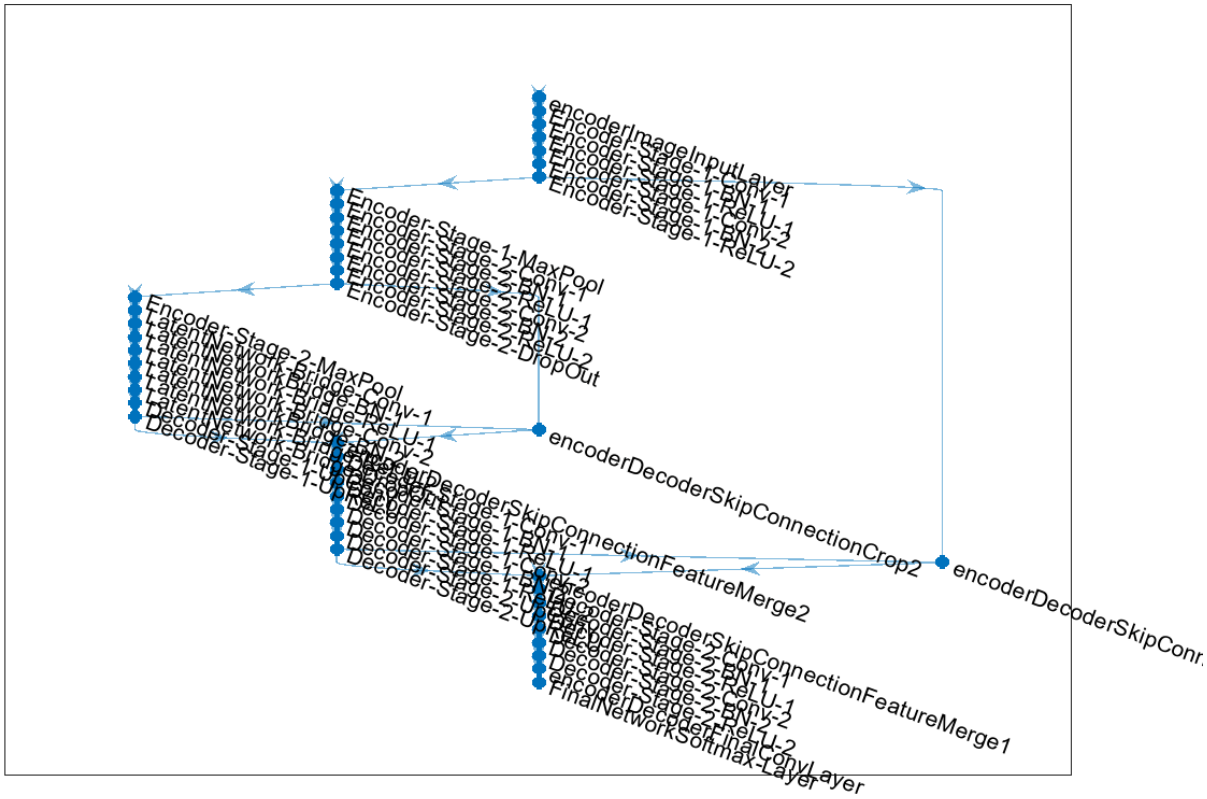
`[___] = unet3d(inputSize,numClasses,Name=Value)` specifies options using one or more name-value arguments in addition to the input arguments in previous syntax. For example, specify `unet3d(inputSize,numClasses,EncoderDepth=4)` to set the encoder depth to 4.

Examples

Create 3-D U-Net Network with Custom Encoder-Decoder Depth

Create a 3-D U-Net network with an encoder-decoder depth of 2. Specify the number of output channels for the first convolution layer as 16.

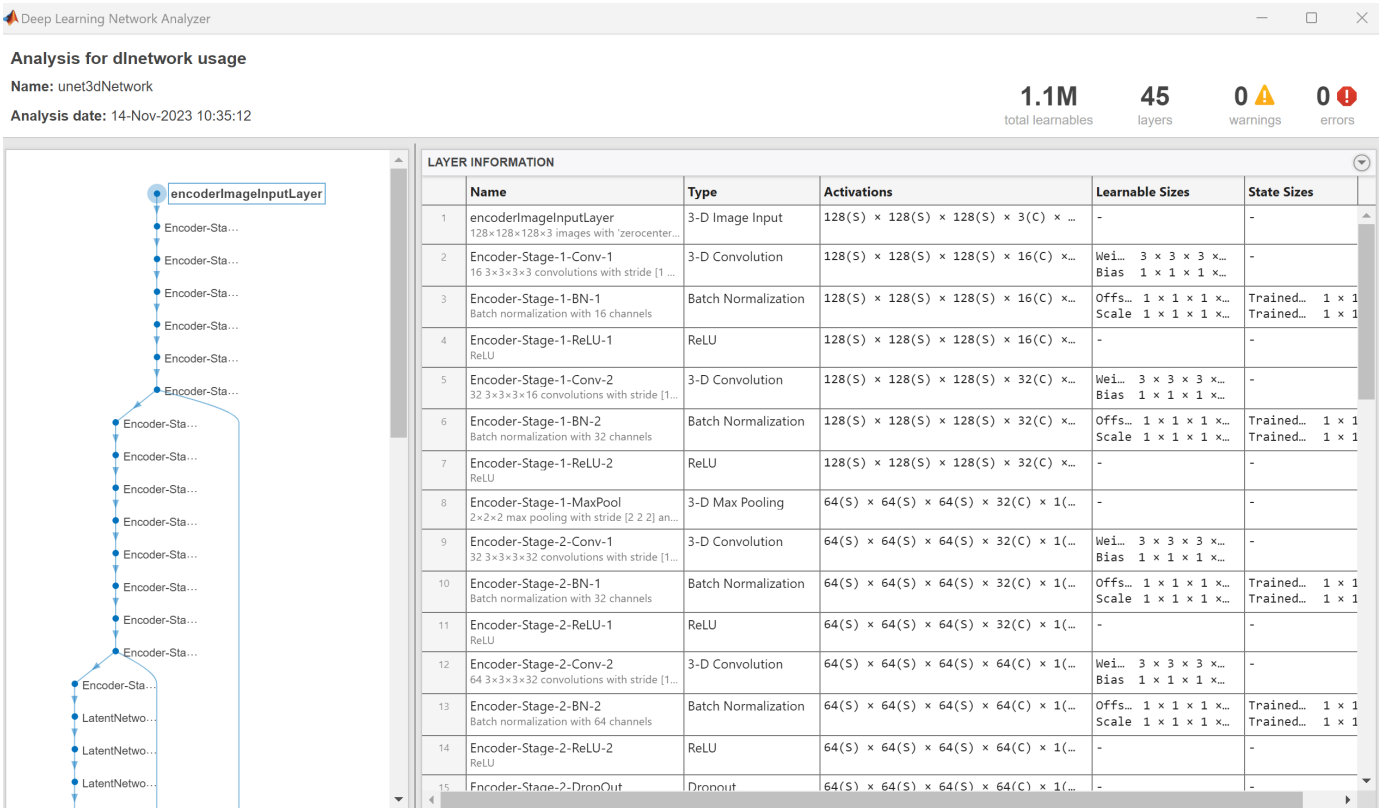
```
imageSize = [128 128 128 3];
numClasses = 5;
encoderDepth = 2;
unet3dNetwork = unet3d(imageSize,numClasses,EncoderDepth=encoderDepth,NumFirstEncoderFilters=16)
```



```
unet3dNetwork =
  dlnetwork with properties:

         Layers: [45×1 nnet.cnn.layer.Layer]
    Connections: [48×2 table]
     Learnables: [46×3 table]
          State: [20×3 table]
     InputNames: {'encoderImageInputLayer'}
    OutputNames: {'FinalNetworkSoftmax-Layer'}
    Initialized: 1

  View summary with summary.
```



Display the network.

```
figure(Units="normalized",Position=[0 0 0.5 0.55]);
plot(unet3dNetwork)
```

Use the deep learning network analyzer to visualize the 3-D U-Net network.

```
analyzeNetwork(unet3dNetwork);
```

The visualization shows the number of output channels for each encoder stage. The first convolution layers in encoder stages 1 and 2 have 16 and 32 output channels, respectively. The second convolution layers in encoder stages 1 and 2 have 32 and 64 output channels, respectively.

Input Arguments

`inputSize` — Network input image size

three-element vector | four-element vector

Network input image size representing a volumetric image, specified as one of these values:

- Three-element vector of the form [*height width depth*]
- Four-element vector of the form [*height width depth channel*]. *channel* denotes the number of image channels.

Note Network input image size must be chosen such that the dimension of the inputs to the max-pooling layers must be even numbers.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`numClasses` — Number of classes

scalar greater than 1

Number of classes to segment, specified as a scalar greater than 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `unet3d(inputSize,numClasses,EncoderDepth=4)` sets the encoder depth to 4.

`EncoderNetwork` — Encoder network

`dlnetwork` object

Encoder network that `unet3d` uses as the encoder, specified as a `dlnetwork` object. You can specify a pretrained or custom encoder network. To use a pretrained encoder network, create the network using the `pretrainedEncoderNetwork` function.

Note If you specify `EncoderNetwork`, the `unet3d` function does not use these name-value arguments to configure the network:

- `NumFirstEncoderFilters`
- `FilterSize`
- `ConvolutionPadding`

`EncoderDepth` — Encoder depth

3 (default) | positive integer

Encoder depth, specified as a positive integer. The 3-D U-Net network is composed of an encoder subnetwork and a corresponding decoder subnetwork. The depth of the network determines the number of times the input volumetric image is downsampled or upsampled during processing. The encoder network downsamples the input volumetric image by a factor of 2^D, where D is the value of `EncoderDepth`. The decoder network upsamples the encoder network output by a factor of 2^D. The depth of the decoder subnetwork is same as that of the encoder subnetwork.

Note If you also specify `EncoderNetwork`, specify the value of `EncoderDepth` using the depth of the `EncoderNetwork` input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`NumFirstEncoderFilters` — Number of output channels for first convolution layer

32 (default) | positive integer

Number of output channels for the first convolution layer in the first encoder stage, specified as a positive integer. The number of output channels for the second convolution layer and the convolution layers in the subsequent encoder stages is set based on this value.

Given stage = {1, 2, ..., *EncoderDepth*}, the number of output channels for the first convolution layer in each encoder stage is equal to

$2^{stage\text{-}1}$ `NumFirstEncoderFilters`

The number of output channels for the second convolution layer in each encoder stage is equal to 2^{stage} `NumFirstEncoderFilters`

The `unet3d` function sets the number of output channels for convolution layers in the decoder stages to match the number in the corresponding encoder stage.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`FilterSize` — Size of 3-D convolution filter

3 (default) | positive scalar integer | three-element row vector of positive integers

Size of the 3-D convolution filter, specified as a positive scalar integer or a three-element row vector of positive integers of the form [f_h f_w f_d]. Typical values for filter dimensions are in the range [3, 7].

If you specify `FilterSize` as a positive scalar integer of value a, then the convolution kernel is of uniform size [`a a a`].

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ConvolutionPadding` — Type of padding

`"same"` (default) | `"valid"`

Type of padding, specified as `"same"` or `"valid"`. The type of padding specifies the padding style for the `convolution3dLayer` in the encoder and the decoder subnetworks. The spatial size of the output feature map depends on the type of padding. Specify one of these options:

- `"same"` — Zero padding is applied to the inputs to convolution layers such that the output and input feature maps are the same size.
- `"valid"` — Zero padding is not applied to the inputs to convolution layers. The convolution layer returns only values of the convolution that are computed without zero padding. The output feature map is smaller than the input feature map.

.

Note To ensure that the *height*, *width*, and *depth* values of the inputs to max-pooling layers are even, choose the network input image size to confirm to any one of these criteria:

- If you specify `ConvolutionPadding` as `"same"`, then the *height*, *width*, and *depth* of the input volumetric image must be a multiple of 2^D.
- If you specify `ConvolutionPadding` as `"valid"`, then the *height*, *width*, and *depth* of the input volumetric image must be chosen such that $\frac{1}{2^D}\left(height - \sum_{i=1}^{D} 2^i(f_h - 1)\right)$, $\frac{1}{2^D}\left(width - \sum_{i=1}^{D} 2^i(f_w - 1)\right)$, and $\frac{1}{2^D}\left(depth - \sum_{i=1}^{D} 2^i(f_d - 1)\right)$ are multiples of 2^D.

  where f_h, f_w and f_d are the height, width, and depth of the three-dimensional convolution kernel, respectively. D is the encoder depth.

Data Types: `char` | `string`

Output Arguments

`unet3dNetwork` — Layers
`dlnetwork` object

Layers that represent the 3-D U-Net network architecture, returned as a `dlnetwork` object.

`outputSize` — Network output image size
four-element vector

Network output image size, returned as a four-element vector of the form [*height*, *width*, *depth*, *channels*]. *channels* is the number of output channels and is equal to the number of classes specified at the input. The *height*, *width*, and *depth* of the output image from the network depend on the type of padding convolution.

- If you specify `ConvolutionPadding` as `"same"`, then the *height*, *width*, and *depth* of the network output image are the same as that of the network input image.
- If you specify `ConvolutionPadding` as `"valid"`, then the *height*, *width*, and *depth* of the network output image are less than that of the network input image.

Data Types: `double`

More About

3-D U-Net Architecture

- The 3-D U-Net architecture consists of an encoder subnetwork and decoder subnetwork that are connected by a bridge section.
- The encoder and decoder subnetworks in the 3-D U-Net architecture consist of multiple stages. `EncoderDepth`, which specifies the depth of the encoder and decoder subnetworks, sets the number of stages.
- Each encoder stage in the 3-D U-Net network consists of two sets of convolutional, batch normalization, and ReLU layers. The ReLU layer is followed by a 2-by-2-by-2 max pooling layer. Likewise, each decoder stage consists of a transposed convolution layer for upsampling, followed by two sets of convolutional, batch normalization, and ReLU layers.
- The bridge section consists of two sets of convolution, batch normalization, and ReLU layers.
- The bias term of all convolution layers is initialized to zero.
- Convolution layer weights in the encoder and decoder subnetworks are initialized using the `'He'` weight initialization method.

Tips

- Use `'same'` padding in convolution layers to maintain the same data size from input to output and enable the use of a broad set of input image sizes.
- Use patch-based approaches for seamless segmentation of large images. You can extract image patches by using the `randomPatchExtractionDatastore` function.
- Use `'valid'` padding in convolution layers to prevent border artifacts while you use patch-based approaches for segmentation.

deeplabv3plus

Create DeepLab v3+ convolutional neural network for semantic image segmentation

Syntax

```
deepLabNetwork = deeplabv3plus(imageSize,numClasses,network)
deepLabNetwork = deeplabv3plus( ___ ,DownsamplingFactor=value)
```

Description

`deepLabNetwork = deeplabv3plus(imageSize,numClasses,network)` returns a DeepLab v3+ layer with the specified base network, number of classes, and image size.

`deepLabNetwork = deeplabv3plus( ___ ,DownsamplingFactor=value)` additionally sets the downsampling factor (output stride) [1] to either 8 or 16. The downsampling factor sets the amount the encoder section of DeepLab v3+ downsamples the input image.

Examples

Create DeepLab v3+ Network Based on ResNet-18

Create a DeepLab v3+ network based on ResNet-18.

```
imageSize = [480 640 3];
numClasses = 5;
network = "resnet18";
net = deeplabv3plus(imageSize,numClasses,network, ...
             DownsamplingFactor=16);
```

Display the network.

```
analyzeNetwork(net)
```

Train DeepLab v3+ Network

Load the triangle data set images using an image datastore. The datastore contains 200 grayscale images of random triangles. Each image is 32-by-32.

```
dataSetDir = fullfile(toolboxdir("vision"),"visiondata","triangleImages");
imageDir = fullfile(dataSetDir,"trainingImages");
imds = imageDatastore(imageDir);
```

Load the triangle data set pixel labels using a pixel label datastore.

```
labelDir = fullfile(dataSetDir, "trainingLabels");
classNames = ["triangle","background"];
labelIDs   = [255 0];
pxds = pixelLabelDatastore(labelDir,classNames,labelIDs);
```

Create a DeepLab v3+ network.

```
imageSize = [256 256];
numClasses = numel(classNames);
net = deeplabv3plus(imageSize,numClasses,"resnet18");
```

Combine image and pixel label data for training and apply a preprocessing transform to resize the training images.

```
cds = combine(imds,pxds);
tds = transform(cds, @(data)preprocessTrainingData(data,imageSize));
```

Specify training options. Lower the mini-batch size to reduce memory usage.

```
opts = trainingOptions("sgdm",...
    MiniBatchSize=8,...
    MaxEpochs=3);
```

Train the network.

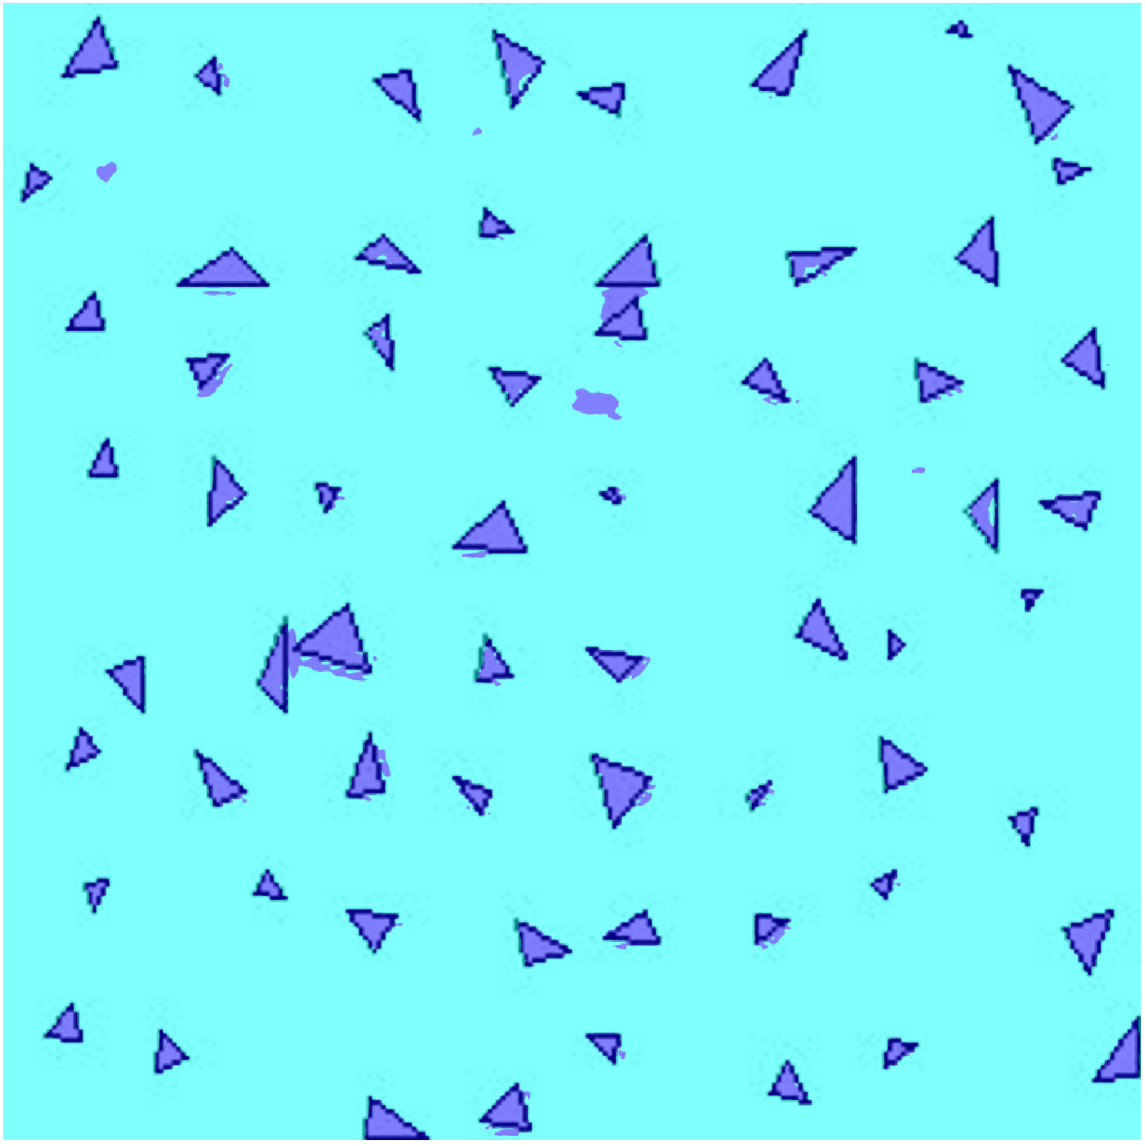
```
net = trainnet(tds,net,"crossentropy",opts);
```

```
    Iteration    Epoch    TimeElapsed    LearnRate    TrainingLoss
    _________    _____    ___________    _________    ____________
            1        1       00:00:04         0.01         0.93844
           50        2       00:04:09         0.01        0.033749
           75        3       00:05:35         0.01        0.026353
Training stopped: Max epochs completed
```

Read a test image.

```
I = imread("triangleTest.jpg");
```

Resize the test image by a factor equal to the input image size divided by 32 so that the triangles in the test image are roughly equal to the size of the triangles during training.



```
I = imresize(I,Scale=imageSize./32);
```

Segment the image.

```
C = semanticseg(I,net);
```

Display the results.

```
B = labeloverlay(I,C);
figure
imshow(B)
```

Supporting Functions

```
function data = preprocessTrainingData(data, imageSize)
% Resize the training image and associated pixel label image.
data{1} = imresize(data{1},imageSize);
data{2} = imresize(data{2},imageSize);

% Convert grayscale input image into RGB for use with ResNet-18, which
% requires RGB image input.
```

```
data{1} = repmat(data{1},1,1,3);
end
```

Input Arguments

`imageSize` — Network input image size

RGB image

Network input image size, specified as an RGB image. The image can have one of these formats.

- 2-element vector in the format [*height width*].
- 3-element vector in the format [*height width*, `3`].

If you specify `imageSize` as a 2-element vector [*height width*], the network will automatically use [*height width* 3] as the input size for RGB images. You must first convert grayscale images to RGB before passing them to the network.

`numClasses` — Number of classes

integer greater than 1

Number of classes for network to classify, specified as an integer greater than 1.

`network` — Base network

`"resnet18"` | `"resnet50"` | `"mobilenetv2"` | `"xception"` | `"inceptionresnetv2"`

Base network, specified as one of these options:

- `"resnet18"` — The base network is a ResNet-18 network.
- `"resnet50"` — The base network is a ResNet-50 network.
- `"mobilenetv2"` — The base network is a MobileNet-v2 network.
- `"xception"` — The base network is an Xception network.
- `"inceptionresnetv2"` — The base network is an Inception-ResNet-v2 network.

To specify each type of base network, you must install the corresponding network add-on. To learn more about these networks, see “Pretrained Deep Neural Networks” (Deep Learning Toolbox).

Output Arguments

`deepLabNetwork` — DeepLab v3+ network

`dlnetwork` object

DeepLab v3+ network, returned as a `dlnetwork` object for semantic image segmentation. The network uses encoder-decoder architecture, dilated convolutions, and skip connections to segment images. You must use the `trainnet` function (requires Deep Learning Toolbox) to train the network before you can use the network for semantic segmentation.

Algorithms

- When you use either the `xception` or `mobilenetv2` base networks to create a DeepLab v3+ network, depth separable convolutions are used in the atrous spatial pyramid pooling (ASPP) and decoder subnetworks. For all other base networks, convolution layers are used.

- This implementation of DeepLab v3+ does not include a global average pooling layer in the ASPP.

bisenetv2

Create BiSeNet v2 convolutional neural network for semantic segmentation

Syntax

```
[net,classes] = bisenetv2
net = bisenetv2(imageSize,numClasses)
[net] = bisenetv2(imageSize,numClasses,Name=Value)
```

Description

Use the `bisenetv2` function to semantically segment images using the BiSeNet v2 convolutional neural network. Using the pretrained network, trained on 171 image classes of the COCO-Stuff data set [2], you can perform inference on test images which contain these classes.

To perform semantic segmentation on a custom data set, you must train the network on your data set using the `trainnet` function.

Note This functionality requires Deep Learning Toolbox and the Computer Vision Toolbox Model for BiSeNet v2 Semantic Segmentation Network. You can install the Computer Vision Toolbox Model for BiSeNet v2 Semantic Segmentation Network from Add-On Explorer. For more information about installing add-ons, see Get and Manage Add-Ons.

`[net,classes] = bisenetv2` returns a pretrained BiSeNet v2 network and the names of the 171 classes that it was trained on.

`net = bisenetv2(imageSize,numClasses)` returns a BiSeNet v2 network pretrained on 171 image classes of the COCO-Stuff data set and configured for transfer learning using input images of the specified size `imageSize` and the specified number of classes `numClasses`. Train this network on a custom data set using the using the `trainnet` function.

`[net] = bisenetv2(imageSize,numClasses,Name=Value)` specifies options using one or more name-value arguments in addition to the input arguments from the previous syntax. When you specify one or more network options using a name-value argument, you create a custom BiSeNet v2 network with uninitialized weights.

For example, `bisenetv2(ChannelRatio=16)` specifies the channel ratio between the semantic branch and detail branch as `16`.

Examples

Segment Image using Pretrained BiSeNet v2 Network

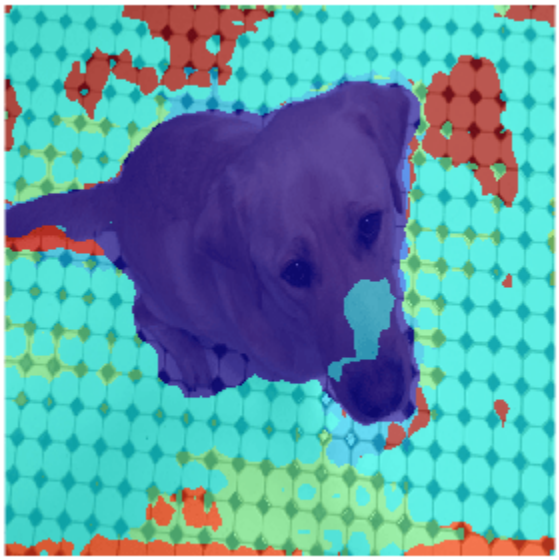
Create a BiSeNet v2 convolutional neural network for semantic segmentation.

```
[net,classes] = bisenetv2;
```

Read a test image into the workspace.

```
I = imread("kobi.png");
```

Resize the image to the input size of the network.



```
inputSize = net.Layers(1).InputSize(1:2);
img = imresize(I,inputSize);
```

Create a segmentation map, a categorical array which relates the labels to each pixel in the input image, of the test image using the `semanticseg` function.

```
segMap = semanticseg(img,net,Classes=classes);
```

Display the segmentation map overlaid on the image, ordered by the smallest object masks on top, using the `labeloverlay` function.

```
segmentedImage = labeloverlay(img,segMap,Transparency=0.4);
imshow(segmentedImage)
```

Input Arguments

`imageSize` — Network input image size

two-element vector | three-element vector

Network input image size, specified as one of these options:

- Two-element vector of the form [*height width*].
- Three-element vector of the form [*height width depth*]. *depth* is the number of image channels. Specify *depth* as 3 for RGB images, as 1 for grayscale images, or as the number of channels for multispectral and hyperspectral images.

`numClasses` — Number of classes
integer greater than 1

Number of classes to segment, specified as an integer greater than 1.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `bisenetv2(ChannelRatio=16)` specifies the channel ratio between the semantic and detail branch as 16.

`ChannelRatio` — Channel ratio
4 (default) | positive integer in the range `[2 64]`

Channel ratio between the semantic branch and detail branch, specified as a positive integer in the range `[2, 64]`. The channel ratio must be a power of 2 no greater than 64.

Tip Decrease this value to enable the detail branch to learn finer features. Increase the channel ratio to enable the semantic branch to capture global context and improve the overall performance of the network, at the expense of less segmented finer features and a slower computing speed. Use empirical analysis to determine the optimal channel ratio for your application.

`ChannelMultiplier` — Channel multiplier
1 (default) | positive scalar

Channel multiplier, specified as a positive scalar. This value scales the number of channels in all convolutional layers other than the inputs to the semantic, detail, and output branches.

Tip Increase this value to improve segmentation accuracy at the cost of larger model size and longer training time.

Depending on the `ChannelRatio` value you specify, the `ChannelMultiplier` argument supports these values:

`ChannelRatio` Value	Supported `ChannelMultiplier` Values
2, 4, 8	1, 1.25, 1.5, 1.75, 2
16	1, 1.5, 2
32	1, 2
64	2

`DepthMultiplier` — Depth multiplier
1 (default) | positive integer

Depth multiplier specified as a positive scalar. This value scales the number of layers of the semantic and detail branches. Increase the depth multiplier to improve learning capacity and accuracy at the

cost of longer processing time. For most applications, use specify a depth multiplier value between 1 and 4.

Output Arguments

`net` — BiSeNet v2 network layers

`dlnetwork` object

BiSeNet v2 network layers, returned as a `dlnetwork` object.

`classes` — Names of classes

categorical array

Names of the classes that the BiSeNet v2 network has been pretrained to segment, returned as a categorical array.

More About

BiSeNet v2 Architecture

- The BiSeNet v2 architecture consists of a detail branch, which captures high-resolution spatial details and a semantic branch, which focuses on contextual information and abstract feature extraction, followed by a feature aggregation layer that combines and balances these pathways.

fcnLayers

(Removed) Create fully convolutional network layer graph for semantic segmentation

Note `fcnLayers` has been removed. Create an FCN network using a `dlnetwork` object instead. For more information, see “Version History”.

Syntax

```
lgraph = fcnLayers(imageSize,numClasses)
lgraph = fcnLayers(imageSize,numClasses,'Type',type)
```

Description

`lgraph = fcnLayers(imageSize,numClasses)` returns a fully convolutional network (FCN), configured as FCN 8s, for semantic segmentation. The FCN is preinitialized using layers and weights from the VGG-16 network.

`fcnLayers` includes a `pixelClassificationLayer` to predict the categorical label for every pixel in an input image. The pixel classification layer only supports RGB images.

This function requires the Deep Learning Toolbox *Model for VGG-16 Network* support package. If this support package is not installed, then the `vgg16` function provides a download link.

`lgraph = fcnLayers(imageSize,numClasses,'Type',type)` returns an FCN configured as a type specified by `type`.

Examples

Create Fully Convolutional Network 8s

Define the image size and number of classes, then create the network.

```
imageSize = [480 640];
numClasses = 5;
lgraph = fcnLayers(imageSize,numClasses)
```

Display the network.

```
plot(lgraph)
```

Create Fully Convolutional Network 16s

Create a FCN 16s.

```
imageSize = [480 640];
numClasses = 5;
lgraph = fcnLayers(imageSize,numClasses,'Type','16s')
```

Display the network.

```
plot(lgraph)
```

Input Arguments

`imageSize` — Network input image size

2-element vector

Network input image size, specified as a 2-element vector in the format [*height*, *width*]. The minimum image size is [224 224] because an FCN is based on the VGG-16 network.

`numClasses` — Number of classes

integer greater than 1

Number of classes in the semantic segmentation, specified as an integer greater than 1.

`type` — Type of FCN model

`'8s'` (default) | `'16s'` | `'32s'`

Type of FCN model, specified as one of the following:

FCN Model	Description
`'32s'`	Upsamples the final feature map by a factor of 32. This option provides coarse segmentation with a lower computational cost.
`'16s'`	Upsamples the final feature map by a factor of 16 after fusing the feature map from the fourth pooling layer. This additional information from earlier layers provides medium-grain segmentation at the cost of additional computation.
`'8s'`	Upsamples the final feature map by a factor of 8 after fusing feature maps from the third and fourth max pooling layers. This additional information from earlier layers provides finer-grain segmentation at the cost of additional computation.

Output Arguments

`lgraph` — Layers

`LayerGraph` object

Layers that represent the FCN network architecture, returned as a `layerGraph` object.

All transposed convolution layers are initialized using bilinear interpolation weights. All transposed convolution layer bias terms are fixed to zero.

Tips

- Networks produced by `fcnLayers` support GPU code generation for deep learning once they are trained with `trainNetwork`. See “Generate Code and Deploy Deep Neural Networks” (Deep Learning Toolbox) for details and examples.

Version History

Introduced in R2017b

R2026a: Removed
Errors starting in R2026a

The `fcnLayers` function has been removed. Use the `dlnetwork` object instead.

R2024b: Warns
Warns starting in R2024b

The `fcnLayers` function issues a warning that it will be removed in a future release. To update your code, create a `dlnetwork` instead. You can use functions such as `addLayers` and `connectLayers` to build the network.

Do not include output layers in the network. Instead, define a loss function. Here are some sample loss functions appropriate for pixel classification:

```
function loss = modelLoss(Y,T)
  z = generalizedDice(Y,T);
  loss = 1 - mean(z,"all");
end

function loss = modelLoss(Y,T)
  mask = ~isnan(T);
  targets(isnan(T)) = 0;
  loss = crossentropy(Y,T,Mask=mask);
end
```

Specify the loss function when you train the network using the `trainnet` function. For example, this code trains a `dlnetwork` network called `net` using the training data `images` and the loss function `modelLoss`.

```
netTrained = trainnet(images,net,@modelLoss,options);
```

R2024a: To be removed
Not recommended starting in R2024a

The `fcnLayers` function will be removed in a future release.

segnetLayers

(Removed) Create SegNet layer graph for semantic segmentation

Note `segnetLayers` has been removed. For supported semantic segmentation networks, see “Get Started with Semantic Segmentation Using Deep Learning”.

You can create a SegNet network using a `dlnetwork` object. For more information, see “Version History”.

Syntax

```
lgraph = segnetLayers(imageSize,numClasses,model)
lgraph = segnetLayers(imageSize,numClasses,encoderDepth)
lgraph = segnetLayers(imageSize,numClasses,encoderDepth,Name,Value)
```

Description

`lgraph = segnetLayers(imageSize,numClasses,model)` returns SegNet layers, `lgraph`, that is preinitialized with layers and weights from a pretrained `model`.

SegNet is a convolutional neural network for semantic image segmentation. The network uses a `pixelClassificationLayer` to predict the categorical label for every pixel in an input image.

Use `segnetLayers` to create the network architecture for SegNet. You must train the network using the Deep Learning Toolbox function `trainNetwork`.

`lgraph = segnetLayers(imageSize,numClasses,encoderDepth)` returns uninitialized SegNet layers configured using the specified encoder depth.

`lgraph = segnetLayers(imageSize,numClasses,encoderDepth,Name,Value)` returns a SegNet layer with additional options specified by one or more `Name,Value` pair arguments.

Examples

Create SegNet With Custom Encoder-Decoder Depth

Create SegNet layers with an encoder/decoder depth of 4.

```
imageSize = [480 640 3];
numClasses = 5;
encoderDepth = 4;
lgraph = segnetLayers(imageSize,numClasses,encoderDepth)
```

```
lgraph =
  LayerGraph with properties:

     InputNames: {'inputImage'}
    OutputNames: {'pixelLabels'}
         Layers: [59x1 nnet.cnn.layer.Layer]
```

```
    Connections: [66x2 table]
```

Display the network.

```
figure
plot(lgraph)
```

Train SegNet

Load training images and pixel labels.

```
dataSetDir = fullfile(toolboxdir('vision'),'visiondata','triangleImages');
imageDir = fullfile(dataSetDir,'trainingImages');
labelDir = fullfile(dataSetDir,'trainingLabels');
```

Create an image datastore holding the training images.

```
imds = imageDatastore(imageDir);
```

Define the class names and their associated label IDs.

```
classNames = ["triangle", "background"];
labelIDs   = [255 0];
```

Create a pixel label datastore holding the ground truth pixel labels for the training images.

```
pxds = pixelLabelDatastore(labelDir,classNames,labelIDs);
```

Combine image and pixel label data for training a semantic segmentation network.

```
ds = combine(imds,pxds);
```

Create SegNet layers.

```
imageSize = [32 32];
numClasses = 2;
lgraph = segnetLayers(imageSize,numClasses,2)
```

```
lgraph =
  LayerGraph with properties:

     InputNames: {'inputImage'}
    OutputNames: {'pixelLabels'}
         Layers: [31x1 nnet.cnn.layer.Layer]
    Connections: [34x2 table]
```

Set up training options.

```
options = trainingOptions('sgdm','InitialLearnRate',1e-3, ...
      'MaxEpochs',20,'VerboseFrequency',10);
```

Train the network.

```
net = trainNetwork(ds,lgraph,options)
```

```
Training on single CPU.
Initializing input data normalization.
```

```

|=========================================================================================|
Training finished: Max epochs completed.

net =
  DAGNetwork with properties:

         Layers: [31x1 nnet.cnn.layer.Layer]
    Connections: [34x2 table]
     InputNames: {'inputImage'}
    OutputNames: {'pixelLabels'}
```

Display the network.

```
plot(lgraph)
```

Input Arguments

`imageSize` — Network input image size

2-element vector | 3-element vector

Network input image size, specified as a:

- 2-element vector in the format [*height*, *width*].
- 3-element vector in the format [*height*, *width*, *depth*]. *depth* is the number of image channels. Set *depth* to `3` for RGB images, `1` for grayscale images, or to the number of channels for multispectral and hyperspectral images.

`numClasses` — Number of classes

integer greater than 1

Number of classes in the semantic segmentation, specified as an integer greater than 1.

`model` — Pretrained network model

`'vgg16'` | `'vgg19'`

Pretrained network model, specified as `'vgg16'` or `'vgg19'`. These models have an encoder depth of 5. When you use a `'vgg16'` model, you must specify RGB inputs. You can convert grayscale images to RGB using the `im2gray` function.

`encoderDepth` — Encoder depth

positive integer

Encoder depth, specified as a positive integer.

SegNet is composed of an encoder and corresponding decoder subnetwork. The depth of these networks determines the number of times the input image is downsampled or upsampled as it is processed. The encoder network downsamples the input image by a factor of 2^D, where D is the value of `encoderDepth`. The decoder network upsamples the encoder network output by a factor of 2^D.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'NumConvolutionLayers',1`

`NumConvolutionLayers` — Number of convolutional layer sections
2 (default) | positive integer | vector of positive integers

Number of convolutional layers in each encoder and decoder section, specified as a positive integer or vector of positive integers.

`NumConvolutionLayers`	Description
scalar	The same number of layers is used for all encoder and decoder sections.
vector	The *k*th element of `NumConvolutionLayers` is the number of convolution layers in the *k*th encoder section and corresponding decoder section. Typical values are in the range [1, 3].

`NumOutputChannels` — Number of output channels
64 (default) | positive integer | vector of positive integers

Number of output channels for each section in the SegNet encoder network, specified as a positive integer or vector of positive integers. `segnetLayers` sets the number of output channels in the decoder to match the corresponding encoder section.

`NumOutputChannels`	Description
scalar	The same number of output channels is used for all encoder and decoder sections.
vector	The *k*th element of `NumOutputChannels` is the number of output channels of the *k*th encoder section and corresponding decoder section.

`FilterSize` — Convolutional layer filter size
3 (default) | positive odd integer | 2-element row vector of positive odd integers

Convolutional layer filter size, specified as a positive odd integer or a 2-element row vector of positive odd integers. Typical values are in the range [3, 7].

`FilterSize`	Description
scalar	The filter is square.
2-element row vector	The filter has the size [*height width*].

Output Arguments

`lgraph` — Layers

`LayerGraph` object

Layers that represent the SegNet network architecture, returned as a `layerGraph` object.

Tips

- The sections within the SegNet encoder and decoder subnetworks are made up of convolutional, batch normalization, and ReLU layers.
- All convolutional layers are configured such that the bias term is fixed to zero.
- Convolution layer weights in the encoder and decoder subnetworks are initialized using the `'MSRA'` weight initialization method. For `'vgg16'` or `'vgg19'` models, only the decoder subnetwork is initialized using MSRA.[1]
- Networks produced by `segnetLayers` support GPU code generation for deep learning once they are trained with `trainNetwork`. See “Generate Code and Deploy Deep Neural Networks” (Deep Learning Toolbox) for details and examples.

Version History

Introduced in R2017b

R2026a: Removed

Errors starting in R2026a

The `segnetLayers` function has been removed. To update your code, create a `dlnetwork` instead. You can use functions such as `addLayers` and `connectLayers` to build the network.

R2024b: Warns

Warns starting in R2024b

The `segnetLayers` function issues a warning that it will be removed in a future release. To update your code, create a `dlnetwork` instead. You can use functions such as `addLayers` and `connectLayers` to build the network.

Do not include output layers in the network. Instead, define a loss function. Here are some sample loss functions appropriate for pixel classification:

```
function loss = modelLoss(Y,T)
  z = generalizedDice(Y,T);
  loss = 1 - mean(z,"all");
end

function loss = modelLoss(Y,T)
  mask = ~isnan(T);
  targets(isnan(T)) = 0;
  loss = crossentropy(Y,T,Mask=mask);
end
```

Specify the loss function when you train the network using the `trainnet` function. For example, this code trains a `dlnetwork` network called `net` using the training data `images` and the loss function `modelLoss`.

```
netTrained = trainnet(images,net,@modelLoss,options);
```

R2024a: To be removed
Not recommended starting in R2024a

The `segnetLayers` function will be removed in a future release. For supported semantic segmentation networks, see “Get Started with Semantic Segmentation Using Deep Learning”.

Extended Capabilities

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

For code generation, you must first create a SegNet network by using the `segnetLayers` function. Then, use the `trainNetwork` function on the resulting `lgraph` object to train the network for segmentation. Once the network is trained and evaluated, you can generate code for the `DAGNetwork` object using GPU Coder.

unetLayers

(Removed) Create U-Net layers for semantic segmentation

Note `unetLayers` has been removed. Use the `unet` function instead. For more information, see "Version History".

Syntax

```
lgraph = unetLayers(imageSize,numClasses)
[lgraph,outputSize] = unetLayers(imageSize,numClasses)
___ = unetLayers(imageSize,numClasses,Name,Value)
```

Description

`lgraph = unetLayers(imageSize,numClasses)` returns a U-Net network. `unetLayers` includes a pixel classification layer in the network to predict the categorical label for every pixel in an input image.

Use `unetLayers` to create the U-Net network architecture. You must train the network using the Deep Learning Toolbox function `trainNetwork`.

`[lgraph,outputSize] = unetLayers(imageSize,numClasses)` also returns the size of the output size from the U-Net network.

`___ = unetLayers(imageSize,numClasses,Name,Value)` specifies options using one or more name-value pair arguments. For example, `unetLayers(imageSize,numClasses,'NumFirstEncoderFilters',64)` additionally sets the number of output channels to `64` for the first encoder stage.

Examples

Create U-Net Network with Custom Encoder-Decoder Depth

Create a U-Net network with an encoder-decoder depth of 3.

```
imageSize = [480 640 3];
numClasses = 5;
encoderDepth = 3;
lgraph = unetLayers(imageSize,numClasses,'EncoderDepth',encoderDepth)
```

```
lgraph =
  LayerGraph with properties:

     InputNames: {'ImageInputLayer'}
    OutputNames: {'Segmentation-Layer'}
         Layers: [46x1 nnet.cnn.layer.Layer]
```

```
    Connections: [48x2 table]
```

Train U-Net

Load training images and pixel labels into the workspace.

```
dataSetDir = fullfile(toolboxdir('vision'),'visiondata','triangleImages');
imageDir = fullfile(dataSetDir,'trainingImages');
labelDir = fullfile(dataSetDir,'trainingLabels');
```

Define the class names and their associated label IDs.

```
classNames = ["triangle","background"];
labelIDs   = [255 0];
```

Create an `imageDatastore` object to store the training images. Create a `pixelLabelDatastore` object to store the ground truth pixel labels for the training images. Then, combine the datastores for training the network.

```
imds = imageDatastore(imageDir);
pxds = pixelLabelDatastore(labelDir,classNames,labelIDs);
ds = combine(imds,pxds);
```

Create the U-Net network.

```
imageSize = [32 32];
numClasses = 2;
lgraph = unetLayers(imageSize,numClasses)
```

```
lgraph =
  LayerGraph with properties:

         Layers: [58×1 nnet.cnn.layer.Layer]
    Connections: [61×2 table]
     InputNames: {'ImageInputLayer'}
    OutputNames: {'Segmentation-Layer'}
```

Set training options.

```
options = trainingOptions('sgdm', ...
    'InitialLearnRate',1e-3, ...
    'MaxEpochs',20, ...
    'VerboseFrequency',10);
```

Train the network.

```
net = trainNetwork(ds,lgraph,options)
```

```
Training on single CPU.
Initializing input data normalization.

|========================================================================================|
```

```
net =
  DAGNetwork with properties:

         Layers: [58×1 nnet.cnn.layer.Layer]
    Connections: [61×2 table]
     InputNames: {'ImageInputLayer'}
    OutputNames: {'Segmentation-Layer'}
```

Input Arguments

`imageSize` — Network input image size

2-element vector | 3-element vector

Network input image size, specified as a:

- 2-element vector in the form [*height*, *width*].
- 3-element vector in the form [*height*, *width*, *depth*]. *depth* is the number of image channels. Set *depth* to 3 for RGB images, to 1 for grayscale images, or to the number of channels for multispectral and hyperspectral images.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`numClasses` — Number of classes

integer greater than 1

Number of classes in the semantic segmentation, specified as an integer greater than 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `"EncoderDepth",3`

`EncoderDepth` — Encoder depth

4 (default) | positive integer

Encoder depth, specified as a positive integer. U-Net is composed of an encoder subnetwork and a corresponding decoder subnetwork. The depth of these networks determines the number of times the input image is downsampled or upsampled during processing. The encoder network downsamples the input image by a factor of 2^D, where D is the value of `EncoderDepth`. The decoder network upsamples the encoder network output by a factor of 2^D.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`NumFirstEncoderFilters` — Number of output channels for first encoder

32 (default) | positive integer

Number of output channels for the first encoder stage, specified as a positive integer or vector of positive integers. In each subsequent encoder stage, the number of output channels doubles. The `unetLayers` function sets the number of output channels in each decoder stage to match the number in the corresponding encoder stage.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`FilterSize` — Convolutional layer filter size
3 (default) | positive odd integer | 2-element row vector of positive odd integers

Convolutional layer filter size, specified as a positive odd integer or a 2-element row vector of positive odd integers. Typical values are in the range [3, 7].

`FilterSize`	Description
scalar	The filter is square.
2-element row vector	The filter has the size [*height width*].

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ConvolutionPadding` — Type of padding
`'same'` (default) | `'valid'`

Type of padding, specified as `'same'` or `'valid'`. The type of padding specifies the padding style for the `convolution2dLayer` in the encoder and the decoder subnetworks. The spatial size of the output feature map depends on the type of padding. If you specify type of padding as:

- `'same'` — Zero padding is applied to the inputs to convolution layers such that the output and input feature maps are the same size.
- `'valid'` — Zero padding is not applied to the inputs to convolution layers. The convolution layer returns only values of the convolution that are computed without zero padding. The output feature map is smaller than the input feature map.

Note To ensure that the *height* and *width* of the inputs to max-pooling layers are even, choose the network input image size to confirm to any one of these criteria:

- If you specify `'ConvolutionPadding'` as `'same'`, then the *height* and *width* of the input image must be a multiple of 2^D.
- If you specify `'ConvolutionPadding'` as `'valid'`, then the *height* and *width* of the input image must be chosen such that $\frac{1}{2^D}\left(height - \sum_{i=1}^{D} 2^i(f_h - 1)\right)$ and $\frac{1}{2^D}\left(width - \sum_{i=1}^{D} 2^i(f_w - 1)\right)$ are multiples of 2^D.

  where f_h and f_w are the height and width of the two-dimensional convolution kernel, respectively. D is the encoder depth.

Data Types: `char` | `string`

Output Arguments

`lgraph` — Layers
`layerGraph` object

Layers that represent the U-Net network architecture, returned as a `layerGraph` object.

`outputSize` — Network output image size
three-element vector

Network output image size, returned as a three-element vector of the form [*height*, *width*, *channels*]. *channels* is the number of output channels and it is equal to the number of classes specified at the input. The *height* and *width* of the output image from the network depend on the type of padding convolution.

- If you specify `'ConvolutionPadding'` as `'same'`, then the *height* and *width* of the network output image are the same as that of the network input image.
- If you specify `'ConvolutionPadding'` as `'valid'`, then the *height* and *width* of the network output image are less than that of the network input image.

Data Types: `double`

More About

U-Net Architecture

- The U-Net architecture consists of an encoder subnetwork and decoder subnetwork that are connected by a bridge section.
- The encoder and decoder subnetworks in the U-Net architecture consists of multiple stages. `EncoderDepth`, which specifies the depth of the encoder and decoder subnetworks, sets the number of stages.
- The stages within the U-Net encoder subnetwork consist of two sets of convolutional and ReLU layers, followed by a 2-by-2 max pooling layer. The decoder subnetwork consists of a transposed convolution layer for upsampling, followed by two sets of convolutional and ReLU layers.
- The bridge section consists of two sets of convolution and ReLU layers.
- The bias term of all convolutional layers is initialized to zero.
- Convolution layer weights in the encoder and decoder subnetworks are initialized using the `'He'` weight initialization method [2].

Tips

- Use `'same'` padding in convolution layers to maintain the same data size from input to output and enable the use of a broad set of input image sizes.
- Use patch-based approaches for seamless segmentation of large images. You can extract image patches by using the `randomPatchExtractionDatastore` function.
- Use `'valid'` padding to prevent border artifacts while you use patch-based approaches for segmentation.
- You can use the network created using `unetLayers` function for GPU code generation after training with `trainNetwork`. For details and examples, see “Generate Code and Deploy Deep Neural Networks” (Deep Learning Toolbox).

Version History

Introduced in R2018b

R2026a: Removed
Errors starting in R2026a

The `unetLayers` function has been removed. Use the `unet` function instead.

R2024b: Warns
Warns starting in R2024b

The `unetLayers` function issues a warning that it will be removed in a future release. Use the `unet` function instead. The `unet` function returns a `dlnetwork` object, which has these advantages over `layerGraph` objects:

- `dlnetwork` objects support a wider range of network architectures which you can then easily train using the `trainnet` function or import from external platforms.
- `dlnetwork` objects provide more flexibility. They have wider support with current and upcoming Deep Learning Toolbox functionality.
- `dlnetwork` objects provide a unified data type that supports network building, prediction, built-in training, compression, and custom training loops.
- `dlnetwork` training and prediction is typically faster than `DAGNetwork` and `SeriesNetwork` training and prediction.

To update your code, replace instances of the `unetLayers` function with the `unet` function. If you want to use a custom or pretrained encoder network, specify the `EncoderNetwork` name-value argument.

Discouraged Usage	Recommended Replacement

This example uses the `unetLayers` function to create a U-Net network, returned as a `LayerGraph` object.
 	
`imageSize = [480 640 3];`
`numClasses = 5;`
`encoderDepth = 3;`
`lgraph = unetLayers(imageSize,numClasses,EncoderDepth=encoderDepth)`
	Here is equivalent code that instead uses the `unet` function to create a U-Net network, which is returned as a `dlnetwork` object.
	
	`imageSize = [480 640 3];`
	`numClasses = 5;`
	`encoderDepth = 3;`
	`unetNetwork = unet(imageSize,numClasses,EncoderDepth=`

R2024a: To be removed
Not recommended starting in R2024a

The `unetLayers` function will be removed in a future release.

R2019b: `NumOutputChannels` argument in `unetLayers` is renamed to `NumFirstEncoderFilters`
Not recommended starting in R2019b

`unetLayers` argument `NumOutputChannels` is renamed to `NumFirstEncoderFilters`. `NumOutputChannels` will not be supported in a future release. Use `NumFirstEncoderFilters` instead. To update your code, replace all instances of `NumOutputChannels` with `NumFirstEncoderFilters`.

Extended Capabilities

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

You can use the U-Net network for code generation. First, create the network using the `unetLayers` function. Then, use the `trainNetwork` function to train the network for segmentation. After training and evaluating the network, you can generate code for the `DAGNetwork` object by using GPU Coder.

unet3dLayers

(Removed) Create 3-D U-Net layers for semantic segmentation of volumetric images

Note `unet3dLayers` has been removed

Use the `unet3d` function instead. For more information, see “Version History”.

Syntax

```
lgraph = unet3dLayers(inputSize,numClasses)
[lgraph,outputSize] = unet3dLayers(inputSize,numClasses)
[___] = unet3dLayers(inputSize,numClasses,Name,Value)
```

Description

`lgraph = unet3dLayers(inputSize,numClasses)` returns a 3-D U-Net network. `unet3dLayers` includes a pixel classification layer in the network to predict the categorical label for each pixel in an input volumetric image.

Use `unet3dLayers` to create the network architecture for 3-D U-Net. Train the network using the Deep Learning Toolbox function `trainNetwork`.

`[lgraph,outputSize] = unet3dLayers(inputSize,numClasses)` also returns the size of an output volumetric image from the 3-D U-Net network.

`[___] = unet3dLayers(inputSize,numClasses,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in previous syntax.

Examples

Create 3-D U-Net Network with Custom Encoder-Decoder Depth

Create a 3-D U-Net network with an encoder-decoder depth of 2. Specify the number of output channels for the first convolution layer as 16.

```
imageSize = [128 128 128 3];
numClasses = 5;
encoderDepth = 2;
lgraph = unet3dLayers(imageSize,numClasses, ...
    'EncoderDepth',encoderDepth,'NumFirstEncoderFilters',16)
```

```
lgraph =
  LayerGraph with properties:

         Layers: [40×1 nnet.cnn.layer.Layer]
    Connections: [41×2 table]
     InputNames: {'ImageInputLayer'}
    OutputNames: {'Segmentation-Layer'}
```

Use the deep learning network analyzer to visualize the 3-D U-Net network.

```
analyzeNetwork(lgraph);
```

The first convolution layers in encoder stages 1 and 2 have 16 and 32 output channels, respectively. The second convolution layers in encoder stages 1 and 2 have 32 and 64 output channels, respectively.

Input Arguments

`inputSize` — Network input image size

three-element vector | four-element vector

Network input image size representing a volumetric image, specified as one of these values:

- Three-element vector of the form [*height width depth*]
- Four-element vector of the form [*height width depth channel*]. *channel* denotes the number of image channels.

Note Network input image size must be chosen such that the dimension of the inputs to the max-pooling layers must be even numbers.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`numClasses` — Number of classes

scalar greater than 1

Number of classes to segment, specified as a scalar greater than 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `unet3dLayers(inputSize,numClasses,'EncoderDepth',4)`

`EncoderDepth` — Encoder depth

3 (default) | positive integer

Encoder depth, specified as a positive integer. The 3-D U-Net network is composed of an encoder subnetwork and a corresponding decoder subnetwork. The depth of the network determines the number of times the input volumetric image is downsampled or upsampled during processing. The encoder network downsamples the input volumetric image by a factor of 2^D, where D is the value of `EncoderDepth`. The decoder network upsamples the encoder network output by a factor of 2^D. The depth of the decoder subnetwork is same as that of the encoder subnetwork.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`NumFirstEncoderFilters` — Number of output channels for first convolution layer
32 (default) | positive integer

Number of output channels for the first convolution layer in the first encoder stage, specified as a positive integer. The number of output channels for the second convolution layer and the convolution layers in the subsequent encoder stages is set based on this value.

Given stage = {1, 2, ..., *EncoderDepth*}, the number of output channels for the first convolution layer in each encoder stage is equal to

$2^{stage-1}$ `NumFirstEncoderFilters`

The number of output channels for the second convolution layer in each encoder stage is equal to

2^{stage} `NumFirstEncoderFilters`

The `unet3dLayers` function sets the number of output channels for convolution layers in the decoder stages to match the number in the corresponding encoder stage.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`FilterSize` — Size of 3-D convolution filter
3 (default) | positive scalar integer | three-element row vector of positive integers

Size of the 3-D convolution filter, specified as a positive scalar integer or a three-element row vector of positive integers of the form $[f_h \ f_w \ f_d]$. Typical values for filter dimensions are in the range [3, 7].

If you specify `FilterSize` as a positive scalar integer of value *a*, then the convolution kernel is of uniform size `[a a a]`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ConvolutionPadding` — Type of padding
`'same'` (default) | `'valid'`

Type of padding, specified as `'same'` or `'valid'`. The type of padding specifies the padding style for the `convolution3dLayer` in the encoder and the decoder subnetworks. The spatial size of the output feature map depends on the type of padding. Specify one of these options:

- `'same'` — Zero padding is applied to the inputs to convolution layers such that the output and input feature maps are the same size.
- `'valid'` — Zero padding is not applied to the inputs to convolution layers. The convolution layer returns only values of the convolution that are computed without zero padding. The output feature map is smaller than the input feature map.

.

Note To ensure that the *height*, *width*, and *depth* values of the inputs to max-pooling layers are even, choose the network input image size to confirm to any one of these criteria:

- If you specify `'ConvolutionPadding'` as `'same'`, then the *height*, *width*, and *depth* of the input volumetric image must be a multiple of 2^D.

- If you specify `'ConvolutionPadding'` as `'valid'`, then the *height*, *width*, and *depth* of the input volumetric image must be chosen such that $\frac{1}{2^D}\left(height - \sum_{i=1}^{D} 2^i(f_h - 1)\right)$, $\frac{1}{2^D}\left(width - \sum_{i=1}^{D} 2^i(f_w - 1)\right)$, and $\frac{1}{2^D}\left(depth - \sum_{i=1}^{D} 2^i(f_d - 1)\right)$ are multiples of 2^D.

  where f_h, f_w and f_d are the height, width, and depth of the three-dimensional convolution kernel, respectively. D is the encoder depth.

Data Types: `char` | `string`

Output Arguments

`lgraph` — Layers

`layerGraph` object

Layers that represent the 3-D U-Net network architecture, returned as a `layerGraph` object.

`outputSize` — Network output image size

four-element vector

Network output image size, returned as a four-element vector of the form [*height*, *width*, *depth*, *channels*]. *channels* is the number of output channels and is equal to the number of classes specified at the input. The *height*, *width*, and *depth* of the output image from the network depend on the type of padding convolution.

- If you specify `ConvolutionPadding` as `'same'`, then the *height*, *width*, and *depth* of the network output image are the same as that of the network input image.
- If you specify `ConvolutionPadding` as `'valid'`, then the *height*, *width*, and *depth* of the network output image are less than that of the network input image.

Data Types: `double`

More About

3-D U-Net Architecture

- The 3-D U-Net architecture consists of an encoder subnetwork and decoder subnetwork that are connected by a bridge section.
- The encoder and decoder subnetworks in the 3-D U-Net architecture consist of multiple stages. `EncoderDepth`, which specifies the depth of the encoder and decoder subnetworks, sets the number of stages.
- Each encoder stage in the 3-D U-Net network consists of two sets of convolutional, batch normalization, and ReLU layers. The ReLU layer is followed by a 2-by-2-by-2 max pooling layer. Likewise, each decoder stage consists of a transposed convolution layer for upsampling, followed by two sets of convolutional, batch normalization, and ReLU layers.
- The bridge section consists of two sets of convolution, batch normalization, and ReLU layers.
- The bias term of all convolution layers is initialized to zero.

- Convolution layer weights in the encoder and decoder subnetworks are initialized using the `'He'` weight initialization method.

Tips

- Use `'same'` padding in convolution layers to maintain the same data size from input to output and enable the use of a broad set of input image sizes.
- Use patch-based approaches for seamless segmentation of large images. You can extract image patches by using the `randomPatchExtractionDatastore` function.
- Use `'valid'` padding in convolution layers to prevent border artifacts while you use patch-based approaches for segmentation.

Version History

Introduced in R2019b

R2026a: Removed

Errors starting in R2026a

The `unet3dLayers` function has been removed. Use the `unet3d` function instead.

R2024b: Warns

Warns starting in R2024b

The `unet3dLayers` function issues a warning that it will be removed in a future release. Use the `unet3d` function instead. The `unet3d` function returns a `dlnetwork` object, which has these advantages over `layerGraph` objects:

- `dlnetwork` objects support a wider range of network architectures which you can then easily train using the `trainnet` function or import from external platforms.
- `dlnetwork` objects provide more flexibility. They have wider support with current and upcoming Deep Learning Toolbox functionality.
- `dlnetwork` objects provide a unified data type that supports network building, prediction, built-in training, compression, and custom training loops.
- `dlnetwork` training and prediction is typically faster than `DAGNetwork` and `SeriesNetwork` training and prediction.

To update your code, replace instances of the `unet3dLayers` function with the `unet3d` function. If you want to use a custom or pretrained encoder network, specify the `EncoderNetwork` name-value argument.

Discouraged Usage	Recommended Replacement

This example uses the `unet3dLayers` function to create a 3-D U-Net network, returned as a `LayerGraph` object.
 	
`imageSize = [128 128 128 3];`
`numClasses = 5;`
`encoderDepth = 2;`
`lgraph = unet3dLayers(imageSize,numClasses,EncoderDepth=encoderDepth,`
`    NumFirstEncoderFilters=16)`
	Here is equivalent code that instead uses the `u3dnet` function to create a U-Net network, is returned as a `dlnetwork` object.
	
	`imageSize = [128 128 128 3];`
	`numClasses = 5;`
	`encoderDepth = 2;`
	`unet3dNetwork = u3dnet(imageSize,numClasses,EncoderDe`
	`    NumFirstEncoderFilters=16);`

R2024a: To be removed
Not recommended starting in R2024a

The `unet3dLayers` function will be removed in a future release.

countEachLabel

Count occurrence of pixel or box labels

Syntax

```
counts = countEachLabel(ds)
```

Description

`counts = countEachLabel(ds)` returns a table containing information about the pixel or box labels and count for the input datastore, `ds`.

Examples

Count Unique Labels in Datastore

Load a table that contains bounding boxes with labels for vehicles.

```
load('vehicleTrainingData.mat');
```

Load a table that contains bounding boxes with labels for stop signs and cars.

```
load('stopSignsAndCars.mat');
```

Combine ground truth boxes and labels, excluding the image filenames in the first column.

```
vehiclesTbl  = vehicleTrainingData(:,2:end);
stopSignsTbl = stopSignsAndCars(:,2:end);
```

Create a boxLabelDatastore using 2 tables, one with vehicle label data and the other with stop signs label data.

```
blds = boxLabelDatastore(vehiclesTbl,stopSignsTbl);
tbl = countEachLabel(blds)
```

```
tbl=4×3 table
     Label      Count    ImageCount
    ________    _____    __________

    vehicle      336        295
    stopSign      42         41
    carRear       10          9
    carFront       9          8
```

Create a histogram plot using the labels and the respective label counts.

```
histogram('Categories',tbl.Label,'BinCounts',tbl.Count);
```

Create another histogram overlaying the respective image counts.

```
hold on;
histogram('Categories',tbl.Label,'BinCounts',tbl.ImageCount);
```

Input Arguments

`ds` — Datastore with labeled data

`PixelLabelDatastore` object | `boxLabelDatastore` object

Datastore with labeled data for training a semantic segmentation network or an object detection network, specified as a `pixelLabelDatastore` or `boxLabelDatastore` object.

Output Arguments

`counts` — Label information

table

Label information, returned as a table. The labeled data table contain three variables.

For `pixelLabelDatastore` inputs, the `counts` output contains:

Pixel Count Variables	Description
`Name`	Pixel label class name
`PixelCount`	Number of pixels in class
`ImagePixelCount`	Total number of pixels in images that had an instance of the class

For `boxLabelDatastore` inputs, the `counts` output table contains:

Box Count Variables	Description
`Label`	Box label class name
`Count`	Total number of labels of the class across all images
`ImageCount`	Total number of images that contain one or more instances of the class

Tips

The output of `countEachLabel` can be used to calculate class weights for class balancing. For example, for labeled pixel data information in `tbl`:

- Uniform class balancing weights each class such that each contains a uniform prior probability:

  ```
  numClasses = height(tbl)
  prior = 1/numClasses;
  classWeights = prior./tbl.PixelCount
  ```

- Inverse frequency balancing weights each class such that underrepresented classes are given higher weight:

  ```
  totalNumberOfPixels = sum(tbl.PixelCount)
  frequency = tbl.PixelCount / totalNumberOfPixels;
  classWeights = 1./frequency
  ```

- Median frequency balancing weights each class using the median frequency. The weight for each class is defined as median(*imageFreq*)/*imageFreq*(c), where *imageFreq*(c) represents the number of pixels of the class divided by the total number of pixels in images that had an instance of the class (c):

  ```
  imageFreq = tbl.PixelCount ./ tbl.ImagePixelCount
  classWeights = median(imageFreq) ./ imageFreq
  ```

When training the network using `trainnet`, you can pass the calculated class weights to the loss function. For an example, see “Semantic Segmentation Using Deep Learning”.

reset

Reset label datastore to initial state

Syntax

```
reset(ds)
```

Description

`reset(ds)` resets the label datastore specified by `ds` to the state where no data has been read from it. Resetting the datastore enables you to read from it again.

Input Arguments

`ds` — Datastore with labeled data

`PixelLabelDatastore` object | `boxLabelDatastore` object

Datastore with labeled data for training a semantic segmentation network or an object detection network, specified as a `pixelLabelDatastore` or `boxLabelDatastore` object.

Version History

Introduced in R2017b

See Also

`trainnet` | `pixelLabelDatastore` | `boxLabelDatastore`

readimage

Read specified pixel label data file

Syntax

```
C = readimage(pxds,k)
[C,info] = readimage(pxds,k)
```

Description

`C = readimage(pxds,k)` returns the k`th` file in the pixel label datastore specified by `pxds`.

`[C,info] = readimage(pxds,k)` also returns information about the extracted data in `info`, including metadata.

Input Arguments

pxds — Input pixel label datastore

`PixelLabelDatastore` object

Input pixel label datastore, specified as a `PixelLabelDatastore` object.

k — File number

positive integer

File number to read from the pixel label datastore, specified as a positive integer.

Output Arguments

C — Output data

categorical matrix

Output data, returned as a categorical matrix.

info — Information about read data

structure array

Information about read data, returned as a structure array. The structure array can contain the following fields.

Field Name	Description
`Filename`	Fully resolved path containing the path string, name of the file, and file extension.
`FileSize`	Total file size, in bytes.

Version History

Introduced in R2017b

See Also

`datastore`

readall

Read all data in label datastore

Syntax

```
data = readall(ds)
```

Description

`data = readall(ds)` returns all the data contained in the label datastore specified by `ds`.

If all the data in the datastore does not fit in memory, then `readall` returns an error.

Input Arguments

ds — Datastore with labeled data

`PixelLabelDatastore` object | `boxLabelDatastore` object

Datastore with labeled data for training a semantic segmentation network or an object detection network, specified as a `pixelLabelDatastore` or `boxLabelDatastore` object.

Output Arguments

data — Output data

cell array of categorical matrices | *M*-by-2 cell array | table

Output data, returned as an *M*-by-2 cell array, cell array of categorical matrices, or a table.

Datastore	Output Description
`PixelLabelDatastore`	Table with `MiniBatchSize` number of rows. For the last batch of data in the datastore, `numObservations` must be divisible by `MiniBatchSize` or `read` returns a partial batch containing all the remaining observations in the datastore.
`boxLabelDatastore`	*N*-by-2 cell matrix. *N* must be less than or equal to `ReadSize(ds)`. The first column must be a cell vector that contains bounding boxes. Each element in the cell vector contains *M*-by-4 matrices in the format [*x*,*y*,*width*,*height*]. The second column must be a cell vector that contains the label names corresponding to each bounding box. Label names are represented as an *M*-by-1 categorical vector.

partition

Partition label datastore

Syntax

```
subds = partition(ds,N,index)

subds = partition(ds,'Files',fileIndex)
subds = partition(ds,'Files',filename)
```

Description

`subds = partition(ds,N,index)` partitions a datastore `ds` into *N* parts and returns the partition corresponding to `index`.

`subds = partition(ds,'Files',fileIndex)` partitions the `PixelLabelDatastore` by files. The partitioned datastore corresponds to the `index` in the `Files` property of the datastore.

`subds = partition(ds,'Files',filename)` partitions the `PixelLabelDatastore` by files. The partitioned datastore corresponds to the file specified by `filename`.

Examples

Partition a Datastore

Load training data that contains bounding boxes with labels for vehicles.

```
data = load('vehicleTrainingData.mat');
trainingData = data.vehicleTrainingData;
blds = boxLabelDatastore(trainingData(:,2:end));
```

Use the `partition` function to partition the box label datastore. The output contains the first 5 rows of the training data.

```
subds = partition(blds,59,5);
```

Read the data. Use the `hasdata` function to check for data.

```
while hasdata(subds)
      % Read one row of box labels at a time
      bxLabels = read(subds);
end
```

Input Arguments

ds — Datastore with labeled data

`PixelLabelDatastore` object | `boxLabelDatastore` object

Datastore with labeled data for training a semantic segmentation network or an object detection network, specified as a `pixelLabelDatastore` or `boxLabelDatastore` object.

`N` — Number of partitions

positive integer

Number of partitions to divide datastore, specified as a positive integer. To obtain an estimate for a reasonable number of partitions, use the `numpartitions` function.

```
numWorkers = 3;
p = parpool('local',numWorkers);
n = numpartitions(ds,p);

parfor ii=1:n
    subds = partition(ds,n,ii);
    while hasdata(subds)
        data = read(subds);
    end
end
```

Example: 3

Data Types: `double`

`index` — Index

positive integer

Index, specified as an integer. The index points to a partitioned datastore of the `N` number of partitioned datastores.

Example: 1

Data Types: `double`

`fileIndex` — File index

positive integer

File index of a file stored within the `Files` property of a `pixelLabelDatastore`, specified as a positive integer.

Example: 1

Data Types: `double`

`filename` — Filename

character vector

Filename, specified as a character vector.

Example: `'file1.csv'`

Example: `'../dir/data/file1.csv'`

Example: `'hdfs://myserver:7867/data/file1.txt'`

Data Types: `char`

Output Arguments

subds — Output datastore
`datastore` object

Output datastore, returned as a datastore object. The output datastore is of the same type as the input datastore, `ds`.

Version History

Introduced in R2017b

See Also

`trainnet` | `boxLabelDatastore` | `pixelLabelDatastore`

numpartitions

Number of partitions for label datastore

Syntax

```
N = numpartitions(ds)
N = numpartitions(ds,pool)
```

Description

`N = numpartitions(ds)` returns the default number of partitions for a label datastore `ds`.

`N = numpartitions(ds,pool)` returns the number of partitions needed to parallelize datastore access over the parallel pool specified by `pool`. To parallelize datastore access, you must have Parallel Computing Toolbox installed.

Input Arguments

`ds` — Datastore with labeled data
`PixelLabelDatastore` object | `boxLabelDatastore` object

Datastore with labeled data for training a semantic segmentation network or an object detection network, specified as a `pixelLabelDatastore` or `boxLabelDatastore` object.

`pool` — Parallel pool
parallel pool object

Parallel pool object.

Example: `gcp`

hasdata

Determine if data is available to read from label datastore

Syntax

```
tf = hasdata(ds)
```

Description

`tf = hasdata(ds)` returns logical `1` (`true`) if there is data available to read from the datastore specified by `ds`. Otherwise, it returns logical `0` (`false`).

Examples

Determine Pixel Data Available to Read

Check if pixel label data can be read from a datastore.

Set the location of the image and pixel label data.

```
dataDir = fullfile(toolboxdir('vision'),'visiondata');
imDir = fullfile(dataDir,'building');
pxDir = fullfile(dataDir,'buildingPixelLabels');
```

Create an image and pixel label datastore.

```
imds = imageDatastore(imDir);
classNames = ["sky" "grass" "building" "sidewalk"];
pixelLabelID = [1 2 3 4];
pxds = pixelLabelDatastore(pxDir,classNames,pixelLabelID);
```

While data is available in the datastore, read the data.

```
while hasdata(pxds)
    T = read(pxds);
end
```

Input Arguments

ds — Datastore with labeled data

`PixelLabelDatastore` object | `boxLabelDatastore` object

Datastore with labeled data for training a semantic segmentation network or an object detection network, specified as a `pixelLabelDatastore` or `boxLabelDatastore` object.

Output Arguments

tf — Datastore data status

`1` | `0`

Datastore data status, returned as a logical `1` (`true`) if there is data available to read from the datastore specified by `ds`. Otherwise, it returns logical `0` (`false`).

Version History

Introduced in R2017b

`trainnet` | `pixelLabelDatastore` | `boxLabelDatastore`

semanticseg

Semantic image segmentation using deep learning

Syntax

```
C = semanticseg(I,network)
[C,score,allScores] = semanticseg(I,network)
[___] = semanticseg(I,network,roi)

pxds = semanticseg(ds,network)

[___] = semanticseg(___,Name=Value)
```

Description

`C = semanticseg(I,network)` returns a semantic segmentation of the input image using deep learning.

`[C,score,allScores] = semanticseg(I,network)` also returns the classification scores for each categorical label in `C`. The function returns the scores in an array that corresponds to each pixel or voxel in the input image.

`[___] = semanticseg(I,network,roi)` returns a semantic segmentation for a rectangular subregion of the input image.

`pxds = semanticseg(ds,network)` returns the semantic segmentation for a collection of images in `ds`, a datastore object.

The function supports parallel computing using multiple MATLAB workers. You can enable parallel computing using the “Computer Vision Toolbox Preferences” dialog.

`[___] = semanticseg(___,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `ExecutionEnvironment="gpu"` sets the hardware resource for processing images to `gpu`.

Examples

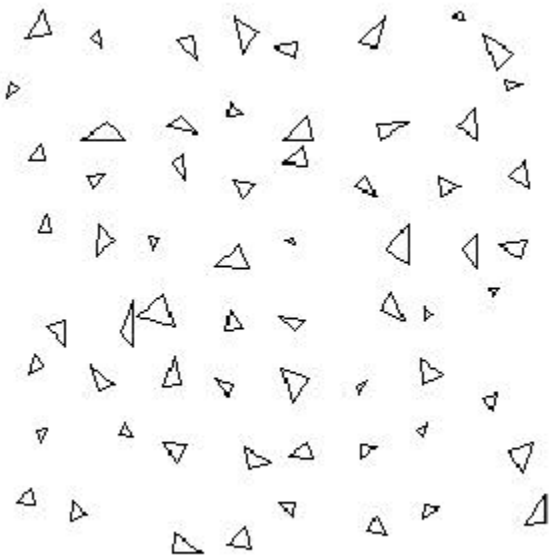
Semantic Image Segmentation

Perform semantic segmentation of a test image and display the results.

Load a pretrained network.

```
load("triangleSegmentationNetwork")
```

List the network layers.



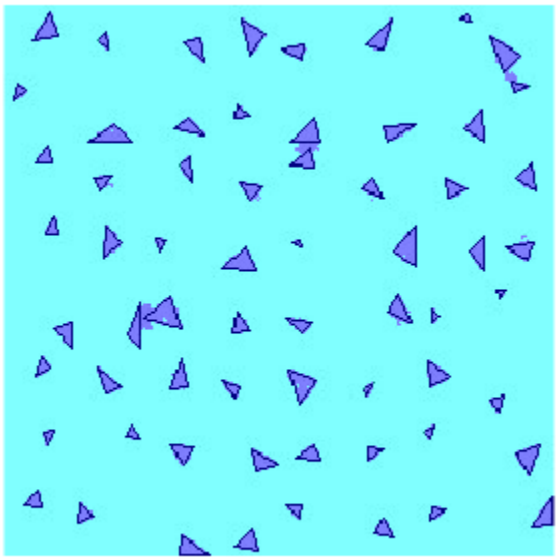
```
net.Layers
```

```
ans =
  9×1 Layer array with layers:
```

```
     1   'imageinput'        Image Input                  32×32×1 images with 'zerocenter' norma
     2   'conv_1'            2-D Convolution              64 3×3×1 convolutions with stride [1  
     3   'relu_1'            ReLU                         ReLU
     4   'maxpool'           2-D Max Pooling              2×2 max pooling with stride [2  2] and
     5   'conv_2'            2-D Convolution              64 3×3×64 convolutions with stride [1
     6   'relu_2'            ReLU                         ReLU
     7   'transposed-conv'   2-D Transposed Convolution   64 4×4×64 transposed convolutions with
     8   'conv_3'            2-D Convolution              2 1×1×64 convolutions with stride [1  
     9   'softmax'           Softmax                      Softmax
```

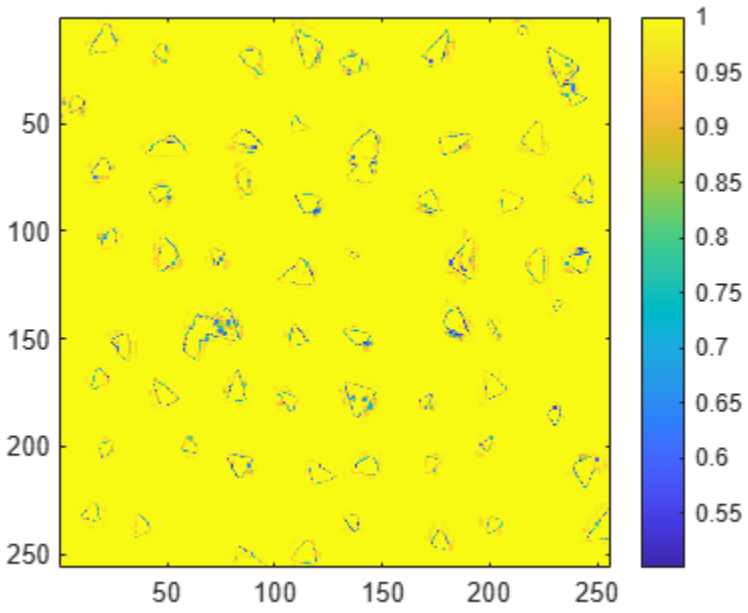
Read and display the test image.

```
I = imread("triangleTest.jpg");
imshow(I)
```



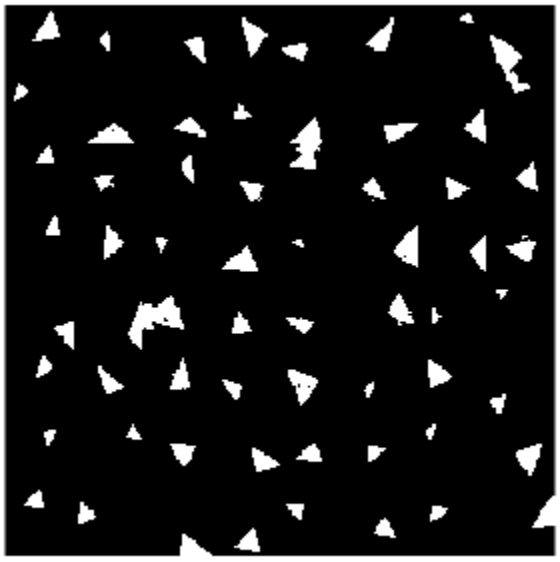
Define the two classes on which the network was trained, then perform semantic image segmentation.

```
classNames = ["triangle" "background"];
[C,scores] = semanticseg(I,net,Classes=classNames,MiniBatchSize=32);
```



Overlay segmentation results on the image and display the results.

```
B = labeloverlay(I,C);
imshow(B)
```



Display the classification confidence scores.

```
imagesc(scores)
axis square
colorbar
```

Create a binary mask with only the triangles.

```
BW = C=="triangle";
imshow(BW)
```

Evaluate Semantic Segmentation Test Set

Run semantic segmentation on a test set of images and compare the results against ground truth data.

Load a pretrained network.

```
data = load("triangleSegmentationNetwork");
net = data.net;
```

Load test images using `imageDatastore`.

```
dataDir = fullfile(toolboxdir("vision"),"visiondata","triangleImages");
testImageDir = fullfile(dataDir,"testImages");
imds = imageDatastore(testImageDir)
```

```
imds =
  ImageDatastore with properties:

                      Files: {
                             ' ...\toolbox\vision\visiondata\triangleImages\testImages\image_001
                             ' ...\toolbox\vision\visiondata\triangleImages\testImages\image_002
                             ' ...\toolbox\vision\visiondata\triangleImages\testImages\image_003
                              ... and 97 more
                             }
                    Folders: {
                             'B:\runnable\matlab\toolbox\vision\visiondata\triangleImages\testIm
                             }
    AlternateFileSystemRoots: {}
                   ReadSize: 1
```

```
                  Labels: {}
      SupportedOutputFormats: ["png"    "jpg"    "jpeg"    "tif"    "tiff"]
         DefaultOutputFormat: "png"
                    ReadFcn: @readDatastoreImage
```

Load ground truth test labels.

```
testLabelDir = fullfile(dataDir,"testLabels");
classNames = ["triangle" "background"];
pixelLabelID = [255 0];
pxdsTruth = pixelLabelDatastore(testLabelDir,classNames,pixelLabelID);
```

Run semantic segmentation on all of the test images with a batch size of 4. You can increase the batch size to increase throughput based on your systems memory resources.

```
pxdsResults = semanticseg(imds,net,Classes=classNames, ...
    MiniBatchSize=4,WriteLocation=tempdir);
```

```
Running semantic segmentation network
-------------------------------------
* Processed 100 images.
```

Compare the results against the ground truth.

```
metrics = evaluateSemanticSegmentation(pxdsResults,pxdsTruth)
```

```
Evaluating semantic segmentation results
----------------------------------------
* Selected metrics: global accuracy, class accuracy, IoU, weighted IoU, BF score.
* Processed 100 images.
* Finalizing... Done.
* Data set metrics:

    GlobalAccuracy    MeanAccuracy    MeanIoU    WeightedIoU    MeanBFScore
    ______________    ____________    _______    ___________    ___________

       0.99074          0.99183       0.91118      0.98299        0.80563

metrics =
  semanticSegmentationMetrics with properties:

              ConfusionMatrix: [2×2 table]
    NormalizedConfusionMatrix: [2×2 table]
               DataSetMetrics: [1×5 table]
                 ClassMetrics: [2×3 table]
                 ImageMetrics: [100×5 table]
```

Semantic Segmentation Using Dilated Convolutions

This example shows how to train a semantic segmentation network using dilated convolutions.

A semantic segmentation network classifies every pixel in an image, resulting in an image that is segmented by class. Applications for semantic segmentation include road segmentation for

autonomous driving and cancer cell segmentation for medical diagnosis. To learn more, see “Get Started with Semantic Segmentation Using Deep Learning”.

Semantic segmentation networks like Deeplab v3+ [1 on page 3-417] make extensive use of dilated convolutions (also known as atrous convolutions) because they can increase the receptive field of the layer (the area of the input which the layers can see) without increasing the number of parameters or computations.

Load Training Data

The example uses a simple dataset of 32-by-32 triangle images for illustration purposes. The dataset includes accompanying pixel label ground truth data. Load the training data using an `imageDatastore` and a `pixelLabelDatastore`.

```
dataFolder = fullfile(toolboxdir("vision"),"visiondata","triangleImages");
imageFolderTrain = fullfile(dataFolder,"trainingImages");
labelFolderTrain = fullfile(dataFolder,"trainingLabels");
```

Create an `imageDatastore` for the images.

```
imdsTrain = imageDatastore(imageFolderTrain);
```

Create a `pixelLabelDatastore` for the ground truth pixel labels.

```
classNames = ["triangle" "background"];
labels = [255 0];
pxdsTrain = pixelLabelDatastore(labelFolderTrain,classNames,labels)
```

```
pxdsTrain =
  PixelLabelDatastore with properties:

                      Files: {200×1 cell}
                 ClassNames: {2×1 cell}
                   ReadSize: 1
                    ReadFcn: @readDatastoreImage
    AlternateFileSystemRoots: {}
```

Create Semantic Segmentation Network

This example uses a simple semantic segmentation network based on dilated convolutions.

Create a data source for training data and get the pixel counts for each label.

```
ds = combine(imdsTrain,pxdsTrain);
tbl = countEachLabel(pxdsTrain)
```

```
tbl=2×3 table
      'triangle'     10326    204800
    'background'    194474    204800
```

The majority of pixel labels are for background. This class imbalance biases the learning process in favor of the dominant class. To fix this, use class weighting to balance the classes. You can use several methods to compute class weights. One common method is inverse frequency weighting where the class weights are the inverse of the class frequencies. This method increases the weight given to under represented classes. Calculate the class weights using inverse frequency weighting.

```
numberPixels = sum(tbl.PixelCount);
frequency = tbl.PixelCount / numberPixels;
classWeights = dlarray(1 ./ frequency,"C");
```

Create a network for pixel classification by using an image input layer with an input size corresponding to the size of the input images. Next, specify three blocks of convolution, batch normalization, and ReLU layers. For each convolutional layer, specify 32 3-by-3 filters with increasing dilation factors and pad the inputs so they are the same size as the outputs by setting the `Padding` name-value argument as `"same"`. To classify the pixels, include a convolutional layer with K 1-by-1 convolutions, where K is the number of classes, followed by a softmax layer. The classification of pixels is done with a custom model loss within the built-in trainer, `trainnet`.

```
inputSize = [32 32 1];
filterSize = 3;
numFilters = 32;
numClasses = numel(classNames);

layers = [
    imageInputLayer(inputSize)

    convolution2dLayer(filterSize,numFilters,DilationFactor=1,Padding="same")
    batchNormalizationLayer
    reluLayer

    convolution2dLayer(filterSize,numFilters,DilationFactor=2,Padding="same")
    batchNormalizationLayer
    reluLayer

    convolution2dLayer(filterSize,numFilters,DilationFactor=4,Padding="same")
    batchNormalizationLayer
    reluLayer

    convolution2dLayer(1,numClasses)
    softmaxLayer];
```

Model Loss Function

The semantic segmentation network can be trained using different loss functions. The built-in trainer `trainnet` (Deep Learning Toolbox) supports custom loss functions as well as some standard loss functions such as "crossentropy" and "mse". A custom loss function manually computes the loss for each batch of training data by comparing the network's predictions to the actual ground truth or target values. Custom loss functions use a function handle with the function syntax *loss = f(Y1,...,Yn,T1,...,Tm)*, where Y1,...,Yn are `dlarray` objects that correspond to the n network predictions and *T1*,...,*Tm* are `dlarray` objects that correspond to the *m* targets.

This example enables you to select from two different loss functions that account for the class imbalance seen in the data. These loss functions are:

1. Weighted cross-entropy loss, which uses the `crossentropy` (Deep Learning Toolbox) function. Weighted cross-entropy loss gives stronger favor to the underrepresented class by scaling the error of that class during training.
2. A custom loss function called `tverskyLoss` that calculates the Tversky loss [2 on page 3-417]. Tversky loss is more specialized loss for class imbalance.

The Tversky loss is based on the Tversky index for measuring overlap between two segmented images. The Tversky index TI_c between one image Y and the corresponding ground truth T is given by

$$\mathrm{TI}_c = \frac{\sum_{m=1}^{M} Y_{\mathrm{cm}} T_{\mathrm{cm}}}{\sum_{m=1}^{M} Y_{\mathrm{cm}} T_{\mathrm{cm}} + \alpha \sum_{m=1}^{M} Y_{\mathrm{cm}} T_{\bar{c}m} + \beta \sum_{m=1}^{M} Y_{\bar{c}m} T_{\mathrm{cm}}}$$

- c corresponds to the class and $\bar{c}$ corresponds to not being in class c.
- M is the number of elements along the first two dimensions of Y.
- α and β are weighting factors that control the contribution that false positives and false negatives for each class make to the loss.

The loss L over the number of classes C is given by

$$L = \sum_{c=1}^{C} 1 - \mathrm{TI}_c$$

Select the loss function to use during training.

```
lossFunction = Tversky Loss
```

```
lossFunction =
"tverskyLoss"
```

```
if strcmp(lossFunction,"tverskyLoss")
    % Declare Tversky loss weighting coefficients for false positives and
    % false negatives. These coefficients are set and passed to the
    % training loss function using trainnet.
    alpha = 0.7;
    beta = 0.3;
    lossFcn = @(Y,T) tverskyLoss(Y,T,alpha,beta);
else
    % Use weighted cross-entropy loss during training.
    lossFcn = @(Y,T) crossentropy(Y,T,classWeights,NormalizationFactor="all-elements");
end
```

Train Network

Specify the training options.

```
options = trainingOptions("sgdm",...
    MaxEpochs=100,...
    MiniBatchSize= 64,...
    InitialLearnRate=1e-2,...
    Verbose=false);
```

Train the network using `trainnet` (Deep Learning Toolbox). Specify the loss as the loss function `lossFcn`.

```
net = trainnet(ds,layers,lossFcn,options);
```

Test Network

Load the test data. Create an `imageDatastore` for the images. Create a `pixelLabelDatastore` for the ground truth pixel labels.

```
imageFolderTest = fullfile(dataFolder,"testImages");
imdsTest = imageDatastore(imageFolderTest);
labelFolderTest = fullfile(dataFolder,"testLabels");
pxdsTest = pixelLabelDatastore(labelFolderTest,classNames,labels);
```

Make predictions using the test data and trained network.

```
pxdsPred = semanticseg(imdsTest,net,...
    Classes=classNames,...
    MiniBatchSize=32,...
    WriteLocation=tempdir);
```

```
Running semantic segmentation network
-------------------------------------
* Processed 100 images.
```

Evaluate the prediction accuracy using `evaluateSemanticSegmentation`.

```
metrics = evaluateSemanticSegmentation(pxdsPred,pxdsTest);
```

```
Evaluating semantic segmentation results
----------------------------------------
* Selected metrics: global accuracy, class accuracy, IoU, weighted IoU, BF score.
* Processed 100 images.
* Finalizing... Done.
* Data set metrics:

    GlobalAccuracy    MeanAccuracy    MeanIoU    WeightedIoU    MeanBFScore
    ______________    ____________    _______    ___________    ___________

       0.99674           0.98562       0.96447      0.99362        0.92831
```

Segment New Image

Read the test image `triangleTest.jpg` and segment the test image using `semanticseg`. Display the results using `labeloverlay`.

```
imgTest = imread("triangleTest.jpg");
[C,scores] = semanticseg(imgTest,net,classes=classNames);

B = labeloverlay(imgTest,C);
montage({imgTest,B})
```

Supporting Functions

```
function loss = tverskyLoss(Y,T,alpha,beta)
    % loss = tverskyLoss(Y,T,alpha,beta) returns the Tversky loss
    % between the predictions Y and the training targets T.

    Pcnot = 1-Y;
    Gcnot = 1-T;
    TP = sum(sum(Y.*T,1),2);
    FP = sum(sum(Y.*Gcnot,1),2);
    FN = sum(sum(Pcnot.*T,1),2);

    epsilon = 1e-8;
    numer = TP + epsilon;
    denom = TP + alpha*FP + beta*FN + epsilon;

    % Compute tversky index.
    lossTIc = 1 - numer./denom;
    lossTI = sum(lossTIc,3);

    % Return average Tversky index loss.
    N = size(Y,4);
    loss = sum(lossTI)/N;
end
```

Input Arguments

`I` — Input image

numeric array

Input image, specified as one of the following.

Image Type	Data Format
Single 2-D grayscale image	2-D matrix of size *H*-by-*W*
Single 2-D color image or 2-D multispectral image	3-D array of size *H*-by-*W*-by-*C*. The number of color channels *C* is 3 for color images.
Series of *P* 2-D images	4-D array of size *H*-by-*W*-by-*C*-by-*P*. The number of color channels *C* is 1 for grayscale images and 3 for color images.
Single 3-D grayscale image with depth *D*	3-D array of size *H*-by-*W*-by-*D*
Single 3-D color image or 3-D multispectral image	4-D array of size *H*-by-*W*-by-*D*-by-*C*. The number of color channels *C* is 3 for color images.
Series of *P* 3-D images	5-D array of size *H*-by-*W*-by-*D*-by-*C*-by-*P*

The input image can also be a `gpuArray` containing one of the preceding image types (requires Parallel Computing Toolbox).

Data Types: `uint8` | `uint16` | `int16` | `double` | `single` | `logical`

`network` — Network

`dlnetwork` object | `taylorPrunableNetwork` object

Network, specified as a `dlnetwork` or `taylorPrunableNetwork` object.

`roi` — Region of interest

4-element numeric vector | 6-element vector

Region of interest, specified as one of the following.

Image Type	ROI Format
2-D image	4-element vector of the form [*x*,*y*,*width*,*height*]
3-D image	6-element vector of the form [*x*,*y*,*z*,*width*,*height*,*depth*]

The vector defines a rectangular or cuboidal region of interest fully contained in the input image. Image pixels outside the region of interest are assigned the `<undefined>` categorical label. If the input image consists of a series of images, then `semanticseg` applies the same `roi` to all images in the series.

Note When using the `roi` argument, the semantic segmentation network must produce an output size that matches the size of the specified ROI. If your network cannot produce an output of this size,

manually crop the input image to the desired ROI using the `imcrop` function, and then process the cropped image with `semanticseg`.

`ds` — Collection of images
datastore object

Collection of images, specified as a datastore. The `read` function of the datastore must return a numeric array, cell array, or table. For cell arrays or tables with multiple columns, the function processes only the first column.

For more information, see “Datastores for Deep Learning” (Deep Learning Toolbox).

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `ExecutionEnvironment="gpu"` sets the hardware resource for processing images to `"gpu"`.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

`OutputType` — Returned segmentation type
`"categorical"` (default) | `"double"` | `"uint8"`

Returned segmentation type, specified as `"categorical"`, `"double"`, or `"uint8"`. When you specify `"double"` or `"uint8"`, the function returns the segmentation results as a label array containing label IDs. The IDs are integer values that correspond to the class names defined in the classification layer used in the input network.

You cannot use the `OutputType` property with an `ImageDatastore` object input.

`MiniBatchSize` — Group of images
128 (default) | integer

Group of images, specified as an integer. Images are grouped and processed together as a batch. Batches are used for processing a large collection of images and they improve computational efficiency. Increasing the '`MiniBatchSize`' value increases the efficiency, but it also takes up more memory.

`ExecutionEnvironment` — Hardware resource
`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource for processing images with a network, specified as `"auto"`, `"gpu"`, or `"cpu"`.

`ExecutionEnvironment`	Description
`"auto"`	Use a GPU if available. Otherwise, use the CPU. The use of GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox).

ExecutionEnvironment	Description
"gpu"	Use the GPU. If a suitable GPU is not available, the function returns an error message.
"cpu"	Use the CPU.

Acceleration — Performance optimization
"auto" (default) | "mex" | "none"

Performance optimization, specified as "auto", "mex", or "none".

Acceleration	Description
"auto"	Automatically apply a number of optimizations suitable for the input network and hardware resource.
"mex"	Compile and execute a MEX function. This option is available when using a GPU only. You must also have a C/C++ compiler installed. For setup instructions, see “Set Up Compiler” (GPU Coder).
"none"	Disable all acceleration.

The default option is "auto". If you use the "auto" option, then MATLAB does not ever generate a MEX function.

Using the Acceleration name-value argument options "auto" and "mex" can offer performance benefits, but at the expense of an increased initial run time. Subsequent calls with compatible parameters are faster. Use performance optimization when you plan to call the function multiple times using new input data.

The "mex" option generates and executes a MEX function based on the network and parameters used in the function call. You can have several MEX functions associated with a single network at one time. Clearing the network variable also clears any MEX functions associated with that network.

The "mex" option is only available when you are using a GPU. Using a GPU requires Parallel Computing Toolbox and a CUDA enabled NVIDIA GPU. For information about the supported compute capabilities, see “GPU Computing Requirements” (Parallel Computing Toolbox). If Parallel Computing Toolbox or a suitable GPU is not available, then the function returns an error.

"mex" acceleration does not support all layers. For a list of supported layers, see “Supported Layers” (GPU Coder).

Classes — Classes into which pixels or voxels are classified
"auto" (default) | cell array of character vectors | string vector | categorical vector

Classes into which pixels or voxels are classified, specified as "auto", a cell array of character vectors, a string vector, or a categorical vector. If the value is a categorical vector *Y*, then the elements of the vector are sorted and ordered according to categories(Y).

If the network is a dlnetwork object, then the number of classes specified by 'Classes' must match the number of channels in the output of the network predictions. By default, when 'Classes' has the value "auto", the classes are numbered from 1 through *C*, where *C* is the number of channels in the output layer of the network.

If the network is a SeriesNetwork or DAGNetwork object, then the number of classes specified by the Classes name-value argument must match the number of classes in the classification output

layer. By default, when `Classes` has the value `"auto"`, the classes are automatically set using the classification output layer.

`WriteLocation` — Folder location
`pwd` (current working folder) (default) | string scalar | character vector

Folder location, specified as `pwd` (your current working folder), a string scalar, or a character vector. The specified folder must exist and have write permissions.

This property applies only when using a datastore that can process images.

`NamePrefix` — Prefix applied to output filenames
`"pixelLabel"` (default) | string scalar | character vector

Prefix applied to output filenames, specified as a string scalar or character vector. The image files are named as follows:

- *<prefix>*`_`*<N>*`.png`, where *N* corresponds to the index of the input image file, `imds.Files`(*N*).

This property applies only when using a datastore that can process images.

`OutputFolderName` — Output folder name
`"semanticsegOutput"` (default) | string scalar | character vector

Output folder name for segmentation results, specified as a string scalar or a character vector. This folder is in the location specified by the value of the `WriteLocation` name-value argument.

If the output folder already exists, the function creates a new folder with the string `"_1"` appended to the end of the name. Set `OutputFoldername` to `""` to write all the results to the folder specified by `WriteLocation`.

`NameSuffix` — Suffix to add to the output image filename
string scalar | character vector

Suffix to add to the output image filename, specified as a string scalar or a character vector. The function appends the specified suffix to the output filename as:

- *<prefix>*`_`*<N>*`<`*suffix*`>.png`, where *N* corresponds to the index of the input image file, `imds.Files`(*N*).

If you do not specify the suffix, the function uses the input filenames as the output file suffixes. The function extracts the input filenames from the `info` output of the `read` object function of the datastore. When the datastore does not provide the filename, the function does not add a suffix.

`Verbose` — Display progress information
`false` or `0` (default) | `true` or `1`

Display progress information, specified as a logical `0` (`false`) or `1` (`true`). Specify `Verbose` as `true` to display progress information. This property applies only when using a datastore that can process images.

Output Arguments

`C` — Categorical labels
categorical array

Categorical labels, returned as a categorical array. The categorical array relates a label to each pixel or voxel in the input image. The images returned by `readall(datastore)` have a one-to-one correspondence with the categorical matrices returned by `readall(pixelLabelDatastore)`. The elements of the label array correspond to the pixel or voxel elements of the input image. If you select an ROI, then the labels are limited to the area within the ROI. Image pixels and voxels outside the region of interest are assigned the `<undefined>` categorical label.

Image Type	Categorical Label Format
Single 2-D image	2-D matrix of size *H*-by-*W*. Element `C`(*i*,*j*) is the categorical label assigned to the pixel `I`(*i*,*j*).
Series of *P* 2-D images	3-D array of size *H*-by-*W*-by-*P*. Element `C`(*i*,*j*,*p*) is the categorical label assigned to the pixel `I`(*i*,*j*,*p*).
Single 3-D image	3-D array of size *H*-by-*W*-by-*D*. Element `C`(*i*,*j*,*k*) is the categorical label assigned to the voxel `I`(*i*,*j*,*k*).
Series of *P* 3-D images	4-D array of size *H*-by-*W*-by-*D*-by-*P*. Element `C`(*i*,*j*,*k*,*p*) is the categorical label assigned to the voxel `I`(*i*,*j*,*k*,*p*).

`score` — Confidence scores

numeric array

Confidence scores for each categorical label in `C`, returned as an array of values between `0` and `1`. The scores represents the confidence in the predicted labels `C`. Higher score values indicate a higher confidence in the predicted label.

Image Type	Score Format
Single 2-D image	2-D matrix of size *H*-by-*W*. Element `score`(*i*,*j*) is the classification score of the pixel `I`(*i*,*j*).
Series of *P* 2-D images	3-D array of size *H*-by-*W*-by-*P*. Element `score`(*i*,*j*,*p*) is the classification score of the pixel `I`(*i*,*j*,*p*).
Single 3-D image	3-D array of size *H*-by-*W*-by-*D*. Element `score`(*i*,*j*,*k*) is the classification score of the voxel `I`(*i*,*j*,*k*).
Series of *P* 3-D images	4-D array of size *H*-by-*W*-by-*D*-by-*P*. Element `score`(*i*,*j*,*k*,*p*) is the classification score of the voxel `I`(*i*,*j*,*k*,*p*).

`allScores` — Scores for all label categories

numeric array

Scores for all label categories that the input network can classify, returned as a numeric array. The format of the array is described in the following table. *L* represents the total number of label categories.

Image Type	All Scores Format
Single 2-D image	3-D array of size *H*-by-*W*-by-*L*. Element `allScores`(*i*,*j*,*q*) is the score of the *q*th label at the pixel `I`(*i*,*j*).
Series of *P* 2-D images	4-D array of size *H*-by-*W*-by-*L*-by-*P*. Element `allScores`(*i*,*j*,*q*,*p*) is the score of the *q*th label at the pixel `I`(*i*,*j*,*p*).
Single 3-D image	4-D array of size *H*-by-*W*-by-*D*-by-*L*. Element `allScores`(*i*,*j*,*k*,*q*) is the score of the *q*th label at the voxel `I`(*i*,*j*,*k*).

Image Type	All Scores Format
Series of *P* 3-D images	5-D array of size *H*-by-*W*-by-*D*-by-*L*-by-*P*. Element `allScores`(*i*,*j*,*k*,*q*,*p*) is the score of the *q*th label at the voxel `I`(*i*,*j*,*k*,*p*).

`pxds` — Semantic segmentation results
`PixelLabelDatastore` object

Semantic segmentation results, returned as a `pixelLabelDatastore` object. The object contains the semantic segmentation results for all the images contained in the `ds` input object. The result for each image is saved as separate `uint8` label matrices of PNG images. You can use `read`(`pxds`) to return the categorical labels assigned to the images in `ds`.

The images in the output of `readall`(`ds`) have a one-to-one correspondence with the categorical matrices in the output of `readall`(`pxds`).

More About

Network Output Size and ROI Input

The output size of a semantic segmentation network is determined by the architecture of its layers, particularly the use of padding in convolutional and pooling layers. Due to these factors, the output size may not always match the input size. In some cases, certain input sizes will produce matching output sizes, while others will not. For example, a network might produce an output of size 100-by-100 pixels for an input of 100-by-100 pixels, but produce an output of 94-by-94 pixels for an input of 95-by-95 pixels.

When specifying a region of interest (ROI) using the `roi` argument, ensure that the network can produce an output that exactly matches the ROI size. If this is not possible, crop the input image to the ROI, and then apply `semanticseg` to the cropped image.

Version History

Introduced in R2017b

R2024a: `DAGNetwork` and `SeriesNetwork` objects are not recommended

Not recommended starting in R2024a

Starting in R2024a, `DAGNetwork` and `SeriesNetwork` objects are not recommended. Instead, specify the semantic segmentation network as a `dlnetwork` object.

There are no plans to remove support for `DAGNetwork` and `SeriesNetwork` objects. However, `dlnetwork` objects have these advantages:

- `dlnetwork` objects support a wider range of network architectures which you can then easily train using the `trainnet` function or import from external platforms.
- `dlnetwork` objects provide more flexibility. They have wider support with current and upcoming Deep Learning Toolbox functionality.
- `dlnetwork` objects provide a unified data type that supports network building, prediction, built-in training, compression, and custom training loops.
- `dlnetwork` training and prediction is typically faster than `DAGNetwork` and `SeriesNetwork` training and prediction.

R2023a: Output file location
Behavior changed in R2023a

The `semanticseg` function now writes output files to the folder specified by the `WriteLocation` and `OutputFolderName` name-value arguments as `<WriteLocation>/<OutputFolderName>`. Prior to R2023a, the function wrote output files directly into the location specified by `WriteLocation`. To get the same results as in previous releases, set the `OutputFolderName` name-value argument to `""`.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- To prepare a `semanticSeg` object for code generation, use `coder.loadDeepLearningNetwork`.
- For code generation, the `semanticSeg` object does not support `imageDatastore` and 3-D images as input.
- For code generation, `ExcecutionEnvironment` and `Acceleration` name value pairs are ignored with compile time warnings.
- For code generation, only `OutputType`, `MiniBatchSize`, and `Classes` name value arguments are supported. These name value arguments must be compile time constants.
- For code generation, `Classes` name value argument does not support string array as input.
- For code generation, `pxds` output argument is not supported.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- To prepare a `semanticSeg` object for code generation, use `coder.loadDeepLearningNetwork`.
- For code generation, the `semanticSeg` object does not support `imageDatastore` and 3-D images as input.
- For code generation, `ExcecutionEnvironment` and `Acceleration` name value pairs are ignored with compile time warnings.
- For code generation, only `OutputType`, `MiniBatchSize`, and `Classes` name value arguments are supported. These name value arguments must be compile time constants.
- For code generation, `Classes` name value argument does not support string array as input.
- For code generation, `pxds` output argument is not supported.

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set `'UseParallel'` to `true` or enable this by default using the Computer Vision Toolbox preferences.

For more information, see “Parallel Computing Toolbox Support”.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU acceleration.

By default, the `semanticseg` function uses a GPU if one is available. You can specify the hardware that the `semanticseg` function uses by setting the `ExecutionEnvironment` argument.

For more information, see “Scale Up Deep Learning in Parallel, on GPUs, and in the Cloud” (Deep Learning Toolbox).

detectKAZEFeatures

Detect KAZE features

Syntax

```
points = detectKAZEFeatures(I)
points = detectKAZEFeatures(I,Name=Value)
```

Description

`points = detectKAZEFeatures(I)` returns a `KAZEPoints` object containing information about KAZE keypoints detected in a 2-D grayscale or binary image. The function uses nonlinear diffusion to construct a scale space for the given image. It then detects multiscale corner features from the scale space.

`points = detectKAZEFeatures(I,Name=Value)` specifies options using one or more name-value arguments in addition to the previous syntax. For example, `detectKAZEFeatures(I,Threshold=0.003)` sets the threshold to exclude less significant local extrema to `0.003`.

Examples

Detect KAZE Point Features in Image

Read an image.

```
I = imread("cameraman.tif");
```

Detect KAZE points in the image.

```
points = detectKAZEFeatures(I);
```

Plot the 20 strongest points.

```
imshow(I)
hold on
plot(selectStrongest(points,20))
hold off
```

Detect KAZE Features and Display Specific Points

Read an image into the workspace.

```
I = imread("cameraman.tif");
```

Detect KAZE features in the image.

```
points = detectKAZEFeatures(I);
```

Select and display the last 5 points detected.

```
imshow(I);
hold on;
plot(points(end-4:end));
hold off;
```

Input Arguments

`I` — Input image

M-by-*N* 2-D grayscale or binary image

Input image, specified as an *M*-by-*N* 2-D grayscale or binary image.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `detectKAZEFeatures(I,Threshold=0.003)` sets the threshold to exclude less significant local extrema to `0.003`.

`Diffusion` — Method to compute conductivity

`"region"` (default) | `"sharpedge"` | `"edge"`

Method to compute conductivity, specified as `"region"`, `"sharpedge"`, or `"edge"`. The computation is based on first-order derivatives of a layer in scale space.

Method	Selected Features
`"region"`	Large regions. Uses the Perona and Malik conductivity coefficient, `1/(1 + dL^2/k^2)`.

Method	Selected Features
`"sharpedge"`	High-contrast edges. Uses the Perona and Malik conductivity coefficient, `exp(-|dL|^2/k^2)`.
`"edge"`	Smoothing on both sides of an edge rather than across it. Uses the Weickert conductivity coefficient.

`Threshold` — Local extrema
`0.0001` (default) | scalar

Local extrema, specified as a scalar greater than or equal to `0`. Increase this value to exclude less significant local extrema.

`NumOctaves` — Multiscale detection factor
3 (default) | positive integer

Multiscale detection factor, specified as a positive integer. Increase this value to detect larger features. To disable multiscale detection, set `NumOctaves` to `1`. When you set the value to `1`, the function performs the detection at the scale of the input image. Recommended values are between 1 and 4.

`NumScaleLevels` — Scale levels
4 (default) | integer

Scale levels, specified as an integer in the range [3,10]. Increase this value to achieve smoother scale changes. Increasing this value also provides additional intermediate scales between octaves.

`ROI` — Rectangular region size
`[1 1 size(I,2) size(I,1)]` (default) | 4-element vector

Rectangular region size for corner detection, specified as a 4-element vector in the format [*y x width height*]. The [*y x*] values are measured from the upper left corner of the rectangle.

Output Arguments

`points` — KAZE points object
`KAZEpoints` object

KAZE points, returned as a `KAZEPoints` object. The object contains information about the point features detected in the 2-D grayscale or binary input image.

Version History

Introduced in R2017b

References

[1] Alcantarilla, P.F., A. Bartoli, and A.J. Davison. "KAZE Features." *ECCV 2012, Part VI, LNCS 7577*. 2012, p. 214

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Generates portable C code using a C++ compiler that links to OpenCV libraries. See “Portable C Code Generation for Functions That Use OpenCV Library”.
- Code generation does not support arrays of point feature objects returned by this function. Instead, use the `Location` property to obtain an *M*-by-2 matrix of coordinates:

  ```
  locations = points.Location;
  ```

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

selectUniform

Select uniformly distributed subset of point features

Syntax

```
pointsOut = selectUniform(pointsIn,N,imageSize)
[pointsOut,indices] = selectUniform(pointsIn,N,imageSize)
```

Description

`pointsOut = selectUniform(pointsIn,N,imageSize)` returns `N` uniformly distributed points with the strongest metrics.

`[pointsOut,indices] = selectUniform(pointsIn,N,imageSize)` returns the indices of the selected points from the input `pointsIn`.

Examples

Select Uniformly Distributed Subset of KAZE Features

Read an image.

```
im = imread("yellowstone_left.png");
```

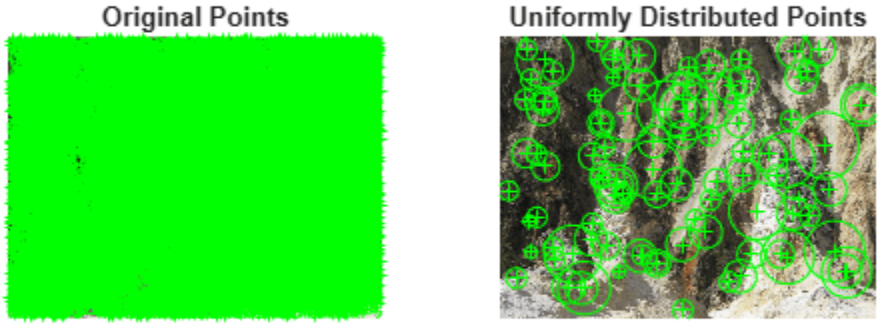
Detect and display KAZE features.

```
points1 = detectKAZEFeatures(im2gray(im))
```

```
points1 =
  6713×1 KAZEPoints array with properties:

       Location: [6713×2 single]
         Metric: [6713×1 single]
          Count: 6713
          Scale: [6713×1 single]
    Orientation: [6713×1 single]
```

```
subplot(1,2,1)
imshow(im)
hold on
plot(points1)
hold off
title("Original Points")
```



Select a uniformly distributed subset of points.

```
numPoints = 100;
points2 = selectUniform(points1,numPoints,size(im))
```

```
points2 =
  100×1 KAZEPoints array with properties:
```

```
       Location: [100×2 single]
         Metric: [100×1 single]
          Count: 100
          Scale: [100×1 single]
    Orientation: [100×1 single]
```

```
subplot(1,2,2)
imshow(im)
hold on
plot(points2)
hold off
title("Uniformly Distributed Points")
```

Select Uniformly Distributed Subset of Harris Features From Image

Load an image.

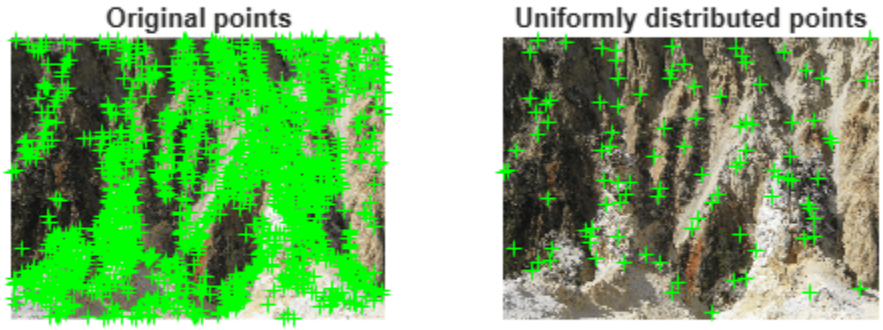
```
im = imread("yellowstone_left.png");
```

Detect many corners by reducing the quality threshold.

```
points1 = detectHarrisFeatures(im2gray(im),MinQuality=0.05);
```

Plot image with detected corners.

```
subplot(1,2,1);
imshow(im);
hold on
plot(points1);
```



```
hold off
title("Original points");
```

Select a uniformly distributed subset of points.

```
numPoints = 100;
points2 = selectUniform(points1,numPoints,size(im));
```

Plot images showing original and subset of points.

```
subplot(1, 2, 2);
imshow(im);
hold on
plot(points2);
hold off
title("Uniformly distributed points");
```

Select A Uniformly Distributed Subset of BRISK Features From Image

Load an image into the workspace.

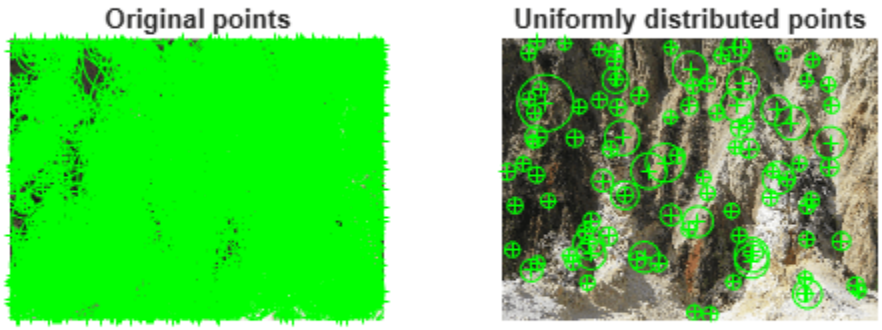
```
im = imread("yellowstone_left.png");
```

Detect many corners by reducing the quality threshold.

```
points1 = detectBRISKFeatures(im2gray(im),MinQuality=0.05);
```

Plot image with detected corners.

```
subplot(1,2,1);
imshow(im);
```



```
hold on
plot(points1);
hold off
title("Original points");
```

Select a uniformly distributed subset of points.

```
numPoints = 100;
points2 = selectUniform(points1,numPoints,size(im));
```

Plot images showing original and subset of points.

```
subplot(1, 2, 2);
imshow(im);
hold on
plot(points2);
hold off
title("Uniformly distributed points");
```

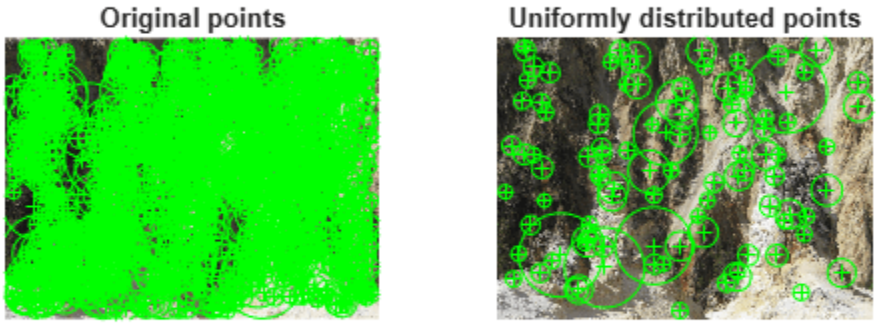
Select Uniformly Distributed Subset of SURF Features from an Image

Load an image.

```
im = imread("yellowstone_left.png");
```

Detect and display SURF features.

```
points1 = detectSURFFeatures(im2gray(im));
subplot(1,2,1);
imshow(im);
hold on
```



```
plot(points1);
hold off
title("Original points");
```

Select a uniformly distributed subset of points.

```
numPoints = 100;
points2 = selectUniform(points1,numPoints,size(im));
```

Plot images showing original and subset of points.

```
subplot(1, 2, 2);
imshow(im);
hold on
plot(points2);
hold off
title("Uniformly distributed points");
```

Input Arguments

`pointsIn` — Points object

point feature object

Points object,specified as an *M*-by-2 matrix of *M* number of [*x* *y*] coordinates, or as one of the point feature objects described in “Point Feature Types”. The object contains information about the point features detected in the input image. To obtain points, use the appropriate detect function that pairs with the point feature type.

`N` — Number of points

integer

Number of uniformly distributed points to select, specified as an integer.

`imageSize` — Size of image
2-element vector | 3-element vector

Size of image, specified as a 2-element vector for grayscale images or a 3-element vector for truecolor images.

Output Arguments

`pointsOut` — Uniformly distributed points
points feature object

Uniformly distributed points, returned as a points feature object.

`indices` — Indices of selected points
N-element vector

Indices of selected points from the input, returned as an *N*-element vector of linear indices into `pointsIn`.

Version History

Introduced in R2012a

R2026a: Function returns indices of selected points

The function can return the indices of selected points from the input.

Functions
`extractFeatures` | `matchFeatures`

Topics
“Point Feature Types”

size

Return size of points object

Syntax

```
sz = size(points)
sz = size(points,1)
sz = size(points,dimension)
[M,N] = size(points)
```

Description

`sz = size(points)` returns the size of the points object. `sz` is defined as the vector `[length(points),1]`.

`sz = size(points,1)` returns the length of `points`.

`sz = size(points,dimension)` returns the length of the points in the specified dimension.

`[M,N] = size(points)` returns `length(points)` for *M* and 1 for *N*

Examples

Find Size of Points Object

Read an image.

```
I = imread('cameraman.tif');
```

Detect corner features.

```
featurePoints = detectHarrisFeatures(I);
```

Find the size of the feature points object.

```
sz = size(featurePoints)
```

```
sz = 1×2

   184     1
```

Plot feature image with detected features.

```
imshow(I); hold on;
plot(featurePoints);
```

Input Arguments

`points` — Points object

point feature object

Points object,specified as one of the point feature objects described in “Point Feature Types”. The object contains information about the feature points detected in the input image. To obtain points, use the appropriate detect function that pairs with the point feature type.

`dimension` — Dimension

integer

Dimension, returned as an integer. For `dim >= 2`, the object returns `1`.

Version History

Introduced in R2012a

selectStrongest

Select points with strongest metrics

Syntax

```
strongestPoints = selectStrongest(pointsIn,N)
[strongestPoints,indices] = selectStrongest(pointsIn,N)
```

Description

`strongestPoints = selectStrongest(pointsIn,N)` returns `N` number of points that have the strongest metrics.

`[strongestPoints,indices] = selectStrongest(pointsIn,N)` returns `N` number of points that have the strongest metrics.

Examples

Select Strongest KAZE Features

Create a `KAZEPoints` object holding 50 points.

```
points = KAZEPoints(ones(50,2),Metric=1:50);
```

Keep the two strongest features.

```
points = selectStrongest(points,2)
```

```
points =
  2×1 KAZEPoints array with properties:

       Location: [2×2 single]
         Metric: [2×1 single]
          Count: 2
          Scale: [2×1 single]
    Orientation: [2×1 single]
```

Input Arguments

`pointsIn` — Points object

M-by-2 matrix | point feature object

Points object,specified as an *M*-by-2 matrix of *M* number of [*x y*] coordinates, or as one of the point feature objects described in “Point Feature Types”. The object contains information about the feature points detected in the input image. To obtain points, use the appropriate detect function that pairs with the point feature type.

`N` — Number of points
integer

Number of strongest points to select, specified as an integer.

Output Arguments

`strongestPoints` — Points object with strongest metrics
M-by-2 matrix | points object

Points object with strongest metrics, returned as an *M*-by-2 matrix or a points object.

`indices` — Indices of selected points
N-element vector

Indices of selected points from the input, returned as an *N*-element vector of linear indices into `pointsIn`.

Version History

Introduced in R2017b

R2026a: Function returns indices of selected points

The function can return the indices of selected points from the input.

plot

Plot detected feature points

Syntax

```
plot(points)
plot(points,ax)
plot(points,ax,Name=Value)
```

Description

`plot(points)` plots detected feature points in the current axis. The input `points` is a feature point object that stores the locations and related information of the detected features.

`plot(points,ax)` displays feature points in the specified axis.

`plot(points,ax,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `plot(ShowOrientation=true)` renders the orientation in the display plot.

Examples

Plot KAZE Points

Read an image.

```
I = imread("cameraman.tif");
```

Detect KAZE points from the image.

```
points = detectKAZEFeatures(I);
```

Extract KAZE features from the detected points.

```
[features,valid_points] = extractFeatures(I,points);
```

Plot the 10 strongest points and show their orientations.

```
imshow(I)
hold on
strongestPoints = selectStrongest(valid_points,10);
plot(strongestPoints,showOrientation=true)
hold off
```

Plot SURF Features

```
I = imread("cameraman.tif");
points = detectSURFFeatures(I);
[features, valid_points] = extractFeatures(I,points);
```

Visualize 10 strongest SURF features, including their scales and orientation which were determined during the descriptor extraction process.

```
imshow(I);
hold on;
strongestPoints = valid_points.selectStrongest(10);
strongestPoints.plot("showOrientation",true);
```

Input Arguments

`points` — Points object

M-by-2 matrix | point feature object

Points object,specified as an *M*-by-2 matrix of *M* number of [*x y*] coordinates, or as one of the point feature objects described in “Point Feature Types”. The object contains information about the feature points detected in the input image. To obtain points, use the appropriate detect function that pairs with the point feature type.

`ax` — Axes handle

handle

Handle to use for display. You can set the handle using `gca`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `plot(ShowOrientation=true)` renders the orientation in the display plot.

`ShowScale` — Display scaled circle

`true` (default) | `false`

Display scaled circle, specified as `true` or `false`. When you set this value to `true`, the object draws a circle proportional to the scale of the detected feature, with the feature point located at its center. When you set this value to `false`, the object turns the display of the circle off.

The algorithm represents the scale of the feature with a circle of `6*Scale` radius. The algorithm uses this equivalent size of circular area to compute the orientation of the feature.

`ShowOrientation` — Display orientation line
`true` (default) | `false`

Display feature point orientation, specified as `true` or `false`. When you set this value to `true`, the object draws a line corresponding to the point's orientation. The object draws the line from the feature point location to the edge of the circle, indicating the scale.

Version History

Introduced in R2011b

Functions
`extractFeatures` | `matchFeatures` | `plot`

plot

Plot points

Syntax

```
plot(points)
plot(points,ax)
```

Description

`plot(points)` plots points in the current axis.

`plot(points,ax)` plots points in the specified axis.

Examples

Plot Corner Features

Read an image.

```
I = imread("cameraman.tif");
```

Detect corner features.

```
featurePoints = detectHarrisFeatures(I);
```

Plot feature image with detected features.

```
imshow(I);
hold on;
plot(featurePoints);
```

Input Arguments

`points` — Points object

M-by-2 matrix | point feature object

Points object,specified as an *M*-by-2 matrix of *M* number of [*x* *y*] coordinates, or as one of the point feature objects described in “Point Feature Types”. The object contains information about the feature points detected in the input image. To obtain points, use the appropriate detect function that pairs with the point feature type.

ax — Axes handle

handle

Handle to use for display. You can set the handle using `gca`.

Functions

`extractFeatures` | `matchFeatures`

plot

Plot parametric model

Syntax

```
plot(model)
plot(model,Name=Value)
H = plot( ___ )
```

Description

`plot(model)` plots a model within the axis limits of the current figure.

`plot(model,Name=Value)` specifies options using one or more name-value arguments in addition to argument from previous syntax. For example, `plot(model,Parent=gca)` sets the color of the plot to red.

`H = plot( ___ )` plots a model and returns a handle `H` to `surf`, a 3-D shaded surface plot or `patch`, a filled polygon region.

Examples

Detect Cylinder in Point Cloud

Load a MAT file containing a point cloud into the workspace.

```
load("object3d.mat");
```

Display the point cloud.

```
figure
pcshow(ptCloud)
title("Detect a Cylinder in a Point Cloud")
```

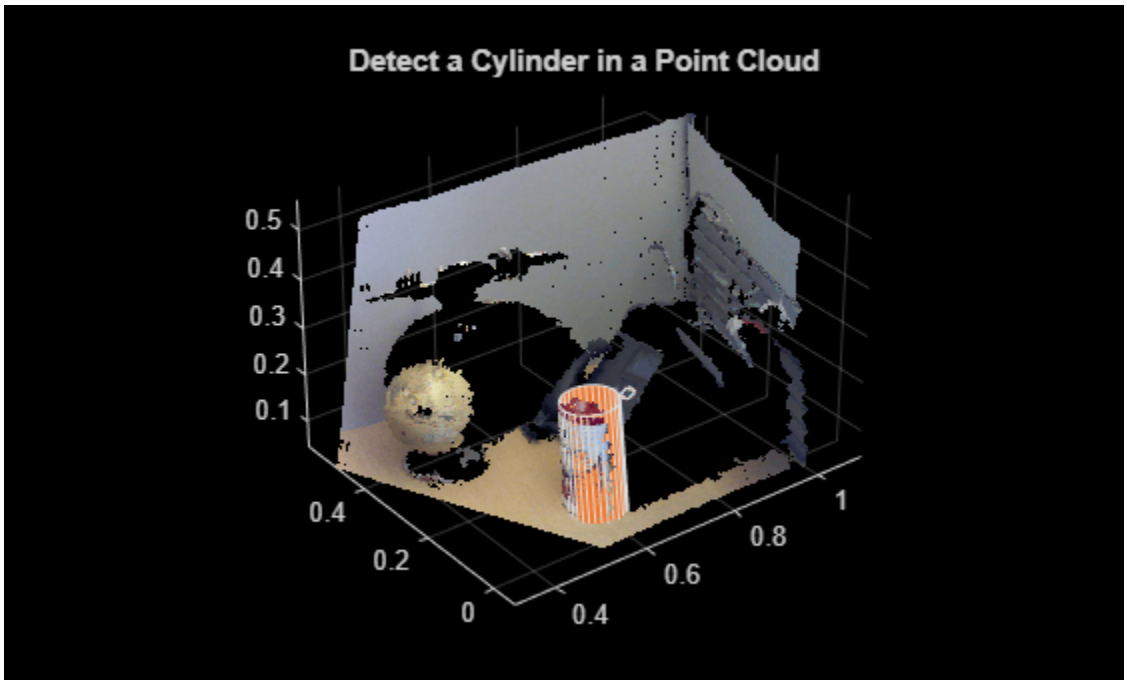
Set the maximum point-to-cylinder distance for cylinder fitting to 5mm.

```
maxDistance = 0.005;
```

Specify a region of interest (ROI) to constrain the fitting function.

```
roi = [0.4 0.6; -inf 0.2; 0.1 inf];
sampleIndices = findPointsInROI(ptCloud,roi);
```

Set the orientation constraint for the fitting function



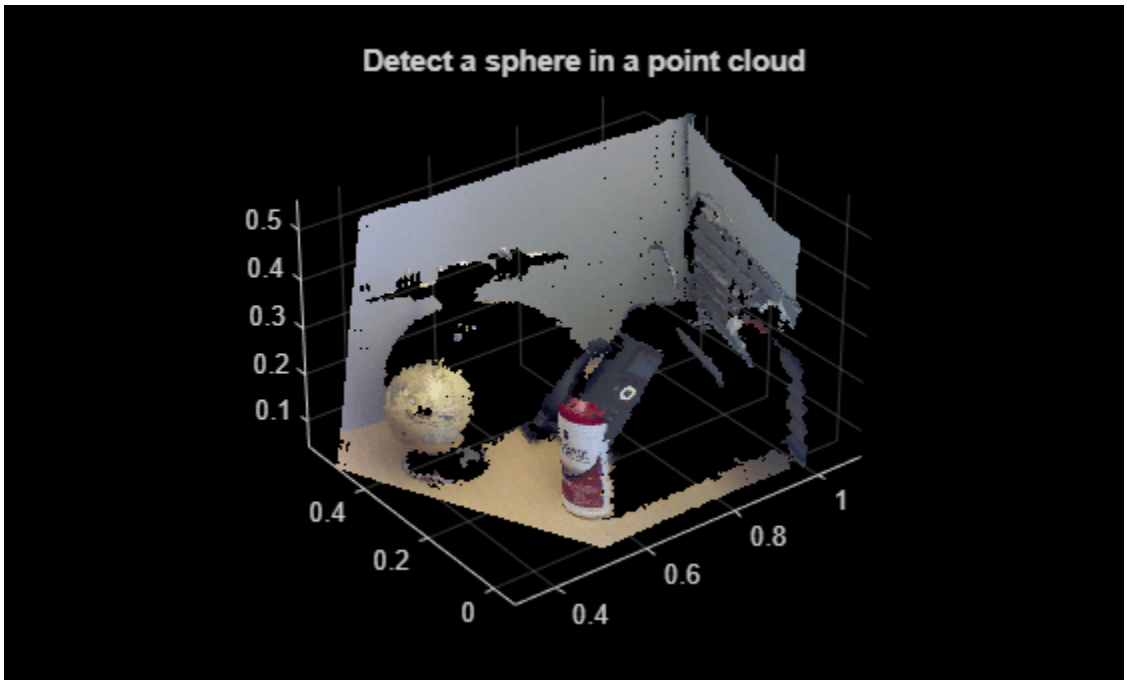
```
referenceVector = [0 0 1];
```

Detect the cylinder in the specified ROI of the point cloud and extract it.

```
model = pcfitcylinder(ptCloud,maxDistance,referenceVector, ...
        SampleIndices=sampleIndices);
```

Plot the model of the detected cylinder.

```
hold on
plot(model)
```



Detect Sphere in Point Cloud

Load a point cloud into the workspace.

```
load("object3d.mat");
```

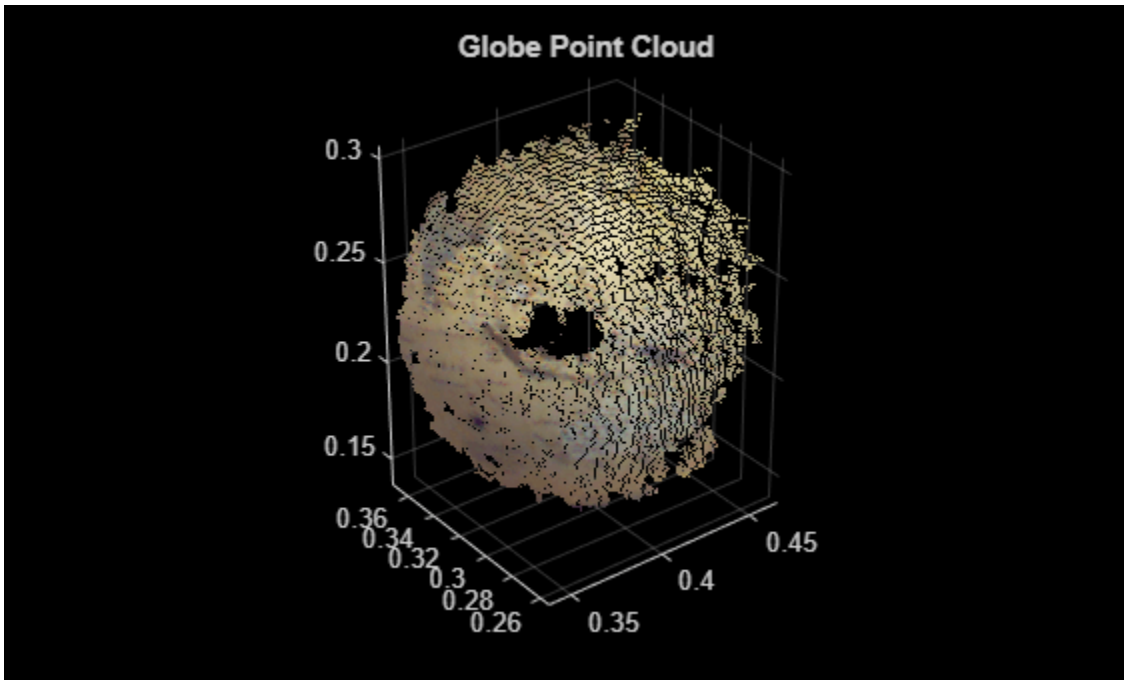
Display the point cloud and label the figure.

```
figure
pcshow(ptCloud)
title("Detect a sphere in a point cloud")
```

Set the maximum point-to-sphere distance for sphere fitting to 1cm.

```
maxDistance = 0.01;
```

Set the region of interest to constrain the search.



```
roi = [-inf,0.5;0.2,0.4;0.1,inf];
sampleIndices = findPointsInROI(ptCloud,roi);
```

Detect the globe in the point cloud and extract it.

```
[model,inlierIndices] = pcfitsphere(ptCloud,maxDistance,SampleIndices=sampleIndices);
globe = select(ptCloud,inlierIndices);
```

Plot the extracted globe.

```
figure
pcshow(globe)
title("Globe Point Cloud")
```

Detect Plane in Point Cloud

Load a MAT file containing a point cloud.

```
load("object3d.mat");
```

Display the point cloud into the workspace.

```
figure
pcshow(ptCloud)
title("Detect a Plane in a Point Cloud")
```

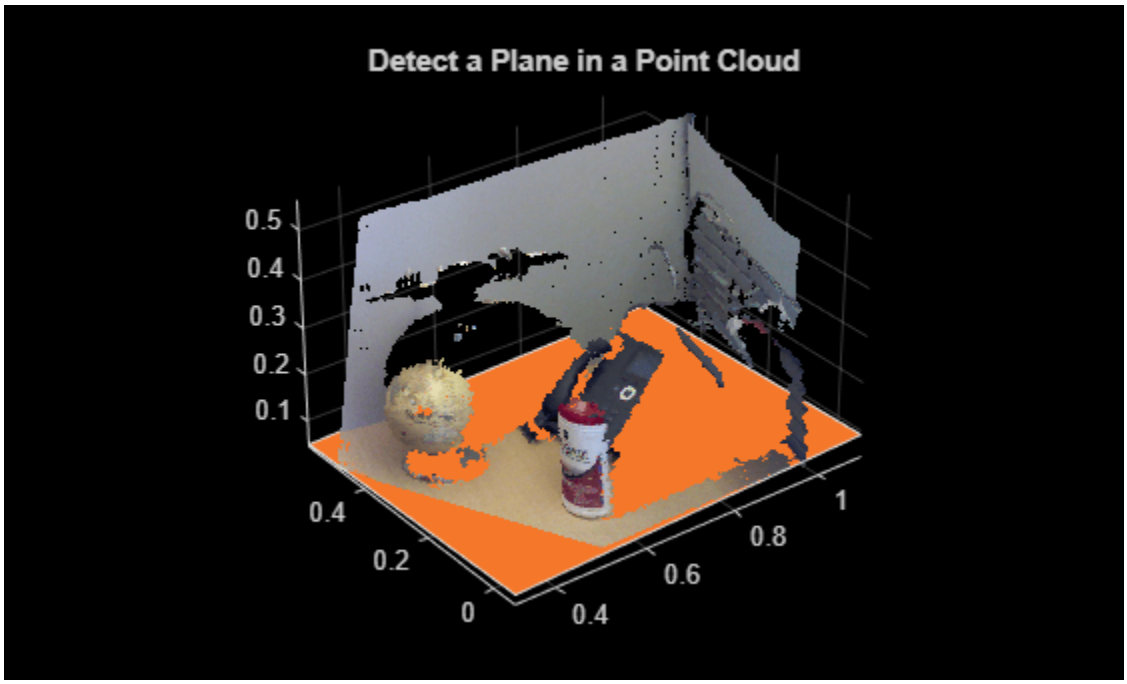
Set the maximum point-to-plane distance for plane fitting to 2cm.

```
maxDistance = 0.02;
```

Specify the normal vector plane for the fitted plane.

```
referenceVector = [0 0 1];
```

Set the maximum angular distance for the fitted plane to 5 degrees.



```
maxAngularDistance = 5;
```

Detect the plane, the table, in the point cloud and extract it.

```
model = pcfitplane(ptCloud,maxDistance,referenceVector,maxAngularDistance);
```

Plot the plane.

```
hold on
plot(model)
```

Input Arguments

`model` — Parametric model
cylinder model object | plane model object | sphere model object

Parametric model returned by the `cylinderModel`, `planeModel`, or the `sphereModel` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `plot(model,Parent=gca)` sets the output axes to the current axes in the current figure.

`Parent` — Output axes
`gca` (default) | `axes`

Output axes, specified as `gca` (the current axes) or `axes` (a custom set axes) for displaying the visualization.

`Color` — Color of the plane
`[245 119 41]` (default) | 1-by-3 RGB vector | short name of color | long name of color

Color of the plane, specified as a 1-by-3 RGB vector or a short or long color name. The default color [245 119 41] is well-suited for visualizing the model when fitting it to point clouds.

Color Name	Short Name	RGB Triplet	Appearance
"red"	"r"	[1 0 0]	
"green"	"g"	[0 1 0]	
"blue"	"b"	[0 0 1]	
"cyan"	"c"	[0 1 1]	
"magenta"	"m"	[1 0 1]	
"yellow"	"y"	[1 1 0]	
"black"	"k"	[0 0 0]	
"white"	"w"	[1 1 1]	

Output Arguments

`H` — Handle to plot

handle

Handle to a plot, returned as a `surf` 3-D shaded surface plot or as a `patch` filled polygon region.

Version History

Introduced in R2015b

length

Number of stored points

Syntax

```
length(points)
```

Description

`length(points)` returns the number of stored points in the points object.

Examples

Check Number of Stored Points

Read an image.

```
I = imread("cameraman.tif");
```

Detect KAZE points from the image.

```
points = detectKAZEFeatures(I);
```

Find number of stored points.

```
numPoints = length(points)
```

```
numPoints =
631
```

Extract KAZE features from the detected points.

```
[features,validPoints] = extractFeatures(I,points);
```

Plot the ten strongest valid extracted points and show their orientations.

```
imshow(I)
hold on
strongestPoints = selectStrongest(validPoints,10);
plot(strongestPoints,showOrientation=true)
hold off
```

Input Arguments

`points` — Points object

point feature object

Points object,specified as one of the point feature objects described in “Point Feature Types”. The object contains information about the feature points detected in the input image. To obtain points, use the appropriate detect function that pairs with the point feature type.

Version History

Introduced in R2017b

isempty

Determine if points object is empty

Syntax

```
isempty(points)
```

Description

`isempty(points)` returns a `true` value, if the points object is empty.

Examples

Check If Points Object Is Empty

Read an image.

```
I = imread('cameraman.tif');
```

Detect KAZE points from the image.

```
points = detectKAZEFeatures(I);
```

Check for points.

```
if isempty(points)
    return;
end
```

Extract KAZE features from the detected points.

```
[features,validPoints] = extractFeatures(I,points);
```

Plot the ten strongest valid extracted points and show their orientations.

```
imshow(I)
hold on
strongestPoints = selectStrongest(validPoints,10);
plot(strongestPoints,'showOrientation',true)
hold off
```

Input Arguments

`points` — Points object

point feature object

Points object,specified as one of the point feature objects described in “Point Feature Types”. The object contains information about the feature points detected in the input image. To obtain points, use the appropriate detect function that pairs with the point feature type.

gather

Retrieve cornerPoints from the GPU

Syntax

```
pointsCPU = gather(pointsGPU)
```

Description

`pointsCPU = gather(pointsGPU)` returns a `cornerPoints` object with data gathered from the GPU for the `Location` and `Metric` properties.

Examples

Find and Plot Corner Points in Image

Read an image.

```
I = imread('cameraman.tif')
```

Create a GPU array object.

```
I = gpuArray(I);
```

Find and display Harris features in the image.

```
pointsGPU = detectHarrisFeatures(I);
imshow(I);
hold on;
plot(pointsGPU.selectStrongest(50));
```

Copy the corner points to the CPU for further processing.

```
pointsCPU = gather(pointsGPU);
```

Input Arguments

pointsGPU — GPU points
`cornerPoints` object

GPU points, specified as a `cornerPoints` object.

Version History

Introduced in R2012a

See Also

`cornerPoints`

plot

Plot MSER regions

Syntax

```
plot(points)
plot(points,ax)
plot(points,ax,Name=Value)
```

Description

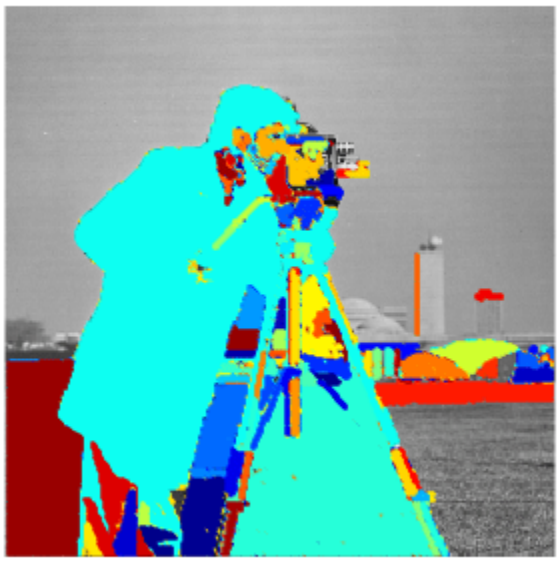
`plot(points)` plots points in the current axis.

`plot(points,ax)` plots points in the specified axis.

`plot(points,ax,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `plot(points,ax,ShowOrientation=true)` sets the logical value to true to show the orientation.

Examples

Plot MSER Regions



Read image and extract MSER features.

```
I = imread("cameraman.tif");
regions = detectMSERFeatures(I);
imshow(I); hold on;
plot(regions);
```

Plot MSER Regions.

```
figure; imshow(I);
hold on;
plot(regions,showPixelList=true,showEllipses=false);
hold off;
```

Input Arguments

`points` — Points
`MSERRegions` object

Points, specified as a points object. The object contains information about the feature points detected in the 2-D grayscale input image.

`ax` — Axes handle
handle

Handle to use for display. You can set the handle using `gca`.

Name-Value Pair Arguments

Example: `plot(points,ax,ShowOrientation=true)` sets the logical value to true to show the orientation.

`showEllipses` — Display ellipsis
`true` (default) | `false`

Display ellipsis around feature, specified as `true` or `false`. When you set this value to `true`, the object draws an ellipse with the same 2nd order moments as the region. When you set this value to `false`, only the ellipses centers are plotted.

`ShowOrientation` — Display orientation line
`true` (default) | `false`

Display feature point orientation, specified as `true` or `false`. When you set this value to `true`, the object draws a line corresponding to the point's orientation. The object draws the line from the feature point location to the edge of the circle, indicating the scale.

`showPixelList` — Display regions using JET colormap
`true` (default) | `false`

Display regions using JET colormap, specified as `true` or `false`.

Version History

Introduced in R2012a

`detectMSERFeatures`

assignDetectionsToTracks

Assign detections to tracks for multiobject tracking

Syntax

```
[assignments,unassignedTracks,unassignedDetections] =
assignDetectionsToTracks(costMatrix,costOfNonAssignment)
[assignments,unassignedTracks,unassignedDetections] =
assignDetectionsToTracks(costMatrix, unassignedTrackCost,
unassignedDetectionCost)
```

Description

`[assignments,unassignedTracks,unassignedDetections] = assignDetectionsToTracks(costMatrix,costOfNonAssignment)` assigns detections to tracks in the context of multiple object tracking using the James Munkres's variant of the Hungarian assignment algorithm. It also determines which tracks are missing and which detections should begin new tracks. It returns the indices of assigned and unassigned tracks, and unassigned detections. The `costMatrix` must be an *M*-by-*N* matrix. In this matrix, *M* represents the number of tracks, and *N* is the number of detections. Each value represents the cost of assigning the N^{th} detection to the M^{th} track. The lower the cost, the more likely that a detection gets assigned to a track. The `costOfNonAssignment` scalar input represents the cost of a track or a detection remaining unassigned.

`[assignments,unassignedTracks,unassignedDetections] = assignDetectionsToTracks(costMatrix, unassignedTrackCost, unassignedDetectionCost)` specifies the cost of unassigned tracks and detections separately. The `unassignedTrackCost` must be a scalar value, or an *M*-element vector, where *M* represents the number of tracks. For the *M*-element vector, each element represents the cost of not assigning any detection to that track. The `unassignedDetectionCost` must be a scalar value or an *N*-element vector, where *N* represents the number of detections.

Examples

Assign Detections to Tracks in a Single Video Frame

This example shows you how to assign a detection to a track for a single video frame.

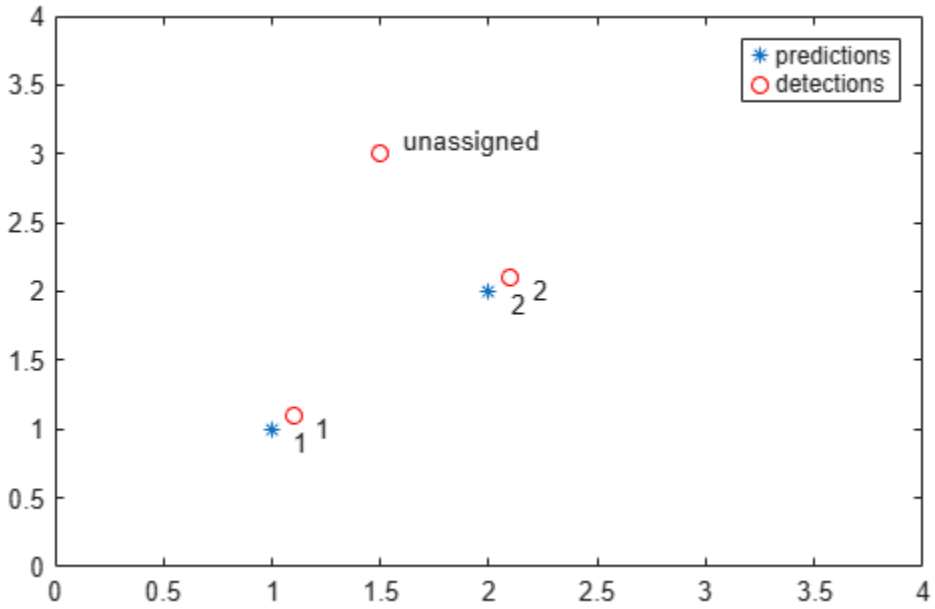
Set the predicted locations of objects in the current frame. Obtain predictions using the Kalman filter System object.

```
predictions = [1,1;2,2];
```

Set the locations of the objects detected in the current frame. For this example, there are 2 tracks and 3 new detections. Thus, at least one of the detections is unmatched, which can indicate a new track.

```
detections = [1.1,1.1;2.1,2.1;1.5,3];
```

Preallocate a cost matrix.



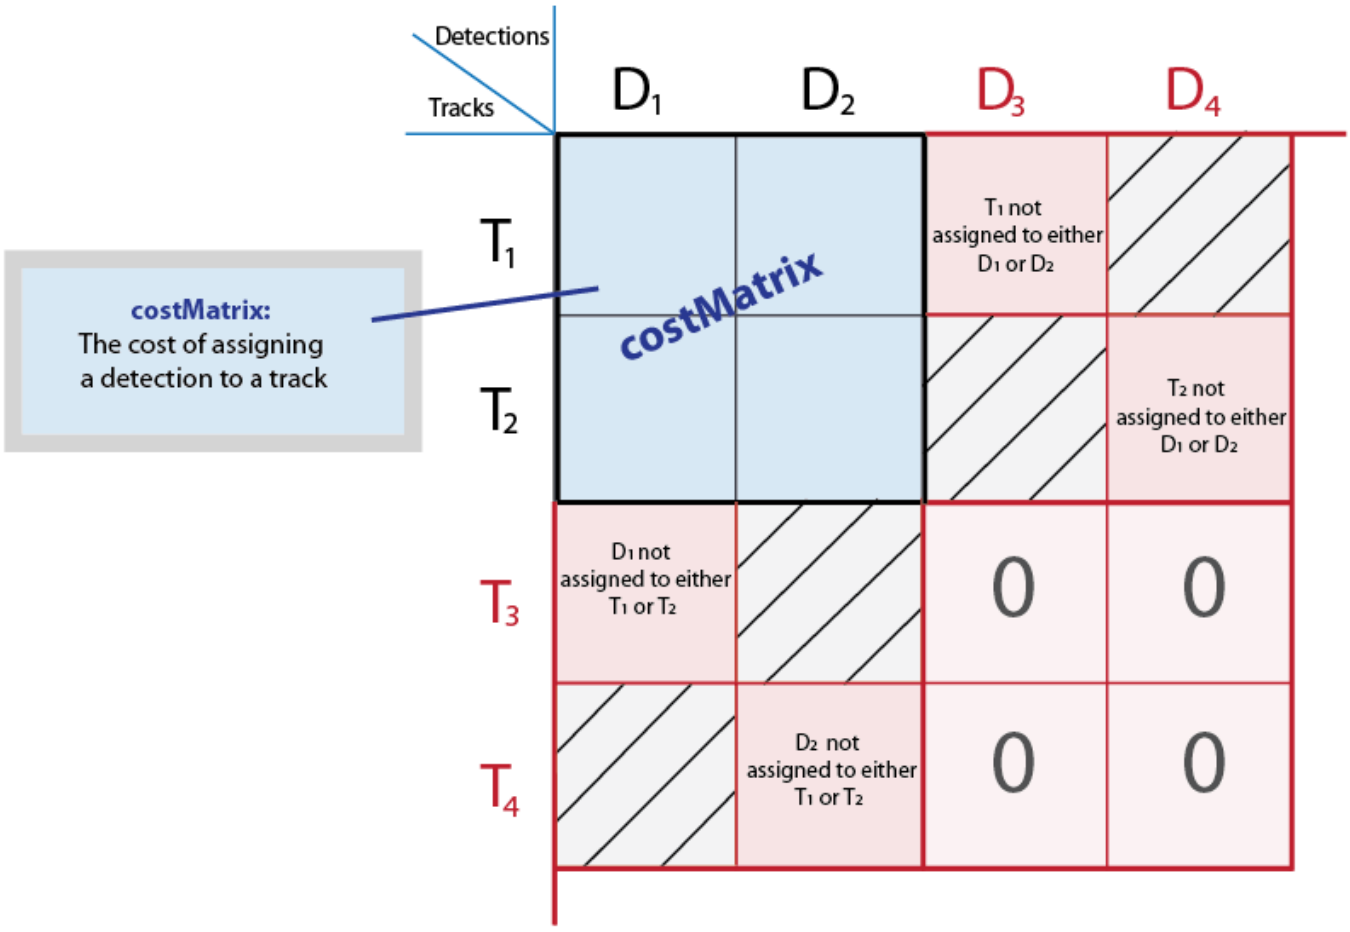
```
cost = zeros(size(predictions,1),size(detections,1));
```

Compute the cost of each prediction matching a detection. The cost here, is defined as the Euclidean distance between the prediction and the detection.

```
for i = 1:size(predictions, 1)
      diff = detections - repmat(predictions(i,:),[size(detections,1),1]);
      cost(i, :) = sqrt(sum(diff .^ 2,2));
end
```

Associate detections with predictions. Detection 1 should match to track 1, and detection 2 should match to track 2. Detection 3 should be unmatched.

```
[assignment,unassignedTracks,unassignedDetections] = ...
            assignDetectionsToTracks(cost,0.2);
  figure;
  plot(predictions(:,1),predictions(:,2),'*',detections(:,1),...
            detections(:,2),'ro');
  hold on;
  legend('predictions','detections');
  for i = 1:size(assignment,1)
    text(predictions(assignment(i, 1),1)+0.1,...
            predictions(assignment(i,1),2)-0.1,num2str(i));
    text(detections(assignment(i, 2),1)+0.1,...
            detections(assignment(i,2),2)-0.1,num2str(i));
  end
  for i = 1:length(unassignedDetections)
    text(detections(unassignedDetections(i),1)+0.1,...
            detections(unassignedDetections(i),2)+0.1,'unassigned');
  end
  xlim([0,4]);
  ylim([0,4]);
```

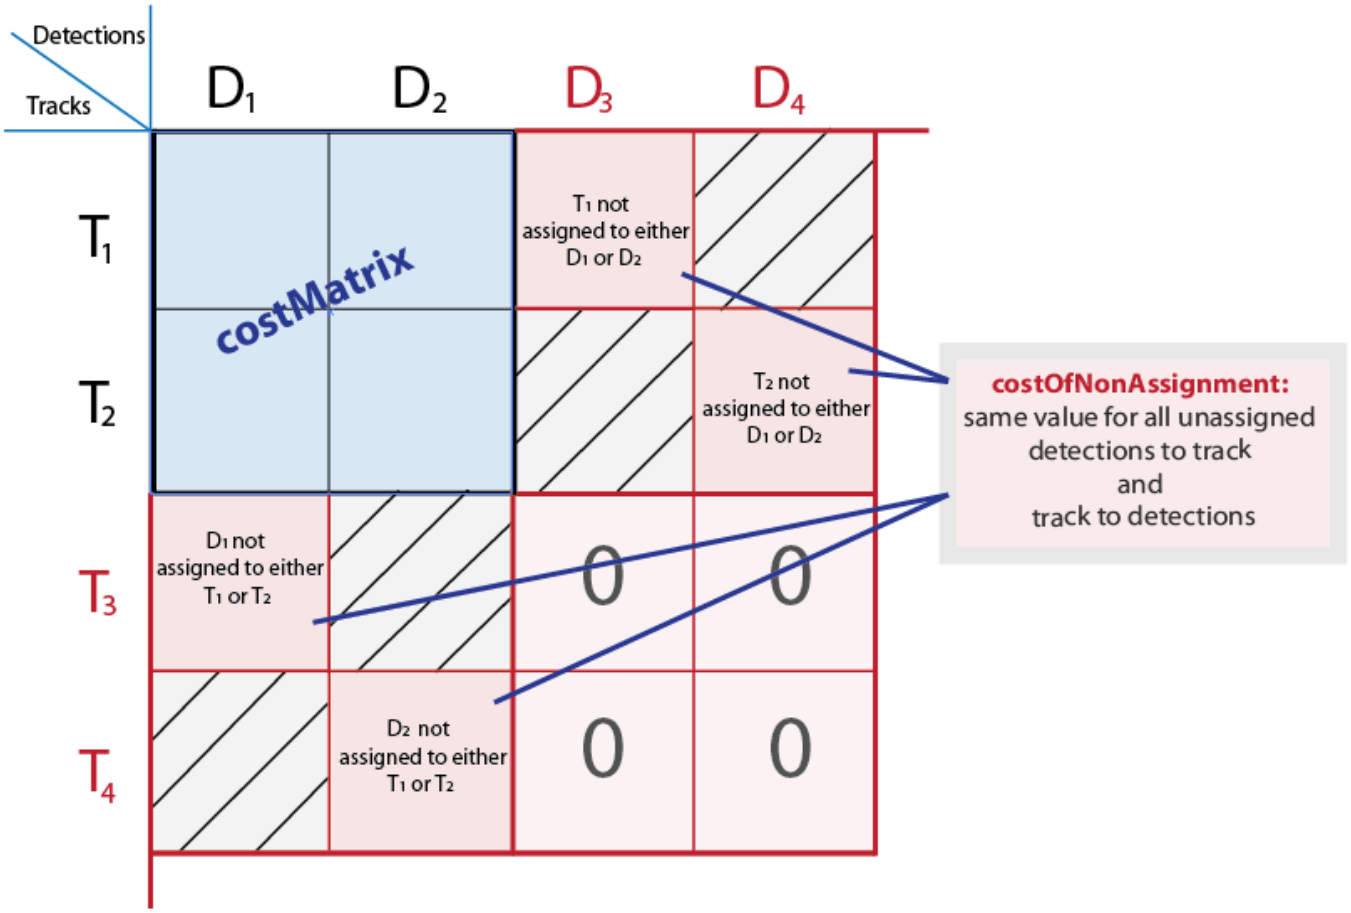


Input Arguments

`costMatrix` — Cost of assigning detection to track

M-by-*N* matrix

Cost of assigning a detection to a track, specified as an *M*-by-*N* matrix, where *M* represents the number of tracks, and *N* is the number of detections. The cost matrix value must be real, nonsparse, and numeric. The lower the cost, the more likely that a detection gets assigned to a track. Each value represents the cost of assigning the N^{th} detection to the M^{th} track. If there is no likelihood of an assignment between a detection and a track, the `costMatrix` input is set to `Inf`. Internally, this function pads the cost matrix with dummy rows and columns to account for the possibility of unassigned tracks and detections. The padded rows represent detections not assigned to any tracks. The padded columns represent tracks not associated with any detections. The function applies the Hungarian assignment algorithm to the padded matrix.



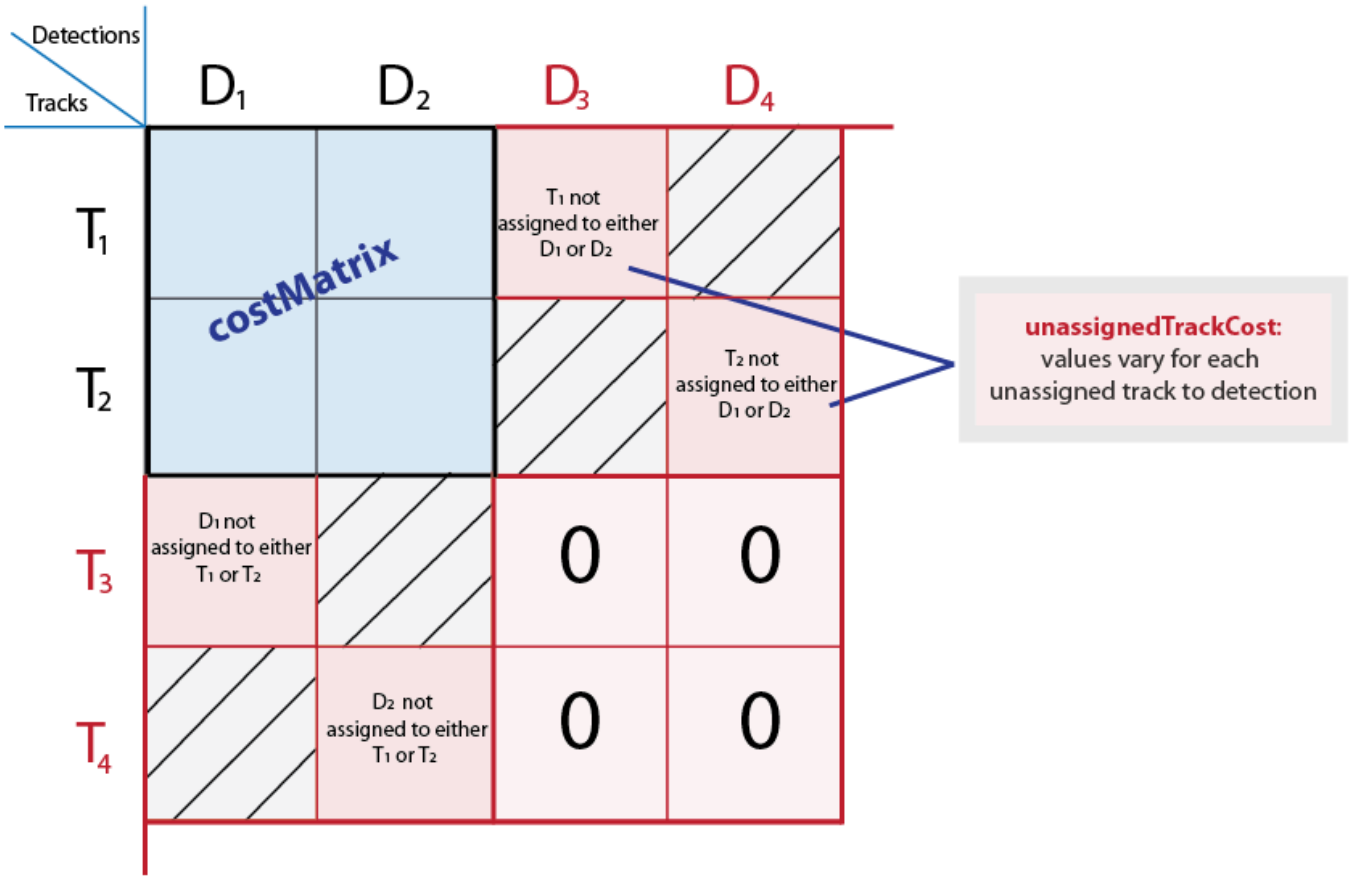
Data Types: `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `single` | `double`

`costOfNonAssignment` — Cost of not assigning detection to any track or track to any detection

scalar | finite

Cost of not assigning detection to any track or track to detection. You can specify this value as a scalar value representing the cost of a track or a detection remaining unassigned. An unassigned detection may become the start of a new track. If a track is unassigned, the object does not appear. The higher the `costOfNonAssignment` value, the higher the likelihood that every track will be assigned a detection.

Internally, this function pads the cost matrix with dummy rows and columns to account for the possibility of unassigned tracks and detections. The padded rows represent detections not assigned to any tracks. The padded columns represent tracks not associated with any detections. To apply the same value to all elements in both the rows and columns, use the syntax with the `costOfNonAssignment` input. To vary the values for different detections or tracks, use the syntax with the `unassignedTrackCost` and `unassignedDetectionCost` inputs.



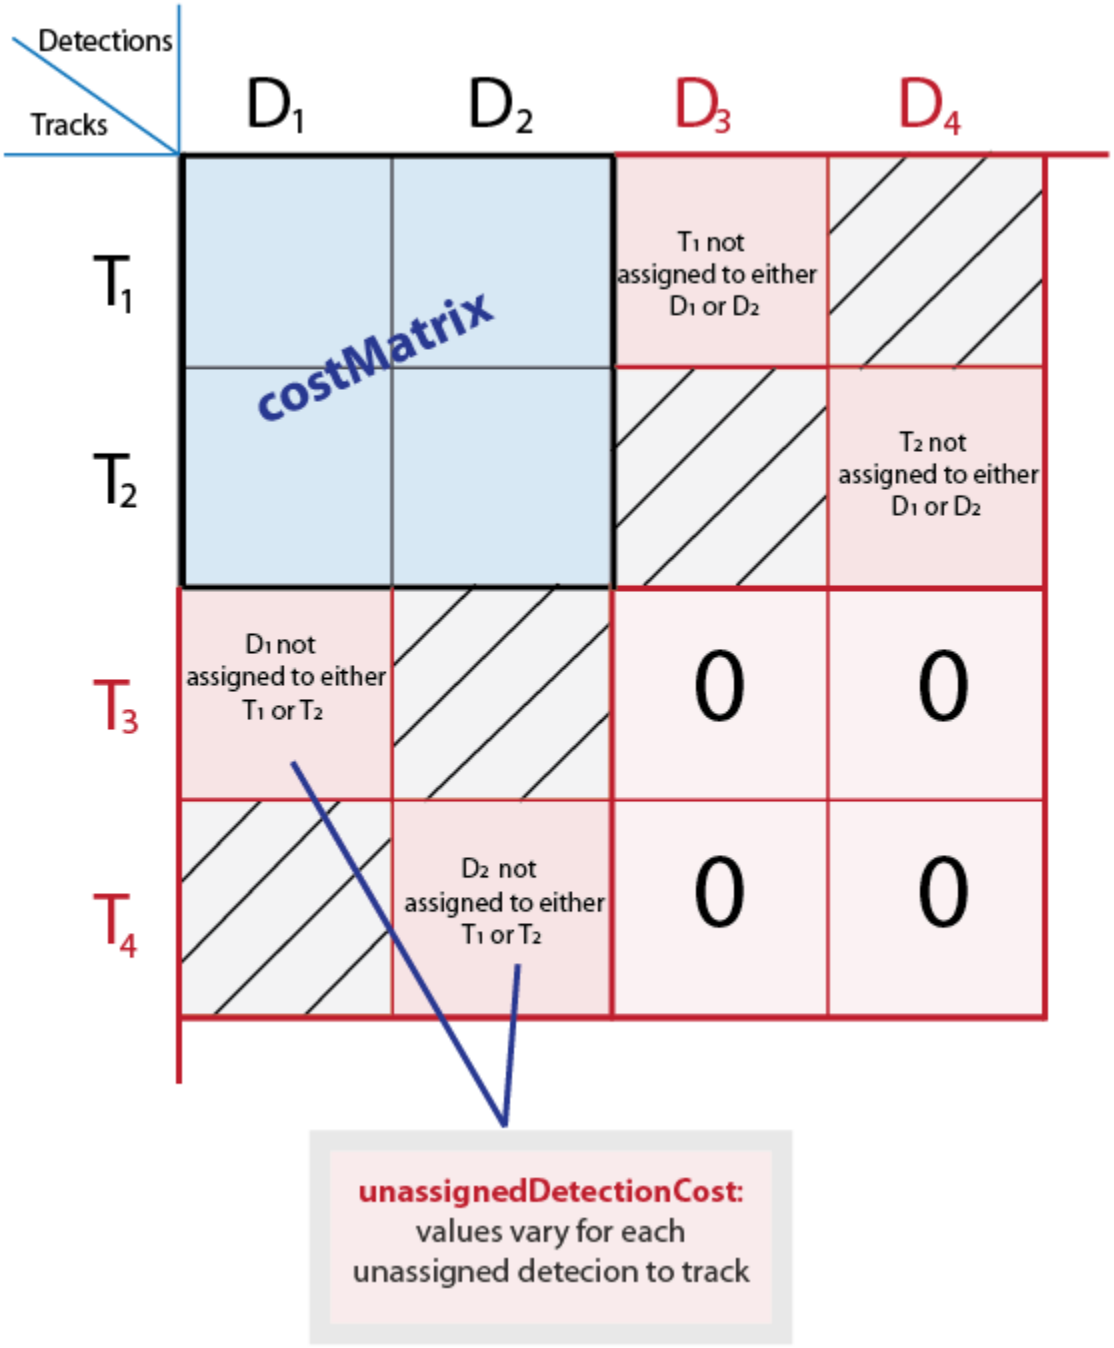
Data Types: `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `single` | `double`

`unassignedTrackCost` — Cost or likelihood of an unassigned track
M-element vector | scalar | finite

Cost or likelihood of an unassigned track. You can specify this value as a scalar value, or an *M*-element vector, where *M* represents the number of tracks. For the *M*-element vector, each element represents the cost of not assigning any detection to that track. A scalar input represents the same cost of being unassigned for all tracks. The cost may vary depending on what you know about each

track and the scene. For example, if an object is about to leave the field of view, the cost of the corresponding track being unassigned should be low.

Internally, this function pads the cost matrix with dummy rows and columns to account for the possibility of unassigned tracks and detections. The padded rows represent detections not assigned to any tracks. The padded columns represent tracks not associated with any detections. To vary the values for different detections or tracks, use the syntax with the `unassignedTrackCost` and `unassignedDetectionCost` inputs. To apply the same value to all elements in both the rows and columns, use the syntax with the `costOfNonAssignment` input.



Data Types: `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `single` | `double`

`unassignedDetectionCost` — Cost of unassigned detection
N-element vector | scalar | finite

Cost of unassigned detection, specified as a scalar value or an *N*-element vector, where *N* represents the number of detections. For the *N*- element vector, each element represents the cost of starting a new track for that detection. A scalar input represents the same cost of being unassigned for all tracks. The cost may vary depending on what you know about each detection and the scene. For example, if a detection appears close to the edge of the image, it is more likely to be a new object.

Internally, this function pads the cost matrix with dummy rows and columns to account for the possibility of unassigned tracks and detections. The padded rows represent detections not assigned to any tracks. The padded columns represent tracks not associated with any detections. To vary the

values for different detections or tracks, use the syntax with the `unassignedTrackCost` and `unassignedDetectionCost` inputs. To apply the same value to all elements in both the rows and columns, use the syntax with the `costOfNonAssignment` input.

Data Types: `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `single` | `double`

Output Arguments

`assignments` — Index pairs of tracks and corresponding detections

L-by-2 matrix

Index pairs of tracks and corresponding detections. This value is returned as an *L*-by-2 matrix of index pairs, with *L* number of pairs. The first column represents the track index and the second column represents the detection index.

Data Types: `uint32`

`unassignedTracks` — Unassigned tracks

P-element vector

Unassigned tracks, returned as a *P*-element vector. *P* represents the number of unassigned tracks. Each element represents a track to which no detections are assigned.

Data Types: `uint32`

`unassignedDetections` — Unassigned detections

Q-element vector

Unassigned detections, returned as a *Q*-element vector, where *Q* represents the number of unassigned detections. Each element represents a detection that was not assigned to any tracks. These detections can begin new tracks.

Data Types: `uint32`

Version History

Introduced in R2012b

Munkres' Assignment Algorithm Modified for Rectangular Matrices

bbox2points

Convert rectangle to corner points list

Syntax

```
points = bbox2points(rectangle)
```

Description

`points = bbox2points(rectangle)` converts the input rectangle, into a list of four [*x* *y*] corner points. The `rectangle` input must be either a single bounding box or a set of bounding boxes.

Examples

Convert Bounding Box to List of Points and Apply Rotation

Define a bounding box.

```
bbox = [10,20,50,60];
```

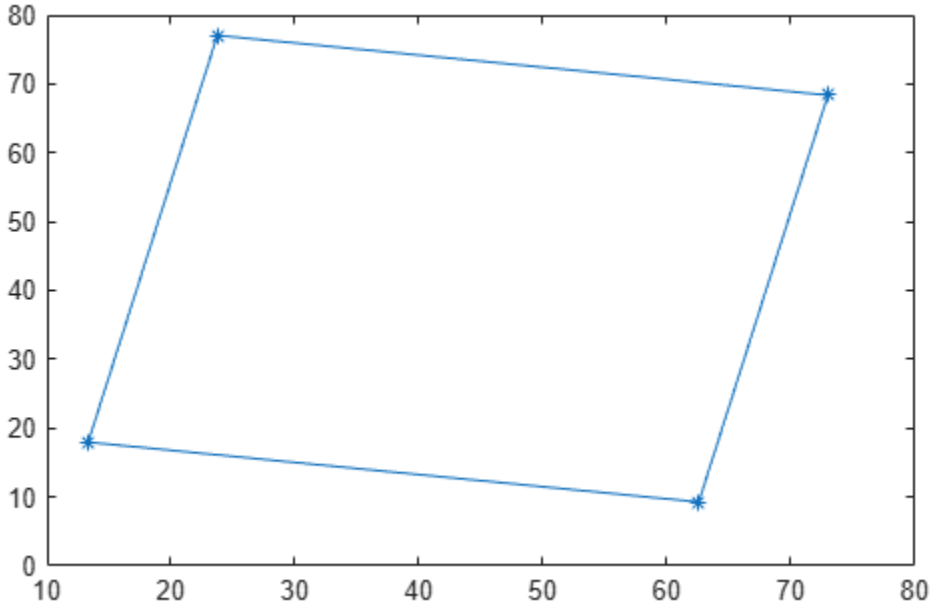
Convert the bounding box to a list of four points.

```
points = bbox2points(bbox);
```

Define a rotation transformation.

```
theta = 10;
tform = affine2d([cosd(theta) -sind(theta) 0; sind(theta) cosd(theta) 0; 0 0 1]);
```

Apply the rotation.



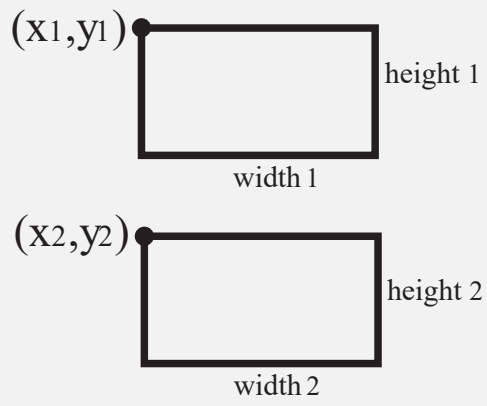
```
points2 = transformPointsForward(tform,points);
```

Close the polygon for display.

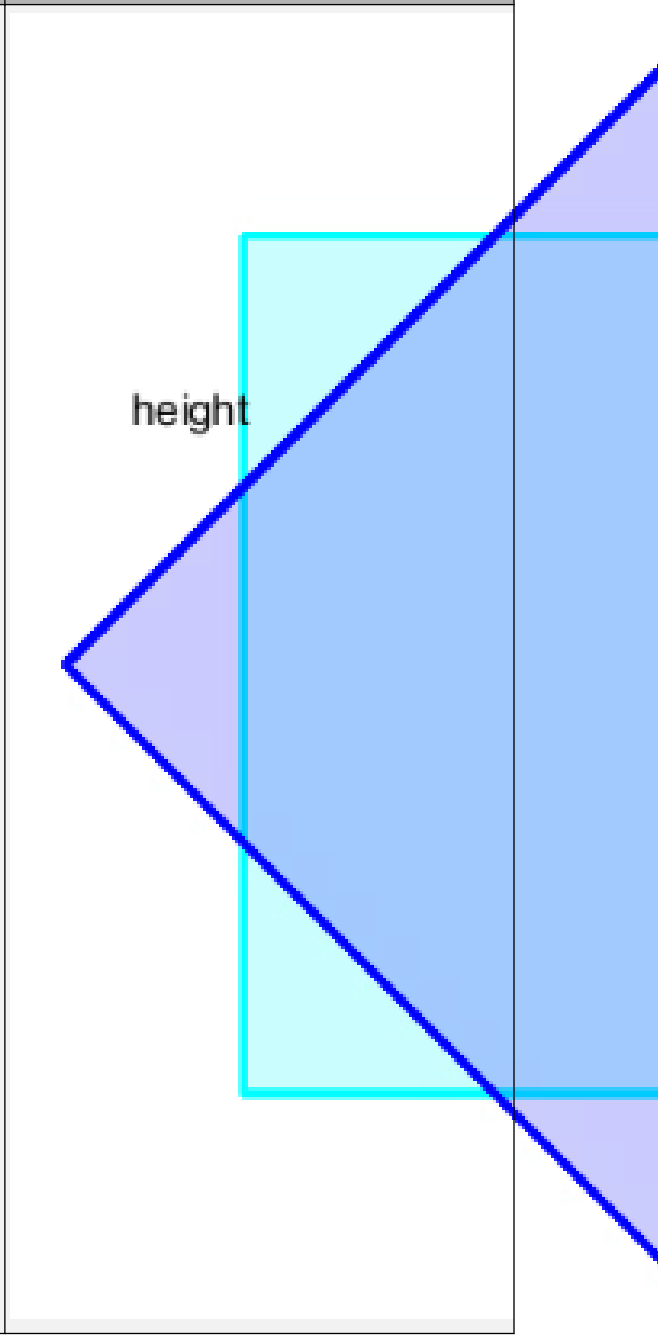
```
points2(end+1,:) = points2(1,:);
```

Plot the rotated box.

```
plot(points2(:,1),points2(:,2), '*-');
```



Input Arguments



`rectangle` — Bounding box

4-element vector | 5-element vector | *M*-by-4 matrix | *M*-by-5 matrix

Bounding box, specified as a 4-element vector, 5-element vector, *M*-by-4 matrix, or *M*-by-5 matrix.

Bounding Box	Example

For one or more rectangles, specify one of:
• An *M*-by-4 matrix where each row specifies a rectangle as [*x y width height*].
$\begin{bmatrix} x_1 & y_1 & width_1 & height_1 \\ x_2 & y_2 & width_2 & height_2 \\ \vdots & \vdots & \vdots & \vdots \\ x_M & y_M & width_M & height_M \end{bmatrix}$
• An *M*-by-5 numeric matrix with rows of the form [*xctr yctr w h yaw*], where:
  • *M* is the number of rotated rectangles.
  • *xctr* and *yctr* specify the center of the rectangle.
  • *w* specifies the width of the rectangle, which is its length along the *x*-axis before rotation.
  • *h* specifies the height of the rectangle, which is its length along the *y*-axis before rotation.
  • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the bounding box.
	

Bounding Box	Example
	

Data Types: `single` | `double` | `int16` | `int32` | `uint16` | `uint32`

Output Arguments

`points` — Rectangle corner coordinates
4-by-2 matrix | 4-by-2-by-*M* array

Rectangle corner coordinates, returned as a 4-by-2 matrix of [*x*,*y*] coordinates, or a 4-by-2-by-*M* array of [*x*,*y*] coordinates. The output points for the rectangle are listed counterclockwise starting from the upper-left corner.

- For a single input bounding box, the function returns the 4-by-2 matrix.
- For multiple input bounding boxes, the function returns the 4-by-2-*M* array for *M* bounding boxes.

Data Types: `single` | `double` | `int16` | `int32` | `uint16` | `uint32`

Version History

Introduced in R2014b

bboxcrop

Crop bounding boxes

Syntax

```
bboxB = bboxcrop(bboxA,window)
[bboxB,indices] = bboxcrop(bboxA,window)
[___] = bboxcrop(___,Name=Value)
```

Description

`bboxB = bboxcrop(bboxA,window)` crops bounding boxes from a set of input bounding boxes, `bboxA`, located in the cropping area, `window`. `bboxB` contains the cropped bounding boxes. This function supports 2-D and 3-D bounding boxes.

`[bboxB,indices] = bboxcrop(bboxA,window)` additionally returns a vector of indices that indicate which bounding boxes in `bboxA` are within the cropping window, `window`.

`[___] = bboxcrop(___,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `OverlapThreshold=1`, sets the positive overlap threshold to `1`.

Examples

Center Crop Image and Corresponding Bounding Boxes

Read an image.

```
I = imread('peppers.png');
```

Define bounding boxes and labels.

```
bboxA = [
    410 230 100 90
    186 78  80  60
    ]
```

```
bboxA = 2×4

   410   230   100    90
   186    78    80    60
```

```
labelsA = [
    "garlic"
    "onion"
    ];
```

Create a center cropping window.

```
targetSize = [256 256];
win = centerCropWindow2d(size(I),targetSize);
```

Center crop the image.

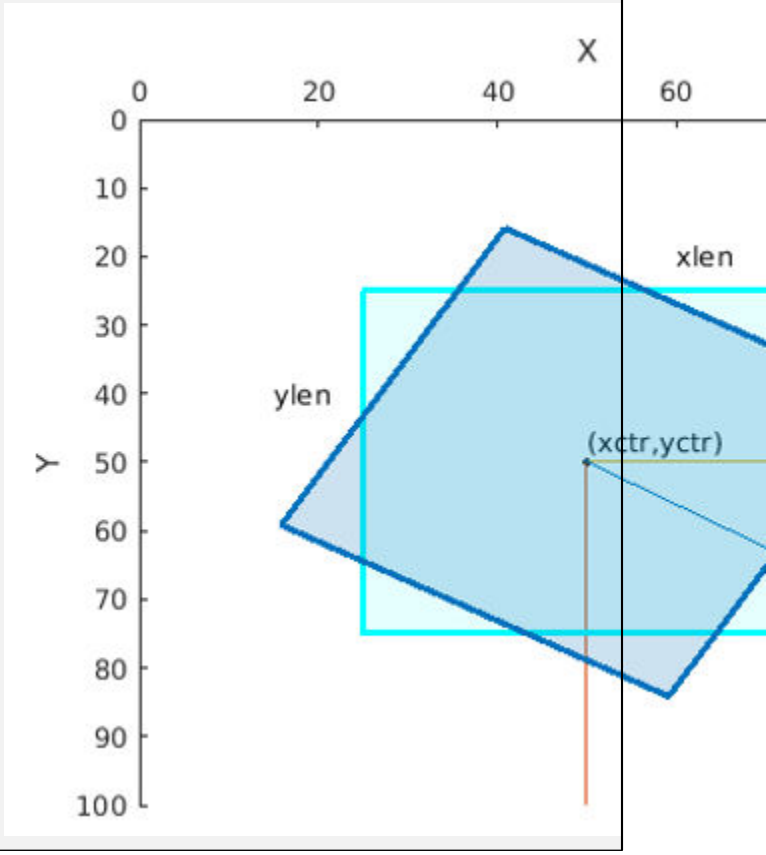
```
[r,c] = deal(win.YLimits(1):win.YLimits(2),win.XLimits(1):win.XLimits(2));
J = I(r,c,:);
```

Center crop boxes and labels. Boxes outside the cropping window are removed.

```
[bboxB,indices] = bboxcrop(bboxA,win);
labelsB = labelsA(indices);
```

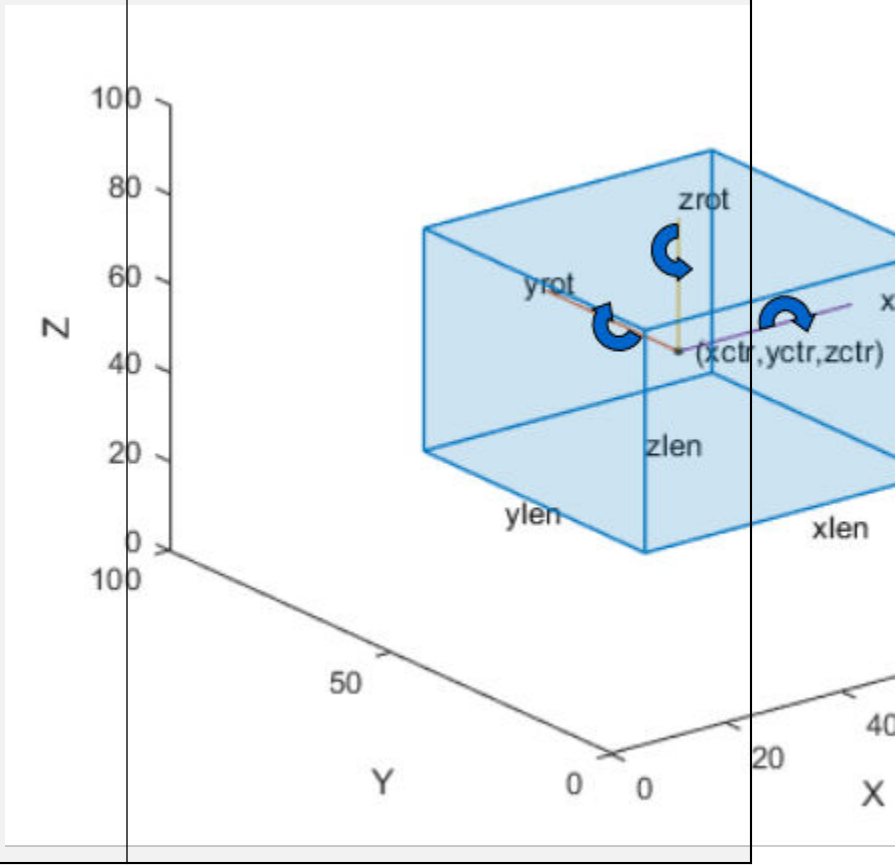
Display the results.

```
figure
I = insertObjectAnnotation(I,'Rectangle',bboxA,labelsA);
J = insertObjectAnnotation(J,'Rectangle',bboxB,labelsB);
imshowpair(I,J,'montage')
```



Input Arguments

bboxA — Bounding boxes



M-by-4 matrix | *M*-by-5 matrix | *M*-by-9 matrix

Bounding boxes, specified as an *M*-by-4, *M*-by-5, or *M*-by-9 nonsparse numeric matrix. *M* is the number of bounding boxes. Each row of the matrix defines a bounding box as either an axis-aligned rectangle, a rotated rectangle, or a cuboid. This table describes the format for each bounding box.

Bounding Box	Description
Axis-aligned rectangle	Defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and y specify the upper-left corner of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis. • *h* specifies the height of the rectangle, which is its length along the *y*-axis.

Bounding Box	Description
Rotated rectangle	Defined in spatial coordinates as an *M*-by-5 numeric matrix with rows of the form [*xctr yctr xlen ylen yaw*], where: • *M* is the number of rotated rectangles. • *xctr* and *yctr* specify the center of the rectangle. • *xlen* specifies the width of the rectangle, which is its length along the *x*-axis before rotation. • *ylen* specifies the height of the rectangle, which is its length along the *y*-axis before rotation. • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the bounding box. 

Bounding Box	Description
Cuboid	Defined in spatial coordinates as an *M*-by-9 numeric matrix with rows of the form [*xctr yctr zctr xlen ylen zlen xrot yrot zrot*], where: • *M* is the number of cuboids. • *xctr*, *yctr*, and *zctr* specify the center of the cuboid. • *xlen*, *ylen*, and *zlen* specify the length of the cuboid along the *x*-axis, *y*-axis, and *z*-axis, respectively, before rotation. • *xrot*, *yrot*, and *zrot* specify the rotation angles of the cuboid around the *x*-axis, *y*-axis, and *z*-axis, respectively. The *xrot*, *yrot*, and *zrot* rotation angles are in degrees about the cuboid center. Each rotation is clockwise-positive with respect to the positive direction of the associated spatial axis. The function computes rotation matrices assuming ZYX order Euler angles [*xrot yrot zrot*]. The figure shows how these values determine the position of a cuboid.

`window` — Cropping window
four-element vector (default) | `images.spatialref.Rectangle` | six-element vector | `images.spatialref.Cuboid` | numeric | image

Cropping window, specified as a four-element vector, a six-element vector, or a `Cuboid` object. The output bounding box positions are relative to the location of the cropping window.

When you specify `bboxA` as a rectangular input, the cropping window must be a four-element vector in the format [*x*,*y*,*width*,*height*], or a `Rectangle` object.

When you specify `bboxA` as a cuboid, the cropping window must be a six-element vector in the format [*x*,*y*,*zwidth*,*height*,*depth*], or a `Cuboid` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `OverlapThreshold=1`, sets the positive overlap threshold to `1`.

`OverlapThreshold` — Overlap threshold
`1` (default) | positive scalar less than or equal to `1`

Overlap threshold, specified as a positive scalar less than or equal to `1`. The amount of overlap between the input boxes, `bboxA`, and the cropping area, `window`, is defined as:

`area`(`intersect` (`bboxA`,`window`))/`area`(`union`(`bboxB`,`window`)).

If the computed overlap value is greater than the value of the `threshold` property, then the boxes are clipped to the bounding rectangle border. Otherwise, the boxes are discarded. Lowering the threshold can result in parts of the object getting discarded.

Note For rotated rectangle bounding boxes, the function only supports the overlap threshold value of 1.

Output Arguments

`bboxB` — Cropped bounding boxes
M2-by-*N* matrix | nonsparse numeric

Cropped bounding boxes, returned as an *M2*-by-*N* matrix of *M2* bounding boxes. The number of bounding boxes returned is less than the number of bounding boxes in the input. Each row, *M2*, of the matrix defines one bounding box of the same type as the input `bboxA`. The output bounding box positions are relative to the location of the cropping window.

`indices` — Indices
vector of integers

Indices, returned as a vector of integers. The indices indicate which bounding boxes in the input, `bboxA`, are within the cropping window.

Version History

Introduced in R2019b

R2022a: Bounding Box Coordinates: Data augmentation for object detection using spatial coordinates

Behavior changed in R2022a

The `bboxresize`, `bboxcrop`, `bboxwarp`, and `showShape` functions assume the input bounding box coordinates for axis-aligned rectangles are specified in spatial coordinates and return the transformed bounding boxes in spatial coordinates.

Extended Capabilities

Thread-Based Environment

Run code in the background using MATLAB® `backgroundPool` or accelerate code with Parallel Computing Toolbox™ `ThreadPool`.

This function fully supports thread-based environments. For more information, see “Run MATLAB Functions in Thread-Based Environment”

`imcrop` | `bboxresize` | `bboxwarp` | `bboxerase`

bboxresize

Resize bounding boxes

Syntax

```
bboxB = bboxresize(bboxA,scale)
```

Description

`bboxB = bboxresize(bboxA,scale)` resizes bounding boxes in `bboxA` by the amount specified by `scale`. This function supports 2-D and 3-D bounding boxes.

Examples

Resize Image and Corresponding Bounding Boxes

Read an image.

```
I = imread('peppers.png');
```

Define bounding boxes and labels.

```
bboxA = [
    410 230 100 90
    186 78  80  60
    ]
```

```
bboxA = 2×4

   410   230   100    90
   186    78    80    60
```

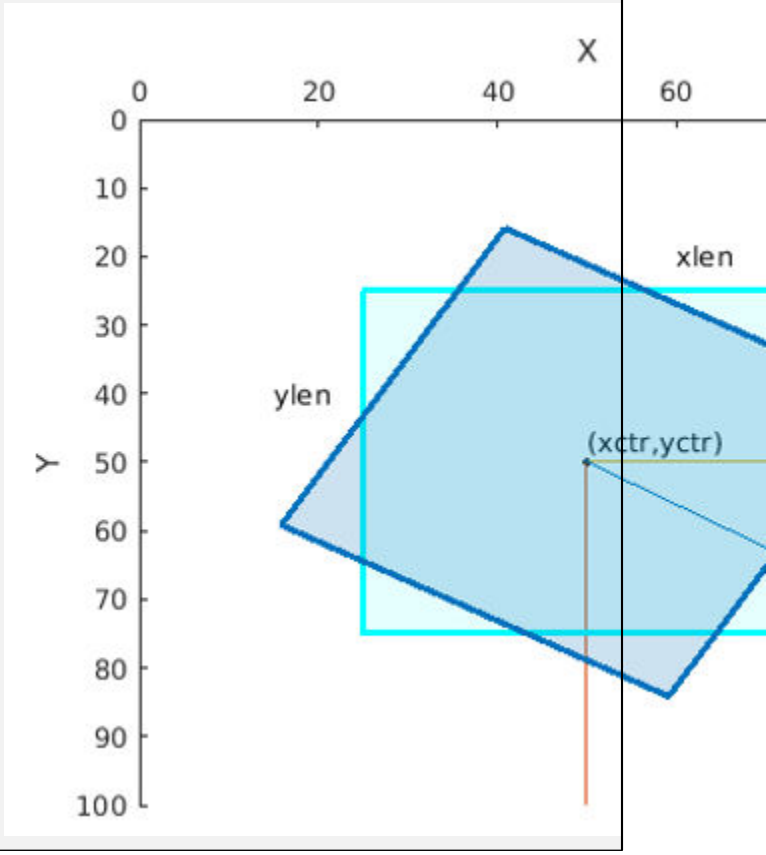
```
labelsA = [
    "garlic"
    "onion"
    ];
```

Resize the image and the bounding boxes.

```
scale = 1.5;
J = imresize(I,scale);
bboxB = bboxresize(bboxA,scale);
```

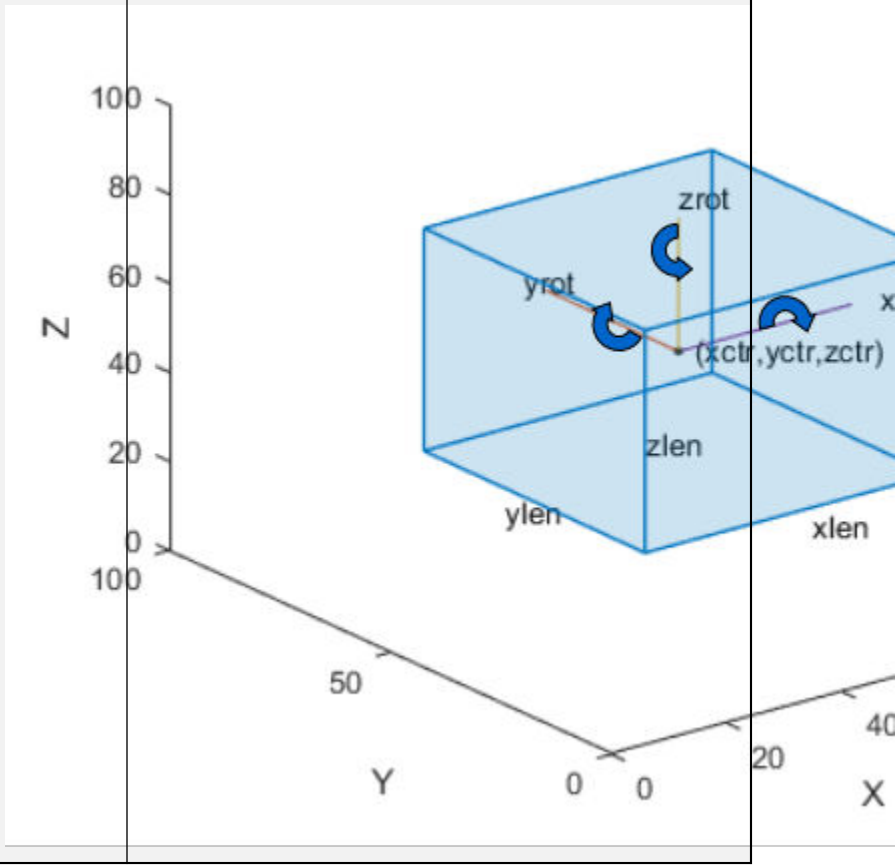
Display the results.

```
figure
I = insertObjectAnnotation(I,'Rectangle',bboxA,labelsA);
J = insertObjectAnnotation(J,'Rectangle',bboxB,labelsA);
imshowpair(I,J,'montage')
```



Input Arguments

bboxA — Bounding boxes



M-by-4 matrix | *M*-by-5 matrix | *M*-by-9 matrix | nonsparse numeric

Bounding boxes, specified as an *M*-by-4, *M*-by-5, or *M*-by-9 nonsparse numeric matrix of *M* bounding boxes. Each row, *M*, of the matrix defines a bounding box as either an axis-aligned rectangle, a rotate rectangle, or a cuboid. The table below describes the format of the bounding boxes.

Bounding Box	Description
Axis-aligned rectangle	Defined in spatial coordinates as an *M*-by-4 numeric matrix with rows of the form [*x y w h*], where: • *M* is the number of axis-aligned rectangles. • *x* and y specify the upper-left corner of the rectangle. • *w* specifies the width of the rectangle, which is its length along the *x*-axis. • *h* specifies the height of the rectangle, which is its length along the *y*-axis.

Bounding Box	Description
Rotated rectangle	Defined in spatial coordinates as an *M*-by-5 numeric matrix with rows of the form [*xctr yctr xlen ylen yaw*], where: • *M* is the number of rotated rectangles. • *xctr* and *yctr* specify the center of the rectangle. • *xlen* specifies the width of the rectangle, which is its length along the *x*-axis before rotation. • *ylen* specifies the height of the rectangle, which is its length along the *y*-axis before rotation. • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the bounding box. 

Bounding Box	Description
Cuboid	Defined in spatial coordinates as an *M*-by-9 numeric matrix with rows of the form [*xctr yctr zctr xlen ylen zlen xrot yrot zrot*], where: • *M* is the number of cuboids. • *xctr*, *yctr*, and *zctr* specify the center of the cuboid. • *xlen*, *ylen*, and *zlen* specify the length of the cuboid along the *x*-axis, *y*-axis, and *z*-axis, respectively, before rotation. • *xrot*, *yrot*, and *zrot* specify the rotation angles of the cuboid around the *x*-axis, *y*-axis, and *z*-axis, respectively. The *xrot*, *yrot*, and *zrot* rotation angles are in degrees about the cuboid center. Each rotation is clockwise-positive with respect to the positive direction of the associated spatial axis. The function computes rotation matrices assuming ZYX order Euler angles [*xrot yrot zrot*]. The figure shows how these values determine the position of a cuboid.

`scale` — Scale

scalar (default) | row vector

Scale, specified as a scalar or a row vector. When you specify a scalar, the function applies the same scale factor to the height and width of the bounding boxes in `bboxA`. When you specify a row vector, the function applies the factor in the first element of the vector to resize the height and the second element to resize the width of the bounding boxes.

Output Arguments

`bboxB` — Warped bounding boxes

M2-by-*N* matrix | nonsparse numeric

Warped bounding boxes, returned as an *M2*-by-*N* matrix of *M2* bounding boxes. The number of bounding boxes returned is less than the number of bounding boxes in the input. Each row, *M2*, of the matrix defines one bounding box of the same type as the input `bboxA`. When `bboxB` contains floating point data, the function returns it with the same type as `bboxA`. Otherwise, the function returns `bboxB` as type `single`.

Version History

Introduced in R2019b

R2022a: Bounding Box Coordinates: Data augmentation for object detection using spatial coordinates

Behavior changed in R2022a

The `bboxresize`, `bboxcrop`, `bboxwarp`, and `showShape` functions assume the input bounding box coordinates for axis-aligned rectangles are specified in spatial coordinates and return the transformed bounding boxes in spatial coordinates.

Extended Capabilities

Thread-Based Environment

Run code in the background using MATLAB® `backgroundPool` or accelerate code with Parallel Computing Toolbox™ `ThreadPool`.

This function fully supports thread-based environments. For more information, see “Run MATLAB Functions in Thread-Based Environment”

bboxwarp

Apply geometric transformation to bounding boxes

Syntax

```
bboxB = bboxwarp(bboxA,tform,ref)
bboxB = bboxwarp(bboxA,tform,ref,"OverlapThreshold",overlapThreshold)
[bboxB,indices] = bboxwarp( ___ )
```

Description

`bboxB = bboxwarp(bboxA,tform,ref)` transforms bounding boxes in `bboxA` according to the geometric transformation defined by `tform`. Bounding boxes can be axis-aligned rectangles, rotated rectangles, or cuboids. The spatial reference object, `ref`, defines the output view into which the boxes are transformed. This function supports 2-D and 3-D bounding boxes.

`bboxB = bboxwarp(bboxA,tform,ref,"OverlapThreshold",overlapThreshold)` also specifies the positive overlap threshold.

`[bboxB,indices] = bboxwarp( ___ )` additionally returns a vector of indices that indicate which bounding boxes in `bboxA` correspond to the warped versions in the output, `bboxB`. You can specify either of the preceding sets of input arguments.

Examples

Transform Images and Corresponding Bounding Boxes

Read an image.

```
I = imread("peppers.png");
```

Define bounding boxes and labels.

```
bboxA = [
    410 230 100 90
    186 78  80  60
    ]
```

```
bboxA = 2×4

   410   230   100    90
   186    78    80    60
```

```
labelsA = [
    "garlic"
    "onion"
    ];
```

Define an affine transform to horizontally flip and translate the image.

```
tform = affinetform2d([-1 0 50; 0 1 50; 0 0 1]);
```

Create an output view for `imwarp`.

```
rout = affineOutputView(size(I),tform);
```

Warp the image.

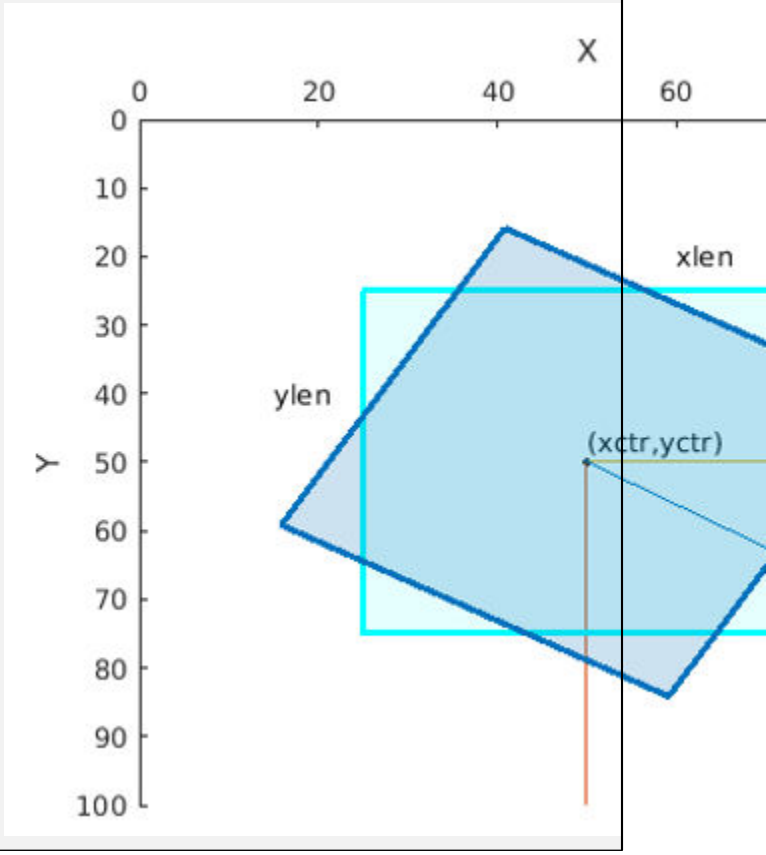
```
J = imwarp(I,tform,"OutputView",rout);
```

Warp the boxes.

```
[bboxB,indices] = bboxwarp(bboxA,tform,rout);
labelsB = labelsA(indices);
```

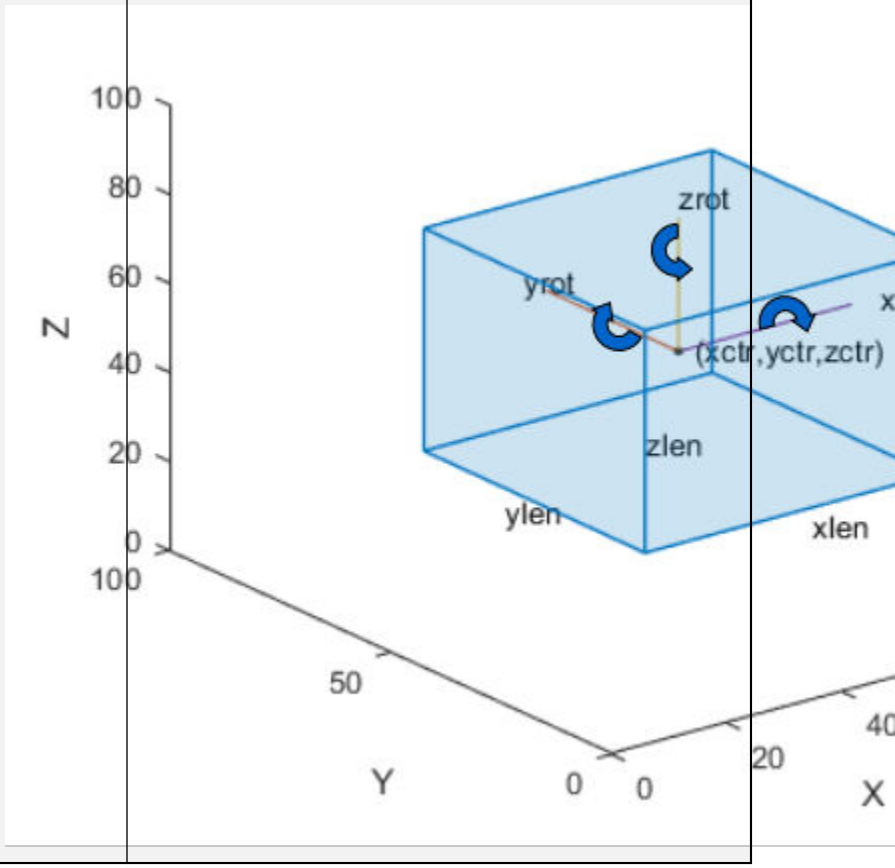
Display the results.

```
annotatedI = insertObjectAnnotation(I,"Rectangle",bboxA,labelsA);
annotatedJ = insertObjectAnnotation(J,"Rectangle",bboxB,labelsB);
figure
montage({annotatedI,annotatedJ})
```



Input Arguments

bboxA — Bounding boxes



M-by-4 matrix | *M*-by-5 matrix | *M*-by-9 matrix

Bounding boxes, specified as an *M*-by-4, *M*-by-5, or *M*-by-9 nonsparse numeric matrix of *M* bounding boxes. Each row, *M*, of the matrix defines a bounding box as either an axis-aligned rectangle, a rotate rectangle, or a cuboid. The table below describes the format of the bounding boxes.

Bounding Box	Description
Axis-aligned rectangle	Defined in spatial coordinates as an M-by-4 numeric matrix with rows of the form [x y w h], where: • M is the number of axis-aligned rectangles. • x and y specify the upper-left corner of the rectangle. • w specifies the width of the rectangle, which is its length along the x-axis. • h specifies the height of the rectangle, which is its length along the y-axis.

Bounding Box	Description
Rotated rectangle	Defined in spatial coordinates as an *M*-by-5 numeric matrix with rows of the form [*xctr yctr xlen ylen yaw*], where: • *M* is the number of rotated rectangles. • *xctr* and *yctr* specify the center of the rectangle. • *xlen* specifies the width of the rectangle, which is its length along the *x*-axis before rotation. • *ylen* specifies the height of the rectangle, which is its length along the *y*-axis before rotation. • *yaw* specifies the rotation angle in degrees. The rotation is clockwise-positive around the center of the bounding box. 

Bounding Box	Description
Cuboid	Defined in spatial coordinates as an *M*-by-9 numeric matrix with rows of the form [*xctr yctr zctr xlen ylen zlen xrot yrot zrot*], where: • *M* is the number of cuboids. • *xctr*, *yctr*, and *zctr* specify the center of the cuboid. • *xlen*, *ylen*, and *zlen* specify the length of the cuboid along the *x*-axis, *y*-axis, and *z*-axis, respectively, before rotation. • *xrot*, *yrot*, and *zrot* specify the rotation angles of the cuboid around the *x*-axis, *y*-axis, and *z*-axis, respectively. The *xrot*, *yrot*, and *zrot* rotation angles are in degrees about the cuboid center. Each rotation is clockwise-positive with respect to the positive direction of the associated spatial axis. The function computes rotation matrices assuming ZYX order Euler angles [*xrot yrot zrot*]. The figure shows how these values determine the position of a cuboid.

`tform` — Geometric transformation

`affinetform2d` object | `affinetform3d` object

Geometric transformation, specified as an `affinetform2d` object for rectangular inputs or an `affinetform3d` object for cuboid inputs. The bboxwarp function supports affine transformations consisting only of scale, rotation, and translation.

Note Rotated rectangles do not support reflection or shear transformations.

`ref` — Spatial reference

`imref2d` object | `imref3d` object

Spatial reference, specified as an `imref2d` object for rectangular inputs or `imref3d` object for cuboid inputs. To obtain one of these objects, you can use the `imwarp` or the `affineOutputView` function. The object defines the output view to transform boxes. Boxes that are transformed completely outside of the output view defined by `ref` are discarded.

```
[J,rout] = imwarp(I,tform);
[bboxB,indices] = bboxwarp(bboxA,tform,rout);

rout = affineOutputView(size(I),tform)
J = imwarp(I,tform,OutputView=rout);
[bboxB,indices] = bboxwarp(bboxA,tform,rout);
```

`overlapThreshold` — Overlap threshold

1 (default) | positive scalar less than or equal to 1

Overlap threshold, specified as a positive scalar less than or equal to `1`. The amount of overlap between transformed boxes and the region *W*, defined by the output view, is defined as:

`area`(`intersect`(`bboxA`,*W*))/`area`(`bboxB`,*W)*.

If the computed overlap value is greater than the value of the `threshold` property, then the transformed boxes are clipped to the bounding rectangle border. Otherwise, the boxes are discarded. Lowering the threshold can result in parts of the object getting discarded.

Output Arguments

`bboxB` — Warped bounding boxes

M2-by-*N* matrix

Warped bounding boxes, returned as an *M2*-by-*N* matrix of *M2* bounding boxes. The number of bounding boxes returned is less than the number of bounding boxes in the input. Each row, *M2*, of the matrix defines one bounding box of the same type as the input `bboxA`. When `bboxB` contains floating point data, the function returns it with the same type as `bboxA`. Otherwise, the function returns `bboxB` as type `single`.

`indices` — Indices

vector of integers

Indices, returned as a vector of integers. The indices indicate which bounding boxes in the input, `bboxA`, that correspond to the warped versions in the output, `bboxB`.

Version History

Introduced in R2019b

R2022b: Supports new geometric transformation objects

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, you can now specify `tform` as an `affinetform2d` or `affinetform3d` geometric transformation object, which use the premultiply convention.

Although you can still specify `tform` as an `affine2d` or `affine3d` geometric transformation object, these objects are not recommended because they use the postmultiply convention. You can streamline your geometric transformation workflows by switching to the new premultiply geometric transformation objects. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

R2022a: Bounding Box Coordinates: Data augmentation for object detection using spatial coordinates

Behavior changed in R2022a

The `bboxresize`, `bboxcrop`, `bboxwarp`, and `showShape` functions assume the input bounding box coordinates for axis-aligned rectangles are specified in spatial coordinates and return the transformed bounding boxes in spatial coordinates.

Extended Capabilities

Thread-Based Environment

Run code in the background using MATLAB® `backgroundPool` or accelerate code with Parallel Computing Toolbox™ `ThreadPool`.

This function fully supports thread-based environments. For more information, see “Run MATLAB Functions in Thread-Based Environment”

bboxOverlapRatio

Compute bounding box overlap ratio

Syntax

```
overlapRatio = bboxOverlapRatio(bboxA,bboxB)
overlapRatio = bboxOverlapRatio(bboxA,bboxB,ratioType)
```

Description

`overlapRatio = bboxOverlapRatio(bboxA,bboxB)` returns the overlap ratio between each pair of bounding boxes `bboxA` and `bboxB`. The function returns the `overlapRatio` value between `0` and `1`, where `1` implies a perfect overlap.

`overlapRatio = bboxOverlapRatio(bboxA,bboxB,ratioType)` additionally lets you specify the method to use for computing the ratio. You must set the `ratioType` to either `'Union'` or `'Min'`.

Examples

Compute the Overlap Ratio Between Two Bounding Boxes

Define two bounding boxes in the format [x y width height].

```
bboxA = [150,80,100,100];
bboxB = bboxA + 50;
```

Display the bounding boxes on an image.

```
I = imread('peppers.png');
RGB = insertShape(I,'filled-rectangle',bboxA,'ShapeColor','green');
RGB = insertShape(RGB,'filled-rectangle',bboxB,'ShapeColor','yellow');
imshow(RGB)
```

Compute the overlap ratio between the two bounding boxes.

```
overlapRatio = bboxOverlapRatio(bboxA,bboxB)
```

```
overlapRatio =
0.0833
```

Compute Overlap Ratio Between Each Pair of Bounding Boxes

Randomly generate two sets of bounding boxes.

```
bboxA = 10*rand(5,4);
bboxB = 10*rand(10,4);
```

Ensure that the width and height of the boxes are positive.

```
bboxA(:,3:4) = bboxA(:,3:4) + 10;
bboxB(:,3:4) = bboxB(:,3:4) + 10;
```

Compute the overlap ratio between each pair.

```
overlapRatio = bboxOverlapRatio(bboxA,bboxB)
```

```
overlapRatio = 5×10

    0.2431    0.2329    0.3418    0.5117    0.7972    0.1567    0.1789    0.4339    0.0906    0.5

    0.4844    0.3290    0.3448    0.1500    0.1854    0.4976    0.5629    0.4430    0.5027    0.2
    0.3681    0.0825    0.3499    0.0840    0.0658    0.5921    0.6498    0.1930    0.7433    0.0
    0.3752    0.1114    0.3114    0.0696    0.0654    0.5408    0.6234    0.2046    0.7557    0.0
```

Input Arguments

bboxA — Bounding box

M-by-4 matrix | *M*-by-5 matrix

Bounding boxes, specified as an *M*-by-4 or *M*-by-5 nonsparse numeric matrix. *M* is the number of bounding boxes. Each row of the matrix defines a bounding box as either an axis-aligned rectangle or a rotated rectangle. This table describes the format for each bounding box.

Bounding Box	Row	Description
Axis-aligned rectangle	[x_{min}, y_{min}, *width*, *height*]	This type of bounding box is defined in pixel coordinates as an *M*-by-4 matrix representing *M* bounding boxes
Rotated rectangle	[x_{center}, y_{center}, *width*, *height*, *yaw*]	This type of bounding box is defined in spatial coordinates as an *M*-by-5 matrix representing *M* bounding boxes. The x_{center} and y_{center} coordinates represent the center of the bounding box. The *width* and *height* elements represent the length of the box along the *x* and *y* axes, respectively. The *yaw* represents the rotation angle in degrees. The amount of rotation about the center of the bounding box is measured in the clockwise direction.

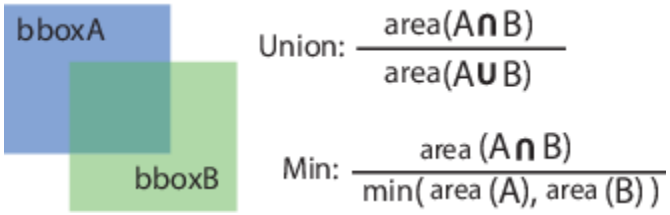
Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

bboxB — Bounding box

M-by-4 matrix | *M*-by-5 matrix

Bounding boxes, specified as an *M*-by-4 or *M*-by-5 nonsparse numeric matrix. *M* is the number of bounding boxes. Each row, *M*, of the matrix defines a bounding box as either an axis-aligned rectangle or a rotated rectangle. This table describes the format for each bounding box.

Bounding Box	Row	Description
Axis-aligned rectangle	[x_{min}, y_{min}, *width*, *height*]	This type of bounding box is defined in pixel coordinates as an *M*-by-4 matrix representing *M* bounding boxes



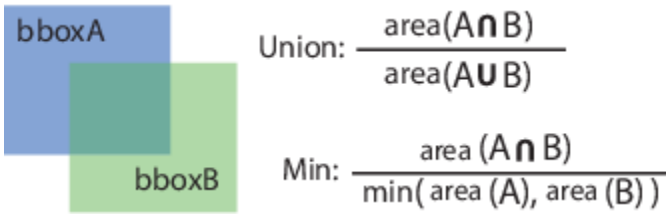
Bounding Box	Row	Description
Rotated rectangle	[x_{center}, y_{center}, *width*, *height*, *yaw*]	This type of bounding box is defined in spatial coordinates as an *M*-by-5 matrix representing *M* bounding boxes. The x_{center} and y_{center} coordinates represent the center of the bounding box. The *width* and *height* elements represent the length of the box along the *x* and *y* axes, respectively. The *yaw* represents the rotation angle in degrees. The amount of rotation about the center of the bounding box is measured in the clockwise direction.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

`ratioType` — Ratio type
`'Union'` (default) | `'Min'`

Ratio type, specified as the character vector `'Union'` or `'Min'`.

- Set the ratio type to `'Union'` to compute the ratio as the area of intersection between `bboxA` and `bboxB`, divided by the area of the union of the two.
- Set the ratio type to `'Min'` to compute the ratio as the area of intersection between `bboxA` and `bboxB`, divided by the minimum area of the two bounding boxes.



Data Types: `char`

Output Arguments

`overlapRatio` — Overlap ratio between two bounding boxes
M-by-*N* matrix

Overlap ratio between two bounding boxes, returned as an *M*-by-*N* matrix. Each (*I*, *J*) element in the output matrix corresponds to the overlap ratio between row *I* in `bboxA` and row *J* in `bboxB`. The function returns `overlapRatio` in the between 0 and 1, where `1` implies a perfect overlap. If either `bboxA` or `bboxB` is double, then the function returns `overlapRatio` as `double`. Otherwise, the function returns it as `single`.

The function computes the overlap ratio based on the ratio type. You can set `ratioType` to `'Union'` or `'Min'`:

Data Types: `single` | `double`

bboxPrecisionRecall

Compute bounding box precision and recall against ground truth

Syntax

```
[precision,recall] = bboxPrecisionRecall(bboxes,groundTruthBboxes)
[precision,recall] = bboxPrecisionRecall(bboxes,groundTruthBboxes,threshold)
```

Description

`[precision,recall] = bboxPrecisionRecall(bboxes,groundTruthBboxes)` measures the accuracy of bounding box overlap between `bboxes` and `groundTruthBboxes`. Precision is a ratio of true positive instances to all positive instances of objects in the detector, based on the ground truth. Recall is a ratio of true positive instances to the sum of true positives and false negatives in the detector, based on the ground truth.

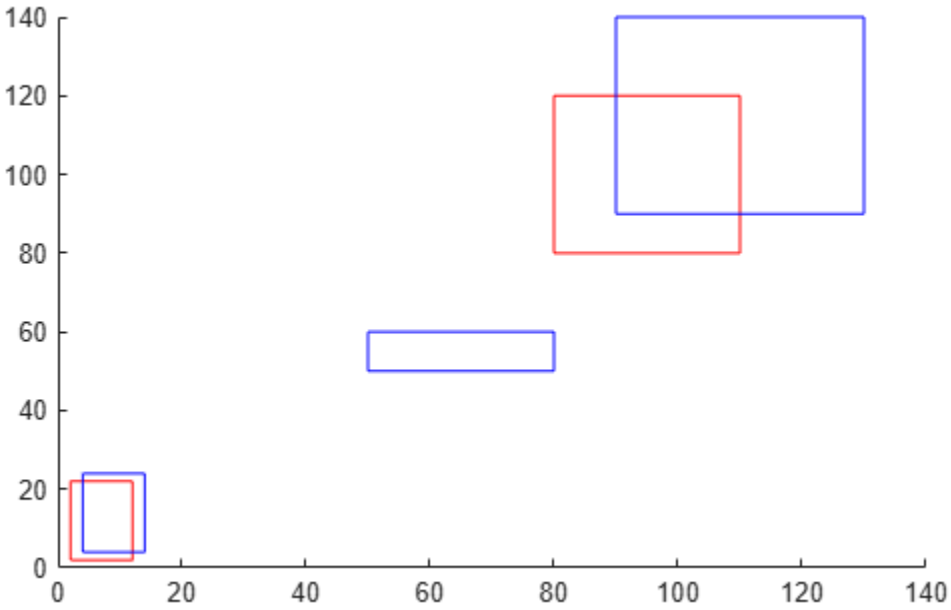
If the bounding box is associated with a class label, `precision` and `recall` contain metrics for each class. If the bounding box is also associated with a confidence score for ranking, use the `evaluateObjectDetection` function.

`[precision,recall] = bboxPrecisionRecall(bboxes,groundTruthBboxes,threshold)` specifies the overlap threshold for assigning a given box to a ground truth box.

Examples

Evaluate Bounding Box Overlap Accuracy

Create two ground truth boxes.



```
groundTruthBoxes = [2 2 10 20; 80 80 30 40];
```

Create three boxes for evaluation.

```
boundingBoxes = [4 4 10 20; 50 50 30 10; 90 90 40 50];
```

Plot the boxes.

```
figure
hold on
for i=1:2
    rectangle('Position',groundTruthBoxes(i,:),'EdgeColor','r');
end
for i=1:3
    rectangle('Position',boundingBoxes(i,:),'EdgeColor','b');
end
```

Evaluate the overlap accuracy against the ground truth data.

```
[precision,recall] = bboxPrecisionRecall(boundingBoxes,groundTruthBoxes)
```

```
precision =
0.3333

recall =
0.5000
```

Evaluate Bounding Box Overlap for Three Classes

Define class names.

```
classNames = ["A","B","C"];
```

Create bounding boxes for evaluation.

```
predictedLabels = {...
    categorical("A",classNames); ...
    categorical(["C";"B"],classNames)};
bboxes = {...
    [10 10 20 30]; ...
    [60 18 20 10; 120 120 5 10]};
boundingBoxes = table(bboxes,predictedLabels,'VariableNames',...
    {'PredictedBoxes','PredictedLabels'});
```

Create ground truth boxes.

```
A = {[10 10 20 28]; []};
B = {[]; [118 120 5 10]};
```

```
C = {[]; [59 19 20 10]};
groundTruthData = table(A,B,C);
```

Evaluate overlap accuracy against ground truth data.

```
[precision,recall] = bboxPrecisionRecall(boundingBoxes,groundTruthData)
```

```
precision = 3×1

     1
     0
     1

recall = 3×1

     1
     0
     1
```

Input Arguments

bboxes — Bounding boxes

M-by-4 matrix | table with *M* rows

Bounding boxes, specified as one of the following. *M* is the number of bounding boxes.

- For single-class bounding boxes, `bboxes` can be an *M*-by-4 matrix, or a table with *M* rows and one column. Each row of the matrix or element in the table represents a bounding box, specified in the format [*x y width height*], where *x* and *y* correspond to the upper left corner of the bounding box.
- For multi-class bounding boxes, `bboxes` is a table with *M* rows and two columns. Each element in the first column represents a bounding box, specified in the format [*x y width height*]. The second column contains the predicted label for each box. The label must be a categorical type defined by the variable (column) names of the `groundTruthBboxes` table.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

groundTruthBboxes — Ground truth bounding boxes

M-by-4 matrix | table with *M* rows

Ground truth bounding boxes, specified as one of the following. *M* is the number of ground truth bounding boxes.

- For single-class bounding boxes, `groundTruthBboxes` can be an *M*-by-4 matrix, or a table with *M* rows and one column. Each row of the matrix or element in the table represents a bounding box, specified in the format [*x y width height*], where *x* and *y* correspond to the upper left corner of the bounding box.
- For multi-class bounding boxes, `groundTruthBboxes` is a table with *M* rows and multiple columns. Each column represents a different class, and the column name specifies the class label. Each element in the table has the format [*x y width height*].

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

`threshold` — Overlap threshold
`0.5` | numeric scalar

Overlap threshold for assigned a detection to a ground truth box, specified as a numeric scalar. The overlap ratio is computed as the IoU (intersection over union).

Output Arguments

`precision` — Precision
numeric scalar | numeric vector

Precision, returned as a numeric scalar for single-class bounding boxes, or a numeric vector consisting of metrics for each class for multi-class bounding boxes. The class order follows the same column order as the `groundTruthBboxes` table.

`recall` — Recall
numeric scalar | numeric vector

Recall, returned as a numeric scalar for single-class bounding boxes, or a numeric vector consisting of metrics for each class for multi-class bounding boxes. The class order follows the same column order as the `groundTruthBboxes` table.

bundleAdjustment

Adjust collection of 3-D points and camera poses

Syntax

```
[xyzRefinedPoints,refinedPoses] = bundleAdjustment(xyzPoints,pointTracks,
cameraPoses,intrinsics)
[wpSetRefined,vSetRefined,pointIndex] = bundleAdjustment(wpSet,vSet,viewIDs,
intrinsics)
[___,reprojectionErrors] = bundleAdjustment(___)
[___] = bundleAdjustment(___,Name=Value)
```

Description

`[xyzRefinedPoints,refinedPoses] = bundleAdjustment(xyzPoints,pointTracks, cameraPoses,intrinsics)` refines 3-D points and camera poses to minimize reprojection errors. The refinement procedure is a variant of the Levenberg-Marquardt algorithm. The function uses the same global reference coordinate system to return both the 3-D points and camera poses.

`[wpSetRefined,vSetRefined,pointIndex] = bundleAdjustment(wpSet,vSet,viewIDs, intrinsics)` refines 3-D points from the world point set, `wpSet`, and refines camera poses from the image view set, `vSet`. `viewIDs` specify the camera poses in `vSet` to refine.

`[___,reprojectionErrors] = bundleAdjustment(___)` returns the mean reprojection error for each 3-D world point, in addition to the arguments from the previous syntax.

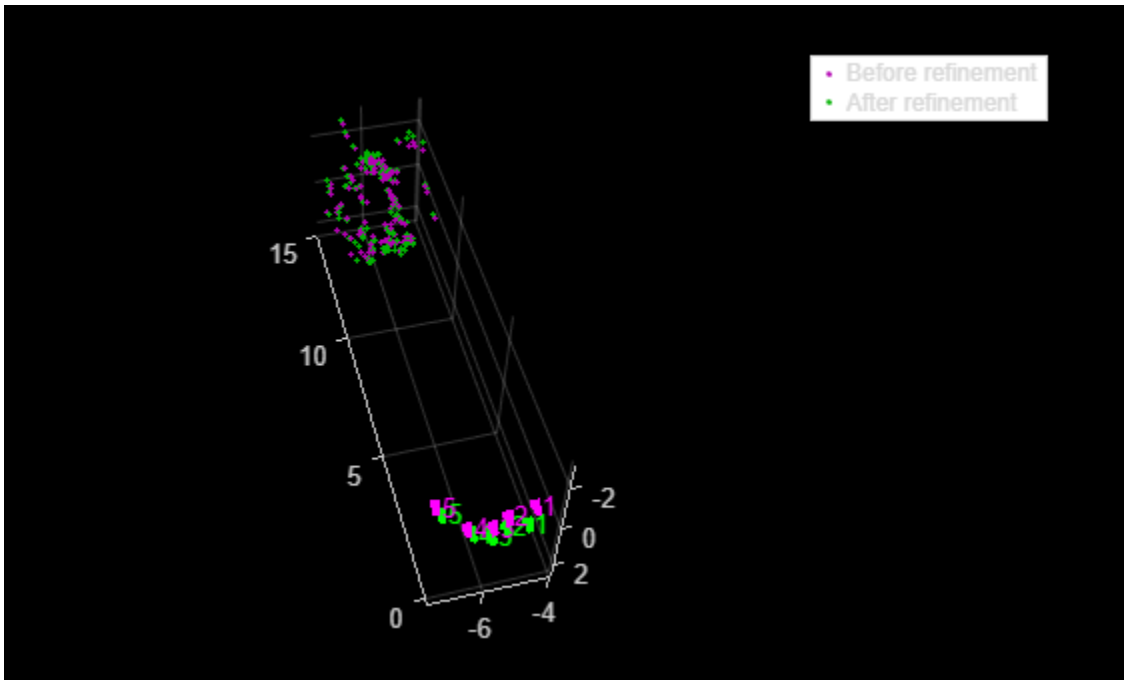
`[___] = bundleAdjustment(___,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `MaxIterations=50` sets the number of iterations to `50`. Unspecified arguments have default values.

Examples

Refine 3-D Points and Camera Poses from Single Camera

Load data for initialization.

```
data = load("globeBA.mat");
```



Refine the camera poses and points.

```
[xyzRefinedPoints,refinedPoses] = ...
    bundleAdjustment(data.xyzPoints,data.pointTracks,data.cameraPoses,data.intrinsics);
```

Display the 3-D points and camera poses before and after the refinement.

```
pcshowpair(pointCloud(data.xyzPoints), pointCloud(xyzRefinedPoints), ...
    AxesVisibility="on", VerticalAxis="y", VerticalAxisDir="down", MarkerSize=40);
hold on
plotCamera(data.cameraPoses, Size=0.1, Color="m");
```

```
plotCamera(refinedPoses, Size=0.1, Color="g");
legend("Before refinement", "After refinement", color="w");
```

Input Arguments

`xyzPoints` — Unrefined 3-D points

M-by-3 matrix

Unrefined 3-D points, specified as an *M*-by-3 matrix of [*x* *y* *z*] locations.

`pointTracks` — Matching points across multiple images

N-element array of `pointTrack` objects

Matching points across multiple images, specified as an *N*-element array of `pointTrack` objects. Each element contains two or more matching points across multiple images.

`cameraPoses` — Camera pose information

two-column table

Camera pose information, specified as a two-column table with columns `ViewId` and `AbsolutePose`. The view IDs relate to the IDs of the objects in the `pointTracks` argument. You can use the `poses` object function to obtain the `cameraPoses` table.

`intrinsics` — Camera intrinsics

`cameraIntrinsics` object | *N*-element array of `cameraIntrinsics` objects

Camera intrinsics, specified as a `cameraIntrinsics` object or an *N*-element array of `cameraIntrinsics` objects. *N* is the number of camera poses or the number of IDs in `viewIDs`. Use a single `cameraIntrinsics` object when images are captured using the same camera. Use a vector `cameraIntrinsics` objects when images are captured by different cameras.

wpSet — 3-D world points
`worldpointset` object

3-D world points, specified as a `worldpointset` object.

vSet — Camera poses
`imageviewset` object

Camera poses, specified as an `imageviewset` object.

viewIDs — View identifiers
N-element array

View identifiers, specified as an *N*-element array. The `viewIDs` represent which camera poses to refine specifying their related views in `imageviewset`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `MaxIterations=50` sets the number of iterations to `50`.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

MaxIterations — Maximum number of iterations
`50` (default) | positive integer

Maximum number of iterations before the Levenberg-Marquardt algorithm stops, specified as a positive integer.

AbsoluteTolerance — Absolute termination tolerance
`1.0` (default) | positive scalar

Absolute termination tolerance of the mean squared reprojection error in pixels, specified as positive scalar.

RelativeTolerance — Relative termination tolerance
`1e-5` (default) | positive scalar

Relative termination tolerance of the reduction in reprojection error between iterations, specified as positive scalar.

PointsUndistorted — Flag to indicate lens distortion
`false` (default) | `true`

Flag to indicate lens distortion, specified as `false` or `true`. When you set `PointsUndistorted` to `false`, the 2-D points in `pointTracks` or in `vSet` must be from images with lens distortion. To use undistorted points, first use the `undistortImage` function to remove distortions from the images, then set `PointsUndistorted`.

FixedViewIDs — View IDs for fixed camera pose
`[]` (default) | vector of nonnegative integers

View IDs for fixed camera pose, specified as a vector of nonnegative integers. Each ID corresponds to the `ViewId` of a fixed camera pose in `cameraPoses`. An empty value for `FixedViewIDs` means that all camera poses are optimized.

`Solver` — Solver
`"sparse-linear-algebra"` (default) | `"preconditioned-conjugate-gradient"`

Solver, specified as `"sparse-linear-algebra"` or `"preconditioned-conjugate-gradient"`. Use the `"sparse-linear-algebra"` solver for low sparsity images. Low sparsity indicates that many camera views observe some of the same world points. Use the `"preconditioned-conjugate-gradient"` (PCG) solver, from the general graphic optimization (g2o) library, for high sparsity images. High sparsity indicates that each camera view observes, only a small portion of the world points, specified by `xyzPoints`.

`Verbose` — Display progress information
`false` (default) | `true`

Display progress information, specified as `false` or `true`.

Output Arguments

`xyzRefinedPoints` — 3-D locations of refined world points
M-by-3 matrix

3-D locations of refined world points, returned as an *M*-by-3 matrix of [*x y z*] locations.

Data Types: `single` | `double`

`refinedPoses` — Refined camera poses
two-column table

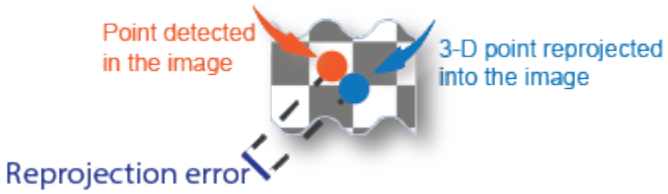
Refined camera poses, returned as a two-column table. The table contains columns for `ViewId` and `AbsolutePose`.

`wpSetRefined` — Refined 3-D world points
`worldpointset` object

Refined 3-D world points, returned as a `worldpointset` object.

`vSetRefined` — Refined camera poses
`imageviewset` object

Refined camera poses, specified as an `imageviewset` object.



`pointIndex` — Indices of refined 3-D world points
M-element array

Indices to `wpSetRefined` of refined 3-D world points, returned as an *M*-element array.

`reprojectionErrors` — Reprojection errors
M-element vector

Reprojection errors, returned as an *M*-element vector. The function projects each world point back into each camera. Then, in each image, the function calculates the reprojection error as the distance

between the detected and the reprojected point. The `reprojectionErrors` vector contains the average reprojection error for each world point.

R2022b: Supports premultiply geometric transformation convention
Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. The `bundleAdjustment` function now supports both the premultiply and the postmultiply convention.

Regardless of the convention, the `cameraPoses` argument must be a two-column table with variables `ViewId` and `AbsolutePose`. You can no longer specify the `cameraPoses` argument as a three-column table with variables `ViewID`, `Orientation`, and `Location`. The `bundleAdjustment` function chooses the convention according to the value of the `AbsolutePose` variable:

- When you specify `AbsolutePose` as a `rigidtform3d` object, the `bundleAdjustment` function uses the premultiply convention and returns `refinedPoses` with the `AbsolutePose` variable as a `rigidtform3d` object.
- When you specify `AbsolutePose` as a `rigid3d` object, the `bundleAdjustment` function uses the postmultiply convention and returns `refinedPoses` with the `AbsolutePose` variable as a `rigid3d` object.

Before, the function returned `refinedPoses` as a three-column table with variables `ViewID`, `Orientation`, and `Location`. If you need to obtain the values of `Orientation` and `Location`, which were in the postmultiply convention, then you can query properties of the geometric transformation object stored in the `AbsolutePose` variable:

- When `AbsolutePose` returns a `rigidtform3d` object, you can query the `R` and `Translation` properties of the object. The value of `R` is the transpose of `Orientation`.
- When `AbsolutePose` returns a `rigid3d` object, you can query the `Rotation` and `Translation` properties of the object. The value of `Rotation` is identical to `Orientation`.

You can streamline your geometric transformation workflows by switching to the premultiply geometric transformation convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

bundleAdjustmentMotion

Adjust collection of 3-D points and camera poses using motion-only bundle adjustment

Syntax

```
refinedPose = bundleAdjustmentMotion(xyzPoints,imagePoints,absolutePose,
intrinsics)
[refinedPose,reprojectionErrors] = bundleAdjustmentMotion( ___ )
[ ___ ] = bundleAdjustmentMotion( ___ ,Name,Value)
```

Description

`refinedPose = bundleAdjustmentMotion(xyzPoints,imagePoints,absolutePose, intrinsics)` returns the refined absolute camera pose that minimizes reprojection errors.

The motion-only refinement procedure is a special case of the Levenberg-Marquardt algorithm for bundle adjustment with 3-D points fixed during optimization. The 3-D points and the camera pose are placed in the same world coordinate system.

`[refinedPose,reprojectionErrors] = bundleAdjustmentMotion( ___ )` additionally returns an *N*-element vector containing the mean reprojection error for each 3-D world point using the arguments from the previous syntax.

`[ ___ ] = bundleAdjustmentMotion( ___ ,Name,Value)` uses additional options specified by one or more name-value arguments. Unspecified arguments have default values.

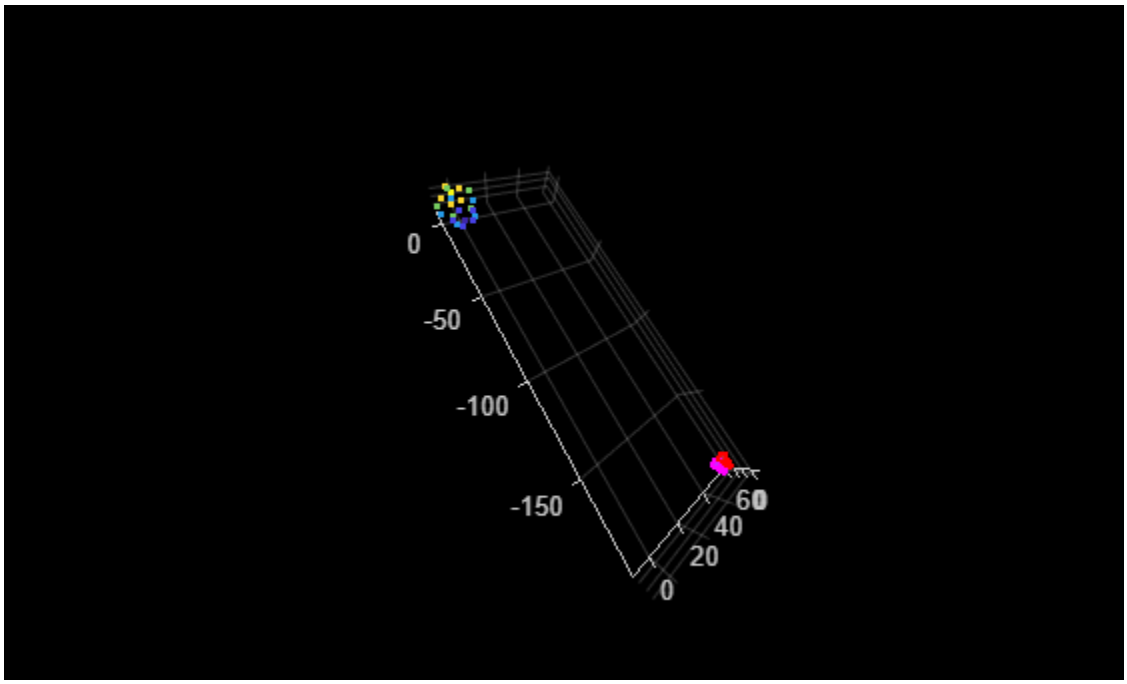
Examples

Refine Absolute Camera Pose

Load data for initialization into the workspace.

```
data = load("globeMotionOnlyBA.mat");
```

Refine the absolute camera poses.



```
refinedPose = bundleAdjustmentMotion(data.xyzPoints,data.imagePoints,data.absPose,data.intrinsics
```

Display the 3-D world points.

```
pcshow(data.xyzPoints,AxesVisibility="on",VerticalAxis="y",VerticalAxisDir="down",MarkerSize=45)
hold on
```

Plot the absolute camera poses before and after refinement.

```
plotCamera(AbsolutePose=data.absPose,Color="r",Size=2);
plotCamera(AbsolutePose=refinedPose,Color="m",Size=2);
```

Input Arguments

`xyzPoints` — Unrefined 3-D points
M-by-3 matrix

Unrefined 3-D points, specified as an *M*-by-3 matrix of [*x*,*y*,*z*] locations.

Data Types: `single` | `double`

`imagePoints` — Image points
M-by-2 matrix | *M*-element feature point array

Image points, specified as an *M*-by-2 matrix or an *M*-element "Point Feature Types" array.

`absolutePose` — Absolute camera pose
`rigidtform3d` object

Absolute camera pose, specified as a `rigidtform3d` object.

`intrinsics` — Camera intrinsics
`cameraIntrinsics` object

Camera intrinsics, specified as a `cameraIntrinsics` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `"MaxIterations",50`

`MaxIterations` — Maximum number of iterations
`50` (default) | positive integer

Maximum number of iterations before the Levenberg-Marquardt algorithm stops, specified as a positive integer.

`AbsoluteTolerance` — Absolute termination tolerance
`1.0` (default) | positive scalar

Absolute termination tolerance of the mean squared reprojection error in pixels, specified as a positive scalar.

`RelativeTolerance` — Relative termination tolerance
`1e-5` (default) | positive scalar

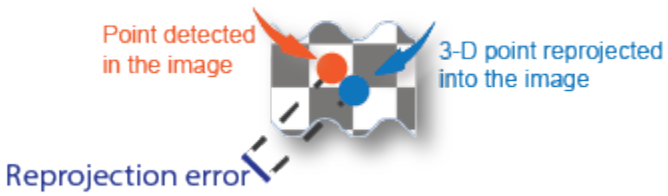
Relative termination tolerance of the reduction in reprojection error between iterations, specified as a positive scalar.

`PointsUndistorted` — Flag to indicate lens distortion
`false` (default) | `true`

Flag to indicate lens distortion, specified as `false` or `true`. When you set `PointsUndistorted` to `false`, the 2-D points in `pointTracks` must be from images with lens distortion. To use undistorted points, use the `undistortImage` function first, then set `PointsUndistorted` to `true`.

`Verbose` — Display progress information
`False` (default) | `true`

Display progress information, specified as `false` or `true`.



Output Arguments

`refinedPose` — Refined absolute pose
`rigidtform3d` object

Refined absolute pose of the camera, returned as a `rigidtform3d` object.

`reprojectionErrors` — Reprojection errors
M-element vector

Reprojection errors, returned as an *M*-element vector. The function projects each world point back into each camera. Then in each image, the function calculates the reprojection error as the distance between the detected and the reprojected point. The `reprojectionErrors` vector contains the average reprojection error for each world point.

Version History

R2022b: Supports premultiply geometric transformation convention

Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, the `bundleAdjustmentMotion` function now supports specifying `absolutePose` as a `rigidtform3d` object, which uses the premultiply convention. Although you can still specify `absolutePose` as a `rigid3d` object, this object is not recommended because it uses the postmultiply convention. The `bundleAdjustmentMotion` function returns `refinedPose` as a geometric transformation object of the same type as `absolutePose`.

You can streamline your geometric transformation workflows by switching to the premultiply geometric transformation convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

bundleAdjustmentStructure

Refine 3-D points using structure-only bundle adjustment

Syntax

```
xyzRefinedPoints = bundleAdjustmentStructure(xyzPoints,pointTracks,
cameraPoses,intrinsics)
[wpSetRefined,vSetRefined,pointIndex] = bundleAdjustmentStructure(wpSet,vSet,
viewID,intrinsics)
[xyzRefinedPoints,reprojectionErrors] = bundleAdjustmentStructure( ___ )
[ ___ ] = bundleAdjustmentStructure( ___ ,Name,Value)
```

Description

`xyzRefinedPoints = bundleAdjustmentStructure(xyzPoints,pointTracks, cameraPoses,intrinsics)` returns the refined 3-D points that minimize reprojection errors.

The structure-only refinement procedure is a special case of bundle adjustment with camera poses fixed during optimization. The 3-D points and the camera poses are placed in the same world coordinate system.

`[wpSetRefined,vSetRefined,pointIndex] = bundleAdjustmentStructure(wpSet,vSet, viewID,intrinsics)` refines 3-D points from the world point set, `wpSet`, and refines camera poses from the image view set, `vSet`. `viewID` specifies the IDs if the views in `vSet`.

`[xyzRefinedPoints,reprojectionErrors] = bundleAdjustmentStructure( ___ )` additionally returns an *N*-element vector containing the mean reprojection error for each 3-D world point using the arguments from the previous syntax.

`[ ___ ] = bundleAdjustmentStructure( ___ ,Name,Value)` uses additional options specified by one or more name-value arguments. Unspecified arguments have default values.

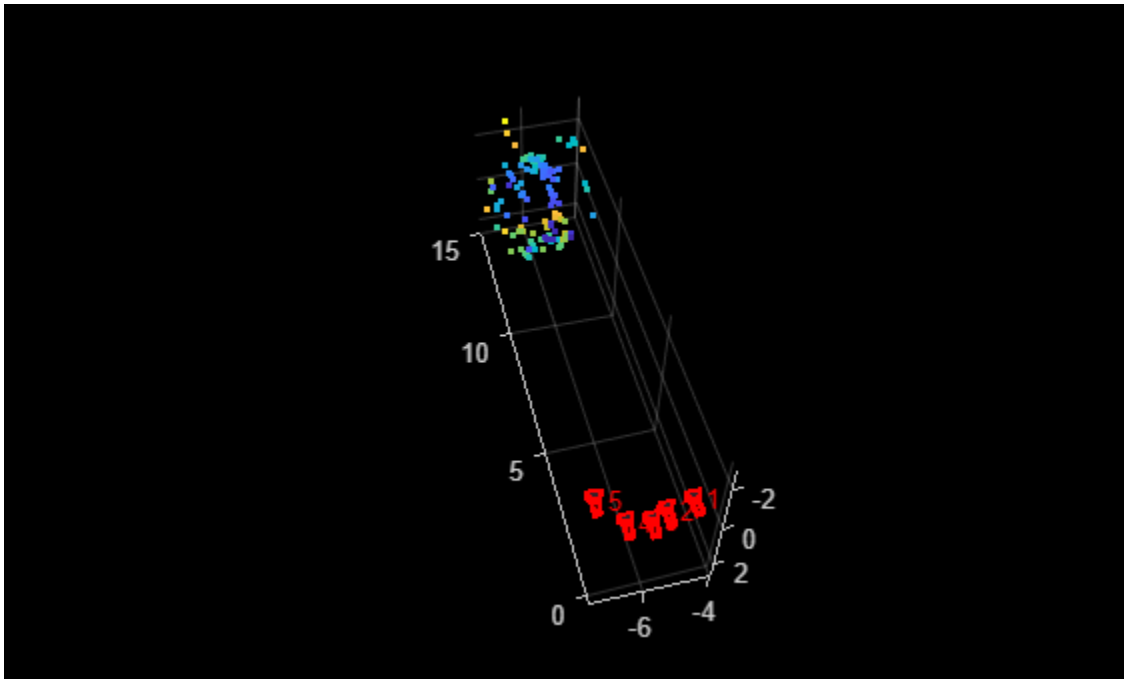
Examples

Refine 3-D Points from Single Camera

Load data for initialization.

```
data = load('globeBA.mat');
```

Refine the 3-D world points.



```
xyzRefinedPoints = bundleAdjustmentStructure(data.xyzPoints,data.pointTracks,data.cameraPoses,da
```

Display the refined 3-D world points.

```
pcshow(xyzRefinedPoints,AxesVisibility="on",VerticalAxis="y",VerticalAxisDir="down",MarkerSize=4
```

Display the cameras.

```
hold on
plotCamera(data.cameraPoses,Size=0.2);
hold off
grid on
```

Input Arguments

`xyzPoints` — Unrefined 3-D points
M-by-3 matrix

Unrefined 3-D points, specified as an *M*-by-3 matrix of [*x*,*y*,*z*] locations.

Data Types: `single` | `double`

`pointTracks` — Matched points
N-element array of `pointTracks` objects

Matched points across multiple images, specified as an *N*-element array of `pointTracks` objects.

`cameraPoses` — Camera poses
table

Camera poses, specified as a table containing the two columns `ViewId` and `AbsolutePose`. You can get the `cameraPoses` table using the `poses` object function of the `imageviewset` object.

`wpSet` — 3-D world points
`worldpointset` object

3-D world points, specified as a `worldpointset` object.

`vSet` — Camera poses
`imageviewset` object

Camera poses, specified as an `imageviewset` object.

`viewID` — View identifiers of the views in `vSet`
N-element array

View identifiers of the views in `vSet`, specified as an *N*-element array. The `viewIDs` represent which camera poses to refine specifying their related views in `imageviewset`.

`intrinsics` — Camera intrinsics
`cameraIntrinsics` object | *N*-element array of `cameraIntrinsics` objects

Camera intrinsics, specified as a `cameraIntrinsics` object or an *N*-element array of `cameraIntrinsics` objects. *N* is the number of camera poses or the number of IDs in `viewIDs`. Use a single `cameraIntrinsics` object when images are captured using the same camera. Use a vector `cameraIntrinsics` objects when images are captured by different cameras.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `MaxIterations=50` sets the number of iterations to `50`.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

`MaxIterations` — Maximum number of iterations
`50` (default) | positive integer

Maximum number of iterations before the Levenberg-Marquardt algorithm stops, specified as a positive integer.

`AbsoluteTolerance` — Absolute termination tolerance
`1.0` (default) | positive scalar

Absolute termination tolerance of the mean squared reprojection error in pixels, specified as a positive scalar.

`RelativeTolerance` — Relative termination tolerance
`1e-5` (default) | positive scalar

Relative termination tolerance of the reduction in reprojection error between iterations, specified as a positive scalar.

`PointsUndistorted` — Flag to indicate lens distortion
`false` (default) | `true`

Flag to indicate lens distortion, specified as `false` or `true`. When you set `PointsUndistorted` to `false`, the 2-D points in `pointTracks` or in `vSet` must be from images with lens distortion. To use undistorted points, first use the `undistortImage` function to remove distortions from the images, then set `PointsUndistorted`.

`Verbose` — Display progress information
`False` (default) | `true`

Display progress information, specified as `false` or `true`.

Output Arguments

`xyzRefinedPoints` — 3-D locations of refined world points
M-by-3 matrix

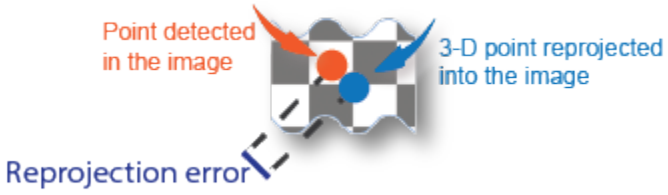
3-D locations of refined world points, returned as an *M*-by-3 matrix of [*x*,*y*, *z*] locations.

Data Types: `single` | `double`

`wpSetRefined` — Refined 3-D world points
`worldpointset` object

Refined 3-D world points, returned as a `worldpointset` object.

`vSetRefined` — Refined camera poses
`imageviewset` object



Refined camera poses, returned as a `imageviewset` object.

`pointIndex` — Indices of refined 3-D world points
M-element array

Indices to `wpSetRefined` of refined 3-D world points, returned as an *M*-element array.

`reprojectionErrors` — Reprojection errors
M-element vector

Reprojection errors, returned as an *M*-element vector. The function projects each world point back into each camera. Then in each image, the function calculates the reprojection error as the distance between the detected and the reprojected point. The `reprojectionErrors` vector contains the average reprojection error for each world point.

Version History

Introduced in R2020a

R2022b: Supports premultiply geometric transformation convention
Behavior changed in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. Accordingly, the `bundleAdjustmentStructure` function now accepts `cameraPoses` as a table whose `AbsolutePose` column stores a `rigidtform3d` object, which uses the premultiply convention. This format is consistent with poses returned by the `poses` function of the `imageviewset` object.

Although you can still specify `cameraPoses` as a table whose `AbsolutePose` column stores a `rigid3d` object, this object is not recommended because it uses the postmultiply convention. You can streamline your geometric transformation workflows by switching to the premultiply geometric transformation convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

pcfromkinect

Point cloud from Kinect for Windows

Syntax

```
ptCloud = pcfromkinect(depthDevice,depthImage)
ptCloud = pcfromkinect(depthDevice,depthImage,colorImage)
ptCloud = pcfromkinect(depthDevice,depthImage,colorImage,alignment)
```

Description

`ptCloud = pcfromkinect(depthDevice,depthImage)` returns a point cloud from a Kinect depth image. The `depthDevice` input can be either a `videoinput` object or an `imaq.VideoDevice` object configured for Kinect (Versions 1 and 2) for Windows.

This function requires the Image Acquisition Toolbox™ software, which supports Kinect for Windows.

`ptCloud = pcfromkinect(depthDevice,depthImage,colorImage)` adds color to the returned point cloud, specified by the `colorImage` input.

The Kinect for Windows system, designed for gaming, produces `depthImage` and `colorImage` as mirror images of the scene. The returned point cloud is corrected to match the actual scene.

`ptCloud = pcfromkinect(depthDevice,depthImage,colorImage,alignment)` additionally specifies the direction of the alignment of the image coordinate system, which can be color centric or depth centric.

Examples

Plot Color Point Cloud from Kinect for Windows

Plot a color point cloud from Kinect images. This example requires the Image Acquisition Toolbox software and the Kinect camera and a connection to the camera.

Create a System object for the color device.

```
colorDevice = imaq.VideoDevice('kinect',1)
```

Create a System object for the depth device.

```
depthDevice = imaq.VideoDevice('kinect',2)
```

Initialize the camera.

```
step(colorDevice);
step(depthDevice);
```

Load one frame from the device.

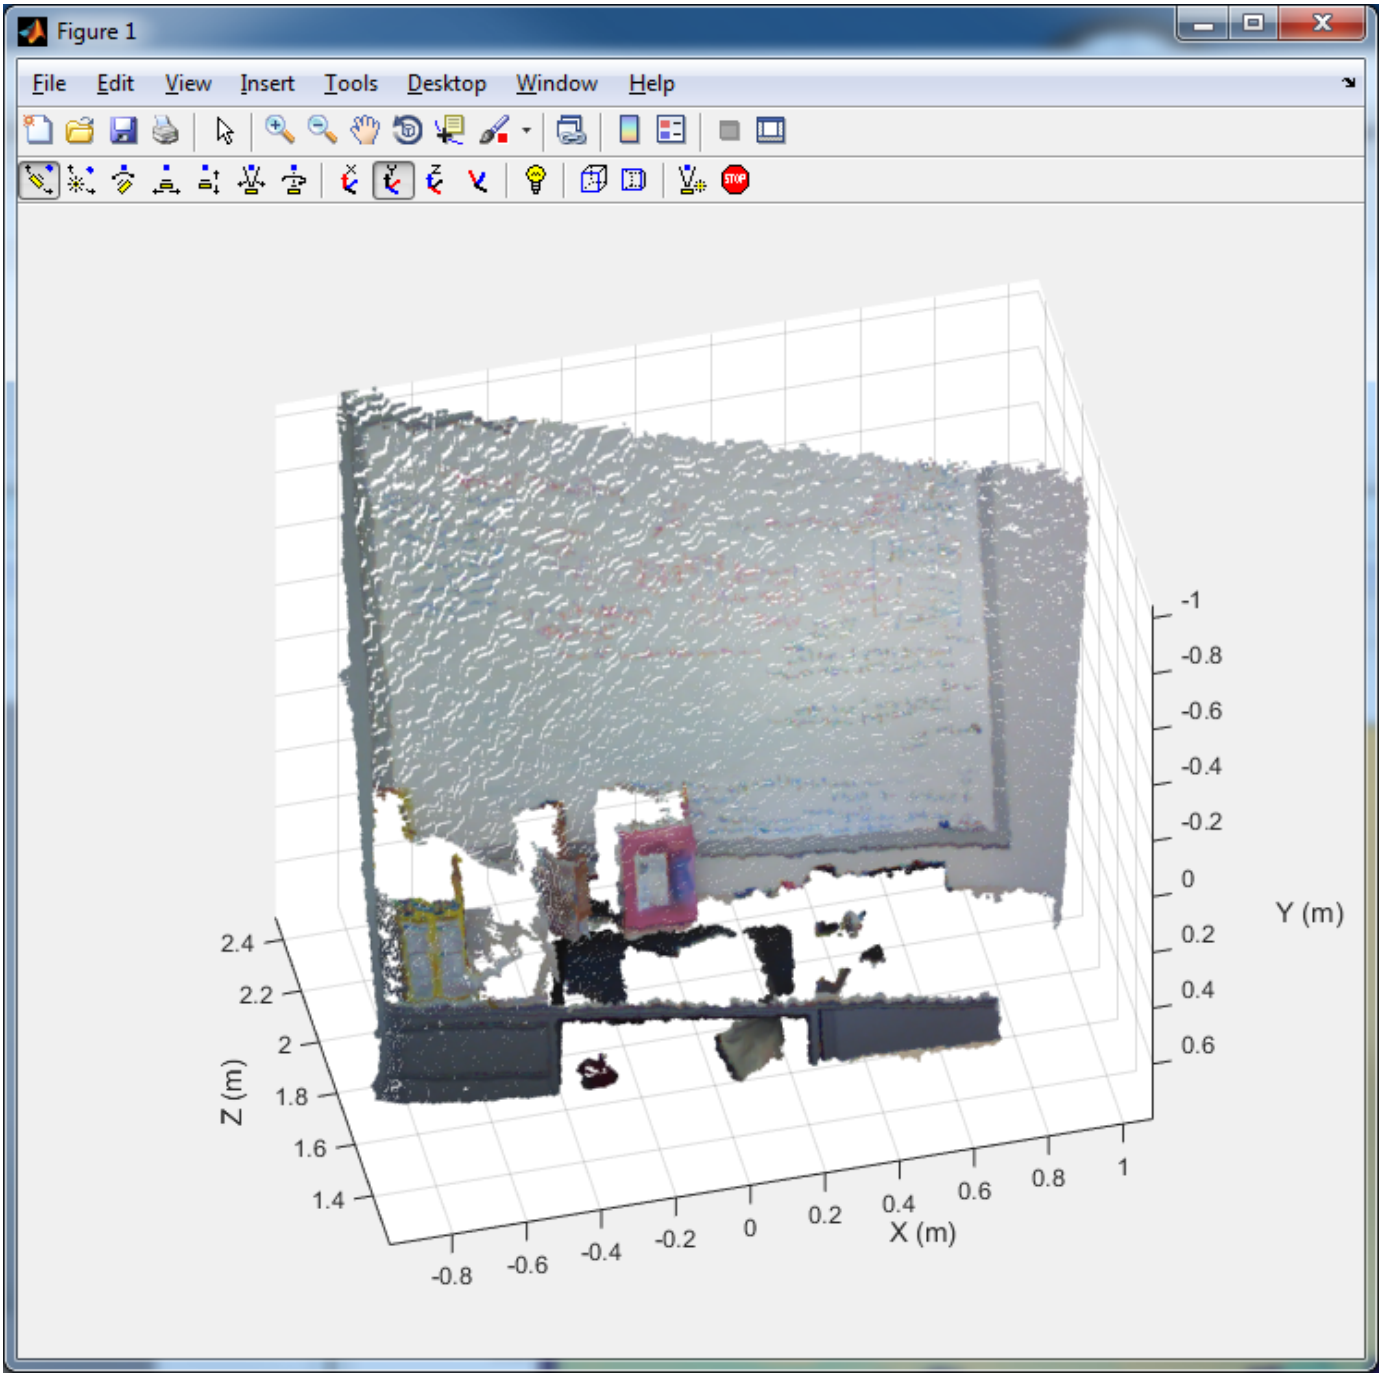
```
colorImage = step(colorDevice);
depthImage = step(depthDevice);
```

Extract the point cloud.

```
ptCloud = pcfromkinect(depthDevice,depthImage,colorImage);
```

Initialize a point cloud player to visualize 3-D point cloud data. The axis is set appropriately to visualize the point cloud from Kinect.

```
player = pcplayer(ptCloud.XLimits,ptCloud.YLimits,ptCloud.ZLimits,...
    'VerticalAxis','y','VerticalAxisDir','down');



xlabel(player.Axes,'X (m)');
ylabel(player.Axes,'Y (m)');
zlabel(player.Axes,'Z (m)');
```

Acquire and view 500 frames of live Kinect point cloud data.

```
for i = 1:500
   colorImage = step(colorDevice);
   depthImage = step(depthDevice);

   ptCloud = pcfromkinect(depthDevice,depthImage,colorImage);

   view(player,ptCloud);
end
```

Release the objects.

```
release(colorDevice);
release(depthDevice);
```

Input Arguments

depthDevice — Input video object

`videoinput` object | `imaq.VideoDevice` object

Input video object, specified as either a `videoinput` object or an `imaq.VideoDevice` object configured for Kinect for Windows.

depthImage — Depth image

M-by-*N* matrix

Depth image, specified as an *M*-by-*N* pixel matrix. The original images, `depthImage` and `colorImage`, from Kinect are mirror images of the scene.

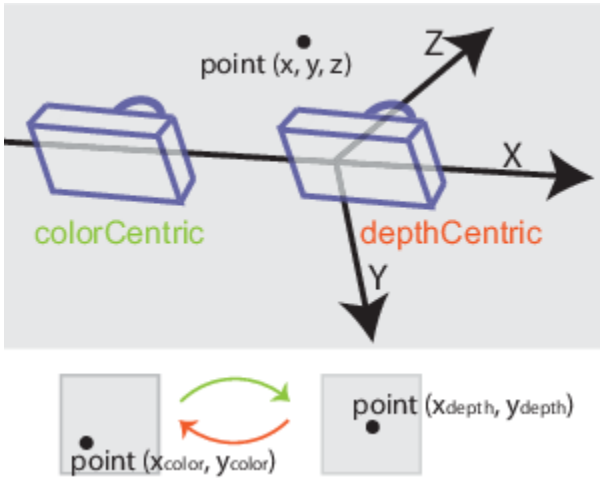
The Kinect depth camera has limited range. The limited range of the Kinect depth camera can cause pixel values in the depth image to not have corresponding 3-D coordinates. These missing pixel values are set to `NaN` in the `Location` property of the returned point cloud.

Data Types: `uint16`

colorImage — Color image

M-by-*N*-by-3 RGB truecolor image

Color image, specified as an *M*-by-*N*-by-3 RGB truecolor image that the Kinect returns. The original images, `depthImage` and `colorImage`, from Kinect are mirror images of the scene.



Data Types: `uint8`

alignment — Direction of the image coordinate system

`'colorCentric'` (default) | `'depthCentric'`

Direction of the image coordinate system, specified as the character vector `'colorCentric'` or `'depthCentric'`. Set this value to `'colorCentric'` to align `depthImage` with `colorImage`. Set `alignment` to `'depthCentric'` to align `colorImage` with `depthImage`.

The origin of a right-handed world coordinate system is at the center of the depth camera. The *x*-axis of the coordinate system points to the right, the *y*-axis points downward, and the *z*-axis points away from the camera.

Note For consistency across Computer Vision Toolbox use of coordinates systems, the coordinate system defined by this function is different from the one defined by Kinect Skeletal metadata.

Output Arguments

`ptCloud` — Point cloud

`pointCloud` object

Point cloud, returned as a `pointCloud` object. The origin of the coordinate system of the returned point cloud is at the center of the depth camera.

Camera Calibrator

Estimate geometric parameters of a single camera

Description

The Camera Calibrator app allows you to estimate camera intrinsics, extrinsics, and lens distortion parameters. You can use these camera parameters for various computer vision applications. These applications include removing the effects of lens distortion from an image, measuring planar objects, or reconstructing 3-D scenes from multiple cameras.

Note Ensure that the images you are using were captured specifically for single camera calibration following the guidelines outlined in “Prepare Camera and Capture Images for Camera Calibration”. Using images captured for multi-sensor calibration can lead to inaccurate camera intrinsics.

Open the Camera Calibrator App

- MATLAB Toolstrip: On the **Apps** tab, under **Image Processing and Computer Vision**, click the app icon.
- MATLAB command prompt: Enter `cameraCalibrator`.

Examples

Open Camera Calibrator App

This example shows you the two ways to open the Camera Calibrator app.

Type `cameraCalibrator` on the MATLAB command line or select it from the MATLAB desktop **Apps** tab.

- “Evaluating the Accuracy of Single Camera Calibration”
- “Measuring Planar Objects with a Calibrated Camera”
- “Structure from Motion from Two Views”
- “Structure from Motion from Multiple Views”
- “Depth Estimation from Stereo Video”

Programmatic Use

`cameraCalibrator` opens the Camera Calibrator app, which enables you to compute parameters needed to remove the effects of lens distortion from an image.

`cameraCalibrator(imageFolder,squareSize)` opens the app and loads calibration images from a specified folder and specifies the size of the checkerboard squares contained in the images. The `squareSize` input must be a scalar in millimeters.

`cameraCalibrator(imageFolder,squareSize,squareSizeUnits)` opens the app, loads calibration images, specifies the checkerboard square size, and the square size units. The `squareSizeUnits` input must be specified as `'millimeters'` (default), `'centimeters'`, or `'inches'`.

`cameraCalibrator( ___ ,highDistortion)` opens the app as described by previous syntaxes and additionally specifies a high distortion logical `highDistortion`. Set `highDistortion` to `true` when the images contain a high level of distortion, which is typical of a wide field of view camera. Set `highDistortion` to `false` (default) when the images do not contain a high level of distortion.

`cameraCalibrator(sessionFile)` opens the app and loads a saved camera calibration session. Set the `sessionFile` to the name of the saved session file. The name must include the path to the MAT file containing the saved session.

Stereo Camera Calibrator

Estimate geometric parameters of a stereo camera

Description

The Stereo Camera Calibrator app allows you to estimate the intrinsic and extrinsic parameters of each camera in a stereo pair. You can also use the app to estimate the translation and rotation between the two cameras.

Open the Stereo Camera Calibrator App

- MATLAB Toolstrip: On the **Apps** tab, under **Image Processing and Computer Vision**, click the app icon.
- MATLAB command prompt: Enter `stereoCameraCalibrator`.

Examples

Open Stereo Camera Calibrator App

This example shows you the two ways to open the Stereo Camera Calibrator app.

Type `stereoCameraCalibrator` on the MATLAB command line or select it from the MATLAB desktop **Apps** tab.

- “Evaluating the Accuracy of Single Camera Calibration”
- “Measuring Planar Objects with a Calibrated Camera”
- “Structure from Motion from Two Views”
- “Structure from Motion from Multiple Views”
- “Depth Estimation from Stereo Video”

Programmatic Use

`stereoCameraCalibrator` opens the Stereo Camera Calibrator app. You can use this app to estimate the intrinsic and extrinsic parameters of each camera in a stereo pair. You can also use the app to estimate the translation and rotation between the two cameras.

`stereoCameraCalibrator(folder1,folder2,squareSize)` opens the Stereo Camera Calibrator app and loads the stereo calibration images. The app uses the checkerboard square size specified by the `squareSize` input. It also uses `folder1` images for camera 1 and `folder2` for camera 2.

`stereoCameraCalibrator(folder1,folder2,squareSize,squareSizeUnits)` additionally specifies the units of the square size. If you do not specify units, the app sets `squareSizeUnits` to `'millimeters'`. Units can be `'millimeters'`, `'centimeters'`, or `'inches'`.

`stereoCameraCalibrator(sessionFile)` opens the app and loads a saved stereo calibration session. Set the `sessionFile` to the name of the saved session MAT-file.

cameraMatrix

(Not recommended) Camera projection matrix

Note `cameraMatrix` is not recommended. Use the `cameraProjection` function instead. For more information, see “Version History”.

Syntax

```
camMatrix = cameraMatrix(cameraParams,tform)
camMatrix = cameraMatrix(cameraParams,rotationMatrix,translationVector)
```

Description

`camMatrix = cameraMatrix(cameraParams,tform)` returns a 4-by-3 camera projection matrix `camMatrix`, which can be used to project a 3-D world point in homogeneous coordinates into an image. `cameraParams` can be a `cameraParameters` object or a `cameraIntrinsics` object.

`camMatrix = cameraMatrix(cameraParams,rotationMatrix,translationVector)` returns a 4-by-3 camera projection matrix. You can use this matrix to project 3-D world points in homogeneous coordinates into an image.

Examples

Compute Camera Matrix

Create a set of calibration images.

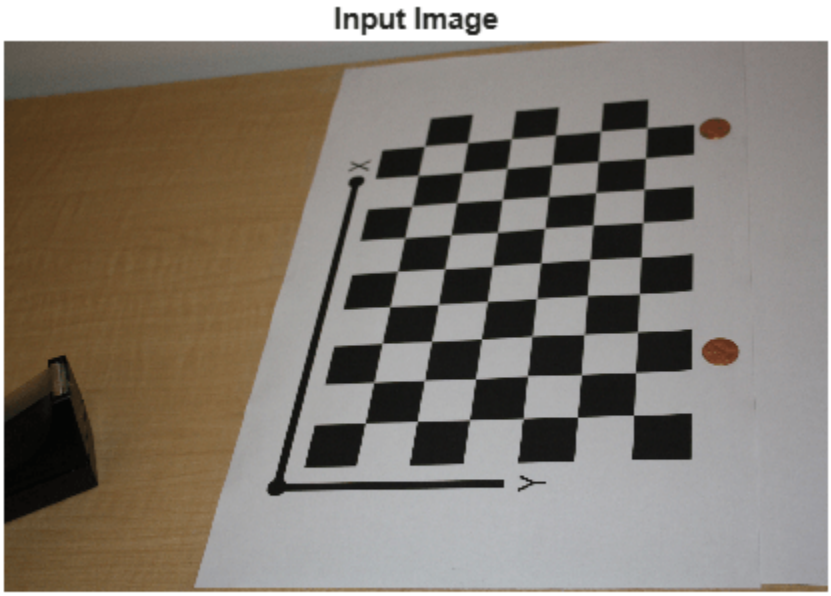
```
images = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
    "calibration","slr"));
```

Detect the checkerboard corners in the images.

```
[imagePoints,patternDims] = detectCheckerboardPoints(images.Files);
```

Generate the world coordinates of the checkerboard corners in the pattern-centric coordinate system, with the upper-left corner at (0,0). The square size is in millimeters.

```
squareSize = 29; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```



Calibrate the camera.

```
I = readimage(images,1);
imageSize = [size(I,1),size(I,2)];
cameraParams = estimateCameraParameters(imagePoints,worldPoints,ImageSize=imageSize);
```

Load image at new location.

```
imOrig = imread(fullfile(toolboxdir("vision"),"visiondata", ...
      "calibration","slr","image9.jpg"));
```

```
figure;
imshow(imOrig);
title("Input Image");
```

Undistort image.

```
im = undistortImage(imOrig,cameraParams);
```

Find reference object in new image.

```
[imagePoints,patternDims] = detectCheckerboardPoints(im);
```

Compute new extrinsics.

```
[rotationMatrix,translationVector] = extrinsics(...
    imagePoints,worldPoints,cameraParams);
```

Calculate camera matrix.

```
P = cameraMatrix(cameraParams,rotationMatrix,translationVector)
```

```
P = 4×3
10^5 ×

    0.0157   -0.0271    0.0000
    0.0404   -0.0046   -0.0000
    0.0199    0.0387    0.0000
    8.9399    9.4399    0.0072
```

Input Arguments

`cameraParams` — Object for storing camera parameters

`cameraParameters` object | `cameraIntrinsics` object

Camera parameters, specified as a `cameraParameters` or `cameraIntrinsics` object. You can return the `cameraParameters` object using the `estimateCameraParameters` function. The `cameraParameters` object contains the intrinsic, extrinsic, and lens distortion parameters of a camera.

`tform` — Transformation

`rigid3d` object

Transformation from world coordinates to camera coordinates, specified as a `rigid3d` object. You can use the `extrinsics` function to obtain the rotation and translation to create the `tform` object.

`rotationMatrix` — Rotation of camera

3-by-3 matrix

Rotation of camera, specified as a 3-by-3 matrix. You can obtain this matrix using the `extrinsics` function. You can also obtain the matrix using the `relativeCameraPose` function by transposing its `orientation` output. The `rotationMatrix` and `translationVector` inputs must be real, nonsparse, and of the same class.

`translationVector` — Translation of camera

1-by-3 vector

Translation of camera, specified as a 1-by-3 vector. The translation vector describes the transformation from the world coordinates to the camera coordinates. You can obtain this vector using the `extrinsics` function. You can also obtain the vector using the `location` and `orientation` outputs of the `relativeCameraPose` function:

- `translationVector` = `-relativeLocation` * `relativeOrientation'`

The `translationVector` inputs must be real, nonsparse, and of the same class.

Output Arguments

`camMatrix` — Camera projection matrix

4-by-3 matrix

Camera projection matrix, returned as a 4-by-3 matrix. The matrix contains the 3-D world points in homogenous coordinates that are projected into the image. When you set `rotationMatrix` and `translationVector` to `double`, the function returns `camMatrix` as `double`. Otherwise it returns `camMatrix` as `single`.

The function computes `camMatrix` as follows:

`camMatrix` = [`rotationMatrix`; `translationVector`] × K.
K: the intrinsic matrix

Then, using the camera matrix and homogeneous coordinates, you can project a world point onto the image.

$w \times [x,y,1] = [X,Y,Z,1] \times$ `camMatrix`.

(X,Y,Z): world coordinates of a point
(x,y): coordinates of the corresponding image point
w: arbitrary scale factor

Data Types: `single` | `double`

Version History

Introduced in R2014b

R2022b: Not recommended

Not recommended starting in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `cameraMatrix` function uses the postmultiply convention. Although there are no plans to remove `cameraMatrix` at this time, you can streamline your geometric transformation workflows by switching to the `cameraProjection` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

To update your code:

- Change instances of the function name `cameraMatrix` to `cameraProjection`.
- Specify the `cameraParams` argument as a `cameraIntrinsics` object. If you have a `cameraParameters` object, then you can get a `cameraIntrinsics` object by querying the `Intrinsics` property. If the `Intrinsics` property is empty according to the `isempty` function, then set the `ImageSize` property of the `cameraParameters` object to an arbitrary vector before querying the `Intrinsics` property. For example:

  ```
  load worldToImageCorrespondences.mat
  if(isempty(cameraParams.Intrinsics))
      cameraParams.ImageSize = [128 128];
  end
  intrinsics = cameraParams.Intrinsics;
  ```

- Specify the transformation as a `rigidtform3d` object using the `tform` argument. `cameraProjection` does not support the `rotationMatrix` and `translationVector` input arguments. Note that you create the `rigidtform3d` object using the transpose of `rotationMatrix` or the transpose of the transformation matrix in the `T` property of `tform`.

Discouraged Usage	Recommended Replacement

This example specifies the transformation as a rotation matrix and a translation vector, then calculates the camera projection matrix using the `cameraMatrix` function.
 	
`camMatrix = cameraMatrix(cameraParams,rotationMatrix,translationVector)`
	This example specifies the transformation as a `rigidtform3d` object, then calculates the camera projection matrix using the `cameraProjection` function. Note that you create the `rigidtform3d` object using the transpose of the rotation matrix, `rotationMatrix`.
	
	`intrinsics = cameraParams.Intrinsics;`
	`tform = rigidtform3d(rotationMatrix',translationVecto`
	`camMatrix = cameraProjection(intrinsics,tform);`

Discouraged Usage	Recommended Replacement

This example specifies the transformation as a `rigid3d` object.
 	
`camMatrix = cameraMatrix(cameraParams,tformOld);`
	This example starts with an existing `rigid3d` object `tformOld`, creates a `rigidtform3d` object using the transpose of the `T` property of `tformOld`, then calculates the camera projection matrix using the `cameraProjection` function.
	
	`intrinsics = cameraParams.Intrinsics;`
	`tform = rigidtform3d(tformOld.T');`
	`camMatrix = cameraProjection(intrinsics,tform);`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use in a MATLAB Function block is not supported.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

cameraPose

Compute relative rotation and translation between camera poses

Syntax

```
cameraPose
```

Description

`cameraPose` returns the camera extrinsics.

Note `cameraPose` was renamed to `relativeCameraPose`. Use the new function name instead. You can also use the `estrelpose` function instead.

Version History

Introduced in R2015b

R2020a: `cameraPose` renamed to `relativeCameraPose`
Behavior changed in R2020a

`cameraPose` was renamed to `relativeCameraPose`. Use the new function name instead. You can also use the `estrelpose` function instead.

cameraProjection

Camera projection matrix

Syntax

```
camProjection = cameraProjection(intrinsics,tform)
```

Description

`camProjection = cameraProjection(intrinsics,tform)` returns a 3-by-4 camera projection matrix `camProjection`. You can use `camProjection` to project a 3-D world point in homogeneous coordinates into an image according to the transformation `tform`.

Examples

Calculate Camera Projection Matrix

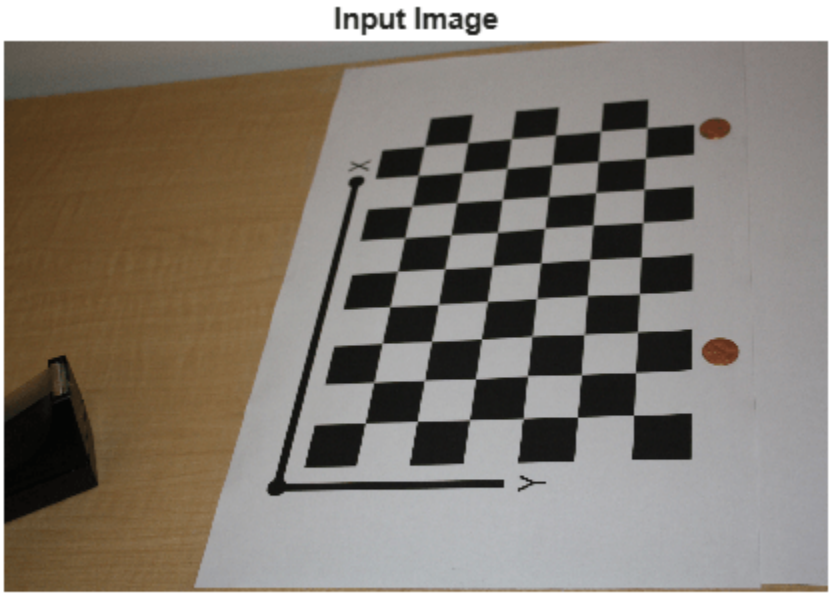
Create a set of calibration images.

```
images = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
      "calibration","slr"));
```

Detect the checkerboard corners in the images.

```
[imagePoints,patternDims] = detectCheckerboardPoints(images.Files);
```

Generate the world coordinates of the checkerboard corners in the pattern-centric coordinate system, with the upper-left corner at (0,0). The square size is in millimeters.



```
squareSize = 29; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Calibrate the camera.

```
I = readimage(images,1);
imageSize = [size(I,1) size(I,2)];
cameraParams = estimateCameraParameters(imagePoints,worldPoints,ImageSize=imageSize);
intrinsics = cameraParams.Intrinsics;
```

Load an image at a new location.

```
imOrig = readimage(images,9);
figure
imshow(imOrig)
title("Input Image")
```

Undistort the image.

```
[im,newIntrinsics] = undistortImage(imOrig,intrinsics,OutputView="full");
```

Find the reference object in the new image.

```
[imagePoints,patternDims] = detectCheckerboardPoints(im);
```

Compensate for the image coordinate system shift.

```
newOrigin = intrinsics.PrincipalPoint-newIntrinsics.PrincipalPoint;
imagePoints = imagePoints+newOrigin;
```

Calculate new extrinsics.

```
camExtrinsics = estimateExtrinsics(imagePoints,worldPoints,intrinsics);
```

Calculate the camera projection matrix.

```
P = cameraProjection(intrinsics,camExtrinsics)
```

```
P = 3×4
10^5 ×

    0.0157    0.0404    0.0199    8.9399
   -0.0271   -0.0046    0.0387    9.4399
    0.0000   -0.0000    0.0000    0.0072
```

Input Arguments

`intrinsics` — Camera intrinsics

`cameraIntrinsics` object

Camera intrinsics, specified as `cameraIntrinsics` object. The object stores information about a camera's intrinsic calibration parameters, including the lens distortion parameters.

`tform` — Transformation
`rigidtform3d` object

Transformation from world coordinates to camera coordinates, specified as a `rigidtform3d` object. You can use the `estimateExtrinsics` function to create the `tform` object. The `R` and `Translation` properties of the object represent the rotation matrix and translation needed to project 3-D world points in homogeneous coordinates into an image.

Output Arguments

`camProjection` — Camera projection matrix
3-by-4 matrix

Camera projection matrix, returned as a 3-by-4 matrix. The matrix contains the 3-D world points in homogenous coordinates that are projected into the image.

The function calculates `camProjection` using the intrinsic matrix K and the `R` and `Translation` properties of the `tform` object as follows:

`camProjection` = $K \times$ `[tform.R tform.Translation']`

Using the camera projection matrix and homogeneous coordinates, you can project a world point onto the image.

$w \times [x,y,1]'$ = `camProjection`$\times [X,Y,Z,1]'$

(X,Y,Z) are the world coordinates of a point
(x,y) are the coordinates of the corresponding image point
w is an arbitrary scale factor

When the `R` and `Translation` properties of the transformation `tform` are of data type `double`, the function returns `camProjection` as `double`. Otherwise the function returns `camProjection` as `single`.

Data Types: `single` | `double`

Version History

Introduced in R2022b

R2022b: Recommended over `cameraMatrix`

Starting in R2022b, many Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `cameraMatrix` function uses the postmultiply convention. Although there are no plans to remove `cameraMatrix` at this time, you can streamline your geometric transformation workflows by switching to the `cameraProjection` function, which supports the premultiply convention. For more information, see "Migrate Geometric Transformations to Premultiply Convention".

relativeCameraPose

(Not recommended) Calculate relative rotation and translation between camera poses

Note `relativeCameraPose` is not recommended. Use the `estrelpose` function instead. For more information, see “Version History”.

Syntax

```
[relativeOrientation,relativeLocation] = relativeCameraPose(M,cameraParams,
inlierPoints1,inlierPoints2)
[relativeOrientation,relativeLocation] = relativeCameraPose(M,cameraParams1,
cameraParams2,inlierPoints1,inlierPoints2)
[relativeOrientation,relativeLocation,validPointsFraction] =
relativeCameraPose(M, ___ )
```

Description

`[relativeOrientation,relativeLocation] = relativeCameraPose(M,cameraParams, inlierPoints1,inlierPoints2)` returns the orientation and location of a calibrated camera relative to its previous pose. The two poses are related by `M`, which must be a fundamental, essential, `affine2d`, or `projective2d` matrix. The function computes the camera location up to scale and returns `relativeLocation` as a unit vector.

`[relativeOrientation,relativeLocation] = relativeCameraPose(M,cameraParams1, cameraParams2,inlierPoints1,inlierPoints2)` returns the orientation and location of the second camera relative to the first one.

`[relativeOrientation,relativeLocation,validPointsFraction] = relativeCameraPose(M, ___ )` additionally returns the fraction of the inlier points that project in front of both cameras.

Input Arguments

`M` — Fundamental, essential, or homography matrix

3-by-3 matrix

Fundamental, essential matrix, or a homography matrix, specified as a 3-by-3 matrix, an affine2d object, or a `projective2d` object containing a homography matrix. You can obtain the 3-by-3 matrix using one of the following functions:

- `estimateFundamentalMatrix` for the fundamental matrix.
- `estimateEssentialMatrix` for the essential matrix
- `estimateGeometricTransform` for the projective or affine 2-D object.

Data Types: `single` | `double`

`cameraParams` — Object for storing camera parameters

`cameraParameters` object | `cameraIntrinsics` object

Camera parameters, specified as a `cameraParameters` or `cameraIntrinsics` object. You can return the `cameraParameters` object using the `estimateCameraParameters` function. The `cameraParameters` object contains the intrinsic, extrinsic, and lens distortion parameters of a camera.

`cameraParams1` — Camera parameters for camera 1
`cameraParameters` object | `cameraIntrinsics` object

Camera parameters for camera 1, specified as a `cameraParameters` or `cameraIntrinsics` object. You can return the `cameraParameters` object using the `estimateCameraParameters` function. The `cameraParameters` object contains the intrinsic, extrinsic, and lens distortion parameters of a camera.

`cameraParams2` — Camera parameters for camera 2
`cameraParameters` object | `cameraIntrinsics` object

Camera parameters for camera 2, specified as a `cameraParameters` or `cameraIntrinsics` object. You can return the `cameraParameters` object using the `estimateCameraParameters` function. The `cameraParameters` object contains the intrinsic, extrinsic, and lens distortion parameters of a camera.

`inlierPoints1` — Coordinates of corresponding points in view 1
`SIFTPoints` | `SURFPoints` | `cornerPoints` | `MSERRegions` | *M*-by-2 matrix of [*x*,*y*] coordinates

Coordinates of corresponding points in view 1, specified as an *M*-by-2 matrix of *M* number of [*x*,*y*] coordinates, or as a `SIFTPoints`, `SURFPoints`, `MSERRegions`, or `cornerPoints` object. You can obtain these points using the `estimateFundamentalMatrix` function or the `estimateEssentialMatrix`.

`inlierPoints2` — Coordinates of corresponding points in view 2
`SIFTPoints` | `SURFPoints` | `cornerPoints` | `MSERRegions` | *M*-by-2 matrix of [*x*,*y*] coordinates

Coordinates of corresponding points in view 2, specified as an *M*-by-2 matrix of *M* number of [*x*,*y*] coordinates, or as a `SIFTPoints`, `SURFPoints`, `MSERRegions`, or `cornerPoints` object. You can obtain these points using the `estimateFundamentalMatrix` function or the `estimateEssentialMatrix`.

Output Arguments

`relativeOrientation` — Orientation of camera
3-by-3 matrix

Orientation of camera, returned as a 3-by-3 matrix. If you use only one camera, the matrix describes the orientation of the second camera pose relative to the first camera pose. If you use two cameras, the matrix describes the orientation of camera 2 relative to camera 1.

Data Types: `single` | `double`

`relativeLocation` — Location of camera
1-by-3 vector

Location of camera, returned as a 1-by-3 unit vector. If you use only one camera, the vector describes the location of the second camera pose relative to the first camera pose. If you use two cameras, the vector describes the location of camera 2 relative to camera 1.

Data Types: `single` | `double`

`validPointsFraction` — Fraction of valid inlier points
scalar

Fraction of valid inlier points that project in front of both cameras, returned as a scalar. If `validPointsFraction` is too small, e.g. less than 0.9, it can indicate that the fundamental matrix is incorrect.

Tips

- You can compute the camera extrinsics, `rotationMatrix` and `translationVector`, corresponding to the camera pose, from `relativeOrientation` and `relativeLocation`:

  ```
  [rotationMatrix,translationVector] = cameraPoseToExtrinsics(relativeOrientation,relativeLocati
  ```

  The orientation of the previous camera pose is the identity matrix, `eye(3)`, and its location is, `[0,0,0]`.
- You can then use `rotationMatrix` and `translationVector` as inputs to the `cameraMatrix` function.
- You can compute four possible combinations of orientation and location from the input fundamental matrix. Three of the combinations are not physically realizable, because they project 3-D points behind one or both cameras. The `relativeCameraPose` function uses `inlierPoints1` and `inlierPoints2` to determine the realizable combination.

Version History

Introduced in R2016b

R2022b: Not recommended
Not recommended starting in R2022b

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `relativeCameraPose` function uses the postmultiply convention. Although there are no plans to remove `relativeCameraPose` at this time, you can streamline your geometric transformation workflows by switching to the `estrelpose` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

To update your code:

- Change instances of the function name `relativeCameraPose` to `estrelpose`.
- Specify the `cameraParams` argument as a `cameraIntrinsics` object. If you have a `cameraParameters` object, then you can get a `cameraIntrinsics` object by querying the `Intrinsics` property. If the `Intrinsics` property is empty according to the `isempty` function, then set the `ImageSize` property of the `cameraParameters` object to an arbitrary vector before querying the `Intrinsics` property. For example:

  ```
  load worldToImageCorrespondences.mat
  if(isempty(cameraParams.Intrinsics))
      cameraParams.ImageSize = [128 128];
  end
  intrinsics = cameraParams.Intrinsics;
  ```

- Replace the two output arguments `relativeOrientation` and `relativeLocation` with a single output argument, `relativePose`. If you need to obtain the orientation matrix and location vector, then you can query the `R` and the `Translation` properties of the `rigidtform3d` object returned by the `worldPose` argument. Note that the value of `R` is the transpose of `relativeOrientation`.

The table shows examples of how to update your code.

Discouraged Usage	Recommended Replacement

This example calculates relative camera poses of a single camera using the `relativeCameraPose` function with the `cameraParams` argument specified as a `cameraParameters` object.
 	
`[relativeOrientationOld,relativeLocation] = relativeCameraPose( ...`
`    M,cameraParams,inlierPoints1,inlierPoints2)`
	This example gets the camera intrinsics using the `Intrinsics` property of a `cameraParameters` object, then estimates the relative camera pose using the `estrelpose` function.
	
	`intrinsics = cameraParams.Intrinsics;`
	`relativePose = estrelpose( ...`
	`    M,intrinsics,inlierPoints1,inlierPoints2);`
	
	If you need to obtain the relative camera orientation and location, then you can query properties of `relativePose`.
	
	`relativeOrientation = relativePose.R;`
	`relativeLocation = relativePose.Translation;`
	
	If you want the orientation in the postmultiply convention, take the transpose of `relativePose.R`.
	
	`relativeOrientationOld = relativePose.R';`

This example calculates the relative camera pose of camera 2 with respect to camera 1 using the `relativeCameraPose` function.
 	
`[relativeOrientation,relativeLocation] = relativeCameraPose( ...`
`    M,cameraParams1,cameraParams2,inlierPoints1,inlierPoints2)`
	This example gets the camera intrinsics of two cameras using the `Intrinsics` property of two `cameraParameters` objects, then estimates the relative camera pose using the `estrelpose` function.
	
	`intrinsics1 = cameraParams1.Intrinsics;`
	`intrinsics2 = cameraParams2.Intrinsics;`
	`relativePose = estrelpose( ...`
	`    M,intrinsics1,intrinsics2,inlierPoints1,inlierPo`

estimateCameraMatrix

(Not recommended) Estimate camera projection matrix from world-to-image point correspondences

Note `estimateCameraMatrix` is not recommended. Use the `estimateCameraProjection` function instead. For more information, see “Version History”.

Syntax

```
camMatrix = estimateCameraMatrix(imagePoints,worldPoints)
[camMatrix,reprojectionErrors] = estimateCameraMatrix(imagePoints,
worldPoints)
```

Description

`camMatrix = estimateCameraMatrix(imagePoints,worldPoints)` returns the camera projection matrix determined from known world points and their corresponding image projections by using the direct linear transformation (DLT) approach.

`[camMatrix,reprojectionErrors] = estimateCameraMatrix(imagePoints, worldPoints)` also returns the reprojection error that quantifies the accuracy of the projected image coordinates.

Examples

Estimate Camera Projection Matrix

Load a 3-D point cloud data captured by an RGB-D sensor into the workspace.

```
ld = load('object3d.mat');
ptCloud = ld.ptCloud;
```

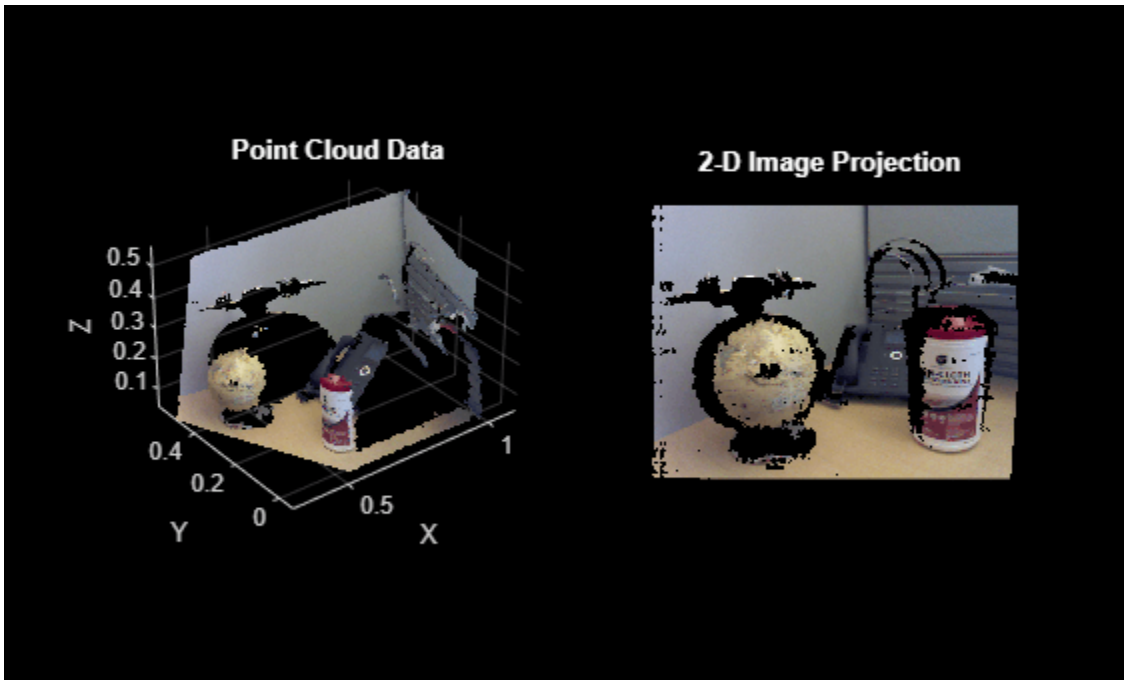
Remove points with `Inf` or `NaN` coordinates from the point cloud.

```
[validPtCloud,validIndices] = removeInvalidPoints(ptCloud);
```

Read the valid world point coordinates. Each entry specifies the *x*, *y*, *z* coordinates of a point in the point cloud.

```
worldPoints = validPtCloud.Location;
```

Define the corresponding image point coordinates as a orthographic projection of point cloud data onto the *yz*-plane.



```
indices = 1:ptCloud.Count;
[y,z] = ind2sub([size(ptCloud.Location,1),size(ptCloud.Location,2)],indices);
imagePoints = [y(validIndices)' z(validIndices)'];
```

Generate the 2-D image projection by using the image point coordinates and their color values.

```
projImage = zeros(max(imagePoints(:,1)),max(imagePoints(:,2)),3);
rgb = validPtCloud.Color;
for j = 1:length(rgb)
projImage(imagePoints(j,1),imagePoints(j,2),:) = rgb(j,:);
end
```

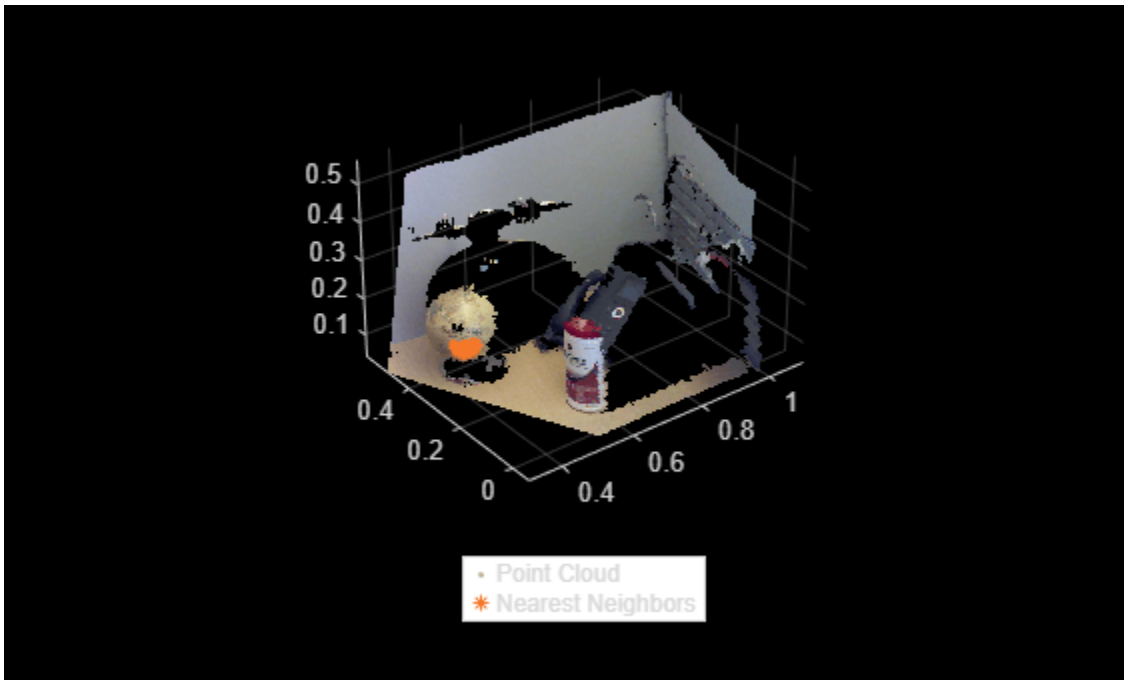
Display the point cloud data and the corresponding 2-D image projection.

```
figure
subplot(1,2,1)
pcshow(ptCloud)
xlabel('X');
ylabel('Y');
zlabel('Z');
title('Point Cloud Data','Color',[1 1 1])
subplot(1,2,2)
imshow(uint8(projImage))
title('2-D Image Projection','Color',[1 1 1])
```

Estimate the camera projection matrix and reprojection error by using the known world points and the image points.

```
[camMatrix,reprojectionErrors] = estimateCameraMatrix(imagePoints,worldPoints);
```

Use the estimated camera projection matrix as input to the `findNearestNeighbors` function and find the nearest neighbors of a query point.



```
point = [0.4 0.3 0.2];  % Specify the query point
K = 1000;  % Specify the number of nearest neighbors to be determined
[indices,dists] = findNearestNeighbors(ptCloud,point,K,camMatrix);  % Get the indices and distanc
```

Use the `select` function to get the point cloud data of nearest neighbors.

```
ptCloudB = select(ptCloud,indices);
```

Display the input point cloud and its nearest neighbors.

```
figure
pcshow(ptCloud)
hold on
plot3(ptCloudB.Location(:,1),ptCloudB.Location(:,2),ptCloudB.Location(:,3),'*')
hold off
legend('Point Cloud','Nearest Neighbors','Location','southoutside','Color',[1 1 1])
```

Input Arguments

`imagePoints` — Coordinates of image projection points

M-by-2 matrix

Coordinates of image projection points, specified as an *M*-by-2 matrix of (*x*, *y*) coordinates. *M* is the number of points and it must be greater than or equal to 6. The input image points must correspond to an undistorted image plane.

Data Types: `single` | `double`

`worldPoints` — 3-D world points

M-by-3 matrix

3-D world points, specified as an *M*-by-3 matrix of (*x*, *y*, *z*) coordinates. *M* is the number of points and it must be greater than or equal to 6. The input world coordinates must be non-coplanar points.

Data Types: `single` | `double`

Output Arguments

`camMatrix` — Camera projection matrix

4-by-3 matrix

Camera projection matrix, returned as a 4-by-3 matrix. The matrix maps the 3-D world points, in homogenous coordinates to the 2-D image coordinates of the projections onto the image plane.

Data Types: `double`

`reprojectionErrors` — Reprojection errors

M-by-1 vector

Reprojection errors, returned as a *M*-by-1 vector. The reprojection error is the error between the reprojected image points and the input image points. For more information on the computation of reprojection errors, see “Algorithms” on page 3-551.

Data Types: `double`

Tips

You can use the `estimateCameraMatrix` function to estimate a camera projection matrix:

- If the world-to-image point correspondences are known, and the camera intrinsics and extrinsics parameters are not known, you can use the `cameraMatrix` function.
- To compute 2-D image points from 3-D world points, refer to the equations in `camMatrix`.
- For use with the `findNearestNeighbors` object function of the `pointCloud` object. The use of a camera projection matrix speeds up the nearest neighbors search in a point cloud generated by an RGB-D sensor, such as Microsoft Kinect.

Algorithms

Given the world points $\boldsymbol{X}$ and the image points $\boldsymbol{x}$, the camera projection matrix C, is obtained by solving the equation

$$\lambda\boldsymbol{x} = C\boldsymbol{X}.$$

The equation is solved using the direct linear transformation (DLT) approach [1]. This approach formulates a homogeneous linear system of equations, and the solution is obtained through generalized eigenvalue decomposition.

Because the image point coordinates are given in pixel values, the approach for computing the camera projection matrix is sensitive to numerical errors. To avoid numerical errors, the input image point coordinates are normalized, so that their centroid is at the origin. Also, the root mean squared distance of the image points from the origin is `sqrt(2)`. These steps summarize the process for estimating the camera projection matrix.

1. Normalize the input image point coordinates with transform T.
2. Estimate camera projection matrix C^N from the normalized input image points.
3. Compute the denormalized camera projection matrix C as $C^N T^{-1}$.
4. Compute the reprojected image point coordinates $\boldsymbol{x}^E$ as $C\boldsymbol{X}$.
5. Compute the reprojection errors as $reprojectionErrors = |\boldsymbol{x} - \boldsymbol{x}^E|$.

Version History

Introduced in R2019a

R2022b: Not recommended

Not recommended starting in R2022b

Starting in R2022b, many Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `estimateCameraMatrix` function uses the postmultiply convention. Although there are no plans to remove `estimateCameraMatrix` at this time, you can streamline your geometric transformation workflows by switching to the `estimateCameraProjection` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

To update your code:

- Change instances of the function name `estimateCameraMatrix` to `estimateCameraProjection`.
- The `estimateCameraProjection` function returns the camera projection matrix in a format consistent with the premultiply convention. The returned camera projection matrix is the transpose of the `camMatrix on page 3-0` argument.

estimateCameraProjection

Estimate camera projection matrix from world-to-image point correspondences

Syntax

```
camProjection = estimateCameraProjection(imagePoints,worldPoints)
[camProjection,reprojectionErrors] = estimateCameraProjection(imagePoints,
worldPoints)
```

Description

`camProjection = estimateCameraProjection(imagePoints,worldPoints)` returns the camera projection matrix determined from known world points and their corresponding image projections by using the direct linear transformation (DLT) approach.

`[camProjection,reprojectionErrors] = estimateCameraProjection(imagePoints, worldPoints)` also returns the reprojection error that quantifies the accuracy of the projected image coordinates.

Examples

Estimate Camera Projection Matrix

Load a 3-D point cloud data captured by an RGB-D sensor into the workspace.

```
load("object3d.mat");
```

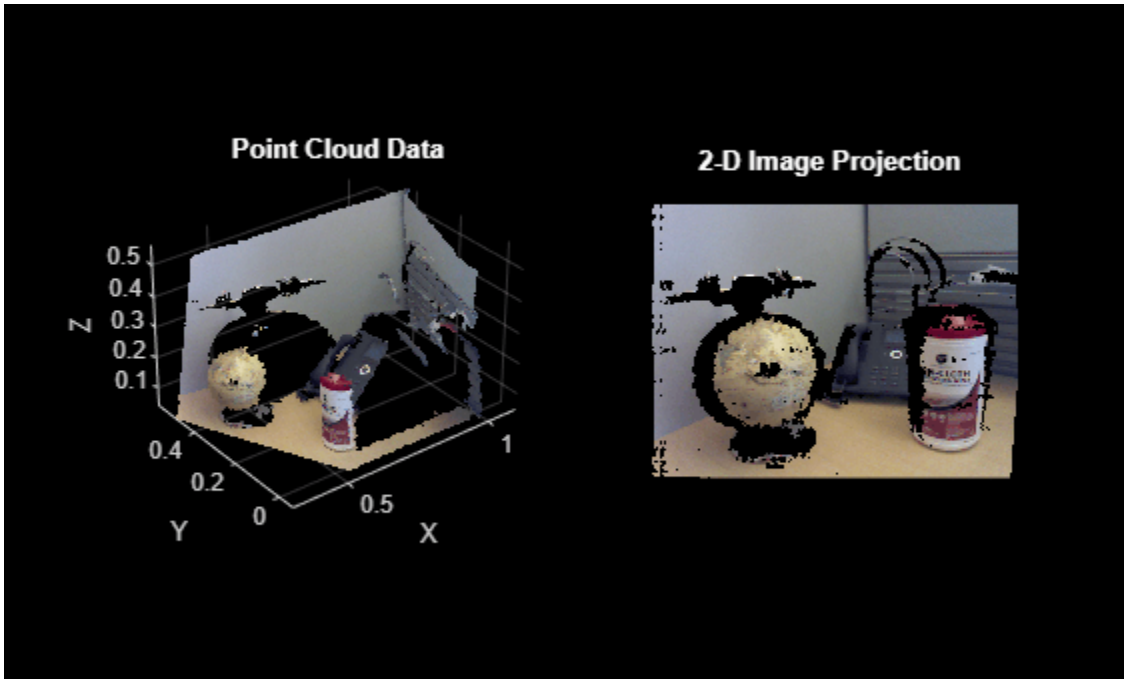
Remove points with `Inf` or `NaN` coordinates from the point cloud.

```
[validPtCloud,validIndices] = removeInvalidPoints(ptCloud);
```

Read the valid world point coordinates. Each entry specifies the (*x*, *y*, *z*) coordinates of a point in the point cloud.

```
worldPoints = validPtCloud.Location;
```

Define the corresponding image point coordinates as an orthographic projection of point cloud data onto the *yz*-plane.



```
indices = 1:ptCloud.Count;
[y,z] = ind2sub([size(ptCloud.Location,1),size(ptCloud.Location,2)],indices);
imagePoints = [y(validIndices)' z(validIndices)'];
```

Generate the 2-D image projection by using the image point coordinates and their color values.

```
projImage = zeros(max(imagePoints(:,1)),max(imagePoints(:,2)),3);
rgb = validPtCloud.Color;
for j = 1:length(rgb)
    projImage(imagePoints(j,1),imagePoints(j,2),:) = rgb(j,:);
end
```

Display the point cloud data and the corresponding 2-D image projection.

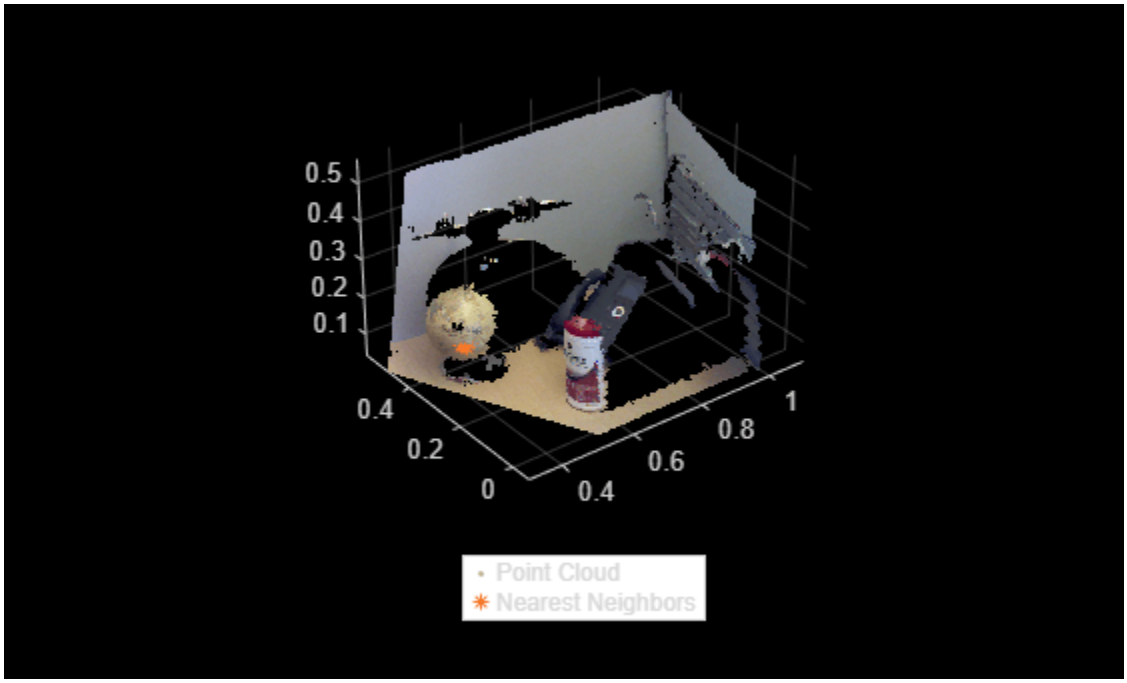
```
figure
subplot(1,2,1)
pcshow(ptCloud)
xlabel("X");
ylabel("Y");
zlabel("Z");
title("Point Cloud Data",Color=[1 1 1])
subplot(1,2,2)
imshow(uint8(projImage))
title("2-D Image Projection",Color=[1 1 1])
```

Estimate the camera projection matrix and reprojection error by using the known world points and the image points.

```
[camProjection,reprojectionErrors] = estimateCameraProjection(imagePoints,worldPoints);
```

Use the estimated camera projection matrix as input to the `findNearestNeighbors` function and find the nearest neighbors of a query point.

```
point = [0.4 0.3 0.2];
K = 50;    % Specify the number of nearest neighbors to be determined
[indices,dists] = findNearestNeighbors(ptCloud,point,K,camProjection');
```



Use the `select` function to get the point cloud data of nearest neighbors.

```
ptCloudB = select(ptCloud,indices);
```

Display the input point cloud and its nearest neighbors.

```
figure
pcshow(ptCloud)
hold on
```

```
plot3(ptCloudB.Location(:,1),ptCloudB.Location(:,2),ptCloudB.Location(:,3),"*")
hold off
legend("Point Cloud","Nearest Neighbors",Location="southoutside",Color=[1 1 1])
```

Input Arguments

`imagePoints` — Coordinates of image projection points

M-by-2 matrix

Coordinates of image projection points, specified as an *M*-by-2 matrix of (*x*, *y*) coordinates. *M* is the number of points and it must be greater than or equal to 6. The input image points must correspond to an undistorted image plane.

Data Types: `single` | `double`

`worldPoints` — 3-D world points

M-by-3 matrix

3-D world points, specified as an *M*-by-3 matrix of non-coplanar (*x*, *y*, *z*) coordinates. *M* is the number of points and must be greater than or equal to 6.

Data Types: `single` | `double`

Output Arguments

`camProjection` — Camera projection matrix

3-by-4 matrix

Camera projection matrix, returned as a 3-by-4 matrix. The matrix maps the 3-D world points, in homogenous coordinates, to the 2-D image coordinates of the projections onto the image plane.

Using the camera projection matrix and homogeneous coordinates, you can project a world point onto the image.

$w \times [x,y,1]' = \text{camProjection} \times [X,Y,Z,1]'$

(X,Y,Z) are the world coordinates of a point
(x,y) are the coordinates of the corresponding image point
w is an arbitrary scale factor

Data Types: `double`

`reprojectionErrors` — Reprojection errors
M-by-1 vector

Reprojection errors, returned as a *M*-by-1 vector. The reprojection error is the error between the reprojected image points and the input image points. For more information on the computation of reprojection errors, see “Algorithms” on page 3-551.

Data Types: `double`

Tips

- This function assumes the camera has negligible lens distortion. If there is lens distortion, calibrate the camera and use the `estworldpose` and `cameraProjection` functions instead.
- If the camera intrinsics and extrinsics parameters are known, you can estimate the camera projection matrix using the `cameraProjection` function.
- You can use the camera projection matrix, `camProjection`, with the `findNearestNeighbors` function to speed up the nearest neighbors search in a point cloud generated by an RGB-D sensor, such as Microsoft Kinect.

Algorithms

Given the world points $\boldsymbol{X}$ and the image points $\boldsymbol{x}$, the camera projection matrix C, is obtained by solving the equation

$\lambda \boldsymbol{x} = C\boldsymbol{X}$.

The equation is solved using the direct linear transformation (DLT) approach [1]. This approach formulates a homogeneous linear system of equations, and the solution is obtained through generalized eigenvalue decomposition.

Because the image point coordinates are given in pixel values, the approach for computing the camera projection matrix is sensitive to numerical errors. To avoid numerical errors, the input image point coordinates are normalized, so that their centroid is at the origin. Also, the root mean squared distance of the image points from the origin is `sqrt(2)`. These steps summarize the process for estimating the camera projection matrix.

1. Normalize the input image point coordinates with transform T.
2. Estimate camera projection matrix C^N from the normalized input image points.
3. Compute the denormalized camera projection matrix C as $C^N T^{-1}$.
4. Compute the reprojected image point coordinates $\boldsymbol{x}^{\boldsymbol{E}}$ as $C\boldsymbol{X}$.
5. Compute the reprojection errors as
   $reprojectionErrors = |\boldsymbol{x} - \boldsymbol{x}^{\boldsymbol{E}}|$.

Version History

Introduced in R2022b

R2022b: Recommended over `estimateCameraMatrix`

Starting in R2022b, many Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `estimateCameraMatrix` function uses the postmultiply convention. Although there are no plans to remove `estimateCameraMatrix` at this time, you can streamline your geometric transformation workflows by switching to the `estimateCameraProjection` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

estimateExtrinsics

Calculate location of calibrated camera

Syntax

```
camExtrinsics = estimateExtrinsics(imagePoints,worldPoints,intrinsics)
```

Description

`camExtrinsics = estimateExtrinsics(imagePoints,worldPoints,intrinsics)` returns the camera extrinsics, which are 3-D rigid transformation that enables you to transform points from the world coordinate to the camera coordinate system.

Examples

Calculate Camera Extrinsics

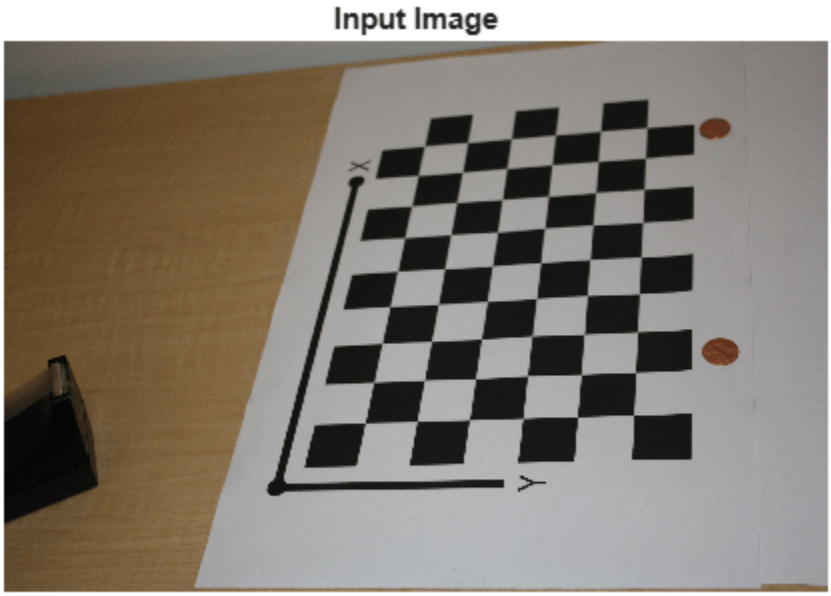
Create a set of calibration images.

```
images = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
      "calibration","slr"));
```

Detect the checkerboard corners in the images.

```
[imagePoints,patternDims] = detectCheckerboardPoints(images.Files);
```

Generate the world coordinates of the checkerboard corners in the pattern-centric coordinate system, with the upper-left corner at (0,0). The square size is in millimeters.



```
squareSize = 29; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSize);
```

Calibrate the camera.

```
I = readimage(images,1);
imageSize = [size(I,1) size(I,2)];
cameraParams = estimateCameraParameters(imagePoints,worldPoints,ImageSize=imageSize);
intrinsics = cameraParams.Intrinsics;
```

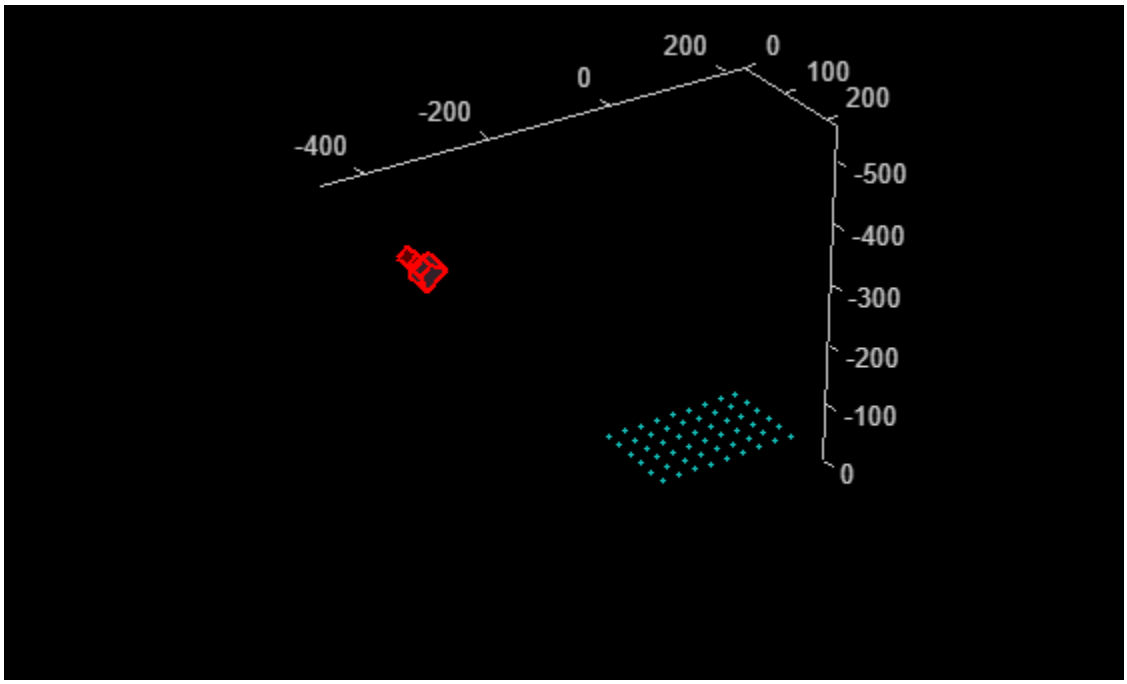
Load an image at a new location.

```
imOrig = readimage(images,9);
figure
imshow(imOrig)
title("Input Image")
```

Undistort the image.

```
[im,newIntrinsics] = undistortImage(imOrig,intrinsics,OutputView="full");
```

Find the reference object in the new image.



```
[imagePoints,patternDims] = detectCheckerboardPoints(im);
```

Calculate new extrinsics.

```
camExtrinsics = estimateExtrinsics(imagePoints,worldPoints,newIntrinsics);
```

Calculate the camera pose.

```
camPose = extr2pose(camExtrinsics);
figure
plotCamera(AbsolutePose=camPose,Size=20);
hold on
pcshow([worldPoints,zeros(size(worldPoints,1),1)], ...
  VerticalAxisDir="down",MarkerSize=40);
```

Input Arguments

`imagePoints` — Image coordinates of points

M-by-2 array

Image coordinates of points, specified as an *M*-by-2 array. The array contains *M* number of [*x*, *y*] coordinates. The `imagePoints` and `worldPoints` inputs must both be `double` or both be `single`.

Data Types: `single` | `double`

`worldPoints` — World coordinates corresponding to image coordinates

M-by-2 matrix

World coordinates corresponding to image coordinates, specified as an *M*-by-2 matrix. The `imagePoints` and `worldPoints` inputs must both be `double` or both be `single`. The function assumes that the points are coplanar with $z = 0$ and the number of points, *M*, must be at least 4.

Data Types: `single` | `double`

`intrinsics` — Camera intrinsics

`cameraIntrinsics` object | `fisheyeIntrinsics` object | `cameraIntrinsicsKB` object

Camera intrinsics, specified as a `cameraIntrinsics`, `fisheyeIntrinsics`, or a `cameraIntrinsicsKB` object. The object stores information about a camera's intrinsic calibration parameters, including the lens distortion parameters.

Output Arguments

`camExtrinsics` — Camera extrinsics

`rigidtform3d` object

Camera extrinsics, returned as a `rigidtform3d` object. The `"R"` and the `"Translation"` properties of the object represent the orientation and location of the camera.

Tips

- This function does not account for lens distortion when `intrinsics` is a `cameraIntrinsics` object. In this case, you can either undistort the image using the `undistortImage` function before detecting the points, or you can undistort the detected points using the `undistortPoints` function.

Algorithms

The `estimateExtrinsics` function uses two different algorithms to compute the extrinsics depending on whether `worldPoints` are specified as an *M*-by-2 matrix. Use an *M*-by-2 matrix for coplanar points where $z = 0$.

The `estimateExtrinsics` function computes the rotation matrix and translation vector for a single image in closed form. During calibration, the extrinsics are estimated numerically to minimize the reprojection errors for all calibration images. Therefore, using the `estimateExtrinsics` function on one of the calibration images returns rotation matrix and translation vector slightly different from the ones obtained during calibration.

Version History

Introduced in R2022b

R2022b: Recommended over `extrinsics`

Starting in R2022b, most Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `extrinsics` function uses the postmultiply convention. Although there are no plans to remove `extrinsics` at this time, you can streamline your geometric transformation workflows by switching to the `estimateExtrinsics` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

R2024a: Added support for the `cameraIntrinsicsKB` object

Support added for the `cameraIntrinsicsKB` object as the `instrinsics` input.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use in a MATLAB Function block is not supported.
- Use of a `fisheyeIntrinsics` object as the `intrinsics` input is not supported.

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

extractLBPFeatures

Extract local binary pattern (LBP) features

Syntax

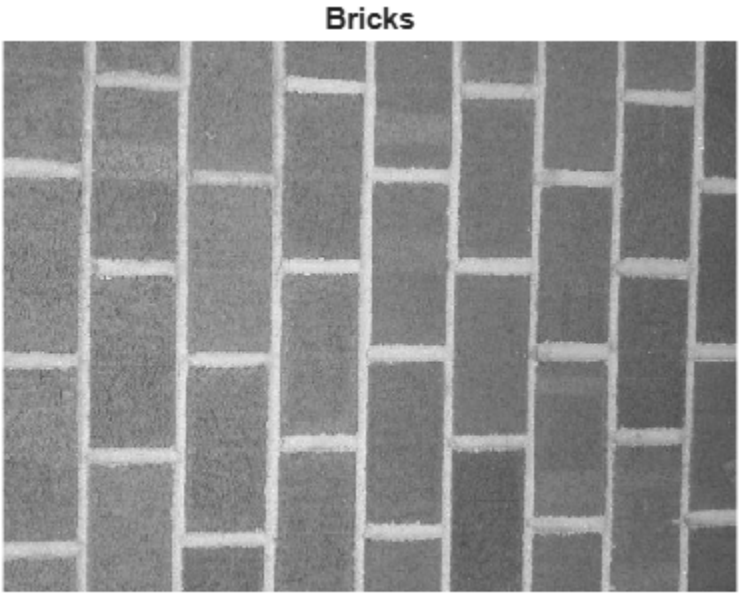
```
features = extractLBPFeatures(I)
features = extractLBPFeatures(I,Name,Value)
```

Description

`features = extractLBPFeatures(I)` returns extracted uniform local binary pattern (LBP) from a grayscale image. The LBP features encode local texture information.

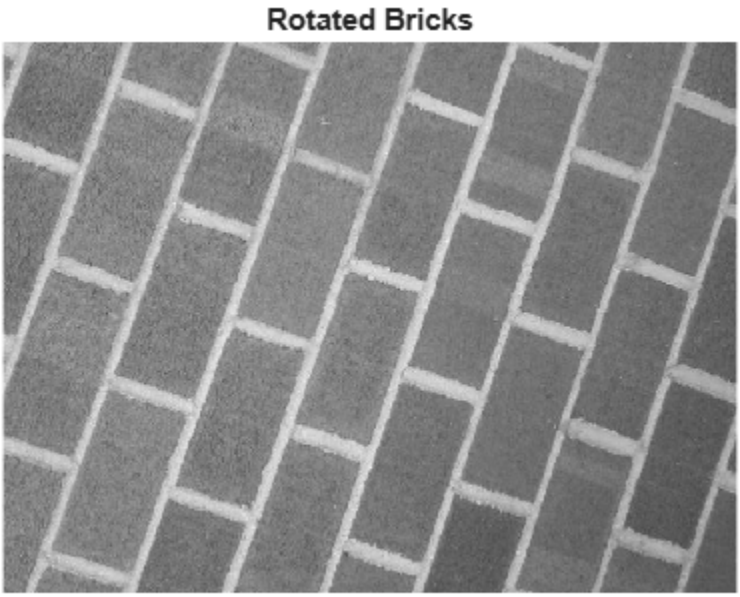
`features = extractLBPFeatures(I,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

Examples



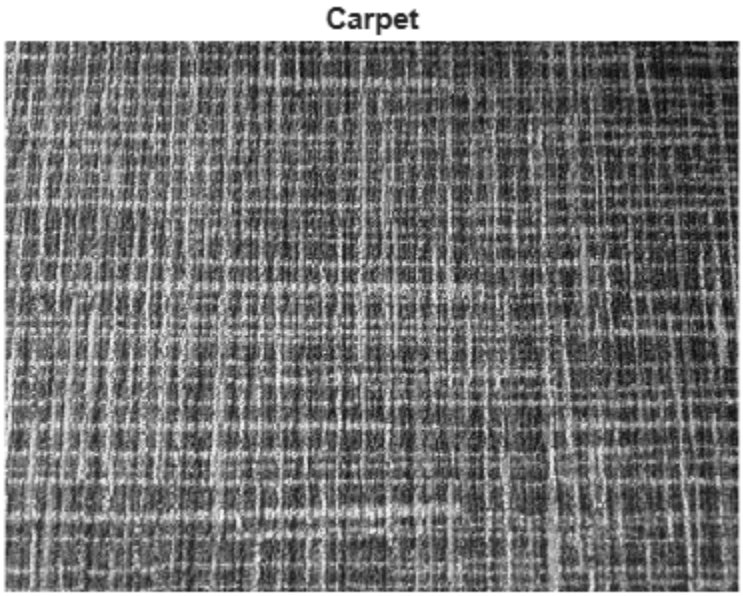
Using LBP Features to Differentiate Images by Texture

Read images that contain different textures.



```
brickWall = imread('bricks.jpg');
rotatedBrickWall = imread('bricksRotated.jpg');
carpet = imread('carpet.jpg');
```

Display the images.

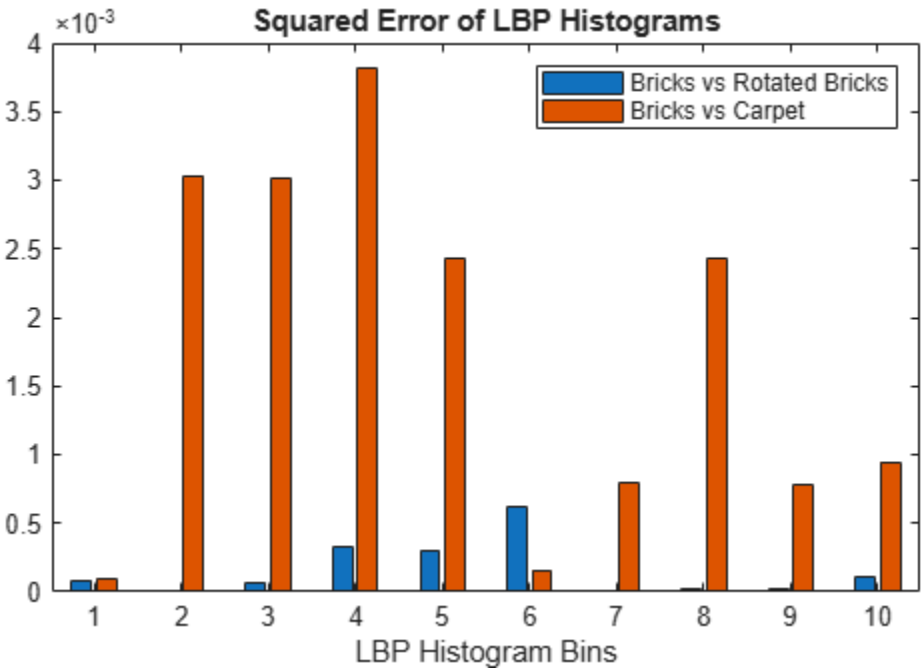


```
figure
imshow(brickWall)
title('Bricks')
```

```
figure
imshow(rotatedBrickWall)
title('Rotated Bricks')
```

```
figure
imshow(carpet)
title('Carpet')
```

Extract LBP features from the images to encode their texture information.



```
lbpBricks1 = extractLBPFeatures(brickWall,'Upright',false);
lbpBricks2 = extractLBPFeatures(rotatedBrickWall,'Upright',false);
lbpCarpet = extractLBPFeatures(carpet,'Upright',false);
```

Gauge the similarity between the LBP features by computing the squared error between them.

```
brickVsBrick = (lbpBricks1 - lbpBricks2).^2;
brickVsCarpet = (lbpBricks1 - lbpCarpet).^2;
```

Visualize the squared error to compare bricks versus bricks and bricks versus carpet. The squared error is smaller when images have similar texture.

```
figure
bar([brickVsBrick; brickVsCarpet]','grouped')
title('Squared Error of LBP Histograms')
xlabel('LBP Histogram Bins')
legend('Bricks vs Rotated Bricks','Bricks vs Carpet')
```

Apply L1 Normalization to LBP Features

Read in a sample image and convert it to grayscale.

```
I = imread('gantrycrane.png');
I = im2gray(I);
```

Extract unnormalized LBP features so that you can apply a custom normalization.

```
lbpFeatures = extractLBPFeatures(I,'CellSize',[32 32],'Normalization','None');
```

Reshape the LBP features into a *number of neighbors* -by- *number of cells* array to access histograms for each individual cell.

```
numNeighbors = 8;
numBins = numNeighbors*(numNeighbors-1)+3;
lbpCellHists = reshape(lbpFeatures,numBins,[]);
```

Normalize each LBP cell histogram using L1 norm.

```
lbpCellHists = bsxfun(@rdivide,lbpCellHists,sum(lbpCellHists));
```

Reshape the LBP features vector back to 1-by- *N* feature vector.

```
lbpFeatures = reshape(lbpCellHists,1,[]);
```

Input Arguments

`I` — Input image

M-by-*N* 2-D grayscale image

Input image, specified as an *M*-by-*N* 2-D grayscale image that is real, and non-sparse.

Data Types: `logical` | `single` | `double` | `int16` | `uint8` | `uint16`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'NumNeighbors',8`

Algorithm Parameters
The LBP algorithm parameters control how local binary patterns are computed for each pixel in the input image.

`NumNeighbors` — Number of neighbors
8 (default) | positive integer

Number of neighbors used to compute the LBP for each pixel in the input image, specified as the comma-separated pair consisting of '`NumNeighbors`' and a positive integer. The set of neighbors is selected from a circularly symmetric pattern around each pixel. Increase the number of neighbors to encode greater detail around each pixel. Typical values range from `4` to `24`.

`Radius` — Radius of circular pattern to select neighbors
1 (default) | positive integer

Radius of circular pattern used to select neighbors for each pixel in the input image, specified as the comma-separated pair consisting of '`Radius`' and a positive integer. To capture detail over a larger spatial scale, increase the radius. Typical values range from `1` to `5`.

`Upright` — Rotation invariance flag
`true` | logical scalar

Rotation invariance flag, specified as the comma-separated pair consisting of '`Upright`' and a logical scalar. When you set this property to `true`, the LBP features do not encode rotation information. Set '`Upright`' to `false` when rotationally invariant features are required.

`Interpolation` — Interpolation method
`'Linear'` (default) | `'Nearest'`

Interpolation method used to compute pixel neighbors, specified as the comma-separated pair consisting of '`Interpolation`' and either `'Linear'` or `'Nearest'`. Use `'Nearest'` for faster computation, but with less accuracy.

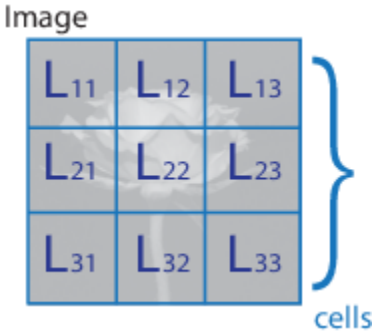
Histogram Parameters
The histogram parameters determine how the distribution of binary patterns is aggregated over the image to produce the output features.

`CellSize` — Cell size
`size(I)` (default) | 2-element vector

Cell size, specified as the comma-separated pair consisting of 'CellSize' and a 2-element vector. The number of cells is calculated as `floor(size(I)/CellSize)`.

`Normalization` — Type of normalization
`'L2'` (default) | `'None'`

Type of normalization applied to each LBP cell histogram, specified as the comma-separated pair consisting of 'Normalization' and either `'L2'` or `'None'`. To apply a custom normalization method as a post-processing step, set this value to `'None'`.

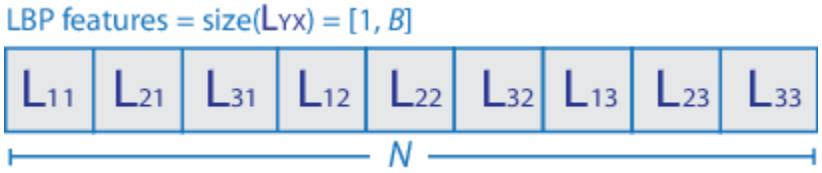


Output Arguments

`features` — LBP feature vector
1-by-*N* vector

LBP feature vector, returned as a 1-by-*N* vector of length *N* representing the number of features. LBP features encode local texture information, which you can use for tasks such as classification, detection, and recognition. The function partitions the input image into non-overlapping cells. To collect information over larger regions, select larger cell sizes. However, when you increase the cell size, you lose local detail. *N*, depends on the number of cells in the image, *numCells*, the number of neighbors, *P*, and the `Upright` parameter.

The number of cells is calculated as:
numCells = prod(`floor(size(I)/CellSize)`)



The figure shows an image with nine cell histograms. Each histogram describes an LBP feature.

The size of the histogram in each cell is [1,*B*], where *B* is the number of bins in the histogram. The number of bins depends on the `Upright` property and the number of neighbors, *P*.

Upright	Number of Bins
`true`	(P x *P*–1) + 3)
`false`	(*P* + 2)

The overall LBP feature length, *N*, depends on the number of cells and the number of bins, *B*:
N = *numCells* x *B*

configureKalmanFilter

Create Kalman filter for object tracking

Syntax

```
kalmanFilter = configureKalmanFilter(MotionModel,InitialLocation,
InitialEstimateError,MotionNoise,MeasurementNoise)
```

Description

`kalmanFilter = configureKalmanFilter(MotionModel,InitialLocation, InitialEstimateError,MotionNoise,MeasurementNoise)` returns a `vision.KalmanFilter` object configured to track a physical object. This object moves with constant velocity or constant acceleration in an *M*-dimensional Cartesian space. The function determines the number of dimensions, *M*, from the length of the `InitialLocation` vector.

This function provides a simple approach for configuring the `vision.KalmanFilter` object for tracking a physical object in a Cartesian coordinate system. The tracked object may move with either constant velocity or constant acceleration. The statistics are the same along all dimensions. If you need to configure a Kalman filter with different assumptions, use the `vision.KalmanFilter` object directly.

Examples

Track an Occluded Object

Detect and track a ball using Kalman filtering, foreground detection, and blob analysis.

Create System objects to read the video frames, detect foreground physical objects, and display results.

```
videoReader = VideoReader('singleball.mp4');
videoPlayer = vision.VideoPlayer('Position',[100,100,500,400]);
foregroundDetector = vision.ForegroundDetector('NumTrainingFrames',10,...
                'InitialVariance',0.05);
blobAnalyzer = vision.BlobAnalysis('AreaOutputPort',false,...
                'MinimumBlobArea',70);
```

Process each video frame to detect and track the ball. After reading the current video frame, the example searches for the ball by using background subtraction and blob analysis. When the ball is first detected, the example creates a Kalman filter. The Kalman filter determines the ball?s location, whether it is detected or not. If the ball is detected, the Kalman filter first predicts its state at the current video frame. The filter then uses the newly detected location to correct the state, producing a filtered location. If the ball is missing, the Kalman filter solely relies on its previous state to predict the ball's current location.

```
  kalmanFilter = []; isTrackInitialized = false;
   while hasFrame(videoReader)
     colorImage  = readFrame(videoReader);
```

```
    foregroundMask = step(foregroundDetector,im2gray(im2single(colorImage)));
    detectedLocation = step(blobAnalyzer,foregroundMask);
    isObjectDetected = size(detectedLocation, 1) > 0;

    if ~isTrackInitialized
      if isObjectDetected
        kalmanFilter = configureKalmanFilter('ConstantAcceleration',...
                 detectedLocation(1,:), [1 1 1]*1e5, [25, 10, 10], 25);
        isTrackInitialized = true;
      end
      label = ''; circle = zeros(0,3);
    else
      if isObjectDetected
        predict(kalmanFilter);
        trackedLocation = correct(kalmanFilter, detectedLocation(1,:));
        label = 'Corrected';
      else
        trackedLocation = predict(kalmanFilter);
        label = 'Predicted';
      end
      circle = [trackedLocation, 5];
    end

    colorImage = insertObjectAnnotation(colorImage,'circle',...
               circle,label,'AnnotationColor','red');
    step(videoPlayer,colorImage);
    pause(0.1);
  end
```

Release resources.

```
release(videoPlayer);
```

Input Arguments

`MotionModel` — Motion model

`'ConstantVelocity'` | `'ConstantAcceleration'`

Motion model, specified as `'ConstantVelocity'` or `'ConstantAcceleration'`. The motion model you select applies to all dimensions. For example, for the 2-D Cartesian coordinate system. This mode applies to both X and Y directions.

Data Types: `char`

`InitialLocation` — Initial location of object

vector

Initial location of object, specified as a numeric vector. This argument also determines the number of dimensions for the coordinate system. For example, if you specify the initial location as a two-element vector, $[x_0, y_0]$, then a 2-D coordinate system is assumed.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialEstimateError` — Initial estimate uncertainty variance

2-element vector | 3-element vector

Initial estimate uncertainty variance, specified as a two- or three-element vector. The initial estimate error specifies the variance of the initial estimates of location, velocity, and acceleration of the tracked object. The function assumes a zero initial velocity and acceleration for the object, at the location you set with the `InitialLocation` property. You can set the `InitialEstimateError` to an approximated value when you have the ability to measure location, velocity, or acceleration: (*assumed values – actual values*)^2 + *the variance of the values*

In many visual object tracking applications, it is common to only have a measurement of the object location from an object detector. In this case, you can set the first element (*LocationVariance*) of `InitialEstimationError` to the same value as `MeasurementNoise`. The velocity and acceleration variance values should be set to large values to indicate that the initial state of these are unknown. For example, if you detect the 2-D location of an object with variance of `1` and use a constant velocity motion model, then you can set *LocationVariance* to `1` and the second element *VelocityVariance* to a high value such as `1e4`.

The value of this property affects the Kalman filter for the first few detections. Later, the estimate error is determined by the noise and the input data. A larger value for the initial estimate error helps the Kalman filter to adapt to the detection results faster. However, a larger value also prevents the Kalman filter from removing noise from the first few detections.

Specify the initial estimate error as a two-element vector for constant velocity or a three-element vector for constant acceleration:

MotionModel	InitialEstimateError
`ConstantVelocity`	[*LocationVariance*, *VelocityVariance*]
`ConstantAcceleration`	[*LocationVariance*, *VelocityVariance*, *AccelerationVariance*]

Data Types: `double` | `single`

`MotionNoise` — Deviation of selected and actual model
2-element vector | 3-element vector

Deviation of selected and actual model, specified as a two- or three-element vector. The motion noise specifies the tolerance of the Kalman filter for the deviation from the chosen model. This tolerance compensates for the difference between the object's actual motion and that of the model you choose whether the difference is from random deviation or just a small change in the motion (e.g. direction or speed). Increasing this value may cause the Kalman filter to change its state to fit the detections. Such an increase may prevent the Kalman filter from removing enough noise from the detections. The values of this property stay constant and therefore may affect the long-term performance of the Kalman filter.

MotionModel	MotionNoise
`ConstantVelocity`	[*LocationVariance*, *VelocityVariance*]
`ConstantAcceleration`	[*LocationVariance*, *VelocityVariance*, *AccelerationVariance*]

Data Types: `double` | `single`

`MeasurementNoise` — Variance inaccuracy of detected location
scalar

Variance inaccuracy of detected location, specified as a scalar. It is directly related to the technique used to detect the physical objects. For instance, if the detected location error is approximately 5 pixels, then set the measurement noise to `5^2`. Increasing the `MeasurementNoise` value enables the Kalman filter to remove more noise from the detections. However, it may also cause the Kalman filter to adhere too closely to the motion model you chose, putting less emphasis on the detections. The values of this property stay constant, and therefore may affect the long-term performance of the Kalman filter.

Data Types: `double` | `single`

Output Arguments

`kalmanFilter` — Configured Kalman filter tracking

object

Configured Kalman filter, returned as a `vision.KalmanFilter` object for tracking.

Algorithms

This function provides a simple approach for configuring the vision.KalmanFilter object for tracking. The Kalman filter implements a discrete time, linear State-Space System. The `configureKalmanFilter` function sets the `vision.KalmanFilter` object properties.

The `InitialLocation` property corresponds to the measurement vector used in the Kalman filter state-space model. This table relates the measurement vector, M, to the state-space model for the Kalman filter.		
State transition model, *A*, and Measurement model, *H*		
The state transition model, A, and the measurement model, H of the state-space model, are set to block diagonal matrices made from M identical submatrices As and Hs, respectively: A = `blkdiag`(As _1, As _2, ..., As _M) H = `blkdiag`(Hs _1, Hs _2, ..., Hs _M)		
The submatrices As and Hs are described below:		
MotionModel	***A*s**	***H*s**
`'ConstantVelocity'`	[1 1; 0 1]	[1 0]
`'ConstantAcceleration'`	[1 1 0.5; 0 1 1; 0 0 1]	[1 0 0]
The Initial State, *x*:		
MotionModel	**Initial state, *x***	
`'ConstantVelocity'`	[`InitialLocation`(1), 0, ..., `InitialLocation`(M), 0]	
`'ConstantAcceleration'`	[`InitialLocation`(1), 0, 0, ..., `InitialLocation`(M), 0, 0]	
The initial state estimation error covariance matrix, *P*:		
P = `diag`(`repmat`(`InitialError`, [1, M]))		

The process noise covariance, *Q*:
Q = `diag(repmat(MotionNoise, [1, M]))`
The measurement noise covariance, *R*:
R = `diag(repmat(MeasurementNoise, [1, M]))`.

detectBRISKFeatures

Detect BRISK features

Syntax

```
points = detectBRISKFeatures(I)
points = detectBRISKFeatures(I,Name,Value)
```

Description

`points = detectBRISKFeatures(I)` returns a `BRISKPoints` object, `points`. The object contains information about BRISK features detected in a 2-D grayscale or binary input image, `I`. The `detectBRISKFeatures` function uses a Binary Robust Invariant Scalable Keypoints (BRISK) algorithm to detect multiscale corner features.

`points = detectBRISKFeatures(I,Name,Value)` uses additional options specified by one or more name-value arguments.

Examples

Detect BRISK Points in an Image and Mark Their Locations

Read the image.

```
I = imread('cameraman.tif');
```

Find the BRISK points.

```
points = detectBRISKFeatures(I);
```

Display the results.

```
imshow(I); hold on;
plot(points.selectStrongest(20));
```

Input Arguments

`I` — Input image

M-by-*N* 2-D grayscale or binary image

Input image, specified as an *M*-by-*N* 2-D grayscale or binary image. The input image must be real and nonsparse.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'MinQuality',0.1,'ROI', [50,150,100,200]` specifies that the detector must use a 10% minimum accepted quality of corners within the designated region of interest. This region of interest is located at *x*=`50`, *y*=`150`. The ROI has a width of `100` pixels and a height of `200` pixels.

`MinContrast` — Minimum intensity difference

0.2 (default) | scalar

Minimum intensity difference between a corner and its surrounding region, specified as the comma-separated pair consisting of '`MinContrast`' and a scalar in the range (0 1). The minimum contrast value represents a fraction of the maximum value of the image class. Increase this value to reduce the number of detected corners.

`MinQuality` — Minimum accepted quality of corners
0.1 (default) | scalar

Minimum accepted quality of corners, specified as the comma-separated pair consisting of '`MinQuality`' and a scalar value in the range [0,1]. The minimum accepted quality of corners represents a fraction of the maximum corner metric value in the image. Increase this value to remove erroneous corners.

`NumOctaves` — Number of octaves
4 (default) | scalar

Number of octaves to implement, specified as a comma-separated pair consisting of '`NumOctaves`' and an integer scalar, greater than or equal to `0`. Increase this value to detect larger blobs. Recommended values are between `1` and `4`. When you set `NumOctaves` to `0`, the function disables multiscale detection. It performs the detection at the scale of the input image, `I`.

`ROI` — Rectangular region
[1 1 `size`(`I`,2) `size`(`I`,1)] (default) | vector

Rectangular region for corner detection, specified as a comma-separated pair consisting of '`ROI`' and a vector of the format [*x y width height*]. The first two integer values [*x y*] represent the location of the upper-left corner of the region of interest. The last two integer values represent the width and height.

Output Arguments

`points` — Brisk points
`BRISKPoints` object

Brisk points, returned as a `BRISKPoints` object. The object contains information about the point features detected in the 2-D grayscale or binary input image.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Generates portable C code using a C++ compiler that links to OpenCV libraries. See “Portable C Code Generation for Functions That Use OpenCV Library”.
- Code generation does not support arrays of point feature objects returned by this function. Instead, use the `Location` property to obtain an *M*-by-2 matrix of coordinates:

```
locations = points.Location;
```

GPU Code Generation
Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

detectCheckerboardPoints

Detect checkerboard pattern in image

Syntax

```
[imagePoints,patternDims] = detectCheckerboardPoints(I)
[imagePoints,patternDims,imagesUsed] = detectCheckerboardPoints(
imageFileNames)
[imagePoints,patternDims,imagesUsed] = detectCheckerboardPoints(images)

[imagePoints,patternDims,pairsUsed] = detectCheckerboardPoints(
imageFileNames1,imageFileNames2)
[imagePoints,patternDims,pairsUsed] = detectCheckerboardPoints(images1,
images2)

[imagePoints,patternDims,pairsUsed] = detectCheckerboardPoints( ___ ,
Name,Value)
```

Description

Single Image Checkerboard Detection

`[imagePoints,patternDims] = detectCheckerboardPoints(I)` detects the keypoints of a checkerboard calibration pattern in a single image, a set of images, or stereo image pairs. The function returns the detected points `imagePoints`, and dimensions of the checkerboard `patternDims`.

`[imagePoints,patternDims,imagesUsed] = detectCheckerboardPoints(imageFileNames)` detects a checkerboard pattern in a set of input images, provided as an array of file names.

`[imagePoints,patternDims,imagesUsed] = detectCheckerboardPoints(images)` detects a checkerboard pattern in a set of input images, provided as an array of grayscale or truecolor images.

Stereo Pair Checkerboard Detection

`[imagePoints,patternDims,pairsUsed] = detectCheckerboardPoints(imageFileNames1,imageFileNames2)` detects a checkerboard pattern in stereo pairs of images, provided as cell arrays of file names.

`[imagePoints,patternDims,pairsUsed] = detectCheckerboardPoints(images1, images2)` detects a checkerboard pattern in stereo pairs of images, provided as arrays of grayscale or truecolor images.

Optional Arguments

`[imagePoints,patternDims,pairsUsed] = detectCheckerboardPoints( ___ , Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. Unspecified properties have default values.

Examples

Detect Checkerboard in Images with High Distortion

Create an `imageDatastore` containing calibration images from a GoPro camera.

```
imds = imageDatastore(fullfile(toolboxdir("vision"),"visiondata","calibration","gopro"));
```

Detect calibration pattern using the `HighDistortion` option, which is good to use with fisheye lens images.

```
[imagePoints,patternDims,imagesUsed] = detectCheckerboardPoints(imds.Files(1:4),HighDistortion=t
```

Display detected points.

```
for i = 1:4
  % Read image
  I = readimage(imds,i);

  % Insert markers at detected point locations
  I = insertMarker(I,imagePoints(:,:,i),"o",MarkerColor="red",Size=10);

  % Display image
  subplot(2,2,i);
  imshow(I);
end
```

Detect Checkerboard in Image

Load an image containing a checkerboard pattern.

```
imageFileName = fullfile(toolboxdir("vision"),"visiondata","calibration","dslr","image01.jpg");
I = imread(imageFileName);
```

Detect the checkerboard points.

```
[imagePoints,patternDims] = detectCheckerboardPoints(I);
```

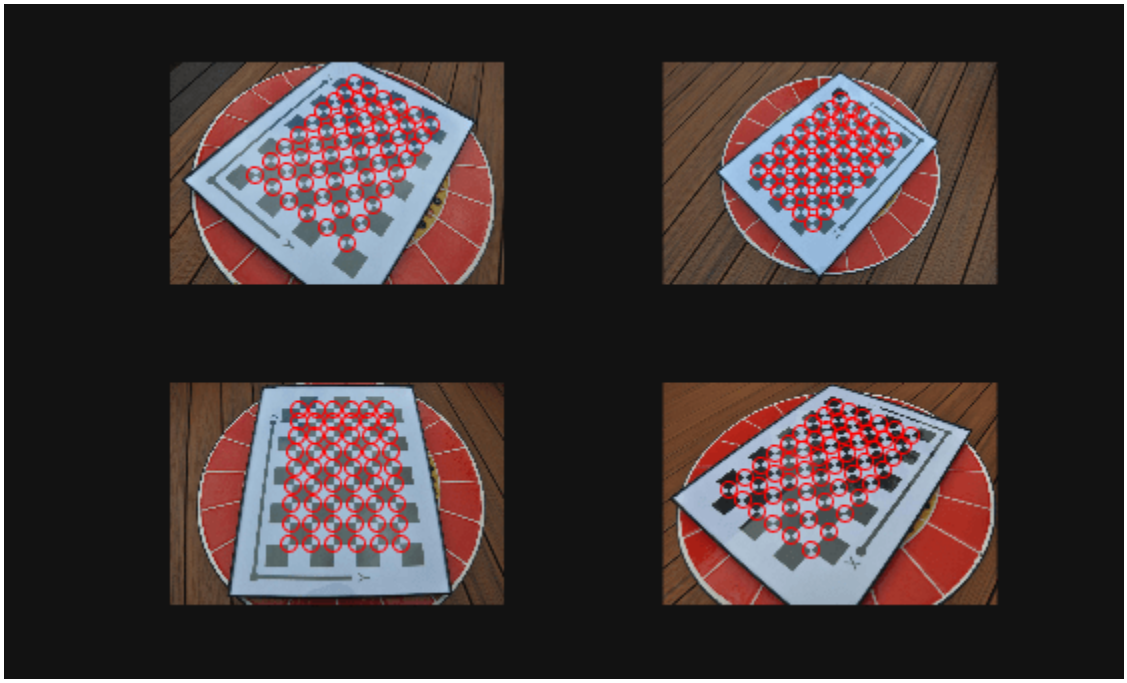
Display detected points.

```
J = insertText(I,imagePoints,1:size(imagePoints,1));
J = insertMarker(J,imagePoints,"o",MarkerColor="red",Size=5);
imshow(J);
title(sprintf("Detected a %d x %d Checkerboard",patternDims));
```

Detect Checkerboard in a Set of Image Files

Create a cell array of file names of calibration images.

```
images = imageDatastore(fullfile(toolboxdir("vision"),"visiondata",...
    "calibration","dslr"));
imageFileNames = images.Files;
```



Detect calibration pattern in the images.

```
[imagePoints,patternDims,imagesUsed] = detectCheckerboardPoints(imageFileNames,PartialDetections=
```

Display the detected points.

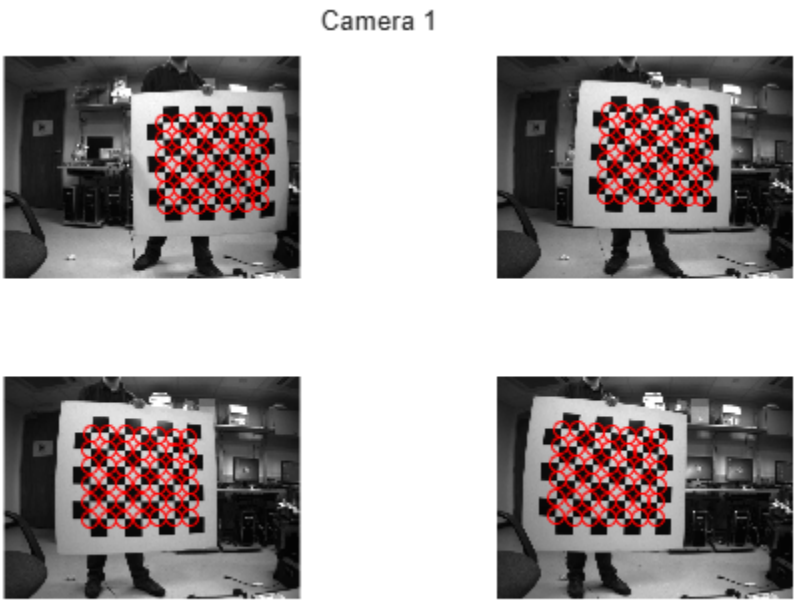
```
imageFileNames = imageFileNames(imagesUsed);
for i = 1:4
  I = imread(imageFileNames{i});
```

```
subplot(2, 2, i);
  imshow(I);
  hold on;
  plot(imagePoints(:,1,i),imagePoints(:,2,i),"ro");
end
```

Detect Checkerboard in Stereo Images

Read in stereo images.

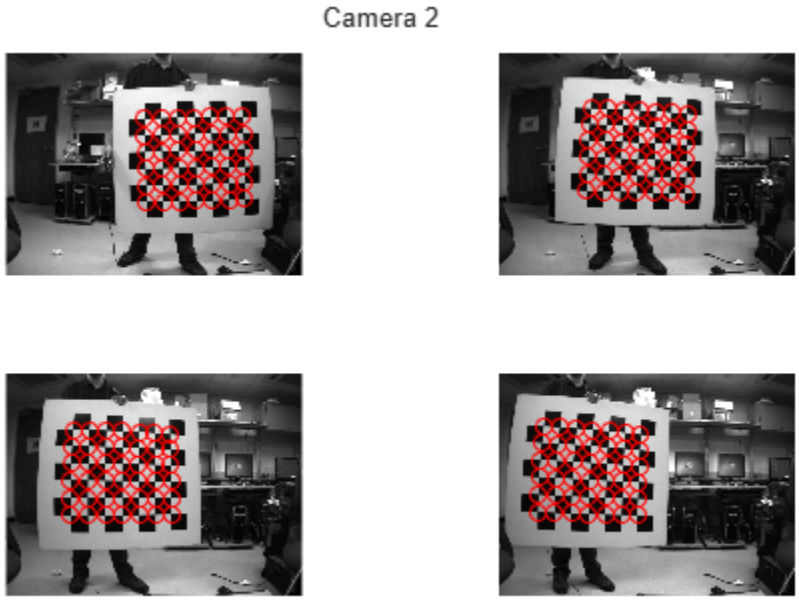
```
numImages = 4;
images1 = cell(1,numImages);
images2 = cell(1,numImages);
for i = 1:numImages
    images1{i} = fullfile(matlabroot,'toolbox','vision',...
        'visiondata','calibration','stereo','left',sprintf('left%02d.png',i));
    images2{i} = fullfile(matlabroot,'toolbox','vision',...
        'visiondata','calibration','stereo','right',sprintf('right%02d.png',i));
end
```



Detect the checkerboards in the images.

```
[imagePoints,patternDims,pairsUsed] = ...
    detectCheckerboardPoints(images1,images2);
```

Display points from `images1`.



```
images1 = images1(pairsUsed);
figure;
for i = 1:numel(images1)
      I = imread(images1{i});
```

```
      subplot(2,2,i);
      imshow(I);
      hold on;
      plot(imagePoints(:,1,i,1),imagePoints(:,2,i,1),'ro');
end
annotation('textbox',[0 0.9 1 0.1],'String','Camera 1',...
    'EdgeColor','none','HorizontalAlignment','center')
```

Display points from `images2`.

```
images2 = images2(pairsUsed);
figure;
for i = 1:numel(images2)
      I = imread(images2{i});
      subplot(2, 2, i);
      imshow(I);
      hold on;
      plot(imagePoints(:,1,i,2),imagePoints(:,2,i,2),'ro');
end
annotation('textbox',[0 0.9 1 0.1],'String','Camera 2',...
    'EdgeColor','none','HorizontalAlignment','center')
```

Input Arguments

`I` — Input image

M-by-*N*-by-3 truecolor image | *M*-by-*N* 2-D grayscale image

Input image, specified as either an *M*-by-*N*-by-3 truecolor or *M*-by-*N* 2-D grayscale. The input image must be real and nonsparse. The function can detect checkerboards with a minimum size of 4-by-4 squares.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

`imageFileNames` — Image file names

N-element cell array of character vectors | *N*-element array of strings

Image file names, specified as an *N*-element cell array of *N* file names.

`imageFileNames1` — File names for camera 1 images

N-element cell array of character vectors | *N*-element array of strings

File names for camera 1 images, specified as an *N*-element cell array of *N* file names. The images contained in this array must be in the same order as images contained in `imageFileNames2`, forming stereo pairs.

`imageFileNames2` — File names for camera 2 images

N-element cell array of character vectors | *N*-element array of strings

File names for camera 2 images, specified as an *N*-element cell array of *N* file names. The images contained in this array must be in the same order as images contained in `imageFileNames1`, forming stereo pairs.

`images` — Images
height-by-*width*-by-*color channel*-by-*number of frames* array

Images, specified as an *H*-by-*W*-by-*B*-by-*F* array containing a set of grayscale or truecolor images. The input dimensions are:
H represents the image height.
W represents the image width.
B represents the color channel. A value of `1` indicates a grayscale image, and a value of `3` indicates a truecolor image.
F represents the number of image frames.

`images1` — Stereo pair images from camera 1
height-by-*width*-by-*color channel*-by-*number of frames* array

Stereo pair images from camera 1, specified as an *H*-by-*W*-by-*B*-by-*F* array containing a set of grayscale or truecolor images. The input dimensions are:
H represents the image height.
W represents the image width.
B represents the color channel. A value of `1` indicates a grayscale image, and a value of `3` indicates a truecolor image.
F represents the number of image frames.

`images2` — Stereo pair images from camera 2
height-by-*width*-by-*color channel*-by-*number of frames* array

Stereo pair images from camera 2, specified as an *H*-by-*W*-by-*B*-by-*F* array containing a set of grayscale or truecolor images. The input dimensions are:
H represents the image height.
W represents the image width.
B represents the color channel. A value of `1` indicates a grayscale image, and a value of `3` indicates a truecolor image.
F represents the number of image frames.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'MinCornerMetric','0.15'`

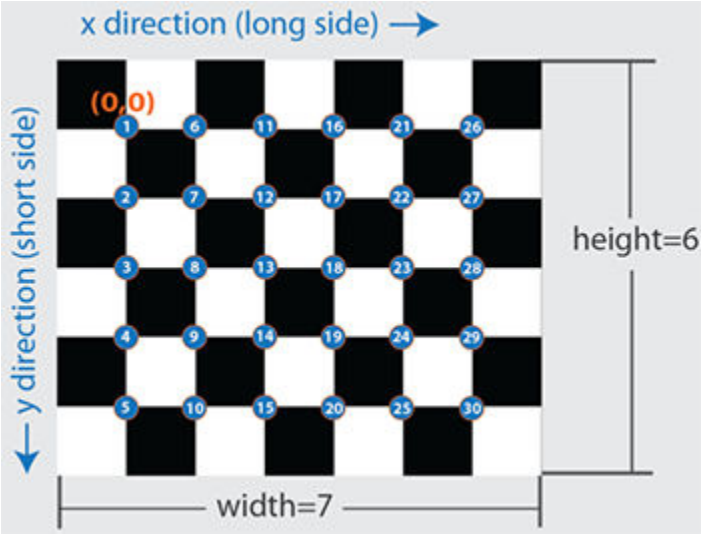
`MinCornerMetric` — Minimum corner metric threshold
`0.15` | `0.12` | nonnegative scalar

Minimum corner metric threshold, specified as a nonnegative scalar. When the image is noisy or highly textured, increase this value to reduce the number of false corner detections. When you set the `'HighDistortion'` property to `false` the function sets the default value to `0.15`. When you set the `'HighDistortion'` property to `true` the function sets the default value to `0.12`. Decreasing the value results in an increase of corner detections.

`HighDistortion` — High distortion
`false` (default) | `true`

High distortion, specified as `false` or `true`. Set `'HighDistortion'` to `true` when the images contain a high level of distortion, which is typical of a wide field of view camera, such as a fisheye camera. Set `'HighDistortion'` to `false` when the images do not contain a high level of distortion. Setting `'HighDistortion'` to `true` can increase the resiliency to image distortion but decreases the processing speed.

`PartialDetections` — Partial detections
`true` (default) | `false`



Partial detections, specified as `true` or `false`. Set `'PartialDetections'` to `true` to return partially detected checkerboards. The function fills missing keypoint detections with `[NaN,NaN]` coordinates. Set `'PartialDetections'` to `false` to discard partially detected checkerboards. This property is ignored for stereo image pairs.

Output Arguments

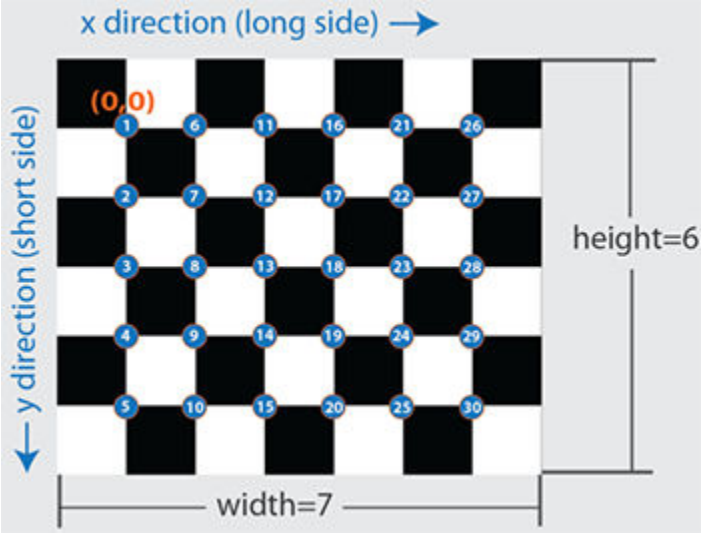
`imagePoints` — Detected checkerboard corner coordinates
M-by-2 matrix | *M*-by-2-by- *number of images* array | *M*-by-2-by-*number of pairs of images*-by-*number of cameras* array

Detected checkerboard corner coordinates, returned as an *M*-by-2 matrix for one image. For multiple images, points are returned as an *M*-by-2-by-*number of images* array, and for stereo pairs of images, the function returns points as an *M*-by-2-by-*number of pairs*-by-*number of cameras* array.

For stereo pairs, `imagePoints`(:,:,:,1) are the points from the first set of images, and `imagePoints`(:,:,:,2) are the points from the second set of images. The output contains *M* number of [*x y*] coordinates. Each coordinate represents a point where square corners are detected on the checkerboard. The number of points the function returns depends on the value of `patternDims`, which indicates the number of squares detected. The function detects the points with sub-pixel accuracy.

The function calculates the number of points, *M*, as follows:
M = `prod`(`patternDims`-1).
If the checkerboard cannot be detected:

```
imagePoints = []
patternDims = [0,0]
```



When you specify the `imageFileNames` input, the function can return `imagePoints` as an *M*-by-2-by-*N* array. In this array, *N* represents the number of images in which a checkerboard is detected. If a checkerboard cannot be detected, the function returns `imagePoints` as one of these two options:

For single camera images only:

- If the complete checkerboard cannot be detected, the function returns a partially detected checkerboard with `[NaN,NaN]` as the *x*-*y* coordinates for missing corners in `imagePoints`. This default behavior can be modified using the `'PartialDetections'` name-value argument.
- When possible, the function orients the partially detected checkerboard such that the location of the origin and the arrangement of the corners is consistent with the completely visible checkerboard. If the function cannot detect a complete checkerboard in any of the input images, the largest detected checkerboard is used as the reference checkerboard and the dimensions of this board is returned in `patternDims`.

`patternDims` — Pattern dimensions
2-element [*height*, *width*] vector

Pattern dimensions, returned as a 2-element [*height*, *width*] vector. The dimensions of the pattern are expressed in terms of the number of squares.

If a checkerboard cannot be detected, the function sets `patternDims` to `[0,0]`.

`imagesUsed` — Pattern detection
N-by-1 logical vector

Pattern detection, returned as an *N*-by-1 logical vector, where *N* is the number of images. The function returns `1` (true) if corners are successfully detected in an image, and `0` (false) if no corners are detected.

The function estimates the checkerboard corners based on a successful detection of the keypoints. If any step in the detection process fails, the function does not return corners for that image, and the corresponding value in the logical vector is false.

`pairsUsed` — Stereo pair pattern detection
N-by-1 logical vector

Stereo pair pattern detection, returned as an *N*-by-1 logical vector, where *N* is the number of images. The function returns `1` (true) if corners are successfully detected in a stereo image pair, and `0` (false) if no corners are detected.

For stereo pair pattern detection, the checkerboard needs to be fully visible in both images for it to be detected. Unlike single camera calibration, partially detected checkerboards are rejected for stereo image pairs.

Version History

Introduced in R2014a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Code generation will not support specifying images as file names or cell arrays of file names. It supports only checkerboard detection in a single image or stereo pair of images. For example, these syntaxes are supported:
  - `detectCheckerboardPoints(I1)`
  - `detectCheckerboardPoints(I1,I2)`

  `I1` and `I2` are single grayscale or RGB images.
- Images must be compile-time constants.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

Thread-Based Environment

Run code in the background using MATLAB® `backgroundPool` or accelerate code with Parallel Computing Toolbox™ `ThreadPool`.

The `detectCheckerboardPoints` function fully supports thread-based environments. For more information, see “Run MATLAB Functions in Thread-Based Environment”.

detectFASTFeatures

Detect corners using FAST algorithm

Syntax

```
points = detectFASTFeatures(I)
points = detectFASTFeatures(I,Name,Value)
```

Description

`points = detectFASTFeatures(I)` returns a `cornerPoints` object `points` that contains information about corner features detected in the 2-D grayscale or binary input using the Features from Accelerated Segment Test (FAST) algorithm.

`points = detectFASTFeatures(I,Name,Value)` uses additional options specified by one or more name-value arguments.

Examples

Find Corner Points in an Image Using the FAST Algorithm

Read the image.

```
I = imread('cameraman.tif');
```

Find the corners.

```
corners = detectFASTFeatures(I);
```

Display the results.

```
imshow(I); hold on;
plot(corners.selectStrongest(50));
```

Input Arguments

`I` — Input image

M-by-*N* 2-D grayscale or binary image

Input image, specified as an *M*-by-*N* 2-D grayscale or binary image. The input image must be real and nonsparse.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'MinQuality','0.01','ROI', [50,150,100,200]` specifies that the detector must use a 1% minimum accepted quality of corners within the designated region of interest. This region of interest is located at *x*=`50`, *y*=`150`. The ROI has a width of `100` pixels, and a height of `200` pixels.

`MinQuality` — Minimum accepted quality of corners

0.1 (default)

Minimum accepted quality of corners, specified as the comma-separated pair consisting of '`MinQuality`' and a scalar value in the range [0,1].

The minimum accepted quality of corners represents a fraction of the maximum corner metric value in the image. Larger values can be used to remove erroneous corners.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`MinContrast` — Minimum intensity
0.2 (default)

Minimum intensity difference between corner and surrounding region, specified as the comma-separated pair consisting of '`MinContrast`' and a scalar value in the range (0,1).

The minimum intensity represents a fraction of the maximum value of the image class. Increasing the value reduces the number of detected corners.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ROI` — Rectangular region
[1 1 `size`(I,2) `size`(I,1)] (default) | vector

Rectangular region for corner detection, specified as a comma-separated pair consisting of '`ROI`' and a vector of the format [*x y width height*]. The first two integer values [*x y*] represent the location of the upper-left corner of the region of interest. The last two integer values represent the width and height.

Example: `'ROI', [50,150,100,200]`

Output Arguments

`points` — Corner points
`cornerPoints` object

Corner points object, returned as a `cornerPoints` object. The object contains information about the feature points detected in the 2-D grayscale or binary input image.

Version History

Introduced in R2013a

R2022a: GPU Use Being Removed for `detectFASTFeatures` function
Errors starting in R2022a

The `detectFASTFeatures` function no longer supports GPU. You can use the `detectHarrisFeatures` on the GPU to detect corner points instead. Although, it won't provide identical results, it might be suitable based on the application.

detectHarrisFeatures

Detect corners using Harris–Stephens algorithm

Syntax

```
points = detectHarrisFeatures(I)
points = detectHarrisFeatures(I,Name,Value)
```

Description

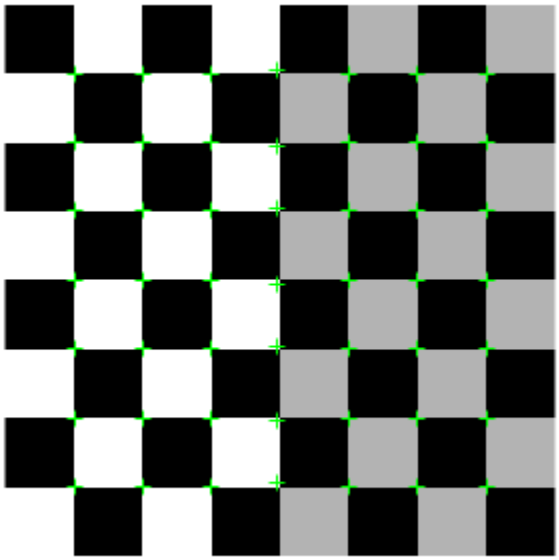
`points = detectHarrisFeatures(I)` returns a `cornerPoints` object `points` that contains information about corner features detected in the 2-D grayscale or binary input using the Harris-Stephens algorithm.

`points = detectHarrisFeatures(I,Name,Value)` uses additional options specified by one or more name-value arguments.

Examples

Find Corner Points Using the Harris-Stephens Algorithm

Read the image.



```
I = checkerboard;
```

Find the corners.

```
corners = detectHarrisFeatures(I);
```

Display the results.

```
imshow(I); hold on;
plot(corners.selectStrongest(50));
```

Input Arguments

`I` — Input image

M-by-*N* 2-D grayscale or binary image

Input image, specified as an *M*-by-*N* 2-D grayscale or binary image. The input image must be real and nonsparse.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'MinQuality','0.01','ROI', [50,150,100,200]` specifies that the detector must use a 1% minimum accepted quality of corners within the designated region of interest. This region of interest is located at x=`50`, y=`150`. The ROI has a width of `100` pixels and a height of `200` pixels.

`MinQuality` — Minimum accepted quality of corners

0.01 (default)

Minimum accepted quality of corners, specified as the comma-separated pair consisting of '`MinQuality`' and a scalar value in the range [0,1].

The minimum accepted quality of corners represents a fraction of the maximum corner metric value in the image. Larger values can be used to remove erroneous corners.

Example: `'MinQuality',0.01`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`FilterSize` — Gaussian filter dimension
5 (default)

Gaussian filter dimension, specified as the comma-separated pair consisting of '`FilterSize`' and an odd integer value in the range [3, `min(size(I))`].

The Gaussian filter smooths the gradient of the input image.

The function uses the `FilterSize` value to calculate the filter's dimensions, `FilterSize`-by-`FilterSize`. It also defines the standard deviation of the Gaussian filter as `FilterSize`/3.

Example: `'FilterSize',5`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ROI` — Rectangular region
[1 1 `size`(I,2) `size`(I,1)] (default) | vector

Rectangular region for corner detection, specified as a comma-separated pair consisting of '`ROI`' and a vector of the format [*x y width height*]. The first two integer values [*x y*] represent the location of the upper-left corner of the region of interest. The last two integer values represent the width and height.

Example: `'ROI',[50,150,100,200]`

Output Arguments

`points` — Corner points
`cornerPoints` object

Corner points object, returned as a `cornerPoints` object. The object contains information about the feature points detected in the 2-D input image.

detectMinEigenFeatures

Detect corners using minimum eigenvalue algorithm

Syntax

```
points = detectMinEigenFeatures(I)
points = detectMinEigenFeatures(I,Name,Value)
```

Description

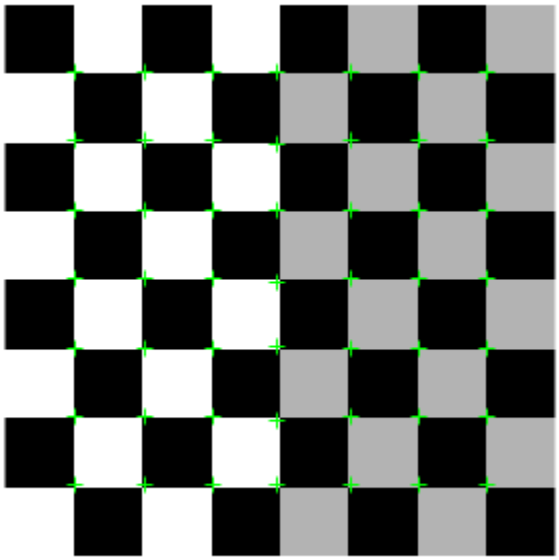
`points = detectMinEigenFeatures(I)` returns a `cornerPoints` object `points` that contains information about corner features detected in the 2-D grayscale or binary input using the minimum eigenvalue algorithm developed by Shi and Tomasi.

`points = detectMinEigenFeatures(I,Name,Value)` uses additional options specified by one or more name-value arguments.

Examples

Find Corner Points Using the Eigenvalue Algorithm

Read the image.



```
I = checkerboard;
```

Find the corners.

```
corners = detectMinEigenFeatures(I);
```

Display the results.

```
imshow(I); hold on;
plot(corners.selectStrongest(50));
```

Input Arguments

`I` — Input image

M-by-*N* 2-D grayscale or binary image

Input image, specified as an *M*-by-*N* 2-D grayscale or binary image. The input image must be real and nonsparse.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'MinQuality','0.01','ROI', [50,150,100,200]` specifies that the detector must use a 1% minimum accepted quality of corners within the designated region of interest. This region of interest is located at x=`50`, y=`150`. The ROI has a width of `100` pixels, and a height of `200` pixels.

`MinQuality` — Minimum accepted quality of corners

0.01 (default)

Minimum accepted quality of corners, specified as the comma-separated pair consisting of '`MinQuality`' and a scalar value in the range [0,1].

The minimum accepted quality of corners represents a fraction of the maximum corner metric value in the image. Larger values can be used to remove erroneous corners.

Example: `'MinQuality', 0.01`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`FilterSize` — Gaussian filter dimension
5 (default)

Gaussian filter dimension, specified as the comma-separated pair consisting of '`FilterSize`' and an odd integer value in the range [3, inf).

The Gaussian filter smooths the gradient of the input image.

The function uses the `FilterSize` value to calculate the filter's dimensions, `FilterSize`-by-`FilterSize`. It also defines the standard deviation as `FilterSize`/3.

Example: `'FilterSize', 5`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ROI` — Rectangular region
[1 1 `size`(I,2) `size`(I,1)] (default) | vector

Rectangular region for corner detection, specified as a comma-separated pair consisting of '`ROI`' and a vector of the format [*x y width height*]. The first two integer values [*x y*] represent the location of the upper-left corner of the region of interest. The last two integer values represent the width and height.

Example: `'ROI', [50,150,100,200]`

Output Arguments

`points` — Corner points
`cornerPoints` object

Corner points, returned as a `cornerPoints` object. The object contains information about the point features detected in the 2-D grayscale or binary input image.

detectMSERFeatures

Detect MSER features

Syntax

```
regions = detectMSERFeatures(I)
[regions,cc] = detectMSERFeatures(I)
[___] = detectMSERFeatures(I,Name,Value)
```

Description

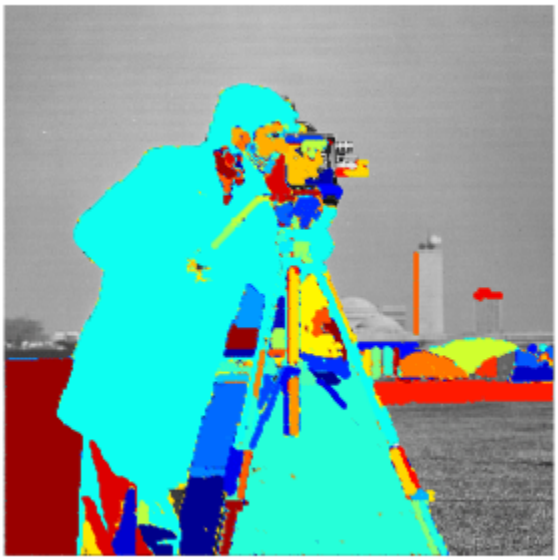
`regions = detectMSERFeatures(I)` returns an `MSERRegions` object, `regions`, containing information about MSER features detected in the 2-D grayscale or binary input image, `I`. This object uses Maximally Stable Extremal Regions (MSER) algorithm to find regions.

Note For Simulink support using this function, you must enable the model configuration settings. To display the dialog box, in the Simulink Editor, select the **Modeling** tab and then select **Model Settings > Model Properties**. In the **Configuration Parameters** dialog box, select **Simulation Target** > `Advanced Parameters` > `Dynamic Memory allocation in MATLAB functions`.

`[regions,cc] = detectMSERFeatures(I)` optionally returns MSER regions in a connected component structure.

`[___] = detectMSERFeatures(I,Name,Value)` sets additional options specified by one or more name-value arguments.

Examples



Find MSER Regions in an Image

Read image and detect MSER regions.

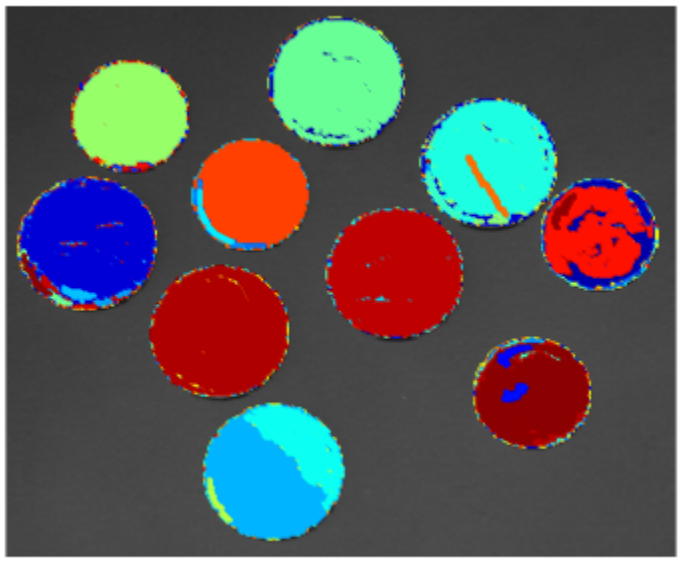
```
I = imread('cameraman.tif');
regions = detectMSERFeatures(I);
```

Visualize MSER regions which are described by pixel lists stored inside the returned 'regions' object.

```
figure; imshow(I); hold on;
plot(regions,'showPixelList',true,'showEllipses',false);
```

Display ellipses and centroids fit into the regions. By default, plot displays ellipses and centroids.

```
figure; imshow(I);
hold on;
plot(regions);
```



Find Circular MSER Regions

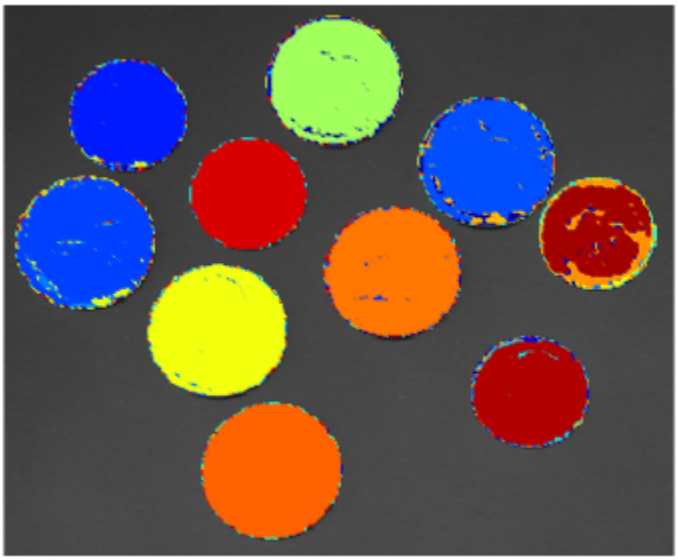
Detect MSER regions.

```
I = imread('coins.png');
[regions,mserCC] = detectMSERFeatures(I);
```

Show all detected MSER Regions.

```
figure
imshow(I)
hold on
plot(regions,'showPixelList',true,'showEllipses',false)
```

Measure the MSER region eccentricity to gauge region circularity.



```
stats = regionprops('table',mserCC,'Eccentricity');
```

Threshold eccentricity values to only keep the circular regions. (Circular regions have low eccentricity.)

```
eccentricityIdx = stats.Eccentricity < 0.55;
circularRegions = regions(eccentricityIdx);
```

Show the circular regions.

```
figure
imshow(I)
hold on
plot(circularRegions,'showPixelList',true,'showEllipses',false)
```

Input Arguments

`I` — Input image

M-by-*N* 2-D grayscale or binary image

Input image, specified as an *M*-by-*N* 2-D grayscale or binary image. It must be real and nonsparse. The function internally converts input images to `uint8` that are not `uint8` before looking for MSER regions.

Data Types: `uint8` | `int16` | `uint16` | `single` | `double` | `logical`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'RegionAreaRange',[30 14000]`, specifies the size of the region in pixels.

`ThresholdDelta` — Step size between intensity threshold levels

2 (default) | percent numeric value

Step size between intensity threshold levels, specified as the comma-separated pair consisting of '`ThresholdDelta`' and a numeric value in the range (0,100]. This value is expressed as a percentage of the input data type range used in selecting extremal regions while testing for their stability. Decrease this value to return more regions. Typical values range from 0.8 to 4.

`RegionAreaRange` — Size of the region
`[30 14000]` (default) | two-element vector

Size of the region in pixels, specified as the comma-separated pair consisting of '`RegionAreaRange`' and a two-element vector. The vector, [*minArea maxArea*], allows the selection of regions containing pixels to be between *minArea* and *maxArea*, inclusive.

`MaxAreaVariation` — Maximum area variation between extremal regions
`0.25` (default) | positive scalar

Maximum area variation between extremal regions at varying intensity thresholds, specified as the comma-separated pair consisting of '`MaxAreaVariation`' and a positive scalar value. Increasing this value returns a greater number of regions, but they may be less stable. Stable regions are very similar in size over varying intensity thresholds. Typical values range from 0.1 to 1.0.

`ROI` — Rectangular region of interest
[1 1 `size`(`I`,2) `size`(`I`,1)] (default) | vector

Rectangular region of interest, specified as a vector. The vector must be in the format [*x y width height*]. When you specify an `ROI`, the function detects corners within the area located at [*x y*] of size specified by [*width height*]. The [*x y*] elements specify the upper left corner of the region.

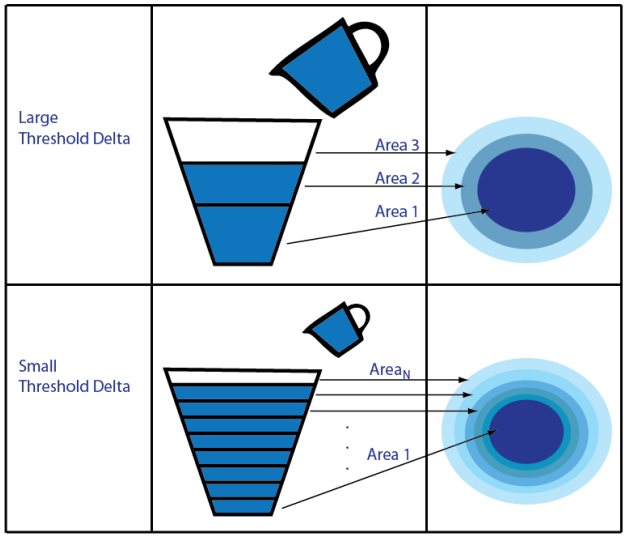
Output Arguments

`regions` — MSER regions object
`MSERRegions` object (default)

MSER regions object, returned as a `MSERRegions` object. The object contains information about MSER features detected in the grayscale or binary input image.

`cc` — Connected component structure
structure

Connected component structure, returned as a structure with four fields. The connected component structure is useful for measuring region properties by using the `regionprops` function. You can also use the “properties” input of the `regionprops` function that provides shape measurements.



The four fields returned in `cc` are:

Field	Description
`Connectivity`	Connectivity of the MSER regions. Default: 8
`ImageSize`	Size of `I`.
`NumObjects`	Number of MSER regions in `I`.
`PixelIdxList`	1-by-`NumObjects` cell array containing `NumObjects` vectors. Each vector represents the linear indices of the pixels in the element’s corresponding MSER region.

Algorithms

Intensity Threshold Levels

The MSER detector incrementally steps through the intensity range of the input image to detect stable regions. The `ThresholdDelta` parameter determines the number of increments the detector tests for stability. You can think of the threshold delta value as the size of a cup to fill a bucket with water. The smaller the cup, the more number of increments it takes to fill up the bucket. The bucket can be thought of as the intensity profile of the region.

The MSER object checks the variation of the region area size between different intensity thresholds. The variation must be less than the value of the `MaxAreaVariation` parameter to be considered stable.

Note MSER feature detection is not suitable for use in images with extreme intensity value changes.

At a high level, MSER can be explained, by thinking of the intensity profile of an image representing a series of buckets. Imagine the tops of the buckets flush with the ground, and a hose turned on at one of the buckets. As the water fills into the bucket, it overflows and the next bucket starts filling up. Smaller regions of water join and become bigger bodies of water, and finally the whole area gets filled. As water is filling up into a bucket, it is checked against the MSER stability criterion. Regions appear, grow and merge at different intensity thresholds.

Version History

Introduced in R2012a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Generates portable C code using a C++ compiler that links to OpenCV libraries. See “Portable C Code Generation for Functions That Use OpenCV Library”.
- For code generation, the function outputs `regions.PixelList` as an array. The region sizes are defined in `regions.Lengths`.
- For code generation, the `MSERRegions` object is not supported. To access the properties of the `MSERRegions` object for code generation, you can use one of these methods:
  - Read each object property and store it in a variable. For example, to access the `Location` property of the `regions` object, read it to the `regionsLoc` variable.

    ```
    function regionsLoc = codeGenTest(inputImg)
        regions = detectMSERFeatures(inputImg);
        regionsLoc = regions.Location;
    end
    codegen codeGenTest -args {inputImg}
    ```

  - Read all properties and store them in a structure. For example, to access all the properties of the `regions` object, read them to the `regionsStruct` structure.

    ```
    function regionsStruct = codeGenTestAll(inputImg)
        regions = detectMSERFeatures(inputImg);
        regionsStruct = struct('Count',regions.Count, ...
                               'Axes',regions.Axes, ...
                               'Location',regions.Location, ...
                               'Orientation',regions.Orientation, ...
                               'PixelList',regions.PixelList);
    end
    codegen codeGenTestAll -args {inputImg}
    ```

- For embedded real-time code generation support, you must enable the variable-size signals. **Code Generation > Interface** from the Configuration Parameters dialog box.
- Code generation does not support arrays of point feature objects returned by this function. Instead, use the `Location` property to obtain an *M*-by-2 matrix of coordinates:

  ```
  locations = points.Location;
  ```

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Refer to the usage notes and limitations in the C/C++ Code Generation section. The same usage notes and limitations apply to GPU code generation.

detectPeopleACF

Detect people using aggregate channel features (ACF)

Note `detectPeopleACF` will be removed in a future release. Use `peopleDetectorACF` instead.

Syntax

```
bboxes = detectPeopleACF(I)
[bboxes,scores] = detectPeopleACF(I)
[___] = detectPeopleACF(I,roi)
[___] = detectPeopleACF(Name,Value)
```

Description

`bboxes = detectPeopleACF(I)` returns a matrix, `bboxes`, that contains the locations of detected upright people in the input image, `I`. The locations are represented as bounding boxes. The function uses the aggregate channel features (ACF) algorithm.

`[bboxes,scores] = detectPeopleACF(I)` also returns the detection scores for each bounding box.

`[___] = detectPeopleACF(I,roi)` detects people within the rectangular search region specified by `roi`, using either of the previous syntaxes.

`[___] = detectPeopleACF(Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. Unspecified properties have default values.

Code Generation Support:
Supports Code Generation: No
Supports MATLAB Function block: No
Code Generation Support, Usage Notes, and Limitations

Examples

Detect People Using Aggregated Channel Features

Read an image.

```
I = imread('visionteam1.jpg');
```

Detect people in the image and store results as bounding boxes and score.

```
[bboxes,scores] = detectPeopleACF(I);
```

Annotate the detected upright people in the image.

```
I = insertObjectAnnotation(I,'rectangle',bboxes,scores);
```

Display the results with annotation.

```
figure
imshow(I)
title('Detected people and detection scores')
```

Input Arguments

`I` — Input image

truecolor image

Input image, specified as a truecolor image. The image must be real and nonsparse.

Data Types: `uint8` | `uint16` | `int16` | `double` | `single`

`roi` — Rectangular search region

four-element vector

Rectangular search region, specified as a four-element vector, [*x*,*y*,*width*,*height*]. The `roi` must be fully contained in `I`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `'Threshold',-1`

`Model` — ACF classification model

`'inria-100x41'` (default) | `'caltech-50x21'`

ACF classification model, specified as the comma-separated pair consisting of 'Model' and either 'inria-100x41' or 'caltech-50x21'. The 'inria-100x41' model was trained using the INRIA Person dataset. The 'caltech-50x21' model was trained using the Caltech Pedestrian dataset.

NumScaleLevels — Number of scale levels per octave
8 (default) | integer

Number of scale levels per octave, specified as the comma-separated pair consisting of 'NumScaleLevels', and an integer. Each octave is a power-of-two downscaling of the image. Increase this number to detect people at finer scale increments. Recommended values are in the range [4,8].

WindowStride — Window stride for sliding window
4 (default) | integer

Window stride for sliding window, specified as the comma-separated pair consisting of 'WindowStride', and an integer. Set this value to the amount you want to move the window, in the *x* and *y* directions. The sliding window scans the images for object detection. The function uses the same stride for the *x* and *y* directions.

SelectStrongest — Select strongest bounding box
true (default) | false

Select strongest bounding box, specified as the comma-separated pair consisting of 'SelectStrongest' and either true or false. The process, often referred to as nonmaximum suppression, eliminates overlapping bounding boxes based on their scores. Set this property to true to use the selectStrongestBbox function to select the strongest bounding box. Set this property to false, to perform a custom selection operation. Setting this property to false returns detected bounding boxes.

MinSize — Minimum region size
two-element vector [*height width*] | [50 21] | [100 41]

Minimum region size in pixels, specified as the comma-separated pair consisting of 'MinSize', and a two-element vector [*height width*]. You can set this property to [50 21] for the 'caltech-50x21' model or [100 41] for the 'inria-100x41' model. You can reduce computation time by setting this value to the known minimum region size for detecting a person. By default, MinSize is set to the smallest region size possible to detect an upright person for the classification model selected.

MaxSize — Maximum region size
size(I) (default) | two-element vector [*height width*]

Maximum region size in pixels, specified as the comma-separated pair consisting of 'MaxSize', and a two-element vector, [*height width*]. You can reduce computation time by setting this value to the known region size for detecting a person. If you do not set this value, by default the function determines the height and width of the image using the size of I.

Threshold — Classification accuracy threshold
–1 (default) | numeric value

Classification accuracy threshold, specified as the comma-separated pair consisting of 'Threshold' and a numerical value. Typical values are in the range [–1,1]. During multiscale object detection, the threshold value controls the person or nonperson classification accuracy and speed. Increase this threshold to speed up the performance at the risk of missing true detections.

Output Arguments

bboxes — Locations of detected people

M-by-4 matrix

Locations of people detected using the aggregate channel features (ACF) algorithm, returned as an *M*-by-4 matrix. The locations are represented as bounding boxes. Each row in `bboxes` contains a four-element vector, [*x*,*y*,*width*,*height*]. This vector specifies the upper-left corner and size of a bounding box, in pixels, for a detected person.

scores — Confidence value

M-by-1 vector

Confidence value for the detections, returned as an *M*-by-1 vector. The vector contains a value for each bounding box in `bboxes`. The score for each detection is the output of a soft-cascade classifier. The range of score values is `[-inf inf]`. Greater scores indicate a higher confidence in the detection.

Version History

Introduced in R2016a

detectSURFFeatures

Detect SURF features

Syntax

```
points = detectSURFFeatures(I)
points = detectSURFFeatures(I,Name,Value)
```

Description

`points = detectSURFFeatures(I)` returns a `SURFPoints` object, `points`, containing information about SURF features detected in the 2-D grayscale or binary input image `I`. The `detectSURFFeatures` function implements the Speeded-Up Robust Features (SURF) algorithm to find blob features.

`points = detectSURFFeatures(I,Name,Value)` specifies options using one or more name-value arguments in addition to the input arguments in the previous syntax.

Examples

Detect SURF Interest Points in a Grayscale Image

Read image and detect interest points.

```
I = imread('cameraman.tif');
points = detectSURFFeatures(I);
```

Display locations of interest in image.

```
imshow(I); hold on;
plot(points.selectStrongest(10));
```

Input Arguments

`I` — Input image

M-by-*N* 2-D grayscale or binary image

Input image, specified as an *M*-by-*N* 2-D grayscale or binary image. The input image must be a real non-sparse value.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `detectSURFFeatures(I,'MetricThreshold',100)`

`MetricThreshold` — Strongest feature threshold

`1000.0` (default) | non-negative scalar

Strongest feature threshold, specified as a non-negative scalar. To return more blobs, decrease the value of this threshold.

`NumOctaves` — Number of octaves

3 (default) | scalar (greater than or equal to 1)

Number of octaves, specified as an integer scalar, greater than or equal to 1. Increase this value to detect larger blobs. Recommended values are between 1 and 4.

Each octave spans a number of scales that are analyzed using varying size filters:

Octave	Filter Sizes
1	9-by-9, 15-by-15, 21-by-21, 27-by-27, ...
2	15-by-15, 27-by-27, 39-by-39, 51-by-51, ...
3	27-by-27, 51-by-51, 75-by-75, 99-by-99, ...
4	....

Higher octaves use larger filters and subsample the image data. Larger number of octaves result in finding larger size blobs. Set the `NumOctaves` parameter appropriately for the image size. For example, a 50-by-50 image require you to set the `NumOctaves` parameter, less than or equal to `2`. The `NumScaleLevels` parameter controls the number of filters used per octave. At least three levels are required to analyze the data in a single octave.

`NumScaleLevels` — Number of scale levels per octave
`4` (default) | integer scalar, greater than or equal to `3`

Number of scale levels per octave to compute, specified as an integer scalar, greater than or equal to `3`. Increase this number to detect more blobs at finer scale increments. Recommended values are between `3` and `6`.

`ROI` — Rectangular region of interest
`[1 1 size(I,2) size(I,1)]` (default) | vector

Rectangular region of interest, specified as a vector. The vector must be in the format [*x y width height*]. When you specify an `ROI`, the function detects blobs within the area at [*x y*] of size specified by [*width height*]. The [*x y*] elements specify the upper left corner of the region.

Output Arguments

`points` — SURF features
`SURFPoints` object

SURF features, returned as a `SURFPoints` object. This object contains information about SURF features detected in a grayscale or binary image.

detectORBFeatures

Detect ORB keypoints

Syntax

```
points = detectORBFeatures(I)
points = detectORBFeatures(I,Name,Value)
```

Description

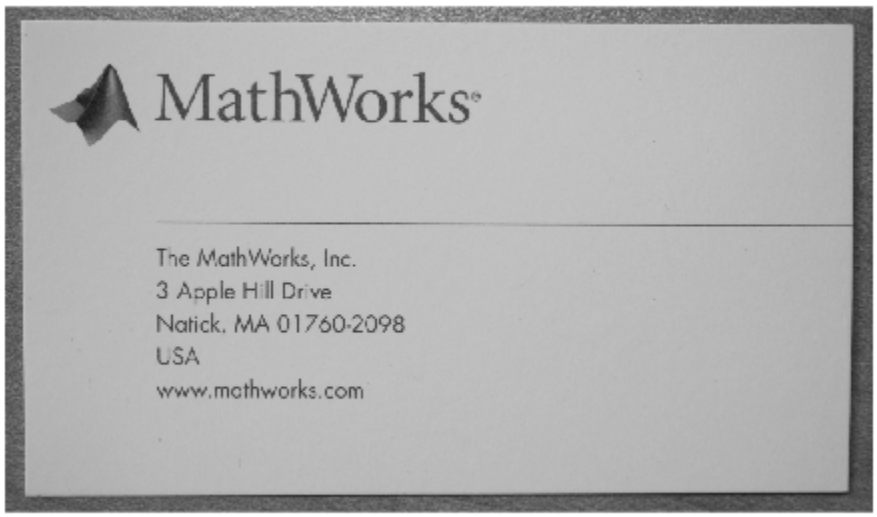
`points = detectORBFeatures(I)` returns an `ORBPoints` object that contains information about ORB keypoints. The ORB keypoints are detected from the input image by using the Oriented FAST and rotated BRIEF (ORB) feature detection method.

`points = detectORBFeatures(I,Name,Value)` specifies options using one or more name-value arguments.

Examples

Detect ORB Keypoints in Grayscale Image

Read an image into the workspace.



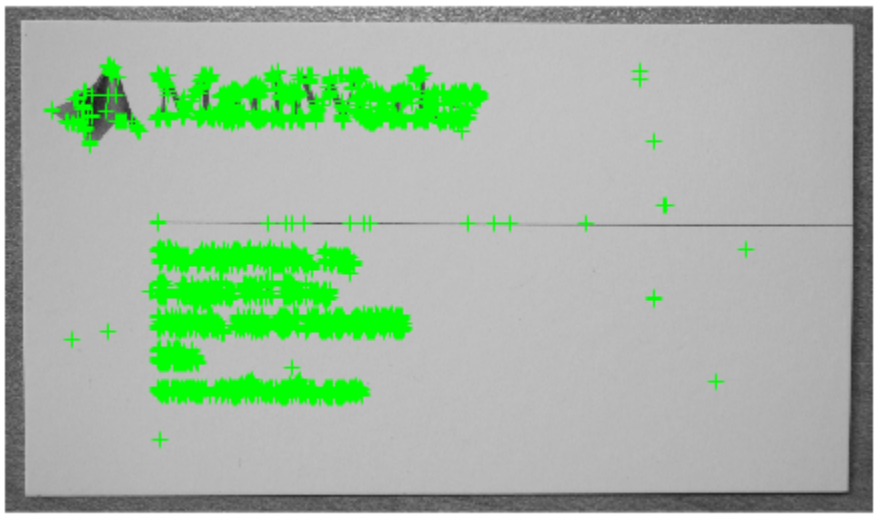
```
I = imread('businessCard.png');
```

Convert the image into a grayscale image.

```
I = im2gray(I);
```

Display the grayscale image.

```
figure
imshow(I)
```

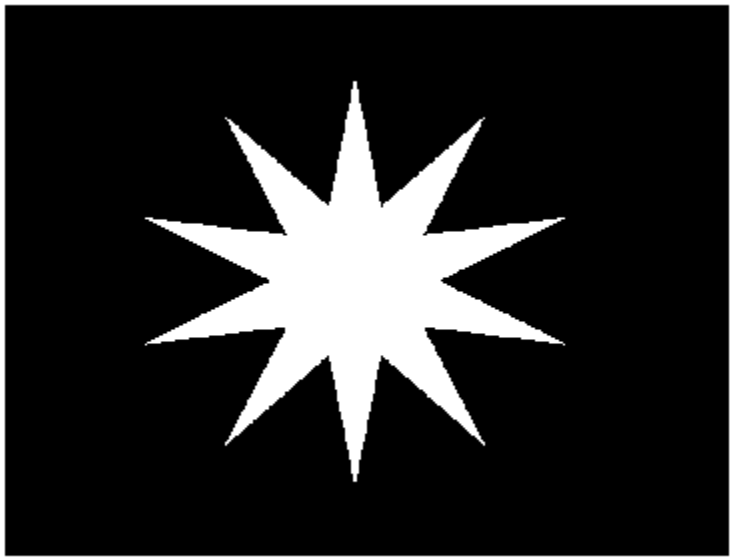


Detect and store ORB keypoints.

```
points = detectORBFeatures(I);
```

Display the grayscale image and plot the detected ORB keypoints. Suppress the display of circles around the detected keypoints. The ORB keypoints are detected in regions with high intensity variance.

```
figure
imshow(I)
hold on
plot(points,'ShowScale',false)
hold off
```



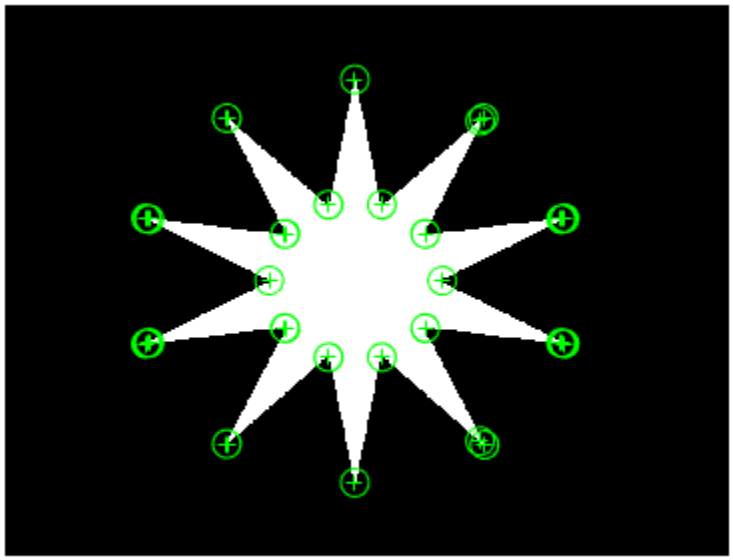
Detect ORB Keypoints in Binary Shape Image

Read a binary image into the workspace.

```
I = imread('star.png');
```

Display the image.

```
figure
imshow(I)
```



Detect and store ORB keypoints. Specify the scale factor for image decomposition as 1.01 and the number of decomposition levels as 3.

```
points = detectORBFeatures(I,'ScaleFactor',1.01,'NumLevels',3);
```

Display the image and plot the detected ORB keypoints. The inflection points in the binary shape image are detected as the ORB keypoints.

```
figure
imshow(I)
hold on
plot(points)
hold off
```

Input Arguments

`I` — Input image

M-by-*N* grayscale or binary image

Input image, specified as an *M*-by-*N* grayscale or binary image. The input image must be real and nonsparse.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `detectORBFeatures(I,'NumLevels',4)`

`ScaleFactor` — Scale factor for image decomposition

`1.2` (default) | scalar greater than 1

Scale factor for image decomposition, specified as the comma-separated pair consisting of `'ScaleFactor'` and a scalar greater than 1. The scale value at each level of decomposition is $\texttt{ScaleFactor}^{(level\text{-}1)}$, where *level* is any value in the range [0, `Numlevels`-1]. Given the input image of size *M*-by-*N*, the image size at each level of decomposition is

$$M_{level} = \frac{M}{ScaleFactor^{(level\ -\ 1)}}$$

$$N_{level} = \frac{N}{ScaleFactor^{(level\ -\ 1)}}$$

.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint64` | `uint32`

`NumLevels` — Number of decomposition levels
8 (default) | scalar greater than or equal to 1

Number of decomposition levels, specified as the comma-separated pair consisting of `'NumLevels'` and a scalar greater than or equal to 1. Increase this value to extract keypoints from the image at more levels of decomposition.

The number of decomposition levels for extracting keypoints is limited by the image size at that level. The image size at a level of decomposition must be at least 63-by-63 for detecting keypoints. The maximum level of decomposition is calculated as

$$level_{\max} = \text{floor}\left(\frac{\log(\min(M,N)) - \log(63)}{\log(\text{ScaleFactor})}\right) + 1$$

If either the default value or the specified value of `'NumLevels'` is greater than $level_{max}$, the function modifies `NumLevels` to $level_{max}$ and returns a warning.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint64` | `uint32`

`ROI` — Region of interest
`[1 1 M N]` (default) | four-element vector

Region of interest for keypoint detection, specified as the comma-separated pair consisting of `'ROI'` and a vector of the format [*x y width height*]. The first two elements represent the location of the upper left corner of the region of interest. The last two elements represent the width and the height of the region of interest. The width and height of the region of interest must each be a value greater than or equal to 63.

Output Arguments

`points` — ORB keypoints
`ORBPoints` object

ORB keypoints, returned as an `ORBPoints` object. The object contains information about keypoints detected in the input image.

Algorithms

The function detects keypoints from the input image by using the ORB feature detection method in [1].

disparity

(Not recommended) Disparity map between stereo images

Note `disparity` is not recommended. Use `disparityBM` or `disparitySGM` instead. For more information, see “Version History”

Syntax

```
disparityMap = disparity(I1,I2)
disparityMap = disparity(I1,I2,Name,Value)
```

Description

`disparityMap = disparity(I1,I2)` returns the disparity map, `disparityMap`, for a pair of stereo images, `I1` and `I2`.

`disparityMap = disparity(I1,I2,Name,Value)` provides additional control for the disparity algorithm by using one or more `Name,Value` pair arguments.

Examples

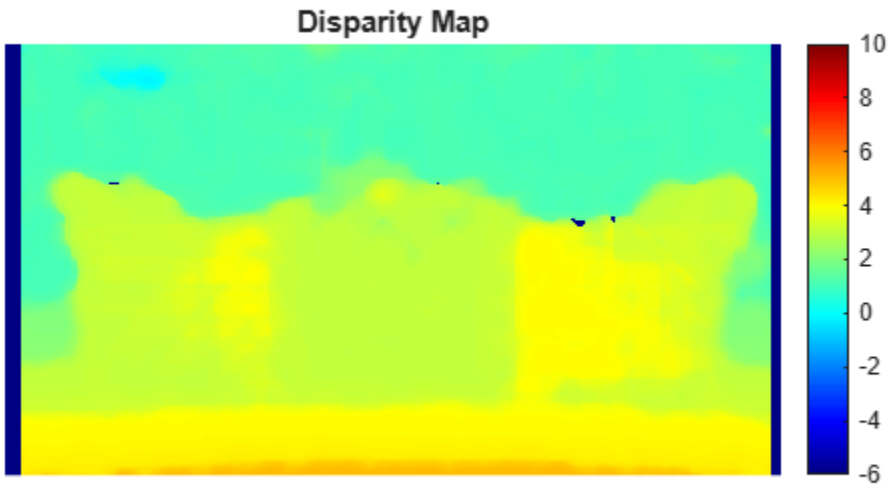
Compute Disparity Map for a Pair of Stereo Images

Load the images and convert them to grayscale.

```
I1 = imread('scene_left.png');
I2 = imread('scene_right.png');
```

Show stereo anaglyph. Use red-cyan stereo glasses to view image in 3-D.

```
figure
imshow(stereoAnaglyph(I1,I2));
title('Red-cyan composite view of the stereo images');
```



Compute the disparity map.

```
disparityRange = [-6 10];
disparityMap = disparity(rgb2gray(I1),rgb2gray(I2),'BlockSize',...
    15,'DisparityRange',disparityRange);
```

Display the disparity map. For better visualization, use the disparity range as the display range for imshow.

```
figure
imshow(disparityMap,disparityRange);
title('Disparity Map');
colormap(gca,jet)
colorbar
```

Input Arguments

`I1` — Input image 1

M-by-*N* 2-D grayscale image

Input image referenced as `I1` corresponding to camera 1, specified in 2-D grayscale. The stereo images, `I1` and `I2`, must be rectified such that the corresponding points are located on the same rows. You can perform this rectification with the `rectifyStereoImages` function.

You can improve the speed of the function by setting the class of `I1` and `I2` to `uint8`, and the number of columns to be divisible by 4. Input images `I1` and `I2` must be real, finite, and nonsparse. They must be the same class.

Data Types: `uint8` | `uint16` | `int16` | `single` | `double`

`I2` — Input image 2

M-by-*N* 2-D grayscale image

Input image referenced as `I2` corresponding to camera 2, specified in 2-D grayscale. The input images must be rectified such that the corresponding points are located on the same rows. You can improve the speed of the function by setting the class of `I1` and `I2` to `uint8`, and the number of columns to be divisible by 4. Input images `I1` and `I2` must be real, finite, and nonsparse. They must be the same class.

Data Types: `uint8` | `uint16` | `int16` | `single` | `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

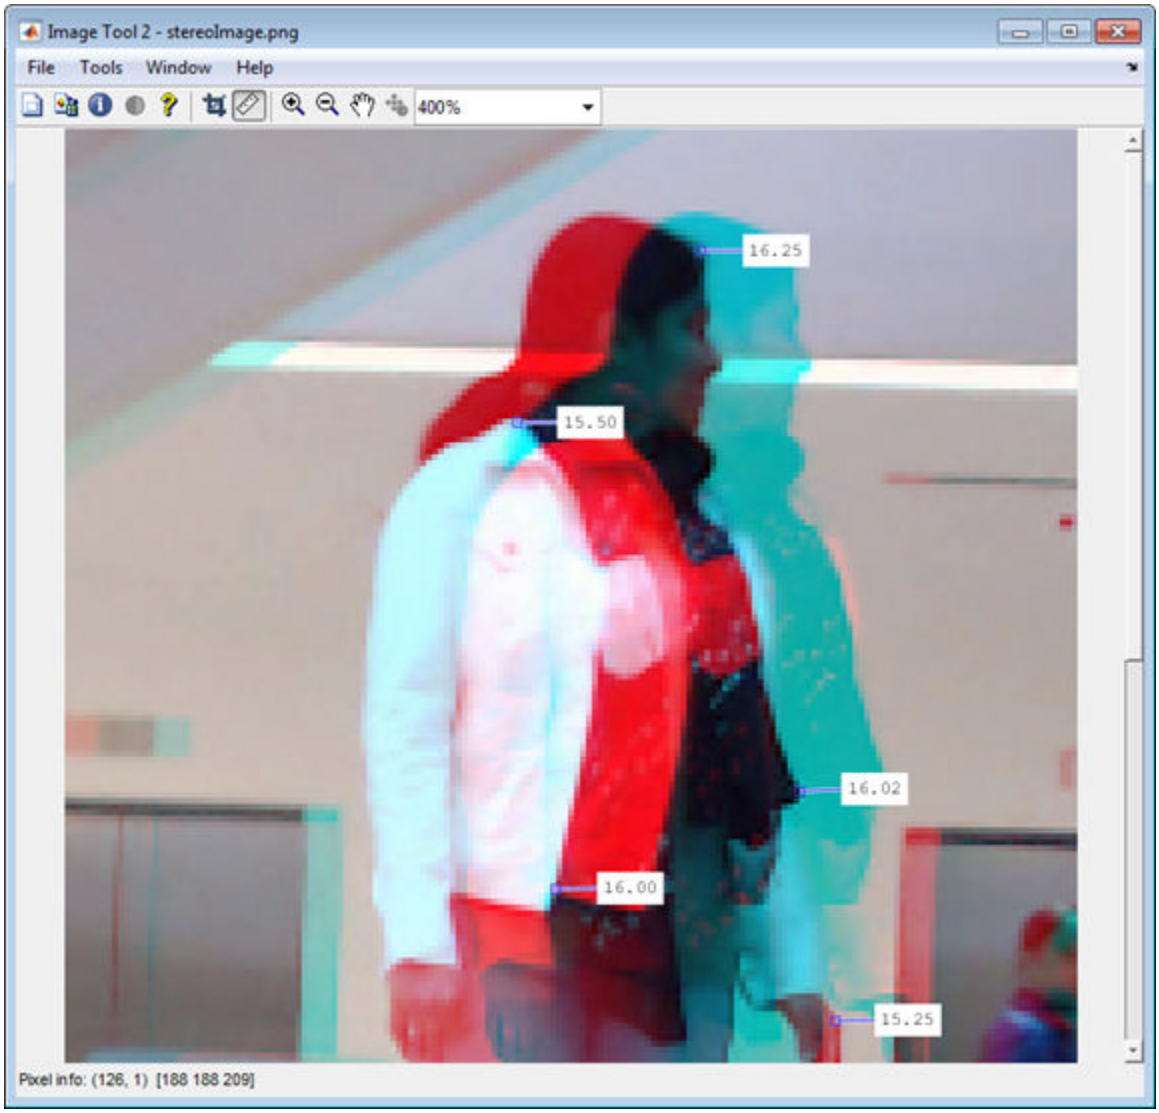
Example: `'Method','BlockMatching'`, specifies the `'Method'` property be set to `'BlockMatching'`.

`Method` — Disparity estimation algorithm

`'SemiGlobal'` (default) | `'BlockMatching'`

Disparity estimation algorithm, specified as the comma-separated pair consisting of '`Method`' and either `'BlockMatching'` or `'SemiGlobal'`. The disparity function implements the basic Block Matching [1] and the Semi-Global Block Matching [3] algorithms. In the `'BlockMatching'` method, the function computes disparity by comparing the sum of absolute differences (SAD) of each block of pixels in the image. In the `'SemiGlobal'` matching method, the function additionally forces similar disparity on neighboring blocks. This additional constraint results in a more complete disparity estimate than in the `'BlockMatching'` method.

The algorithms perform these steps:



1. Compute a measure of contrast of the image by using the Sobel filter.
2. Compute the disparity for each pixel in `I1`.
3. Mark elements of the disparity map, `disparityMap`, that were not computed reliably. The function uses –`realmax`(`'single'`) to mark these elements.

`DisparityRange` — Range of disparity

`[0 64]` (default) | two-element vector

Range of disparity, specified as the comma-separated pair consisting of '`DisparityRange`' and a two-element vector. The two-element vector must be in the format [*MinDisparity*, *MaxDisparity*]. Both elements must be an integer and can be negative. *MinDisparity* and *MaxDisparity* must be in the range [-*image width*, *image width*]. The difference between *MaxDisparity* and *MinDisparity* must be divisible by `16`. `DisparityRange` must be real, finite, and nonsparse. If the camera used to take `I1` was to the right of the camera used to take `I2`, then *MinDisparity* must be negative.

The disparity range depends on the distance between the two cameras and the distance between the cameras and the object of interest. Increase the `DisparityRange` when the cameras are far apart or the objects are close to the cameras. To determine a reasonable disparity for your configuration, display the stereo anaglyph of the input images in the Image Viewer app and use the Distance tool to measure distances between pairs of corresponding points. Modify the *MaxDisparity* to correspond to the measurement.

`BlockSize` — Square block size
15 (default) | odd integer

Square block size, specified as the comma-separated pair consisting of '`BlockSize`' and an odd integer in the range [5,255]. This value sets the width for the square block size. The function uses the square block of pixels for comparisons between `I1` and I2. `BlockSize` must be real, finite, and nonsparse.

`ContrastThreshold` — Contrast threshold range
`0.5` (default) | scalar value

Contrast threshold range, specified as the comma-separated pair consisting of '`ContrastThreshold`' and a scalar value in the range (0,1]. The contrast threshold defines an acceptable range of contrast values. Increasing this parameter results in fewer pixels being marked as unreliable.`ContrastThreshold` must be real, finite, and nonsparse.

`UniquenessThreshold` — Minimum value of uniqueness
15 (default) | non-negative integer

Minimum value of uniqueness, specified as the comma-separated pair consisting of 'UniquenessThreshold' and a nonnegative integer. Increasing this parameter results in the function marking more pixels unreliable. When the uniqueness value for a pixel is low, the disparity computed for it is less reliable. Setting the threshold to 0 disables uniqueness thresholding. UniquenessThreshold must be real, finite, and nonsparse.

The function defines uniqueness as a ratio of the optimal disparity estimation and the less optimal disparity estimation. For example:
Let K be the best estimated disparity, and let V be the corresponding SAD (Sum of Absolute Difference) value.
Consider V as the smallest SAD value over the whole disparity range, and v as the smallest SAD value over the whole disparity range, excluding K, K-1, and K+1.
If $v < V * (1+0.01*\text{UniquenessThreshold})$, then the function marks the disparity for the pixel as unreliable.

DistanceThreshold — Maximum distance for left-to-right image checking
[] (disabled) (default) | non-negative integer

Maximum distance for left-to-right image checking between two points, specified as the comma-separated pair consisting of 'DistanceThreshold' and a nonnegative integer. Increasing this parameter results in fewer pixels being marked as unreliable. Conversely, when you decrease the value of the distance threshold, you increase the reliability of the disparity map. You can set this parameter to an empty matrix [] to disable it. DistanceThreshold must be real, finite, and nonsparse.

The distance threshold specifies the maximum distance between a point in I1 and the same point found from I2. The function finds the distance and marks the pixel in the following way:
Let p_1 be a point in image I_1.
Step 1: The function searches for point p_1's best match in image I_2 (left-to-right check) and finds point p_2.
Step 2: The function searches for p_2's best match in image I_1 (right-to-left check) and finds point p_3.
If the search returns a distance between p_1 and p_3 greater than DistanceThreshold, the function marks the disparity for the point p_1 as unreliable.

TextureThreshold — Minimum texture threshold
0.0002 (default) | scalar value

Minimum texture threshold, specified as the comma-separated pair consisting of 'TextureThreshold' and a scalar value in the range [0, 1). The texture threshold defines the minimum texture value for a pixel to be reliable. The lower the texture for a block of pixels, the less reliable the computed disparity is for the pixels. Increasing this parameter results in more pixels being marked as unreliable. You can set this parameter to 0 to disable it. This parameter applies only when you set Method to 'BlockMatching'.

The texture of a pixel is defined as the sum of the saturated contrast computed over the BlockSize-by-BlockSize window around the pixel. The function considers the disparity computed for the pixel unreliable and marks it, when the texture falls below the value defined by:

$$\textit{Texture} < X * \text{TextureThreshold} * \text{BlockSize}^2$$

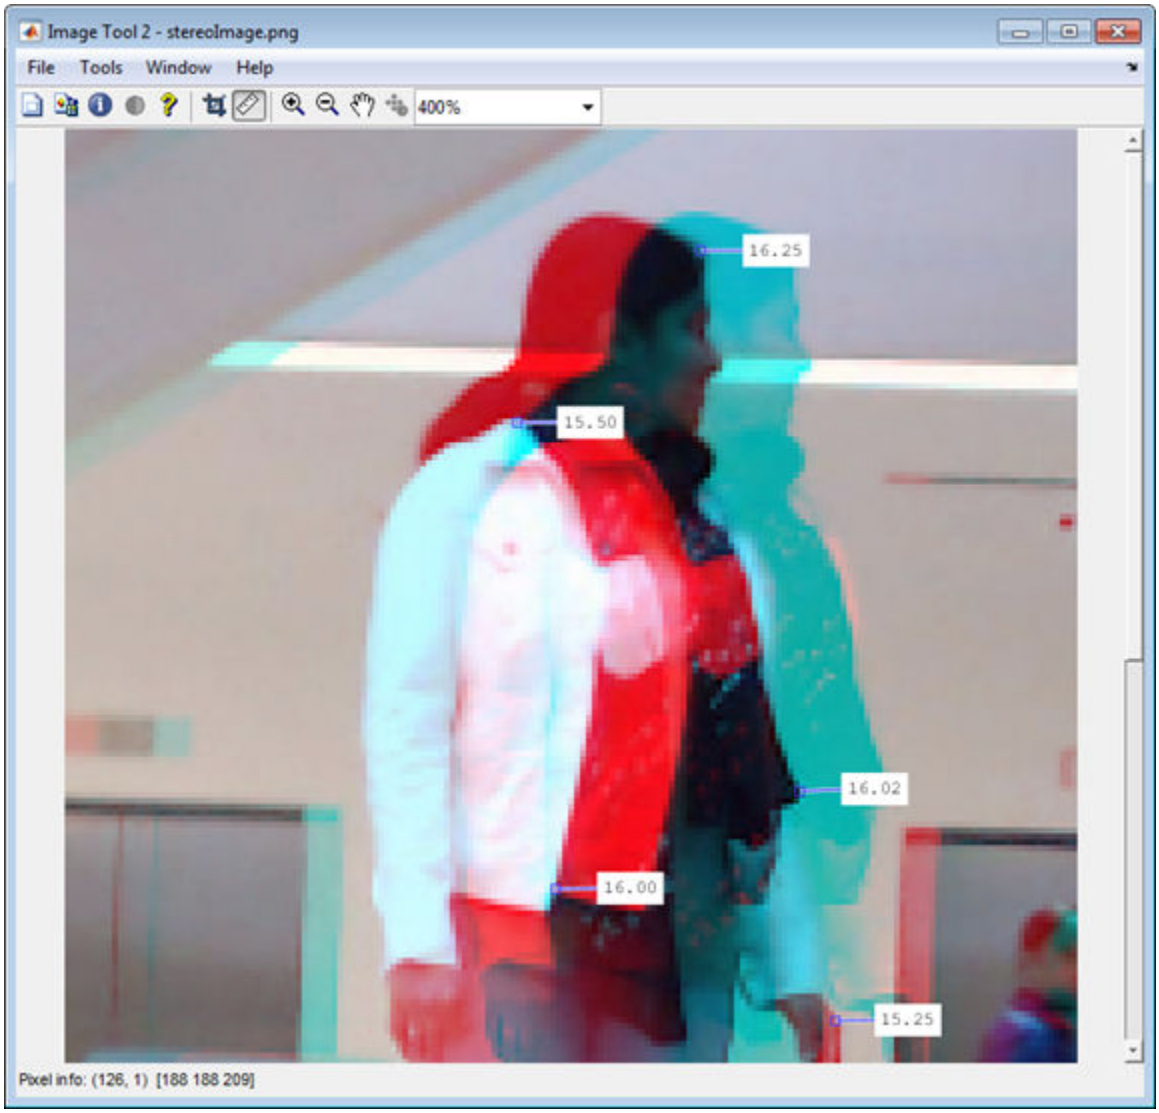
X represents the maximum value supported by the class of the input images, I1 and I2.

TextureThreshold must be real, finite, and nonsparse.

Output Arguments

`disparityMap` — Disparity map

M-by-*N* 2-D grayscale image



Disparity map for a pair of stereo images, returned as an *M*-by-*N* 2-D grayscale image. The function returns the disparity map with the same size as the input images, `I1` and `I2`. Each element of the output specifies the disparity for the corresponding pixel in the image references as `I1`. The returned disparity values are rounded to $1/16$th pixel.

The function computes the disparity map in three steps:

1. Compute a measure of contrast of the image by using the Sobel filter.
2. Compute the disparity for each of the pixels by using block matching and the sum of absolute differences (SAD).
3. Optionally, mark the pixels which contain unreliable disparity values. The function sets the pixel to the value returned by -`realmax`('`single`').

Tips

If your resulting disparity map looks noisy, try modifying the `DisparityRange`. The disparity range depends on the distance between the two cameras and the distance between the cameras and the object of interest. Increase the `DisparityRange` when the cameras are far apart or the objects are close to the cameras. To determine a reasonable disparity for your configuration, display the stereo anaglyph of the input images in the Image Viewer app and use the Distance tool to measure distances between pairs of corresponding points. Modify the *MaxDisparity* to correspond to the measurement.

Version History

Introduced in R2011b

R2019a: `disparity` function will be removed

Not recommended starting in R2019a

The `disparity` function will be removed in a future release. Use `disparityBM` or `disparitySGM` instead. Use `disparityBM` to compute disparity map using block matching method. Use `disparitySGM` to compute disparity map using semi-global matching method.

disparityBM

Compute disparity map using block matching

Syntax

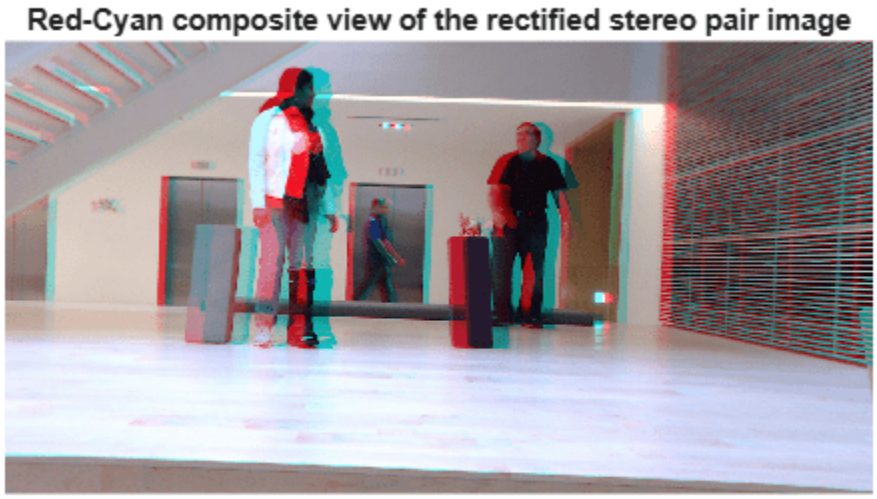
```
disparityMap = disparityBM(I1,I2)
disparityMap = disparityBM(I1,I2,Name,Value)
```

Description

`disparityMap = disparityBM(I1,I2)` computes disparity map from a pair of rectified stereo images `I1` and `I2`, by using the block matching method. To know more about rectifying stereo images, see “Image Rectification” on page 3-640.

`disparityMap = disparityBM(I1,I2,Name,Value)` specifies options using one or more name-value pair arguments.

Examples



Compute Disparity Map by Using Block Matching Method

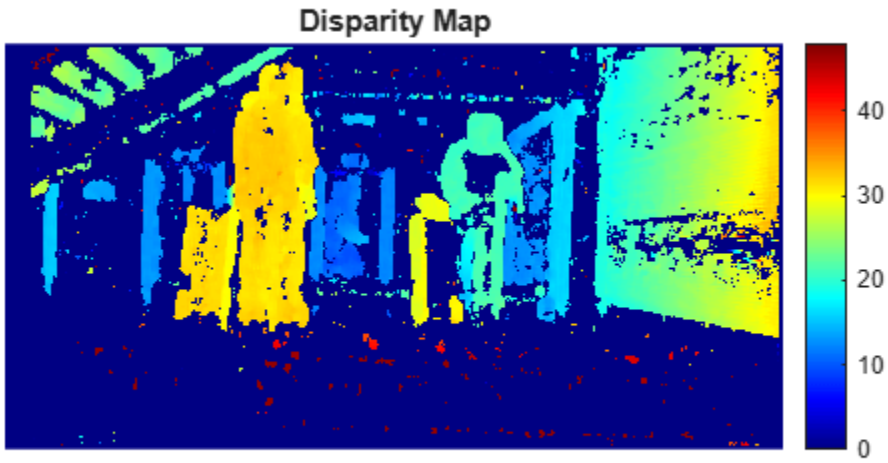
Load a rectified stereo pair image.

```
I1 = imread('rectified_left.png');
I2 = imread('rectified_right.png');
```

Create the stereo anaglyph of the rectified stereo pair image and display it. You can view the image in 3-D by using red-cyan stereo glasses.

```
A = stereoAnaglyph(I1,I2);
figure
imshow(A)
title('Red-Cyan composite view of the rectified stereo pair image')
```

Convert the rectified input color images to grayscale images.



```
J1 = im2gray(I1);
J2 = im2gray(I2);
```

Compute the disparity map. Specify the range of disparity as [0, 48], and the minimum value of uniqueness as 20.

```
disparityRange = [0 48];
disparityMap = disparityBM(J1,J2,'DisparityRange',disparityRange,'UniquenessThreshold',20);
```

Display the disparity map. Set the display range to the same value as the disparity range.

```
figure
imshow(disparityMap,disparityRange)

Input Arguments

`I1` — Input image 1

2-D grayscale image | `gpuArray` object

Input image referenced as `I1` corresponding to camera 1, specified as a 2-D grayscale image or a `gpuArray` object. The function uses this image as the reference image for computing the disparity map. The input images `I1` and `I2` must be real, finite, and nonsparse. Also, `I1` and `I2` must be of the same size and same data type.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16`

`I2` — Input image 2

2-D grayscale image | `gpuArray` object

Input image referenced as `I2` corresponding to camera 2, specified as a 2-D grayscale image or a `gpuArray` object. The input images `I1` and `I2` must be real, finite, and nonsparse. `I1` and `I2` must be of the same size and same data type.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `disparityBM(I1,I2,'DisparityRange',[0 64])`

`DisparityRange` — Range of disparity
`[0 64]` (default) | two-element vector

Range of disparity, specified as the comma-separated pair consisting of `'DisparityRange'` and a two-element vector of the form [*MinDisparity MaxDisparity*]. *MinDisparity* is the minimum disparity and *MaxDisparity* is the maximum disparity. The conditions this range must satisfy depend on the type of input images.

If the input images are grayscale images of width *N*, then:

- *MinDisparity* and *MaxDisparity* must be integers in the range (–*N*, *N*).
- The difference between the *MaxDisparity* and *MinDisparity* values must be divisible by 16 and less than the width of the input images.

If the input images are `gpuArray` objects of width *N*, then:

- The value of *MinDisparity* must be equal to zero.

  The value of *MaxDisparity* must be in the range (16, *N*). If *N* is greater than 256, then the *MaxDisparity* must be chosen as less than or equal to 256.

  The difference between the *MaxDisparity* and *MinDisparity* values must be divisible by 16.

The default value for the range of disparity is `[0 64]`. For more information on choosing the range of disparity, see “Choosing Range of Disparity” on page 3-640.

`BlockSize` — Size of squared block
`15` (default) | odd integer

Size of the squared block, specified as the comma-separated pair consisting of `'BlockSize'` and an odd integer. This value specifies the width of the search window used for block matching pixels in the rectified stereo pair image. The range for the size squared block depend on the type of input images.

If the input images are grayscale images, the `'BlockSize'` value must be an odd integer in the range [5, 255].

If the input images are `gpuArray` objects, the `'BlockSize'` value must be an odd integer in the range [5, 51].

The default value is 15.

`ContrastThreshold` — Range of contrast threshold
`0.5` (default) | scalar in the range (0, 1]

Range of contrast threshold, specified as the comma-separated pair consisting of `'ContrastThreshold'` and a scalar value in the range (0, 1]. The contrast threshold defines an acceptable range of contrast values. If the contrast value of a pixel in the reference image is below the contrast threshold, then the disparity computed for that pixel is considered unreliable. Increasing this parameter results in disparity for fewer pixels being marked as unreliable.

`UniquenessThreshold` — Minimum value of uniqueness
`15` (default) | nonnegative integer

Minimum value of uniqueness, specified as the comma-separated pair consisting of `'UniquenessThreshold'` and a nonnegative integer.

The function marks the estimated disparity value K for a pixel as unreliable, if:

$v < V \times (1 + 0.01 \times \texttt{UniquenessThreshold})$,

where V is the sum of absolute difference (SAD) corresponding to the disparity value K. v is the smallest SAD value over the whole disparity range, excluding K, K–1, and K+1.

Increasing the value of `UniquenessThreshold` results in disparity values for more pixels being marked as unreliable. To disable the use of uniqueness threshold, set this value to `[]`.

Note If the input images are `gpuArray` objects, then the `'UniquenessThreshold'` name-value pair argument does not apply.

`DistanceThreshold` — Maximum distance between conjugate pixels in stereo pair image

`[]` (disabled) (default) | nonnegative integer

Maximum distance between conjugate pixels in stereo pair image, specified as the comma-separated pair consisting of `'DistanceThreshold'` and a nonnegative integer. The distance threshold specifies the maximum distance between a pixel in `I1` and the same pixel found in `I2`.

For pixel p_1 in the reference image `I1`, the function performs a left-to-right check to find its best matching pixel p_2 in image `I2`. For pixel p_2, the function performs a right-to-left check to find its best matching pixel p_3 in the reference image `I1`. If the distance between p_1 and p_3 is greater than the `DistanceThreshold`, the function marks the disparity for the pixel p_1 in the reference image `I1` as unreliable.

Increasing the value of `DistanceThreshold` results in disparity values for fewer pixels being marked as unreliable. Conversely, decreasing the value of `DistanceThreshold`, increases the reliability of the disparity map. To disable the use of distance threshold, set this value to `[]`.

Note If the input images are `gpuArray` objects, then the `'DistanceThreshold'` name-value pair argument does not apply.

`TextureThreshold` — Minimum texture threshold

`0.0002` (default) | scalar value in the range [0, 1)

Minimum texture threshold, specified as the comma-separated pair consisting of `'TextureThreshold'` and a scalar value in the range [0, 1).

The texture of a pixel is defined as the sum of the saturated contrast computed over the `BlockSize`-by-`BlockSize` window around the pixel. The texture threshold defines the minimum texture value for a pixel to have reliable disparity value. The function considers the disparity for a pixel as unreliable, if:

$texture < intensity_{max} \times \texttt{TextureThreshold} \times \texttt{BlockSize}^2$,

where *texture* is the texture of a pixel. $intensity_{max}$ is the maximum value supported by the data type of input images `I1` and `I2`.

Increasing the value of `'TextureThreshold'` results in disparity values for more pixels being marked as unreliable. To disable the use of texture threshold, set this value to `[]`.

Output Arguments

`disparityMap` — Disparity map

2-D grayscale image | `gpuArray` object

Disparity map for rectified stereo pair image, returned as a 2-D grayscale image or a `gpuArray` object. The function returns the disparity map with the same size as input images `I1` and `I2`. Each value in this output refers to the displacement between conjugate pixels in the stereo pair image. For details about computing the disparity map, see “Computing Disparity Map Using Block Matching” on page 3-641.

Data Types: `single`

More About

Image Rectification

The input images `I1` and `I2` must be rectified before computing the disparity map. The rectification ensures that the corresponding points in the stereo pair image are on the same rows. You can rectify the input stereo pair image by using the `rectifyStereoImages` function. The reference image must be the same for rectification and disparity map computation.

Algorithms

Choosing Range of Disparity

The range of disparity must be chosen to cover the minimum and the maximum amount of horizontal shift between the corresponding pixels in the rectified stereo pair image. You can determine the approximate horizontal shift values from the stereo anaglyph of the stereo pair image. Compute the stereo anaglyph of the rectified images by using the `stereoAnaglyph` function. Display the stereo anaglyph in the Image Viewer app. To measure the amount of horizontal shift between the corresponding points in the stereo pair image, select **Measure Distance** from the **Tools** menu in Image Viewer. Choose the minimum and maximum disparity values for the range of disparity based on this measurement.

For example, this figure displays the stereo anaglyph of a rectified stereo pair image and the horizontal shift values measured between the corresponding points in the stereo pair image. The minimum and maximum shift values are computed as 12.3101 and 32.3757 respectively. Based on these values, the range of disparity can be chosen as [0, 48].

Computing Disparity Map Using Block Matching

The function computes the disparity map by following these steps:

1. Compute the disparity for each pixel by using the block matching method given in [1].
   - For CPU — The sum of absolute difference (SAD) is used as the cost function in block matching. The cost function estimates the displacement between pixels in the rectified stereo pair image.
2. Optionally, mark the pixels for unreliability based on the `ContrastThreshold`, `UniquenessThreshold`, `DistanceThreshold`, and `TextureThreshold` name-value pairs. The function sets the unreliable disparity values to `NaN`.

Version History

Introduced in R2019a

R2022a: GPU Use Being Removed for `disparityBM` function
Behavior changed in R2022a

The `disparityBM` function no longer supports GPU. You can use the enhanced `disparitySGM` on the GPU instead. Results will not be identical using the `disparitySGM` function, but the semi-global algorithm used in the `disparitySGM` is normally recommended over the block matching algorithm in the `disparityBM` function.

disparitySGM

Compute disparity map through semi-global matching

Syntax

```
disparityMap = disparitySGM(I1,I2)
[disparityMap,disparityRangeUsed] = disparitySGM(I1,I2)
___ = disparitySGM(I1,I2,Name,Value)
```

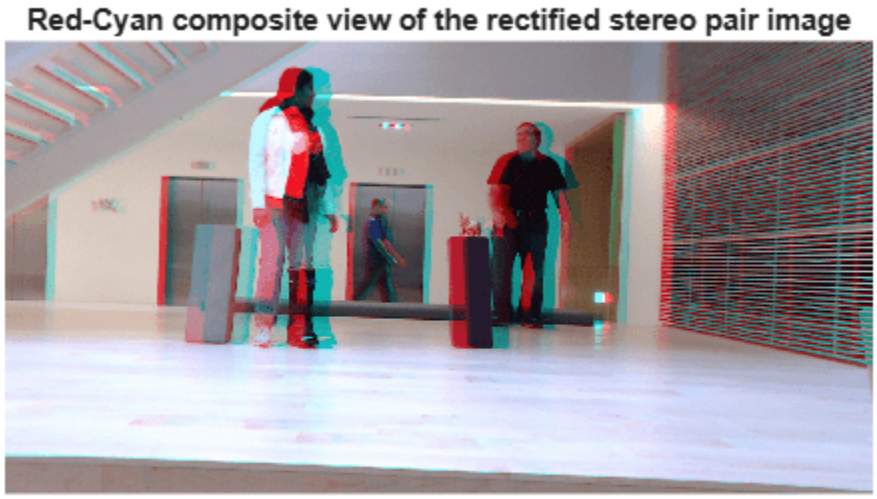
Description

`disparityMap = disparitySGM(I1,I2)` computes disparity map from a pair of rectified stereo images `I1` and `I2`, by using semi-global matching (SGM) method. To know more about rectifying stereo images, see “Image Rectification” on page 3-647.

`[disparityMap,disparityRangeUsed] = disparitySGM(I1,I2)` additionally returns the actual values of the disparity range used to estimate disparity, which may differ from those provided using the `DisparityRange` name-value argument.

`___ = disparitySGM(I1,I2,Name,Value)` specifies additional options using one or more name-value pair arguments along with any of the previous syntaxes.

Examples



Compute Disparity Map by Using Semi-Global Matching Method

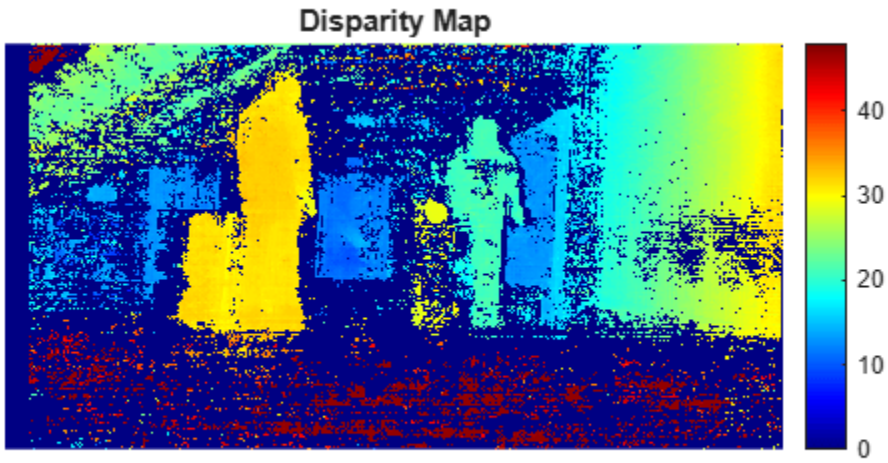
Load a rectified stereo pair image.

```
I1 = imread("rectified_left.png");
I2 = imread("rectified_right.png");
```

Create the stereo anaglyph of the rectified stereo pair image and display it. You can view the image in 3-D by using red-cyan stereo glasses.

```
A = stereoAnaglyph(I1,I2);
figure
imshow(A)
title("Red-Cyan composite view of the rectified stereo pair image")
```

Convert the rectified input color images to grayscale images.



```
J1 = im2gray(I1);
J2 = im2gray(I2);
```

Compute the disparity map through semi-global matching. Specify the range of disparity as [0, 48], and the minimum value of uniqueness as 20.

```
disparityRange = [0 48];
disparityMap = disparitySGM(J1,J2,"DisparityRange",disparityRange,"UniquenessThreshold",20);
```

Display the disparity map. Set the display range to the same value as the disparity range.

```
figure
imshow(disparityMap,disparityRange)
title("Disparity Map")
colormap jet
colorbar
```

Input Arguments

`I1` — Input image 1

2-D grayscale image | `gpuArray` object

Input image referenced as `I1` corresponding to camera 1, specified as a 2-D grayscale image or a `gpuArray` object. The function uses this image as the reference image for computing the disparity map. The input images `I1` and `I2` must be real, finite, and nonsparse. Also, `I1` and `I2` must be of the same size and same data type.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16`

`I2` — Input image 2

2-D grayscale image | `gpuArray` object

Input image referenced as `I2` corresponding to camera 2, specified as a 2-D grayscale image or a `gpuArray` object. The input images `I1` and `I2` must be real, finite, and nonsparse. `I1` and `I2` must be of the same size and same data type.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `disparitySGM(I1,I2,'DisparityRange',[0 64])`

`DisparityRange` — Range of disparity
`[0 128]` (default) | two-element vector

Range of disparity, specified as the comma-separated pair consisting of `'DisparityRange'` and a two-element vector of the form [*MinDisparity MaxDisparity*]. *MinDisparity* is the minimum disparity and *MaxDisparity* is the maximum disparity.

For input images of width *N*, the *MinDisparity* and *MaxDisparity* must be integers in the range (–*N*, *N*). The difference between the *MaxDisparity* and *MinDisparity* values must be less than or equal to 128. If the difference is not divisible by 8, the function internally rounds up the disparity range to the nearest multiple of 8. The function returns the actual value used in the disparity map computation in the `disparityRangeUsed` output argument.

The default value for the range of disparity is `[0 128]`. For more information on choosing the range of disparity, see “Choosing Range of Disparity” on page 3-647.

Data Types: `integers`

`UniquenessThreshold` — Minimum value of uniqueness
15 (default) | non-negative integer

Minimum value of uniqueness, specified as the comma-separated pair consisting of `'UniquenessThreshold'` and a nonnegative integer.

The function marks the estimated disparity value *K* for a pixel as unreliable, if:

$$v < V \times (1 + 0.01 \times \texttt{UniquenessThreshold}),$$

where *V* is the Hamming distance corresponding to the disparity value *K*. *v* is the smallest Hamming distance value over the whole disparity range, excluding *K*, *K*–1, and *K*+1.

Increasing the value of `UniquenessThreshold` results in disparity values for more pixels being marked as unreliable. To disable the use of uniqueness threshold, set this value to 0.

Output Arguments

`disparityMap` — Disparity map
2-D grayscale image | `gpuArray` object

Disparity map for rectified stereo pair image, returned as a 2-D grayscale image or a `gpuArray` object. The function returns the disparity map with the same size as input images `I1` and `I2`. Each value in this output refers to the displacement between conjugate pixels in the stereo pair image. For details about computing the disparity map, see “Computing Disparity Map Using Semi-Global Matching” on page 3-648.

Data Types: `single`

`disparityRangeUsed` — Range of disparity actually used in the disparity map computation
2 element vector

Range of disparity actually used in the disparity map computation, returned as a two-element vector of the form [*MinDisparity MaxDisparity*]. *MinDisparity* is the minimum disparity and *MaxDisparity* is the maximum disparity. This value can differ from the value specified using the `DisparityRange` name-value argument in order to satisfy internal numerical constraints, where the difference between the *MaxDisparity* and *MinDisparity* values must be divisible by 8.

Data Types: `double`

More About

Image Rectification

The input images `I1` and `I2` must be rectified before computing the disparity map. The rectification ensures that the corresponding points in the stereo pair image are on the same rows. You can rectify the input stereo pair image by using the `rectifyStereoImages` function. The reference image must be the same for rectification and disparity map computation.

Tips

- Ensure accurate rectification — Imperfect rectification can significantly degrade the quality of the disparitySGM function results. Use the `rectifyStereoImages` function to rectify the input stereo image pair `I1` and `I2`, so that the corresponding points are on the same rows. Use the `stereoAnaglyph` function to inspect the rectification results by creating an anaglyph image.
- Apply post-processing — For better results, improve disparity maps by applying image processing operations such as median filtering (`medfilt2`), hole filling (`imfill`), or bilateral filtering (`imbilatfilt`).
- Explore deep learning-based alternatives — For well-rectified, narrow-baseline stereo setups where classical SGM struggles with texture-less regions or repeated patterns, try `opticalFlowRAFT` as a deep learning-based alternative. For more information on comparison between classical SGM and RAFT deep learning model, see “Compare RAFT Optical Flow and Semi-Global Matching for Stereo Reconstruction”.

Algorithms

Choosing Range of Disparity

The range of disparity must be chosen to cover the minimum and the maximum amount of horizontal shift between the corresponding pixels in the rectified stereo pair image. You can determine the approximate horizontal shift values from the stereo anaglyph of the stereo pair image. Compute the stereo anaglyph of the rectified images by using the `stereoAnaglyph` function. Display the stereo anaglyph in the Image Viewer app. To measure the amount of horizontal shift between the corresponding points in the stereo pair image, select **Measure Distance** from the **Tools** menu in Image Viewer. Choose the minimum and maximum disparity values for the range of disparity based on this measurement.

For example, this figure displays the stereo anaglyph of a rectified stereo pair image and the horizontal shift values measured between the corresponding points in the stereo pair image. The minimum and maximum shift values are computed as 12.3101 and 32.3757 respectively. Based on these values, the range of disparity can be chosen as [0, 48].

Computing Disparity Map Using Semi-Global Matching

1. Compute Census transform of the rectified stereo pair image.
2. Compute Hamming distance between pixels in the census-transformed image to obtain the matching cost matrix.
3. Compute the pixel-wise disparity from matching cost matrix by using the semi-global matching method given in [1].
4. Optionally, mark the pixels for unreliability based on the `UniquenessThreshold` name-value pair. The function sets the disparity values of the unreliable pixels to `NaN`.

Version History

Introduced in R2019a

R2026a: Disparity Range No Longer Required to Be Divisible by 8
Behavior changed in R2026a

When you specify the `DisparityRange` name-value argument, the difference between the *MaxDisparity* and *MinDisparity* values is no longer required to be divisible by 8. If the difference is not divisible by 8, the function internally rounds up the disparity range to the nearest multiple of 8. To see the actual value used in the disparity map computation, use the `disparityRangeUsed` output argument.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.
Usage notes and limitations:

- The name-value pair arguments, `'DisparityRange'` and `'UniquenessThreshold'` must be compile-time constants.
- Supports code generation only in generic `MATLAB Host Computer` target platform.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- The input images `I1` and `I2` must be rectified, same size, and of same data type.
- GPU code generation supports the `'UniquenessThreshold'` and `'disparityMap'` name-value pairs.
- For very large inputs, the memory requirements of the algorithm may exceed the GPU device limits. In such cases, consider reducing the input size to proceed with code generation.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

The `disparitySGM` function fully supports GPU arrays. To run the function on a GPU, specify the input data as a `gpuArray`. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

dist

Calculate distance between transformations

Syntax

```
distance = dist(transformation1,transformation2)
distance = dist(transformation1,transformation2,weights)
distance = dist(rotation1,rotation2)
```

Description

`distance = dist(transformation1,transformation2)` returns the distance `distance` between the poses represented by transformation `transformation1` and transformation `transformation2`.

For the homogeneous transformation object `se3`, the `dist` function calculates translational and rotational distance independently and combines them in a weighted sum. Translational distance is the Euclidean distance, and rotational distance is the angular difference between the rotation quaternions of `transformation1` and `transformation2`.

`distance = dist(transformation1,transformation2,weights)` specifies the weights `weights` for the translational and rotational distances for calculating the weighted sum of two homogeneous transformations.

`distance = dist(rotation1,rotation2)` returns the distance `distance` between the poses represented by transformation `rotation1` and transformation `rotation2`.

For the homogeneous transformation object `se3`, the `dist` function calculates translational and rotational distance independently and combines them in a weighted sum. Translational distance is the Euclidean distance, and rotational distance is the angular difference between the rotation quaternions of `rotation1` and `rotation2`.

For rotation object `so3`, the `dist` function calculates the rotational distance as the angular difference between the rotation quaternions of `rotation1` and `rotation2`.

Input Arguments

`transformation1` — First transformation

`se3` object | *N*-element array of transformation objects

First transformation, specified as a scalar `se3` object or as an *N*-element array of transformation objects, where *N* is the total number of transformations. If you specify `transformation1` as an array, each element must be of the same type.

Either `transformation1` or `transformation2` must be a scalar transformation object of the same type. For example, if `transformation1` is an array of `se3` objects, `transformation2` must be a scalar `se3` object.

`transformation2` — Last transformation

`se3` object | *N*-element array of transformation objects

Last transformation, specified as a scalar `se3` object or as an *N*-element array of transformation objects, where *N* is the total number of transformations. If you specify `transformation2` as an array, each element must be of the same type.

Either `transformation1` or `transformation2` must be a scalar transformation object of the same type. For example, if `transformation1` is an array of `se3` objects, `transformation2` must be a scalar `se3` object.

`rotation1` — First rotation
`so3` object | *N*-element array of rotation objects

First rotation, specified as a scalar `so3` object, or as an *N*-element array of rotation objects, where *N* is the total number of rotations. If you specify `rotation1` as an array, each element must be of the same type.

Either `rotation1` or `rotation2` must be a scalar rotation object of the same type. For example, if `rotation1` is an array of `so3` objects, `rotation2` must be a scalar `so3` object.

`rotation2` — Last rotation
`so3` object | *N*-element array of rotation objects

Last rotation, specified as a scalar `so3` object, or as an *N*-element array of rotation objects, where *N* is the total number of rotations. If you specify `rotation2` as an array, each element must be of the same type.

Either `rotation1` or `rotation2` must be a scalar rotation object of the same type. For example, if `rotation1` is an array of `se3` objects, `rotation2` must be a scalar `se3` object.

`weights` — Weights of translation and rotation in distance sum
`[1.0 0.1]` (default) | two-element row vector

Weights of the translation and rotation in the distance sum, specified as a two-element row vector in the form [*WeightXYZ WeightQ*]. *WeightXYZ* is the translational weight and *WeightQ* is the rotational weight. Both weights must be nonnegative numeric values.

Data Types: `single` | `double`

Output Arguments

`distance` — Distance between transformations or rotations
nonnegative numeric scalar

Distance between transformations, returned as a nonnegative numeric scalar. The distance calculate changes depending on the transformation object type of `transformation1` and `transformation2` or `rotation1` and `rotation2`:

- `se3` — The `dist` function calculates translational and rotational distance independently and combines them in a weighted sum specified by the `weights` argument. The translational distance is the Euclidean distance between `transformation1` and `transformation2`. The rotational distance is the angular difference between the rotations of `transformation1` and `transformation2`.
- `so3` — The `dist` function calculates the rotational distance as the angular difference between the rotations of `rotation1` and `rotation2`.

To calculate the rotational distance, the `dist` function converts the rotation matrix of `transformation1` and `transformation2` or `rotation1` and `rotation2` into `quaternion` objects and uses the `quaternion` `dist` function to calculate the angular distance.

epipolarLine

Compute epipolar lines for stereo images

Syntax

```
lines = epipolarLine(F,points)
lines = epipolarLine(F',points)
```

Description

`lines = epipolarLine(F,points)` returns an *M*-by-3 matrix, `lines`. The matrix represents the computed epipolar lines in image `I2` corresponding to the `points` in image `I1`. The input `F` represents the fundamental matrix that maps points in `I1` to epipolar lines in image `I2`.

`lines = epipolarLine(F',points)` The matrix represents the computed epipolar lines in image `I1` corresponding to the `points` in image `I2`.

Examples

Compute Fundamental Matrix

This example shows you how to compute the fundamental matrix. It uses the least median of squares method to find the inliers.

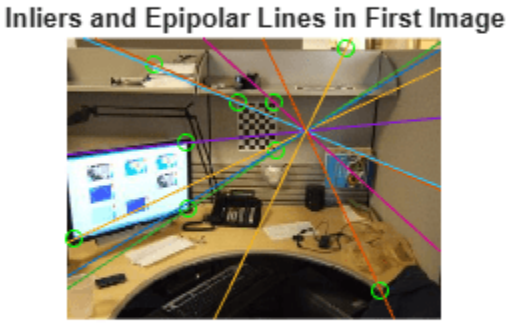
The points, matched_points1 and matched_points2, have been putatively matched.

```
load stereoPointPairs
[fLMedS,inliers] = estimateFundamentalMatrix(matchedPoints1,...
    matchedPoints2,'NumTrials',4000);
```

Show the inliers in the first image.

```
I1 = imread('viprectification_deskLeft.png');
figure;
subplot(121);
imshow(I1);
title('Inliers and Epipolar Lines in First Image'); hold on;
plot(matchedPoints1(inliers,1),matchedPoints1(inliers,2),'go')
```

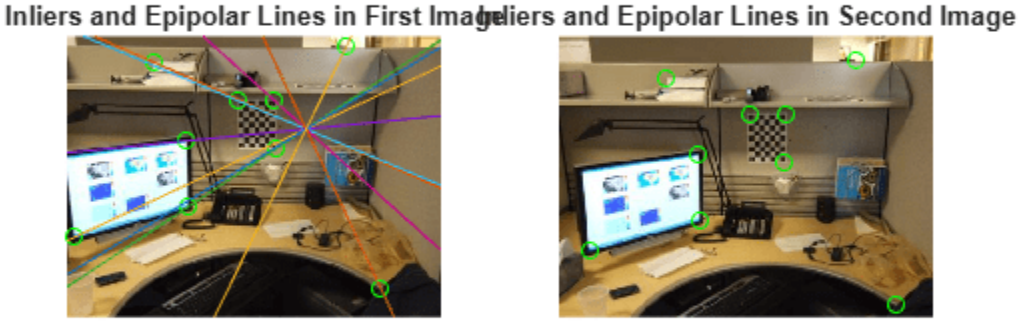
Compute the epipolar lines in the first image.



```
epiLines = epipolarLine(fLMedS',matchedPoints2(inliers,:));
```

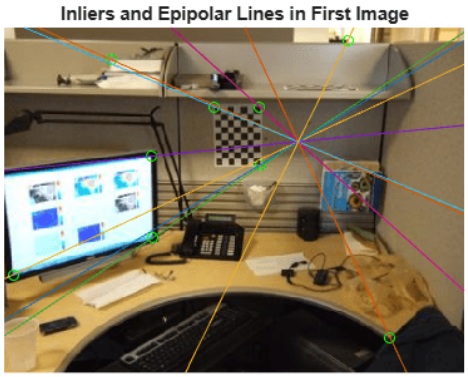
Compute the intersection points of the lines and the image border.

```
points = lineToBorderPoints(epiLines,size(I1));
```

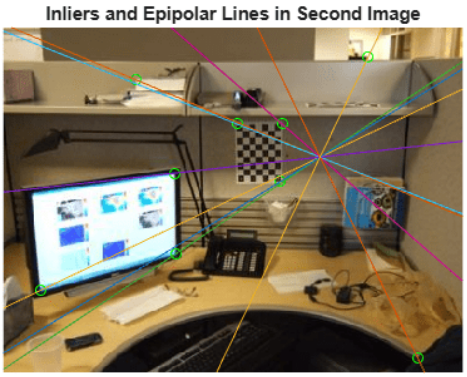


Show the epipolar lines in the first image

```
line(points(:,[1,3])',points(:,[2,4])');
```



Show the inliers in the second image.



```
I2 = imread('viprectification_deskRight.png');
subplot(122);
imshow(I2);
title('Inliers and Epipolar Lines in Second Image'); hold on;
plot(matchedPoints2(inliers,1),matchedPoints2(inliers,2),'go')
```

Compute and show the epipolar lines in the second image.

```
epiLines = epipolarLine(fLMedS,matchedPoints1(inliers,:));
points = lineToBorderPoints(epiLines,size(I2));
line(points(:,[1,3])',points(:,[2,4])');
truesize;
```

Input Arguments

F — Fundamental matrix

3-by-3 matrix (default)

Fundamental matrix, specified as a 3-by-3 matrix. `F` must be double or single. If $P1$ represents a point in the first image $I1$ that corresponds to $P2$, a point in the second image $I2$, then:
$[P_2,1] * F * [P_1,1]' = 0$

In computer vision, the fundamental matrix is a 3-by-3 matrix which relates corresponding points in stereo images. When two cameras view a 3-D scene from two distinct positions, there are a number of geometric relations between the 3-D points and their projections onto the 2-D images that lead to constraints between the image points. Two images of the same scene are related by epipolar geometry.

Data Types: `single` | `double`

F' — Fundamental matrix

3-by-3 matrix (default)

Fundamental matrix, specified as a 3-by-3 matrix. The `F'` fundamental matrix maps points in image `I2` to epipolar lines in image `I1`.

Data Types: `single` | `double`

points — Coordinates of points

M-by-2 | point feature object

Coordinates of points, specified as an *M*-by-2 matrix, where *M* is the number of points, or a point feature object. The matrix contains the (x,y) coordinates for each point. For details on supported point feature objects, see “Point Feature Types”.

Data Types: `single` | `double`

Output Arguments

`lines` — Lines

M-by-3 matrix

An *M*-by-3 matrix, where *M* represents the number of lines. Each row of the matrix must be of the form, [*A*,*B*,*C*]. These values corresponds to the definition of the line:
$A * x + B * y + C = 0$.

Version History

Introduced in R2011a

R2022a: Epipolar Line: `epipolarLine` function accepts feature point objects

Behavior changed in R2022a

Support added to specify feature point objects described in “Point Feature Types”.

estgeotform2d

Estimate 2-D geometric transformation from matching point pairs

Syntax

```
tform = estgeotform2d(matchedPoints1,matchedPoints2,transformType)
[tform,inlierIndex] = estgeotform2d( ___ )
[tform,inlierIndex,status] = estgeotform2d( ___ )
[ ___ ] = estgeotform2d( ___ ,Name=Value)
```

Description

`tform = estgeotform2d(matchedPoints1,matchedPoints2,transformType)` estimates a 2-D geometric transformation between two images by mapping the inliers in the matched points from one image `matchedPoints1` to the inliers in the matched points from another image `matchedPoints2`.

`[tform,inlierIndex] = estgeotform2d( ___ )` additionally returns a vector specifying each matched point pair as either an inlier or an outlier using the input arguments from the previous syntax.

`[tform,inlierIndex,status] = estgeotform2d( ___ )` additionally returns a status code indicating whether or not the function could estimate a transformation and, if not, why it failed. If you do not specify the `status` output, the function instead returns an error for conditions that cannot produce results.

`[ ___ ] = estgeotform2d( ___ ,Name=Value)` specifies additional options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `Confidence=99` sets the confidence value for finding the maximum number of inliers to 99.

Examples

Fit 2-D Geometric Transformation to SURF Feature Points

Read an image and display it.

```
original = imread("cameraman.tif");
imshow(original)
title("Original Image")
```

Distort and display the transformed image.

```
distorted = imresize(original,0.7);
distorted = imrotate(distorted,31);

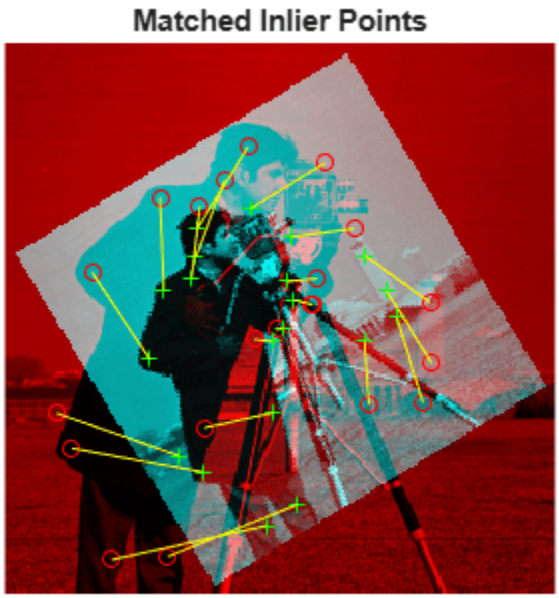
imshow(distorted)
title("Transformed Image")
```

Detect and extract features from the original and the transformed images.

```
ptsOriginal  = detectSURFFeatures(original);
ptsDistorted = detectSURFFeatures(distorted);
[featuresOriginal,validPtsOriginal] = extractFeatures(original,ptsOriginal);
[featuresDistorted,validPtsDistorted] = extractFeatures(distorted,ptsDistorted);
```

Match and display features between the images.

```
index_pairs = matchFeatures(featuresOriginal,featuresDistorted);
matchedPtsOriginal  = validPtsOriginal(index_pairs(:,1));
matchedPtsDistorted = validPtsDistorted(index_pairs(:,2));



showMatchedFeatures(original,distorted,matchedPtsOriginal,matchedPtsDistorted)
title("Matched SURF Points With Outliers")
```

Exclude the outliers, estimate the transformation matrix, and display the results.

```
[tform,inlierIdx] = estgeotform2d(matchedPtsDistorted,matchedPtsOriginal,"similarity");
inlierPtsDistorted = matchedPtsDistorted(inlierIdx,:);
inlierPtsOriginal  = matchedPtsOriginal(inlierIdx,:);

showMatchedFeatures(original,distorted,inlierPtsOriginal,inlierPtsDistorted)
title("Matched Inlier Points")
```

Use the estimated transformation to recover and display the original image from the distorted image.

```
outputView = imref2d(size(original));
Ir = imwarp(distorted,tform,"OutputView",outputView);

imshow(Ir)
title("Recovered Image")
```

Input Arguments

`matchedPoints1` — Matched points from first image

M-by-2 matrix | point feature object

Matched points from the first image, specified as an *M*-by-2 matrix of *M* number of [*x* *y*] coordinates, or as one of the point feature objects described in “Point Feature Types”.

`matchedPoints2` — Matched points from second image

M-by-2 matrix | point feature object

Matched points from the second image, specified as an *M*-by-2 matrix of *M* number of [*x* *y*] coordinates, or as one of the point feature objects described in “Point Feature Types”.

`transformType` — Transformation type

`"rigid"` | `"similarity"` | `"affine"` | `"projective"` | `"translation"`

Transformation type, specified as `"rigid"`, `"similarity"`, `"affine"`, `"projective"`, or `"translation"`. Each transform type requires a minimum number of matched pairs of points to estimate a transformation. You can generally improve the accuracy of a transformation by using a larger number of matched pairs of points. This table shows the type of object associated with each transformation type and the minimum number of matched pairs of points the transformation requires.

Transformation Type	`tform` Object	Minimum Number of Matched Pairs of Points
`"rigid"`	`rigidtform2d`	2
`"similarity"`	`simtform2d`	2
`"affine"`	`affinetform2d`	3
`"projective"`	`projtform2d`	4
`"translation"`	`transltform2d`	1

Data Types: `string`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `Confidence=99` sets the confidence value for finding the maximum number of inliers to `99`.

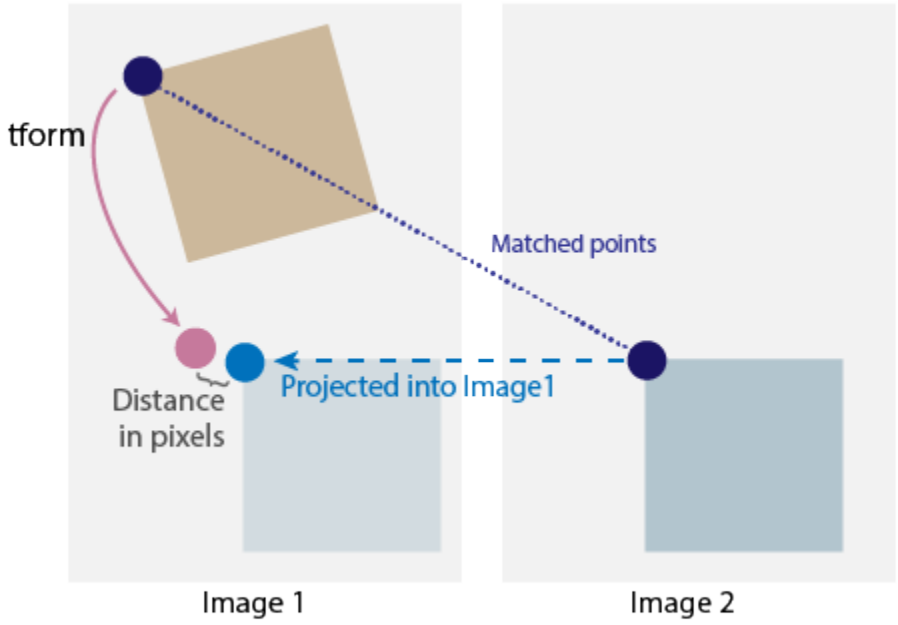
`MaxNumTrials` — Maximum random trials

`1000` (default) | positive integer

Maximum number of random trials, specified as a positive integer. This value specifies the number of randomized attempts the function makes to find matching point pairs. Specifying a higher value causes the function to perform additional computations, which increases the likelihood of finding inliers.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Confidence` — Confidence of finding maximum number of inliers
99 (default) | positive numeric scalar



Confidence of finding the maximum number of inliers, specified as a positive numeric scalar in the range (0, 100). Increasing this value causes the function to perform additional computations, which increases the likelihood of finding a greater number of inliers.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`MaxDistance` — Maximum distance from point to projection
`1.5` (default) | positive numeric scalar

Maximum distance from a point to the projection of the corresponding point, specified as a positive numeric scalar. `MaxDistance` specifies the maximum distance, in pixels, that a point can differ from the projected location of its corresponding point to be considered an inlier. The corresponding projection is based on the estimated transform.

The function checks for a transformation from `matchedPoints1` to `matchedPoints2`, and then calculates the distance between the matched points in each pair after applying the transformation. If the distance between the matched points in a pair is greater than the `MaxDistance` value, then the pair is considered an outlier for that transformation. If the distance is less than `MaxDistance`, then the pair is considered an inlier.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`tform` — Geometric transformation
`rigidtform2d` object | `simtform2d` object | `affinetform2d` object | `projtform2d` object | `transltform2d` object

Geometric transformation, returned as a `rigidtform2d`, `simtform2d`, `affinetform2d`, `projtform2d`, or `transltform2d` object.

The returned geometric transformation matrix maps the inliers in `matchedPoints1` to the inliers in `matchedPoints2`. The function returns an object specific to the transformation type specified by the `transformType` input argument.

`transformType`	Geometric Transformation Object
`"rigid"`	`rigidtform2d`
`"similarity"`	`simtform2d`
`"affine"`	`affinetform2d`
`"projective"`	`projtform2d`
`"translation"`	`transltform2d`

`inlierIndex` — Index of inliers
M-by-1 logical vector

Index of inliers, returned as an *M*-by-1 logical vector, where *M* is the number of point pairs. Each element contains either a logical `1` (`true`), indicating that the corresponding point pair is an inlier, or a logical `0` (`false`), indicating that the corresponding point pair is an outlier.

Data Types: `logical`

`status` — Status code
`0` | `1` | `2`

Status code, returned as `0`, `1`, or `2`. The status code indicates whether or not the function could estimate the transformation and, if not, why it failed.

Value	Description
`0`	No error
`1`	`matchedPoints1` and `matchedPoints2` inputs do not contain enough points
`2`	Not enough inliers found

If you do not specify the `status` code output, the function returns an error if it cannot produce results.

Data Types: `int32`

Algorithms

The function excludes outliers using the M-estimator sample consensus (MSAC) algorithm. The MSAC algorithm is a variant of the random sample consensus (RANSAC) algorithm. Results may not be identical between runs due to the randomized nature of the MSAC algorithm.

Version History

Introduced in R2022b

R2022b: Recommended over `estimateGeometricTransform2D`

Starting in R2022b, many Computer Vision Toolbox functions create and perform geometric transformations using the premultiply convention. However, the `estimateGeometricTransform2D` function estimates geometric transformations using the old postmultiply convention. Although there are no plans to remove `estimateGeometricTransform2D` at this time, you can streamline your geometric transformation workflows by switching to the `estgeotform2d` function, which supports the premultiply convention. For more information, see “Migrate Geometric Transformations to Premultiply Convention”.

estgeotform3d

Estimate 3-D geometric transformation from matching point pairs

Syntax

```
tform = estgeotform3d(matchedPoints1,matchedPoints2,transformType)
[tform,inlierIndex] = estgeotform3d( ___ )
[tform,inlierIndex,status] = estgeotform3d( ___ )
[ ___ ] = estgeotform3d( ___ ,Name=Value)
```

Description

`tform = estgeotform3d(matchedPoints1,matchedPoints2,transformType)` estimates a 3-D geometric transformation between two sets of 3-D points by mapping the inliers in the matched points from one set of 3-D points `matchedPoints1` to the inliers in the matched points from the other set of 3-D points `matchedPoints2`.

`[tform,inlierIndex] = estgeotform3d( ___ )` additionally returns a vector specifying each matched point pair as either an inlier or an outlier using the input arguments from the previous syntax.

`[tform,inlierIndex,status] = estgeotform3d( ___ )` additionally returns a status code indicating whether or not the function could estimate a transformation and, if not, why it failed. If you do not specify the `status` output, the function instead returns an error for conditions that cannot produce results.

`[ ___ ] = estgeotform3d( ___ ,Name=Value)` specifies additional options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `Confidence=99` sets the confidence value for finding the maximum number of inliers to 99.

Examples

Fit 3-D Geometric Transformation to Point Clouds

Load a point cloud file into the workspace.

```
ptCloud1 = pcread("teapot.ply")
```

```
ptCloud1 =
  pointCloud with properties:

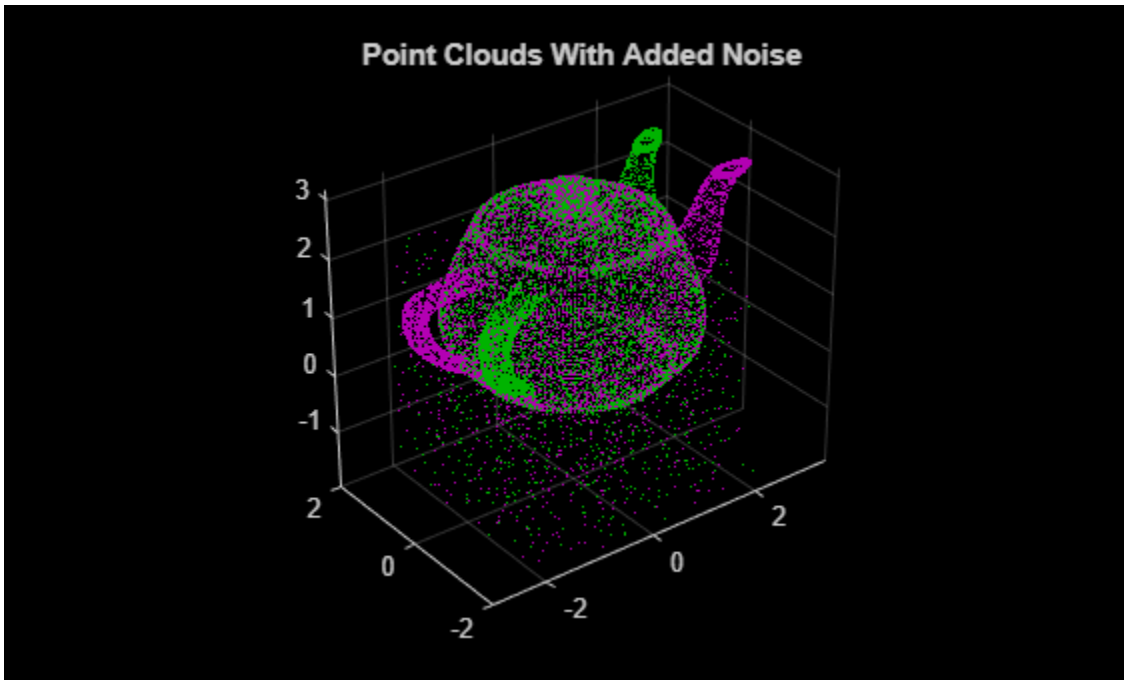
     Location: [41472×3 single]
        Count: 41472
      XLimits: [-3 3.4340]
      YLimits: [-2 2]
      ZLimits: [0 3.1500]
        Color: []
       Normal: []
    Intensity: []
```

```
ptCloud1 = pcdownsample(ptCloud1,"random",0.25);
```

Create a rigid 3-D transformation object with a 30-degree rotation about the *z*-axis.

```
eulerAngles = [0 0 30];
trans = [0 0 0];
tform = rigidtform3d(eulerAngles,trans);
```

Transform the point cloud using the transformation object.



```
ptCloud2 = pctransform(ptCloud1,tform);
```

To introduce noise, add random points to both point clouds.

```
noise1 = rescale(rand(1000,3),-2,2);
ptCloud1 = pointCloud([ptCloud1.Location;noise1]);
noise2 = rescale(rand(1000,3),-2,2);
ptCloud2 = pointCloud([ptCloud2.Location;noise2]);
```

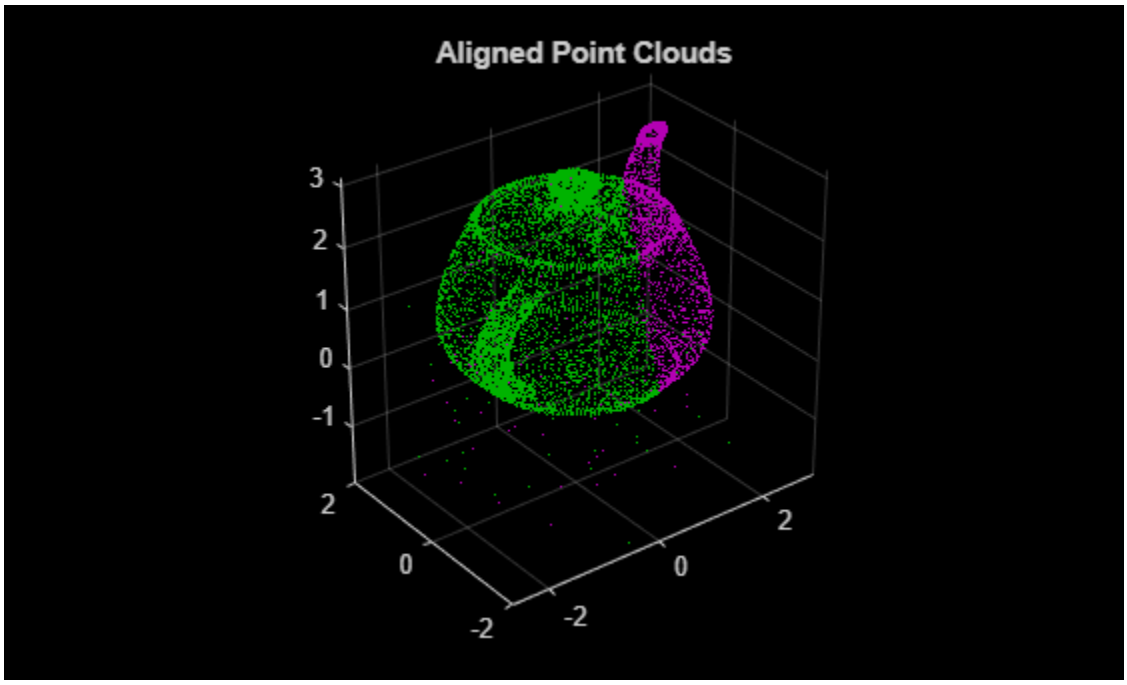
Visualize the noisy point clouds.

```
figure
pcshowpair(ptCloud1,ptCloud2)
title("Point Clouds With Added Noise")
```

Extract matched points from the point clouds.

```
matchedPoints1 = ptCloud1.Location;
matchedPoints2 = ptCloud2.Location;
```

Estimate the rigid transformation between the point clouds.



```
[tformEst,inlierIndex] = estgeotform3d(matchedPoints1, ...
    matchedPoints2,"rigid");
```

Extract the inlier points.

```
inliersPtCloud1 = transformPointsForward(tformEst, ...
    matchedPoints1(inlierIndex,:));
inliersPtCloud2 = matchedPoints2(inlierIndex,:);
```

Visualize the inliers of the aligned point clouds.

```
figure
firstPtCloud = pointCloud(inliersPtCloud1);
secondPtCloud = pointCloud(inliersPtCloud2);
pcshowpair(firstPtCloud,secondPtCloud)
title("Aligned Point Clouds")
```

Input Arguments

`matchedPoints1` — Matched points from first image

M-by-3 matrix of [*x*,*y*,*z*] coordinates

Matched points from the first image, specified as an *M*-by-3 matrix in which each row is a set of (*x*,*y*,*z*) coordinates and *M* is the number of matched points.

`matchedPoints2` — Matched points from second image

M-by-3 matrix of [*x*,*y*,*z*] coordinates

Matched points from the second image, specified as an *M*-by-3 matrix in which each row is a set of (*x*,*y*,*z*) coordinates and *M* is the number of matched points.

`transformType` — Transformation type

`"rigid"` | `"similarity"` | `"translation"`

Transformation type, specified as `"rigid"`, `"similarity"`, or `"translation"`. Each transform type requires a minimum number of matched pairs of points to estimate a transformation. You can generally improve the accuracy of a transformation by using a larger number of matched pairs of points. This table shows the type of object associated with each transformation type and the minimum number of matched pairs of points the transformation requires.

transformType	**tform Object**	**Minimum Number of Matched Pairs of Points**
`"rigid"`	`rigidtform3d`	3
`"similarity"`	`simtform3d`	3
`"translation"`	`transltform3d`	1

Data Types: `string`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `Confidence=99` sets the confidence value for finding the maximum number of inliers to 99.

`MaxNumTrials` — Maximum random trials

`1000` (default) | positive integer

Maximum number of random trials, specified as a positive integer. This value specifies the number of randomized attempts the function makes to find matching point pairs. Specifying a higher value causes the function to perform additional computations, which increases the likelihood of finding inliers.

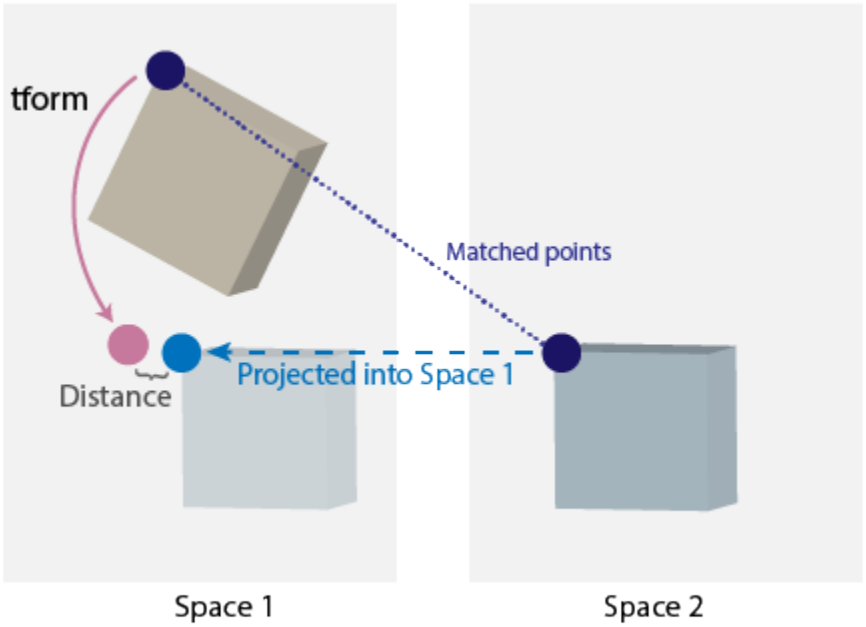
Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Confidence` — Confidence of finding maximum number of inliers

`99` (default) | positive numeric scalar

Confidence of finding the maximum number of inliers, specified as a positive numeric scalar in the range (0, 100). Increasing this value causes the function to perform additional computations, which increases the likelihood of finding a greater number of inliers.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`



`MaxDistance` — Maximum distance from point to projection

`1.5` (default) | positive numeric scalar

Maximum distance from a point to the projection of the corresponding point, specified as a positive numeric scalar. `MaxDistance` specifies the maximum distance, in pixels, that a point can differ from the projected location of its corresponding point to be considered an inlier. The corresponding projection is based on the estimated transform.

The function checks for a transformation from `matchedPoints1` to `matchedPoints2`, and then calculates the distance between the matched points in each pair after applying the transformation. If the distance between the matched points in a pair is greater than the `MaxDistance` value, then the

pair is considered an outlier for that transformation. If the distance is less than `MaxDistance`, then the pair is considered an inlier.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`tform` — Geometric transformation

`rigidtform3d` object | `simtform3d` object | `transltform3d` object

Geometric transformation, returned as a `rigidtform3d`, `simtform3d`, or `transltform3d` object.

The returned geometric transformation matrix maps the inliers in `matchedPoints1` to the inliers in `matchedPoints2`. The function returns an object specific to the transformation type specified by the `transformType` input argument.

`transformType`	`tform`
`"rigid"`	`rigidtform3d`
`"similarity"`	`simtform3d`
`"translation"`	`transltform3d`

`inlierIndex` — Inliers

M-by-1 logical vector

Inliers, returned as an *M*-by-1 logical vector of *M* point pairs. Each element contains either a logical true, `1`, to indicate the point pair is an inlier, or a logical false, `0`, to indicate the point pair is an outlier.

`status` — Status code

`0` | `1` | `2`

Status code, returned as `0`, `1`, or `2`. The status code indicates whether or not the function could estimate the transformation and, if not, why it failed.

Value	Description
`0`	No error
`1`	`matchedPoints1` and `matchedPoints2` inputs do not contain enough points
`2`	Not enough inliers found

If you do not specify the `status` code output, the function returns an error if it cannot produce results.

Data Types: `int32`

Algorithms

The function excludes outliers using the M-estimator sample consensus (MSAC) algorithm. The MSAC algorithm is a variant of the random sample consensus (RANSAC) algorithm. Results may not be identical between runs due to the randomized nature of the MSAC algorithm.

estimateCameraParameters

Calibrate a single or stereo camera

Syntax

```
[cameraParams,imagesUsed,estimationErrors] = estimateCameraParameters(
imagePoints,worldPoints)
[stereoParams,pairsUsed,estimationErrors] = estimateCameraParameters(
imagePoints,worldPoints)
cameraParams = estimateCameraParameters( ___ ,Name=Value)
```

Description

`[cameraParams,imagesUsed,estimationErrors] = estimateCameraParameters( imagePoints,worldPoints)` returns an object `cameraParams`, containing estimates for the intrinsic and extrinsic parameters and the distortion coefficients of a single and stereo camera. The function also returns the images you used to estimate the camera parameters and the standard estimation errors for the single camera calibration. The `estimateCameraParameters` function estimates extrinsic and intrinsic parameters.

`[stereoParams,pairsUsed,estimationErrors] = estimateCameraParameters( imagePoints,worldPoints)` returns `stereoParams`, a `stereoParameters` object containing the parameters of the stereo camera. The function also returns the images you used to estimate the stereo parameters and the standard estimation errors for the stereo camera calibration.

`cameraParams = estimateCameraParameters( ___ ,Name=Value)` specifies options using one or more name-value arguments in addition to any combination of arguments from previous syntaxes. For example, `WorldUnits="mm"` sets the world units to millimeters.

Examples

Single Camera Calibration

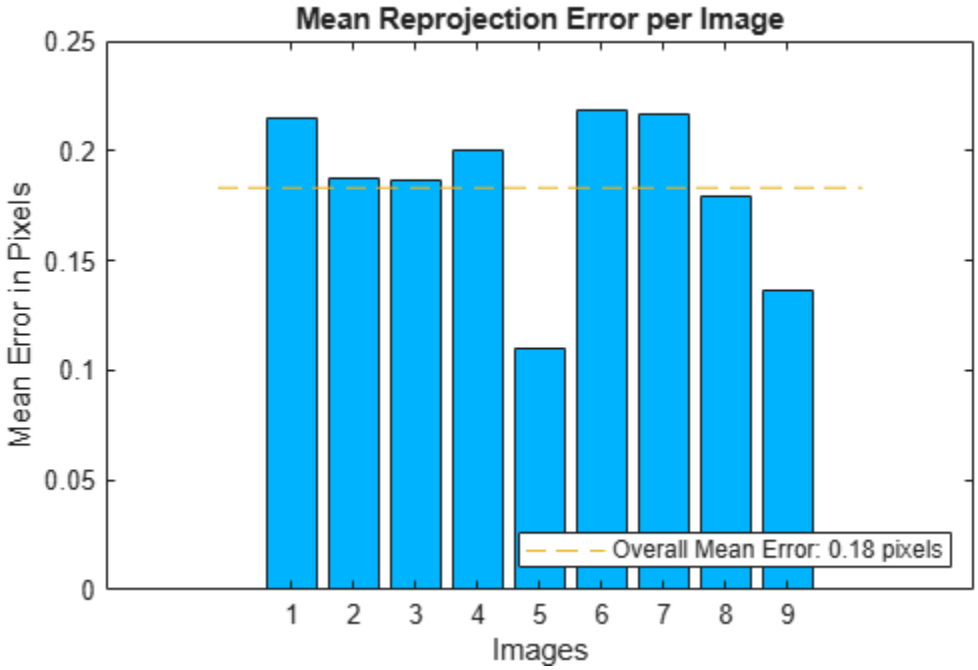
Create a set of calibration images.

```
imds = imageDatastore(fullfile(toolboxdir("vision"),"visiondata",...
            "calibration","mono"));
imageFileNames = imds.Files;
```

Detect the calibration pattern.

```
[imagePoints,patternDims] = detectCheckerboardPoints(imageFileNames);
```

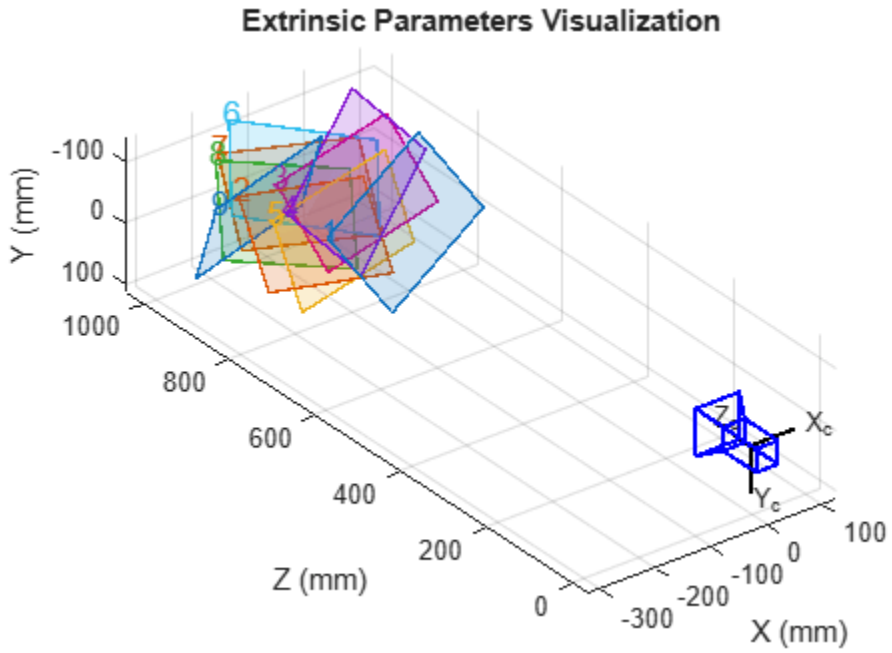
Generate the world coordinates of the corners of the squares.



```
squareSizeInMM = 29; % millimeters
worldPoints = patternWorldPoints("checkerboard",patternDims,squareSizeInMM);
```

Calibrate the camera.

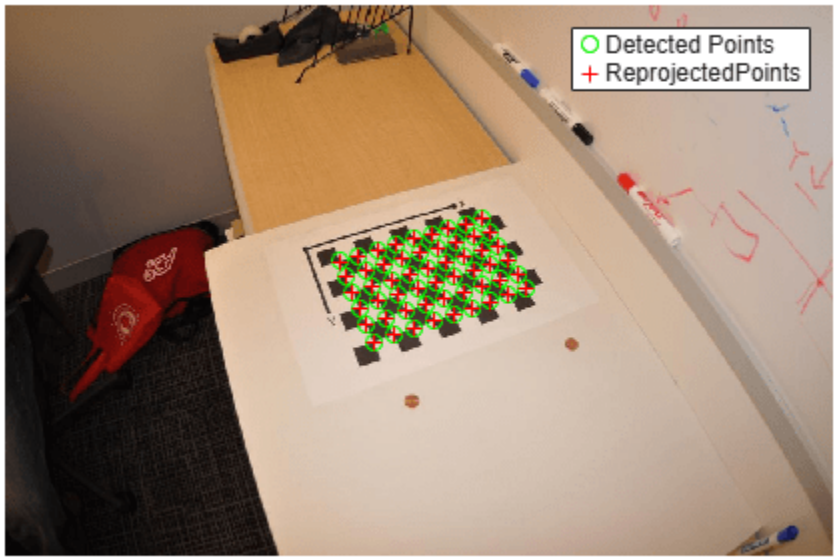
```
I = preview(imds);
imageSize = size(I,1:2);
params = estimateCameraParameters(imagePoints,worldPoints,ImageSize=imageSize);
```



Visualize the calibration accuracy.

```
showReprojectionErrors(params);
```

Visualize camera extrinsics.



```
figure;
showExtrinsics(params);
```

```
drawnow;
```

Plot detected and reprojected points.

```
figure;
imshow(imageFileNames{1});
hold on;
plot(imagePoints(:,1,1), imagePoints(:,2,1),"go");
plot(params.ReprojectedPoints(:,1,1),params.ReprojectedPoints(:,2,1),"r+");
legend("Detected Points","ReprojectedPoints");
hold off;
```

Perform Stereo Camera Calibration

Specify calibration images.

```
leftImages = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
    "calibration","stereo","left"));
rightImages = imageDatastore(fullfile(toolboxdir("vision"),"visiondata", ...
    "calibration","stereo","right"));
```

Detect the checkerboards.

```
[imagePoints,patternDims] = ...
  detectCheckerboardPoints(leftImages.Files,rightImages.Files);
```

Specify the world coordinates of the checkerboard keypoints. Square size is in millimeters.
